Conclusions: Numerous antiepileptic medications have been effectively utilized in treating psychiatric conditions. Perampanel, in particular, has demonstrated effectiveness in managing nocturnal seizures, preserving sleep architecture, and treating restless legs syndrome. A study conducted in Spain revealed that combining perampanel with either an antidepressant or an anxiolytic significantly enhances sleep quality after three months in patients without epilepsy (Abenza-Abildúa MJ, Suárez-Gisbert E, Thuissard-Vasallo IJ, Andreu-Vazquez C. Perampanel in chronic insomnia. Clin Neurol Neurosurg. 2020 May 1;192).

While there are no large-scale clinical trials specifically targeting mood disorders, some ongoing research is exploring the broader psychiatric effects of Perampanel, including its impact on anxiety disorders.

Long acting injectables: new therapeutic weapons in the battle for shortening the Duration of Untreated Psychosis

R. De Hita Santillana[1]*, M. L. Costa Ferreira da Silva[1] and M. del Valle Martin[2]

[1]Hospital Universitario Jose Germain and [2]Hospital Universitario Severo Ochoa, Leganés, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2071

Introduction: Duration of untreated psychosis (DUP) is defined as the time from manifestation of the first psychotic symptom to initiation of adequate antipsychotic drug treatment. It is associated with poorer response rates to antipsychotic medications and impaired cognition, which traslates in worse positive and negative symtomps. Various hypotheses for how untreated psychosis could impact brain function have been proposed. Dopaminergic hyperactivity leading to a progressive reduction in regional brain volumes and oxidative injury due to persistent catecholaminergic activity and prolonged activation of the hypothalamic–pituitary–adrenal axis provide possible explanations for how chronic psychosis could be neurotoxic. In addition, glutamate-mediated excitotoxicity may also contribute to these effects through neuronal overstimulation that leads to an excessive influx of calcium and subsequent excitotoxicity and, ultimately, cell death via apoptosis.
Objectives: To analyze the advantages of long-acting injectable therapy in the treatment of psychotic disorders in patients with prolongued duration of untreated psychosis with a case communication.
Methods: We present a 61 year old female patient, native of a rural area of Peru who moved to Spain and started treatment in our outpatient department. She does not provide any medical report. The family reports that she began to present symptoms from her first pregnancy, and has had to be admitted to hospital several times for suicide attempts. She had never taken any antipsychotic drug. During the last 30 years she developed symptoms consisting of erotomaniac and paranoid delusional ideation, cenesthetic and auditory hallucinations, soliloquy, self care deficit and disorganised speech and behaviour. She presented periods of maniac mood. As a result, she ended up isolated, taken care by his father and highly dependent on instrumental activities of daily living.
Results: Treatment with Risperidone was started, although the patient presented poor adherence to it. She was finally admitted to hospital for a month and we introduced once-monthly Risperidone and Valproate with significant clinical improvement.
Conclusions: Long acting injectables are a good therapeutic option in patients with psychotic disorders, even with prolongued duration of untreated psychosis.

Long term effects of cariprazine add-on therapy in the patients with risperidone induced hyperprolactinemia

J. Dedovic[1]*, A. Tomcuk[2], A. Macic[3], V. Roganovic[4] and S. Dedovic[4]

[1]Addiction Department; [2]Centre for Mental Health Promotion; [3]Management Department, Special Psychiatric Hospital Dobrota Kotor, Kotor and [4]Health Center Budva, Budva, Montenegro
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2072

Introduction: The treatment strategies for antipsychotics induced hyperprolactinemia apart from switching to prolactine-sparing antipsychotics, reducing the doses of antipsychotics and adding dopamine agonists such is bromocriptine, include add-on therapy with third generation antipsychotics (aripiprazole, cariprazine)
During the previous years, some studies with adjunctive aripiprazole therapy have been conducted, however the research with cariprazine in this purpose are absent.
Objectives: The main goal of this research is to analyse both short-term and long-term changes in the level of prolactine after adding cariprazine in the long acting risperidone treatment of patients with psychotic disorders.
Methods: Six inpatients threated during the first three months of 2024, that were consecutive diagnosed with hyperprolactinemia induced by long acting risperidone Depo therapy, were included for the participation in this research. For all study participants, the long acting antipsychotics therapy was previously used for more than 3 months and in all of them other possible causes of hyperprolactinemia were excluded by neuroimaging procedures and examinations of consultant endocrinologist. After starting adjunctive therapy with cariprazine in the dose range between 1.5 and 3mg daily, for at least three weeks, while risperidone therapy remained at the same dose, prolactine levels were firstly re-examined. The second control of prolactine levels were done after 6 months.
Results: All patients were diagnosed with ICD 10 categories of psychotic disorders, 2 of them (33.3%) with F20 category (Schizophrenia), 3 of them (50%) with F 29 category (nonspecific psychosis) and 1 of them (16,6%) with F23 category (acute psychosis). On average age of the patients were 37,6 years, 3 of them had male and 3 female sex. Prolactine base values (T0) were between 612 mlU/L and 4051,53 mlU/L (on average 2150,7 mlU/L). After introducing cariprazine adjunctive therapy for at least three weeks, the levels of prolactine (T1) substantially declined in five out of six patients (83,3%). This second values of prolactine were in the range between 306 mlU/L and 2014,4 mlU/L which represents 22,9% to 67% reduction of their initial level (on average 47,34%). In only one study case, the prolactine level has raised from 667,73 to 765,88 (14,7%). The third value of prolactine (T2) were re-examined after the 6 months of introducing the cariprazine treatment and values of prolactine remained at low levels.
Conclusions: The main conclusion of this pilot study can be that cariprazine adjunctive therapy is valuable pharmacological intervention for the treatment of risperidone induced hyperprolactinemia and that these effects sustain over the 6 months period. However, the number of participants in this research is rather small, and for that reason, further investigation at the bigger number of participants are necessary for definite conclusions.

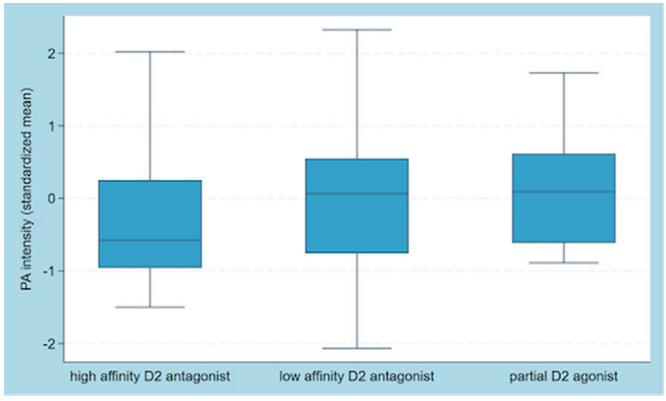
Psychological Adverse Effects of Antipsychotic Medication after Remission of First Episode Psychosis: a HAMLETT Ecological Momentary Assessment Study

M. Djordjevic[1]*, S. S. Gangadin[1], L. de Haan[2], H. E. Jongsma[1], P. P. Oomen[1], C. J. Simons[3], M. Marcelis[3], M. Nijland[1], M. J. Begemann[1], I. E. Sommer[1], M. Kikkert[4] and W. Veling[1]



[1]Department of Psychiatry, University Medical Center Groningen (UMCG), Groningen; [2]Department of Psychiatry, Amsterdam University Medical Center (Amsterdam UMC), Amsterdam; [3]Department of Psychiatry and Neuropsychology, Maastricht University, Maastricht and [4]Department of Research, Arkin Mental Health Care, Amsterdam, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2073

Introduction: Current evidence on psychological adverse effects (AEs) of antipsychotic medication after remission of First Episode Psychosis (FEP), and the impact of these AEs on daily life, is limited.
Objectives: To investigate serial cross-sectional associations between antipsychotic medication regimen and psychological AEs after remission of FEP.
Methods: This Ecological Momentary Assessment (EMA) study investigates baseline data of 56 participants from the HAMLETT trial (Handling Antipsychotic Medication: Long-term Evaluation of Targeted Treatment). Momentary mental states indicative of blunted affect intensity and variability, reduced initiative of social contact, avolition and tiredness were assessed 10x/day for eight consecutive days. Based on neurobiological mechanisms likely mediating these psychological AEs, antipsychotic medications were grouped based on their Dopamine-2 (D_2) and Histamine-1 (H_1) receptor profile. Multilevel mixed-effects regression models were employed overall and separately for mornings, daytimes and evenings, to investigate serial cross-sectional associations between medication type or dosage and concurrent psychological AEs. All models were adjusted for fixed effects of age, gender, tobacco and cannabis use in the past month and symptom severity during FEP (based on the Comprehensive Assessment of Symptoms and History, CASH).
Results: In total, 85 out of 453 HAMLETT-participants took part in the EMA add-on study. At baseline, 56 (66%) of those participants completed >26 EMA questionnaires and were currently taking antipsychotic medication, yielding a total of 3,005 questionnaires for our analyses. The distribution of antipsychotic medication regimens was relatively equally spread (25% high affinity D_2 antagonists, 48% low affinity D_2 antagonists, 27% partial D_2 agonists). Higher dosage (Beta (B) = -1.11 [95% Confidence Interval (CI): -1.97; -0.24]) and use of high affinity D_2 antagonists, as compared with partial D_2 agonists (B = 12.98 [95%CI: 2.43; 23.53]) and low affinity D_2 antagonists (B = 10.04 [95% CI: 0.59; 19.49]), were associated with decreased positive affect (PA) (see Figure 1). Higher dosage was also associated with small increases in PA variability (B = 0.23 [95% CI: 0.04; 0.42]. The remaining psychological AEs were not associated with dosage or D_2 profile, neither was H_1 profile associated with these AEs. Results were relatively consistent across daytimes, though effect sizes were greatest in the evenings.

Image:

Conclusions: After remission of FEP, higher dosage of antipsychotic medication and use of high affinity D_2 antagonists, as compared with partial D_2 agonists and low affinity D_2 antagonists, can be associated with decreased, though not invariable, positive affect as estimated using EMA.

Disclosure of Interest: None Declared

EPV1574

Use of High-Dose Sertraline for Obsessive-Compulsive Disorder: A Case Report

R. Fernández-Fernández[1]*, Á. Izquierdo de la Puente[2], P. del Sol Calderón[2], A. Rodríguez-Rodríguez[3] and D. Gómez-Olmeda[1]

[1]Hospital Universitario Infanta Cristina, Parla; [2]Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda and [3]HM Puerta del Sur, Móstoles, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2074

Introduction: The administration of high-dose sertraline for the treatment of obsessive-compulsive disorder has been investigated as a potentially more efficacious strategy in cases of treatment resistance, compared to standard dosing regimen. Studies have also evaluated the safety and tolerability of doses as high as 650 mg/day (Levy et al. Compr Psychiatry 2024; 133:152486).
Objectives: To highlight the importance of understanding the potential use of high-dose sertraline for the treatment of treatment-resistant obsessive-compulsive disorder.
Methods: Case report and literature review
Results: This is a 50-year-old woman referred from the emergency department, where she presented with thoughts of death and was diagnosed with 'Depressive Disorder. Impulsion Phobia without

warning signs' and treated with Sertraline 100 mg. During the first consultation, the patient reported the following symptoms:

- Marked emotional overwhelm and hypervigilance.
- Intrusive thoughts related to her father, generating significant guilt.
- Thoughts in which she feels the desire to harm herself.
- Compulsive need to check everything she writes, regardless of the context, to confirm she has not written anything bad about herself or her family.
- Compulsive need to review past actions to ensure she did not say anything inappropriate (despite not having spoken).
- Compulsive need to revisit conversations to ensure she had not said anything inappropriate, which eventually led her to stop speaking altogether.
- Mixed insomnia due to anticipatory anxiety about the thoughts she might have during the night.

During this initial visit, a diagnosis of Obsessive-Compulsive Disorder with mixed obsessive thoughts and acts (ICD-10; F42.2) was made. The Y-BOCS was administered, with the patient scoring 19 for obsessions and 12 for compulsions (total score: 31, indicating severe OCD). The dose of sertraline was increased to 300 mg, and aripiprazole was added. However, aripiprazole had to be discontinued after 15 days due to poor tolerance, and risperidone was introduced, which also had to be discontinued after 15 days due to poor tolerance.
After four months of follow-up and monotherapy with sertraline, the patient presented with almost complete resolution of symptoms, a stable mood, calm demeanor, and regained control over her thoughts, along with the disappearance of the compulsive checking behavior. A Y-BOCS was administered again, with a score of 8 for obsessions and 5 for compulsions (mild severity).
Conclusions: The use of high-dose sertraline (250-400 mg/day) may be an effective alternative for maintaining monotherapy in patients with treatment-resistant obsessive-compulsive disorder. However, it is important to consider that previous studies have shown a better response but not a higher overall response rate (Ninan et al. J Clin Psychiatry 2006; 67:15-22).

EPV1575

Clinical experience with Brexpiprazole in bipolar depression, off-label use. A six cases report

S. Garcia Jorge[1]*, D. Fresno Fresno[1] and P. Hervias Higueras[1]

[1]Psychiatry, Hospital Universitario del Henares, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2075

Introduction: In 2015, the United States Food and Drug Administration (FDA) approved Brexpiprazole as an adjuvant treatment for adults with major depressive disorder and as a treatment for adults with schizophrenia. Although studies suggest that Brexpiprazole is an effective adjunctive treatment for major depressive disorder in Europe, the European Medicines Agency (EMA) approved Brexpiprazole only for the treatment of schizophrenia in adult patients.
Objectives: To observe the safety, tolerability, and efficacy of brexpiprazole in patients with bipolar depression.
Methods: We followed, during 2 months, six patients diagnosed with bipolar disorder who met DSM-5 criteria for a major depressive episode. Four of them were women, two men. All were being treated with mood stabilizing drugs (2 with valproic acid and 4 with lithium). The average age was 43 years.
Visits were conducted every 15 days. At each visit, we evaluated depressive symptom improvement, any adverse effects, and the emergence of manic or hypomanic symptoms.
All patients were informed of the off-label use of this drug and gave their consent.
Results: Five out of six patients continued treatment throughout the study; only one patient discontinued due to adverse effects (amenorrhea). All patients who maintained treatment demonstrated a subjective improvement in depressive symptoms, as observed by both, clinicians and the patients themselves. No patients presented with manic or hypomanic symptoms suggestive of a shift to a manic pole.
Conclusions: Although off-label, brexpiprazole may be beneficial for certain patients with depressive symptoms and a diagnosis of bipolar disorder. It displayed a good tolerability profile, with no observed shifts to mania in our small sample.

When an antipsychotic working as an antidepressant, do they have a therapeutic window?

I. Hacisalihoglu Aydin[1]*, A. Salifu[2], K. Settle[3] and R. S. El-Mallakh[1]

[1]Mood Disorders Research Program, Depression Center, Department of Psychiatry and Behavioral Sciences, University of Louisville School of Medicine; [2]University of Louisville School of Medicine and [3]University of Louisville School of Arts and Sciences, Louisville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2076

Introduction: Therapeutic window in psychopharmacology is the range of drug concentrations that achieve desired effects safely, with treatment failure more likely when levels fall outside this optimal range. The role of dopamine receptor partial agonists (DRPA) in the treatment of depression is a case in point.
Objectives: We discussed the unique mechanisms, and effective antidepressant doses of DRPAs within their therapeutic windows.
Methods: PubMed search was conducted, focusing on randomized controlled trials, open-label studies, and reviews evaluating aripiprazole, brexpiprazole, and cariprazine as augmentation therapies for major depressive disorder in adults.
Results: Clinical trials have investigated aripiprazole, brexpiprazole, and cariprazine as adjuncts to antidepressants, and the effective antidepressant dose is generally lower than the minimal antipsychotic dose. Specifically, the antidepressant doses are 2 – 10 mg for aripiprazole (antipsychotic dose 10 – 30 mg), 2 – 3 mg for brexpiprazole (antipsychotic dose 4 mg), and 1.5 – 3 mg for cariprazine (antipsychotic dose 1.5 – 4.5 mg). This is because at subantipsychotic doses partial agonists increase the dopamine signal, but at antipsychotic doses they reduce the dopamine signal to the level of the intrinsic activity of the drug (generally 25 – 40% of the maximal dopamine signal) which is generally inadequate for an antidepressant response.

Conclusions: DRPAs can increase or reduce the dopamine signal depending on receptor occupancy. At higher receptor occupancy they reduce the dopamine signal, while at lower receptor occupancy (when unoccupied receptors can interact with endogenous dopamine) their intrinsic activity can increase the dopamine signal. Understanding the drug-receptor relationship is crucial, as the assumption that higher doses are always more effective is incorrect.

Examine the effects of Atomoxtine alone versus Atomoxtine combined with Risperidone at sample of Egyptian children suffering from ADHD

M. M. Hamouda[1]

[1]Psychiatry , Al-Azhar Faculty Of Medicine , Cairo, Egypt
doi: 10.1192/j.eurpsy.2025.2077

Introduction: A frequent developmental condition of inattention that may or may not be accompanied by hyperactivity is known as Attention Deficit Hyperactivity Disorder.[1]One's inability to focus, excessive activity, and behavior that is inappropriate for their age, all of these traits are indicative of ADHD.[2]The data for Atomoxetine indicates that it is safe and effective in treating ADHD in children and teenagers[3]. For kids and teenagers with disruptive behaviors, ADHD, and developmental disorders, Risperidone may be a safe, effective medication. Numerous investigations have demonstrated the high effectiveness of risperidone[4]

Objectives: To study the Efficacy of Atomoxetine alone vs. Atomoxtine with Antipsychotic (Risperidone) on ADHD children.

Methods: This follow-up study was carried out from January to June 2024 on 54 ADHD children (6–18 years old) who were receiving treatment at the psychiatry clinic at Al Hussian University Hospital in Cairo, Egypt. This study was authorized by the Al-Azhar Faculty of Medicine's Ethical Committee. Following an explanation of the purpose of the study and the acquisition of verbal agreement, all children underwent semi-structured clinical interviews and were excluded from other psychiatric & medical conditions.

Based on the DSM IV criteria, ADHD has been diagnosed in all of the study children. Conner's 2 test for ADHD, or SCID, was used for every child in the study. Implementing medicinal treatment for every child and monitoring their progress, who were divided into two groups. The first group, which consisted of 27 children diagnosed as ADHD children, received only Atomoxetine, independent of the kind of ADHD. In contrast, 27 recently diagnosed children with ADHD, irrespective of their kind of ADHD, received a combination of Atomoxetine and antipsychotic(Risperidone) medication in the second group.

SPSS 20.0 was employed. The qualitative data were expressed in terms of percentages and figures, and the significance of the outcomes was assessed at the 5% level.

Results: When Atomoxetine was administered to 27 children, it demonstrated a moderate level of efficacy to 12 from 27 patients (44.4%) for all children with ADHD, regardless of type, but it significantly improved the inattention type of ADHD in 4 from 4 patients (100%).Given to 27 children, the combination of Atomoxetine and Risperidone demonstrated greater effect on 24 from 27 patients with (88.9%) for all ADHD children, and it showed a discernible improvement on 9 out of 9 with (100%) for ADHD hyperactivity type.

Conclusions: All types of ADHD are responsive to Atomoxetine or Atomoxetine / Antipsychotic (Risperidone) combination, But Atomoxetine effect is more on Attention deficit variant than other variants, while Antipsychotic (Risperidone) is more effective on hyperactivity and aggression.

Clozapine-induced Agranulocytosis: A Case Presentation and Literature Review

P. A. Hernández Liebo[1], M. Polo Gay[1], J. Romay González[1], C. Sevilla Díez[1], I. Ibarra Muñoz[1], M. de la Fuente Gómez[2]*, A. Herrán Gómez[1] and J. Vázquez Bourgon[1]

[1]Psychiatry, University Hospital Marqués de Valdecilla and [2]Hospital Universitario Marqués de Valdecilla, Santander, Spain

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2078

Introduction: Clozapine has the strongest evidence for efficacy for schizophrenia that has proved refractory to adequate trials of standard antipsychotic medication. Its use is limited to these cases due to the uncommon but severe adverse effect agranulocytosis or severe neutropenia, defined as a neutrophil count under 500/microL. It is seen in 0,4 % of clozapine patients and it usually occurs in the first three months. Risk is managed with close blood count (BC) monitoring protocol.

Objectives: This work aims to improve the understanding and management of this condition.

Methods: With this purpose, we present a clinical report and rewiew its management in literature.

Results: We present the case of a 60-year-old man with the diagnosis of resistant schizophrenia who is hospitalized in the acute Psychiatry Unit due to decompensation, where clozapine is initiated with gradual dose augmentation and weekly BC. After improvement of psychotic symptoms, the patient is transferred to a subacute care facility. Two months later, BC revealed mild neutropenia (1000/microL; defined as 1000-1500/microL) becoming severe (100/microL) on the next test one week later. Clozapine is then interrupted and replaced with olanzapine. Neutrophils descend to zero within one day and three days later, with all granulocytes in low levels, the patient presents fever and diarrhea, being finally hospitalized in Internal Medicine. Empirical intravenous antibiotic therapy is prescribed as well as filgastrim, a granulocite-colony stimulating factor (G-CSF). Antibiotic is adjusted after *Enterococo Faecalis* is isolated in blood cultives. Despite eleven days without clozapine and eight days with G-CSF, agranulocytosis persisted. Taking in consideration the severity of the case and the non existence of acute psychotic symptoms, olanzapine is interrupted and benzodiacepine medication is increased, with BC normalization within three days and remission of digestive symptoms and fever. G-CSF is interrupted and the patient is re-transferred to the subacute unit, with initiation of aripiprazol in the following days.

Upon the appereance of mild neutropenia, closer blood monitorization is recommended (three times a week); with interruption of clozapine and daily monitoring in case of moderate or severe neutropenia. In relation to when to reintroduce antipsychotic treatment,

clinical guidelines are cautious, emphasizing the need of close hematological monitoring and careful evaluation of risks and benefits. However, most recommend waiting for complete neutrophil recovery, taking into account the severity of the psychotic symptoms. Olanzapine, with similar mechanism of action but much lower risk, is usually the election.

Image 1:

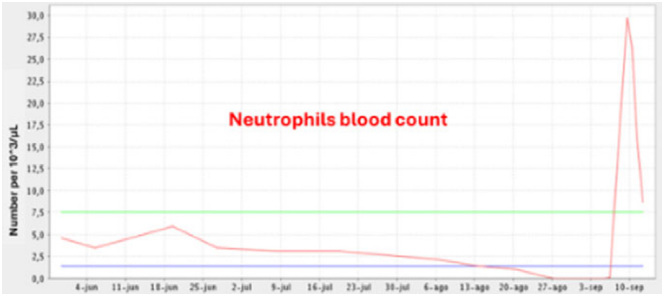

Image 2:

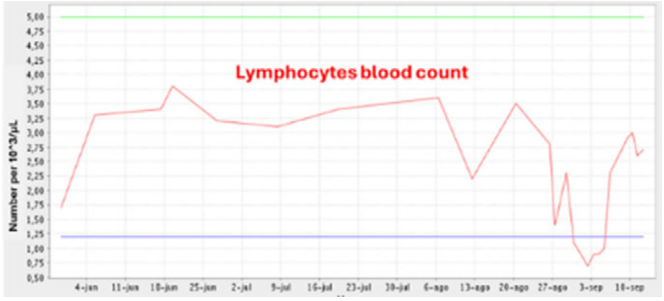

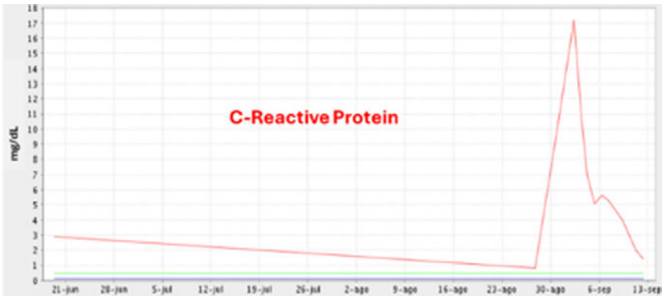

Image 3:

Conclusions: Although clozapine-induced agranulocytosis is rare, its complexity and severity requires a fine review of its management, considering that this probably has an impact on the patient's clinical evolution.

Prolactin level changes according to atypical antipsychotics use

J. Hong[1]* and ?.-H. Jeong[2]
[1]Psychiatry, Iksan hospital, Iksan and [2]Psychiatry, St. Vincent's Hospital, Suwon, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2079

Introduction: Antipsychotic drugs are known as the major cause of non-neoplastic hyperprolactinemia.
Objectives: This study aimed to investigate the levels of serum prolactin elevation depending on the use of antipsychotic drugs in patients through the Clinical Data Warehouse.(CDW)
Methods: We conducted a cohort search in the CDW application with the following condition. The subjects who aged more than 18 years old and visited from March 1, 2017, to May 31, 2022 at the Department of St. Vincent's Hospital, The Catholic University of Korea. The subjects were diagnosed according to ICD-10 for schizophrenia, schizotypal and delusional disorders, manic episodes, and bipolar affective disorders. And the subjects who was taking one of risperidone, blonanserin, amisulpride, and olanzapine. The subjects also conducted serum prolactin level tests. After that, we reviewed the medical data.
Results: Among the 117 subjects included in the analysis, the mean serum prolactin level was 64.654.6ng/ml. Serum prolactin levels were significantly higher in subjects taking risperidone or amisulpride compared to blonanserin and olanzapine. The female subjects who took blonanserin, olanzapine, and risperidone had significantly higher prolactin levels, but there was no difference in serum prolactin levels between the sex in the subjects who took amisulpride.
Conclusions: This study suggests the need for regular monitoring of serum prolactin levels in patients who are taking antipsychotics, especially in female patients. And we showed that there is a possibility to conduct more effective and simpler big data research using the CDW. Further studies on the subjects with controlled confounding variables and larger sample groups are needed.

A Case of Severe Neuroleptic Malignant Syndrome in a Patient with Chronic Schizophrenia

P. Ibáñez Mendoza[1]*, Á. de Vicente Blanco[1], B. Orgaz Álvarez[1], M. Velasco Santos[1], C. Herranz Serfaty[1], V. Giunti[1] and L. Nocete Navarro[1]
[1]Psychiatry, Hospital Universitario La Paz, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2080

Introduction: Neuroleptic Malignant Syndrome (NMS) is a rare, idiosyncratic, and potentially lethal reaction to psychopharmacological treatment. Several heat-related disorders are influenced by psychopharmacological use, making differential diagnosis challenging. As there are no specific clinical or laboratory findings for NMS, excluding other causes of hyperthermia is essential for accurate diagnosis.

Objectives: To describe a case of severe NMS and review the key elements of differential diagnosis and treatment options.
Methods: A case report and a non-systematic review of the literature.
Results: A 54-year-old male was admitted to the hospital after being found unconscious on the street during a hot August day, with apparent cranioencephalic trauma and a core temperature of 41°C. The patient had a known history of chronic schizophrenia, managed with risperidone (6 mg/day) and quetiapine (800 mg/day), with no recent medication changes. Initial examination in the Emergency Department revealed tachycardia, tachypnea, normotension, diaphoresis and confusion. Laboratory results showed mild leukocytosis with neutrophilia, hyperkalemia, hypernatremia, and elevated acute phase reactants, including a creatine kinase (CK) level exceeding 3000 IU/L. Lactic acidosis and impaired renal function (creatinine 1.9 mg/dL) were also noted. Infectious causes were ruled out, and neuroimaging did not reveal any acute findings to account for the symptoms. Due to persistent decreased consciousness, the patient required intubation and supportive care in the Intensive Care Unit (ICU).
The patient exhibited persistent hyperthermia that was unresponsive to antipyretics and physical cooling measures. Upon suspicion of NMS, antipsychotic medications were discontinued, and treatment with a dopamine agonist and dantrolene was initiated. Muscle rigidity, which developed later, further supported the NMS diagnosis. Electroencephalography (EEG) findings were consistent with NMS. Given the patient's slow recovery, electroconvulsive therapy (ECT) was started but discontinued after two sessions due to ICU-related infectious complications.
After 19 days of hospitalization and treatment, the patient showed significant clinical improvement, allowing for extubation and discontinuation of intensive care interventions.
Conclusions: This case emphasizes the importance of early recognition and treatment of Neuroleptic Malignant Syndrome to avoid complications and mortality. Differentiating NMS from classical heat stroke can be challenging, with muscle rigidity serving as a critical diagnostic feature.

Edema associated with Haloperidol: A Rare Observation

R. Jbir[1]*, F. Guermazi[1], N. Bouattour[1], D. Mnif[1], R. Masmoudi[1], I. Bouaziz[2], R. Atheymen[2], K. Ksouda[2], K. Zghal[2], I. Baati[1] and J. Masmoudi[1]

[1]Psychiatry 'A' deprtment, Hedi Chaker university hospital and [2]Regional Pharmacovigilance Center, faculty of medicine of sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2081

Introduction: Haloperidol (Haldol®) is first-generation antipsychotic that still have a place in the treatment of schizophrenia. However, this molecule is associated with numerous side effects, particularly extrapyramidal symptoms. Edema has been rarely described with haloperidol, and may have an immunoallergic or pharmacodynamic mechanism.
Objectives: Our aim is to study a rare case of facial and limb edema attributed to haloperidol.
Methods: We report the case of a 22-year-old female patient with schizophrenia who developed facial and limb edema after taking haloperidol.
Results: We report the case of a 22-year-old woman. She was admitted to our psychiatric department "A" as an involuntary inpatient after she threatened to stab her father. She was diagnosed with schizophrenia. The patient has no past medical history. The somatic examination and the admission report were correct.
Given the need for a slow-release neuroleptic, the patient was treated with haloperidol in gradually increasing doses up to 30 mg per day. Six weeks after starting treatment, the patient developed progressive edema of the face, eyelids and all 4 limbs, with a marked increase in weight and body mass index from 31 to 36.6.
The patient was examined by internists. An etiologic investigation of this edema was initiated, excluding renal origin (strictly normal renal work-up and negative proteinuria), cardiac origin (in view of a negative pro-brain natriuretic peptide, D-dimer and troponins and a normal cardiac echography), hepatic (in the presence of a strictly normal work-up including: protidemia, albuminemia, transaminases, PAL, GGT, bilirubin and prothrombin levels) and endocrine (a normal thyroid work-up) origin.
The edema progressively worsened on haloperidol over a period of 10 days. A drug-induced origin was suspected. We contacted the regional pharmacovigilance center in Sfax, which incriminated haloperidol and recommended its immediate discontinuation.
After discontinuing the drug, the edema regressed progressively until it disappeared completely after 15 days, confirming that haloperidol was the drug responsible and contraindicating its further use.
The responsibility of haloperidol in the genesis of the edema was retained with a plausible score (C2S2I2B3). The scores were calculated according to the French Bégaud method.
Conclusions: Edema is not a common side effect of typical antipsychotics, especially haloperidol. However, it is important to emphasize that this effect, although rare, can occur. Clinicians are advised to be aware of edema in all patients taking first or second antipsychotics.

Chlorpromazine induced acute cytolytic hepatitis: Case report and a literature review

R. Jbir[1,2]*, F. Guermazi[2], N. Bouattour[2], D. Mnif[2], F. Cherif[2], I. Bouaziz[3], R. Atheymen[3], K. Ksouda[3], K. Zghal[3], I. Baati[2] and J. Masmoudi[2]

[1]psychiatry 'A' department; [2]Psychiatry 'A' deprtment, Hedi Chaker university hospital and [3]Regional Pharmacovigilance Center, faculty of medicine of sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2082

Introduction: Chlorpromazine is historically the first antipsychotic drug. It has played a decisive role in the development of neuropsychopharmacology. However, it can induce adverse effects, sometimes fatal.
Objectives: To study the relationship between acute cytolytic hepatitis and treatment with chlorpromazine.
Methods: We report the case of a patient treated for schizophrenia who developed an acute cytolytic hepatitis after taking chlorpromazine.

Results: We report the case of a 22-year-old woman with no significant medical history, has been diagnosed with schizophrenia who was admitted to our department for physical hetero-aggressiveness.
The clinical examination and laboratory tests performed on admission were normal. The patient was treated with 15 mg of haloperidol and 30 mg of diazepam and 50 mg of chlorpromazine.
On the twelfth day, the patient developed a fever of 38.4°C and abdominal pain. Laboratory tests revealed predominant hepatic cytolysis with elevated ALAT (ASAT: 372 IU/L; ALAT: 463 IU/L), with hepatic cholestasis (PAL: 156 IU/L; GGT: 238 IU/L). Total bilirubin and prothrombin levels were normal with no evidence of jaundice or pruritus
The ALAT/PAL ratio was 8.8 > 5, indicating cytolytic hepatitis. The rest of the clinical and biological examination was completely normal.
Drug-induced hepatitis was suspected and the three drugs were stopped after consultation with the regional pharmacovigilance center in Sfax. The biological control showed a decrease in transaminases (ALAT=5.4*N, ASAT=1.3*N) 3 days after stopping the treatment. Viral serology (hepatitis A,B and C) was negative and liver ultrasound showed hepatomegaly suggestive of drug-induced hepatitis.
Haloperidol-induced cytolysis was initially suspected, and the prescription of chlorpromazine was authorized. Due to the patient's instability, she was treated with chlorpromazine at a dose of 25 mg*3/d. Twenty-four hours after administration of this neuroleptic, the patient presented a worsening of hepatic status: ALAT=20*N, ASAT=14.4*N, PAL=2.6*N, GGT=19*N. The ALAT/PAL ratio was 7.6, indicating cytolytic impairment requiring immediate discontinuation of chlorpromazine.
The pharmacovigilance investigation blamed chlorpromazine and contraindicated its use. The evolution was characterized by an improvement of the hepatic balance three days after discontinuation of chlorpromazine.
Normalization of transaminases was achieved within 3 weeks. GGT and PAL were normalized after 2 months of discontinuation.
Chlorpromazine was classified as probable (C2S3I3B3(R+)). The score was calculated according to the French Bégaud method.
Conclusions: Edema is not a common side effect of typical antipsychotics. However, it is crucial to emphasize that this effect can occur. Clinicians are advised to watch for edema in all patients taking antipsychotics.

EPV1584

Effects of liraglutide on depressive behavior and cognitive function in the probe trial of Morris water maze test

D.-I. Jon[1]* and J. G. Lee[2]
[1]Hallym Univ. Sacred Heart Hospital, Anyang and [2]Haeundae Paik Hospital, Busan, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2083

Introduction: Liraglutide, a glucagon-like peptide-1 (GLP-1) agonist, is an interesting candidate for improving metabolic syndrome and cognition in psychiatric disorders.
Objectives: We investigated the effects of liraglutide on a depression-like phenotype in mice exposed to chronic unpredictable stress (CUS).
Methods: Learning and memory were also assessed using the Morris water maze (MWM) test. Liraglutide (0.3 mg/kg/day for 21 days) was administered to mice with or without exposure to CUS. After 21 days of CUS, the forced swim test (FST) was performed to assess its antidepressant effect. To evaluate cognitive function, liraglutide was administered to mice under stress-free conditions for 21 days, and then the MWM test was performed on 6 consecutive days.
Results: Chronic liraglutide treatment reduced FST immobility in mice with and without CUS. In the probe trial of the Morris water maze test, the search error rate was reduced and the time spent and path length in the target quadrant and the number of platform crossings were increased.
Conclusions: Additional animal model experiments and molecular level studies are needed to support the results obtained in this study. Liraglutide appears to exert antidepressant effects and could improve cognitive function. Based on these results, GLP-1 agonists could have potential as novel antidepressants. It may also help with metabolic syndrome, cognitive dysfunction, and depressive symptoms.

Acute Generalized Exanthematous Pustulosis Secondary to Low-Dose Olanzapine: A Case Report and Mini-Review of the Literature

S. Kukurt[1]
[1]Psychiatry, Bezmialem Vakif University, Istanbul, Türkiye
doi: 10.1192/j.eurpsy.2025.2084

Introduction: Acute generalised exanthematous pustulosis (AGEP) is a rare but severe cutaneous reaction often triggered by medications like antibiotics, calcium channel blockers, and antipsychotics. It is characterised by the rapid onset of non-follicular sterile pustules, fever, and leukocytosis with neutrophilia and eosinophilia. The European SCAR study reports an incidence of 1–5 cases per million annually, with a mortality rate of up to 5% in severe cases (Szatkowski et al. JCM 2022; 11:397). While AGEP is well-documented with various drugs, AGEP induced by low-dose olanzapine is particularly noteworthy due to its rarity and the lack of substantial evidence in existing literature.
Objectives: The aim of this report is to highlight the potential for AGEP to develop even at low doses of olanzapine and to review similar cases from the literature.
Methods: We present the case of a 19-year-old male treated with low-dose olanzapine (2.5 mg) for severe insomnia who developed AGEP. A literature review was conducted to identify other instances of AGEP related to olanzapine. The review utilised PubMed and Google Scholar databases, focussing on cases with detailed patient information including age, gender, dosage, and time to symptom onset (Table 1).
Results: A 19-year-old male with a one-year history of severe sleep deprivation, reporting only one hour of sleep per day in the past week, was prescribed olanzapine 2.5 mg after failed attempts with melatonin, hydroxyzine, and mirtazapine. Two days later, he developed a pruritic rash on the neck, spreading to the trunk and limbs, along with a fever of 38.5°C. Blood tests revealed leukocytosis

(12,000/μL), neutrophilia, and eosinophilia but normal liver and kidney function. Dermatological evaluation confirmed AGEP. Olanzapine was discontinued, and cetirizine, an H1 antagonist, was administered. Symptoms improved within 24 hours, and the rash resolved within a week.

Table 1: Summary of Olanzapine-Induced AGEP Cases

Study	Age	Gender	Dosage (mg)	Symptom onset (days)
Christen et al. Acta Medica (Hradec Kralove) 2006; 49:75-6.	56	Male	10	5
Patel et al. Crit Care Med 2018; 46:469.	38	Male	10	3
Jakhar et al. Indian J Psychiatry 2021; 63:411-3.	57	Female	20	2
OUR CASE	19	Male	2.5	2

Conclusions: This case underscores the need to recognize rare hypersensitivity reactions like AGEP, even at low doses of olanzapine. Early detection and discontinuation of the drug are essential to avoid complications. Literature shows AGEP can occur across various dosages, with symptom onset typically within days. Clinicians should be cautious when prescribing olanzapine, regardless of dose, and closely monitor patients for signs of AGEP to prevent severe outcomes.

Disclosure of Interest: None Declared

Rare but elevated incidence of hematological malignancy after clozapine use in schizophrenia: a population cohort study

F. T. T. Lai[1,2,3]*, Y. Hu[1], Y. Chai[1,4] and L. Gao[1,5]

[1]Department of Pharmacology and Pharmacy, University of Hong Kong; [2]Laboratory of Data Discovery for Health; [3]Department of Family Medicine and Primary Care, University of Hong Kong, Hong Kong, Hong Kong; [4]School of Public Health, Shenzhen University, Shenzhen and [5]School of Pharmacy, Xi'an Jiaotong University, Xi'an, China

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2085

Introduction: Clozapine is widely regarded as a safe and highly efficacious psychotropic drug that is largely underused worldwide. Recent disproportionality analyses and nationwide case-control studies suggested a potential association between clozapine use and hematological malignancy (HM). Nevertheless, the absolute rate difference is not well-established due to the absence of analytic cohort studies. The clinical significance of such a potential risk remains unclear.

Objectives: We aim to estimate the rate ratio and rate difference of HM associated with clozapine use.

Methods: We extracted data from a territory-wide public healthcare database from January 2001 to August 2022 in Hong Kong to conduct a retrospective cohort study of anonymized patients aged 18+ with a diagnosis of schizophrenia who used clozapine or olanzapine (drug comparator with highly similar chemical structure and pharmacological mechanisms) for 90^{+} days, with at least two prior other antipsychotic use records within both groups. Weighted by inverse probability of treatment based on propensity scores, Poisson regression was used to estimate the incidence rate ratio (IRR) of HM between clozapine and olanzapine users. The absolute rate difference was also estimated.

Results: In total, 9,965 patients were included, with 834 clozapine users. Both groups were followed up for an average of more than seven years. Clozapine users had a significant IRR of 2.22 (95% CI [1.52, 3.34]; $p<0.001$) for HM compared to olanzapine users. Absolute rate difference was estimated to be 57.40 (95% CI [33.24, 81.55]) per 100,000 person-years. Findings were consistent across sub-groups by age and sex in terms of effect size, although the IRR was non-significant for those aged 65 or older. Sensitivity analyses all supported the robustness of the results and showed good specificity to HM but no other cancers.

Conclusions: Absolute rate difference in HM incidence associated with clozapine is small despite a twofold elevated rate. Given the rarity of HM and existing blood monitoring requirements, more restrictive indication for clozapine or special warnings may not be necessary.

Long-Acting Injectable Antipsychotics: Are They the Missing Link in Early Psychosis Treatment?

I. M. Lopes[1]*, D. Seabra[2], G. Santos[1], N. Ramalho[1], T. Coelho Rocha[1], J. Alves Leal[1], J. F. Cunha[3], J. Moura[1], D. Santos[1], A. Garcia[1], M. Rosa[1], C. Pires[1], L. Lopes[4] and M. Cameira[5]

[1]Psychiatry, ULS Arco Ribeirinho; [2]Psychiatry, USL Arco Ribeirinho; [3]Psychiatry, ULS Barreiro, Barreiro; [4]Psychiatry, ULS Alto Minho, Viana do Castelo and [5]Psychiatry, ULS São José, Lisboa, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2086

Introduction: Research into early interventions following a first episode of psychosis (FEP) has enabled a focused approach on prognostic-modifying factors. Among these, poor medication adherence contributes to relapse, as well as cognitive and functional deterioration. Several studies report discontinuation rates of oral antipsychotics (OAPs) after FEP at 70%, regardless of the prescribed OAP. The early introduction of long-acting injectable antipsychotics (LAIAs) could present an alternative.

Objectives: This study aims to review the efficacy of LAIAs in the early stages of psychosis and compare the most relevant international guidelines on this topic.

Methods: Methodology: A non-systematic literature review using the keywords "long-acting injectable" and "first episode psychosis," limited to articles published in English and Portuguese in the last 10 years from the PubMed®/MEDLINE® database, and clinical practice guidelines on psychosis, schizophrenia, and FEP from NICE, APA, and RANZCP.

Results: Despite frequent selection biases (such as reserving LAIAs for patients with worse prognostic factors), significant benefits of LAIAs over OAPs in preventing hospitalization and relapse during the early phases of psychosis are consistently reported. LAIAs reduce non-adherence due to forgetfulness or reduced insight, while their

different pharmacokinetics minimize withdrawal symptoms, drug interactions, and fluctuations in plasma concentration, enhancing tolerability. No second-generation LAIA was found to be clearly superior in terms of efficacy. Various guidelines recommend offering this treatment option early, favoring an informed and collaborative decision-making process. However, despite documented benefits in robust studies, they do not consider LAIAs as a first-line treatment.
Conclusions: Discussion/Conclusions: Significant variations in the proportion of patients on LAIAs across countries suggest that factors other than efficacy may influence its use. Greater understanding of these factors could help identify potential barriers to optimal implementation. New evidence may prompt a review of the guidelines.

The Effects of St. John's Wort and its Interactions with SSRI's

R. A. Maldonado-Puebla[1]*, N. Choudhury[2] and B. Carr[2]
[1]College of Osteopathic Medicine, Nova Southeastern University, Clearwater and [2]Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2087

Introduction: Hypericum perforatum, commonly known as St. John's Wort, is a widely used herbal remedy for mild to moderate depression. It significantly affects drug metabolism by inducing the Cytochrome P450 enzyme system, particularly the CYP3A4 enzyme. This interaction can alter the metabolism of various medications, including oral contraceptives, cancer drugs, HIV antiretrovirals, and antidepressants. St. John's Wort increases levels of serotonin, dopamine, and norepinephrine via reuptake inhibition, similar to the action of selective serotonin reuptake inhibitors (SSRIs). However, combining St. John's Wort with SSRIs can dangerously elevate serotonin levels, potentially leading to serotonin syndrome, a serious and potentially life-threatening condition. This review explores the interactions between St. John's Wort and SSRIs, focusing on metabolic effects and the risk of serotonin syndrome.
Objectives: To determine the impact St. John's Wort has on the metabolism of anti-depressants and to discover the differences in severity of serotonin syndrome between various SSRI's.
Methods: A comprehensive literature review was conducted using PubMed, Google Scholar, and Medline. The review focused on documented drug-drug interactions between St. John's Wort and SSRIs, particularly their effects on the CYP enzyme system and the incidence of serotonin syndrome in patients taking both therapies.
Results: The review identified that St. John's Wort affects the metabolism of several antidepressants, primarily through the CYP3A4, CYP2C9, and CYP2C19 enzymes. SSRIs such as citalopram, escitalopram, and sertraline, metabolized by CYP2C19, are more likely to interact with St. John's Wort than those metabolized by CYP2D6, such as paroxetine, fluoxetine, and fluvoxamine. The most significant adverse effect observed was serotonin syndrome, with case studies highlighting sertraline and paroxetine as the most commonly involved SSRIs. Dosages of SSRIs ranged from 20 mg to 75 mg, with St. John's Wort dosages typically between 600 mg to 900 mg per day. All reported cases of serotonin syndrome involved both sertraline and paroxetine, suggesting that these SSRIs may have a higher risk when combined with St. John's Wort, though a larger sample size is needed for statistical validation.
Conclusions: The literature underscores the critical need to screen for patient's who may have added St.John's Wort into their treatment regimen, especially when taking SSRIs. St. John's Wort can significantly alter the metabolism of SSRIs and increase the risk of serotonin syndrome. While interactions with sertraline and paroxetine are well-documented, further research is necessary to determine the risk profile of other SSRIs in combination with St. John's Wort.

EPV1594

Xerostomia Induced by Psychiatric Medications: Prevalence, Impact, and Management

R. A. Maldonado-Puebla[1]*, M. Murugappan[2] and B. Carr[2]
[1]College of Osteopathic Medicine, Nova Southeastern University, Clearwater and [2]Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2088

Introduction: Xerostomia, or dry mouth caused by reduced salivary flow, is a frequently reported adverse effect of various psychiatric medications, particularly tricyclic antidepressants (TCAs), antipsychotics, SSRIs, SNRIs, and anticholinergics. This condition can lead to severe oral health problems causing many patients to discontinue their medication. Anticholinergics and psychotropic medications cause xerostomia by blocking acetylcholine from binding to muscarinic receptors in the salivary glands. Determining rates of xerostomia among psychotropic medications could be useful for those who are at higher risk of xerostomia.
Objectives: To investigate the prevalence and clinical impact of xerostomia caused by psychiatric medications and to identify effective management strategies.
Methods: A narrative literature review of clinical trials, observational studies, and case reports was performed to gather data on the prevalence, severity, and management of xerostomia in patients on psychiatric medications. The review included TCAs (amitriptyline, nortriptyline), antipsychotics (clozapine, olanzapine, chlorpromazine), SSRIs (paroxetine, fluoxetine, sertraline, citalopram), SNRIs (venlafaxine, duloxetine), and anticholinergics (benztropine, trihexyphenidyl). Patient-reported outcomes and interventions were analyzed.
Results: Table 1: Prevalence of Xerostomia by Medication

Medication	Prevalence (%)	Severity (Mild/ Moderate/ Severe)	Management Strategies
Amitriptyline	30-50	Moderate to Severe	Saliva Substitutes, Pilocarpine
Clozapine	10-30	Mild to Moderate	Dose Reduction, Hydration
Paroxetine	20-40	Mild to Moderate	Sugar-free Chewing Gum, Hydration
Anticholinergics*	20-65	Moderate to Severe	Dose Adjustment, Saliva Substitutes

*Anticholinergics include benztropine and trihexyphenidyl, commonly used to manage extrapyramidal symptoms.
The prevalence of xerostomia was highest with amitriptyline (30-50%), followed by paroxetine (20-40%) and clozapine (10-30%). Anticholinergics contributed to xerostomia in 20-65% of cases. Amitriptyline and anticholinergics often caused moderate to severe cases of xerostomia. Management strategies included the use of saliva substitutes and pilocarpine for TCAs and anticholinergics, dose reduction and increased hydration for antipsychotics, and sugar-free chewing gum for SSRIs. Other medications not listed that are notable for significantly inducing xerostomia among their medication class include citalopram for SSRIs, venlafaxine for SNRIs, and chlorpromazine for antipsychotics.
Conclusions: TCAs and anticholinergics pose the highest risk for the side effect of xerostomia among psychiatric medications. Effective management requires a multifaceted approach, including pharmacologic and non-pharmacologic interventions. Future research should aim to explore alternative medications with lower xerostomia risk.

EPV1595

A meta-analytic approach on Vortioxetine and acute depression

I. Berardelli[1], E. Rogante[2], F. Formica[3], R. Iannazzo[3], A. V. Mammoliti[3]*, R. Riccioni[3], S. Veizi[3], R. S. McIntyre[4] and M. Pompili[1]

[1]Department of Neurosciences, Mental Health and Sensory Organs, Faculty of Medicine and Psychology, Suicide Prevention Centre, Sant'Andrea Hospital, Sapienza University of Rome, Via di Grottarossa, 1035, 00189; [2]Department of Human Neurosciences, Sapienza University of Rome; [3]Psychiatry Residency Training Program, Faculty of Medicine and Psychology, Sapienza University of Rome, Psychiatry Unit, Sant'Andrea Hospital,00185, Rome, Italy and [4]Department of Psychiatry, Canada Department of Pharmacology, University of Toronto, Toronto, Canada
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2089

Introduction: Major Depressive Disorder (MDD) is a chronic, recurrent illness characterized by various combinations of signs and symptoms, severity levels, and loss of functions. Among the available pharmacological treatments for MDD, Vortioxetine, a serotonin transporter inhibitor (SERT), has been widely used for its multimodal action on serotonin neurotransmission, which produces important changes also on glutamate, GABA, norepinephrine, acetylcholine, and dopamine.
Objectives: The aim of this systematic review and meta-analysis is to evaluate the acute efficacy of Vortioxetine across multiple dosing to evaluate if there is a dose response effect and as well is there a dose response issue with respect to side effects.
Methods: According to PRISMA guidelines we systematically searched 3 major electronic databases (PubMed/MEDLINE, PsycINFO, and Cochrane Central Register of Controlled Trials) for Randomized Controlled Trial (RCT) studies published between January 2013 and April 2024. The RCTs evaluate the efficacy of Vortioxetine on acute depression, compared with placebo or other antidepressants, through improvements in depressive symptoms based on MADRS or HAM-D scores. Twenty-four studies were included in the analysis.
Results: In general, Vortioxetine significantly improved depression severity, anxiety symptoms, cognitive function, with high response and remission rates. It was also well tolerated with a relatively low occurrence of severe or serious treatment emergent adverse events (TEAEs), with nausea as the most frequent adverse event, and/or discontinuation due to intolerability. Observing the results of the meta-analysis, the effect was significant for both Vortioxetine 10 and 20 mg with a greater effect-size for vortioxetine 20 mg. These different results could explain a better clinical efficacy of Vortioxetine 20 mg than Vortioxetine 10 mg for acute symptoms of depression.
Conclusions: In conclusion, the results of the present study underlined the efficacy and safety of Vortioxetine and pointed out that the optimal dosage of Vortioxetine for the treatment of acute symptoms of depression varies between 10 and 20 mg with 20 mg for a better management of acute depression. When choosing initial therapy for MDD in clinical practice, it is important to consider not only drug efficacy but also patient preferences such as AEs and possible adherence. Thus, Vortioxetine should be consider efficacious as a first, and second line therapy.

Clozapine response in patients with treatment-resistant schizophrenia: a preliminary report

Z. Maridaki[1]*, L. Mantonakis[1], E. Vasilopoulos[1], N. Smyrnis[2], N. Stefanis[1], N. Kokras[1] and E. Tzavellas[1]

[1]1st department of Psychiatry, Eginitio Hospital, National and Kapodistrian University of Athens and [2]2nd Department of Psychiatry, "ATTIKON" University General Hospital, National and Kapodistrian University of Athens, Athens, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2090

Introduction: Clozapine, the first atypical antipsychotic agent, serves as the gold standard treatment for treatment-resistant schizophrenia (TRS), being the most effective choice. Despite the fact that early commencement of clozapine is related to a higher response rate of patients, many psychiatrists remain reluctant towards its initiation. Identifying sociodemographic and clinical features correlating to clozapine response could facilitate the prompt clozapine initiation and ameliorate clinical outcomes.
Objectives: Our department presents the preliminary results of a prospective cohort study on patients diagnosed with TRS, as defined by the Treatment Response and Resistance in Psychosis (TRRIP) Working Group criteria, before clozapine initiation prospectively for 6 months. The study aims to evaluate the potential association of several sociodemographic and clinical factors with clozapine response.
Methods: The patients included in our study were required to have a history of treatment-resistant schizophrenia, as specified by the TRRIP criteria and no history of treatment with clozapine. The TRS patients were submitted to clinical assessments in baseline and 6 months after clozapine initiation included the following: the Positive and Negative Syndrome Scale (PANSS), the Perrsonal and Social Performance Scale (PSP), past medical history, sociodemographic data, blood tests, and monitoring of clozapine blood levels.
Results: 30 patients have been screened until now, of which, 26 met the inclusion criteria. 4 patients withdrew from the study before the

6-month follow-up, 4 patients discontinued clozapine due to serious adverse events. 18 patients successfully completed the follow-up. 50% of the TRS patients showed significant clinical response to clozapine, as described by >20% increase in PANSS score. Clozapine responders also showed a significant increase in functionality, as assessed by the elevation of the PSP score (p <0,001), as expected. However, neither PSP score nor PANSS positive, negative or total score at baseline were predictive of clozapine response. Regarding the patients' sociodemographic data, no statistically significant differences were identified between clozapine responders and non-responders.This study is also in accordance with the existing literature suggesting a significant delay in clozapine prescription by physicians. In our study, 80% of patients were prescribed more than three different antipsychotics before clozapine was initiated.
Conclusions: Clozapine is an effective treatment for TRS, as supported by the preliminary results of our study. 50% of the TRS patients showed significant clinical response to clozapine, as shown by reduction in PANSS score, and increase in PSP score, as a measure of functionality. However, larger clinical samples are needed to showcase further, more delicate differences among the two groups, to highlight potential predictive factors of clozapine response.

EPV1597

Drug-induced stuttering: Focus on medication with Antipsychotics

J. Marta[1]*, Â. Ferreira[1], A. F. Reis[1], T. Cardoso[1], C. Batista[1], J. Miranda[1] and V. Vila Nova[1]
[1]Setúbal Hospital Center, Setúbal, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2091

Introduction: Stuttering is a disruption in speech fluency, characterised by repetition of sounds, syllables, or words, consonant prolongations, and blockages. It can be classified as developmental or acquired, the latter being psychogenic or neurogenic. Neurogenic stuttering is often associated with brain injuries, stroke, neurodegenerative conditions, or side effects of certain medications. Drug-induced stuttering (DIS) is a recognised but rare side effect of psychotropic medications, particularly antipsychotics. Although uncommon, DIS significantly impacts quality of life, especially in males aged 20 to 40. Clinicians may mistakenly attribute the onset of stuttering to the progression of psychiatric or neurological conditions, overlooking the potential role of medication. The exact mechanism of DIS remains unclear, but it is likely related to disruptions in neurotransmitter systems.
Objectives: This review aims to explore the pathophysiology and neurochemical pathways involved in antipsychotic-induced stuttering (AIS) through a literature review.
Methods: A non-systematic literature review was conducted using PubMed with the keywords "psychopharmacology", "stuttering", and "fluency disorder".
Results: Clozapine emerges as the primary drug implicated in DIS, though cases involving olanzapine, risperidone and aripiprazole have also been reported. The pathogenesis of AIS likely involves neurotransmitter system disruptions, particularly dopamine, glutamate and serotonin, within circuits such as the cortico-basal ganglia-thalamocortical loop and white matter fiber tracts. Dopamine dysregulation appears to play a central role, as antipsychotics that block dopamine receptors may impair motor control in speech-related pathways, and additionally in the prefrontal cortex and nigrostriatal pathway. This disruption alters the balance between different brain regions, leading to deficits in motor control over the muscles involved in verbal articulation, which subsequently manifest as stuttering. Furthermore, cognitive and sensory disorders may also contribute to DIS pathogenesis.
Interestingly, stuttering improvement has been noted in some individuals with the same medications that induce it in others, reflecting the variability of dopamine's role in different brain processes.
Conclusions: DIS, particularly from antipsychotic medications, is a rare but significant clinical issue that may be overlooked. It can cause substantial social impairment, especially in psychiatric patients, who are vulnerable to stigma. Careful monitoring of medication side effects, particularly in those with no prior stuttering history, is essential to provide the best possible care. Drug withdrawal or dose adjustment is often an effective intervention for managing DIS.

EPV1599

Impact of Paliperidone Palmitate 6-Month Treatment After Hospital Discharge

M. J. Mateos-Sexmero[1], O. Martin Santiago[1]*, B. Arribas-Simón[1], O. Segurado-Martín[1] and C. Alario-Ruiz[1]
[1]Psychiatry, Hospital Clínico, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2092

Introduction: Rehospitalization is common in psychosis, often due to poor adherence to antipsychotic treatments. Long-acting injectable antipsychotics (LAIs), particularly paliperidone palmitate 6-month (PP6M), have shown promise in improving adherence and reducing relapses compared to monthly or quarterly formulations . Rapid initiation of PP6M during hospitalization may further optimize post-discharge outcomes and enhance the therapeutic adherence, minimizing the risk of a new outbreak, reducing the impact of rehospitalization and improving patients' quality of life.
Objectives: To evaluate clinical outcomes and treatment adherence in schizophrenia and other psychotic disorders after rapid PP6M initiation during psychiatric hospitalization.
Methods: A retrospective analysis of 24 hospitalized patients diagnosded with schizophrenia and other psychotic disorders treated with PP6M within 7–10 days was conducted. Treatment adherence, follow-up attendance, and adverse effects were evaluated using McNemar's test for statistical analysis.
Results: Patients had a mean age of 36.8 years (SD=10.85), 64% were male, with an average of 2 prior hospitalizations (SD=3.16) in the past two years. Previously, 57% were on monthly LAIs. Post-discharge, 83% attended follow-ups. Antipsychotic monotherapy increased by 27% (p = .10) to 59%, while attendance at over 80% of appointments improved by 47% (p ≤ .001). Akathisia was reported in 25% of patients.
Conclusions: PP6M significantly improves adherence by simplifying treatment regimens. Increased follow-up attendance (47%) and greater use of monotherapy reflect better patient outcomes. These findings align with prior evidence on the efficacy of LAIs in preventing relapses. Rapid initiation of PP6M can reduce

rehospitalizations and optimize hospital resources. The low incidence of akathisia (25%) supports its safety and tolerability for long-term use.

doi: 10.1192/j.eurpsy.2025.2093

Introduction: Methylphenidate (MPH), a common stimulant medication for attention-deficit hyperactivity disorder (ADHD), has been shown to enhance both fine and gross motor skills in individuals with ADHD.
Objectives: This study aims to assess the acute effects of a single dose of MPH on agility and balance motor tests, as well as physiological parameters such as heart rate (HR) and blood pressure (BP) at rest and after motor tests, in young healthy participants diagnosed with ADHD.
Methods: A randomized crossover design was employed to evaluate agility and balance motor performance with and without MPH treatment. The study included 35 physical education students (mean age 25.3±3.6 years) diagnosed with ADHD, 65.7% of whom were male. Each participant used their prescribed MPH medication. Motor tests included a zigzag agility test, with and without leading a ball, and a balance test. Physiological measurements, including HR, BP, and core temperature, were recorded at rest and after the motor tests. Subjective sense of effort was evaluated using the RPE scale.
Results: The agility test without a ball showed a small but significant improvement following MPH treatment (without MPH 7.4 ±0.8, with MPH 7.4±0.8, p= 0.25) . No significant differences were found in the balance test or the agility drill with a ball, regardless of MPH treatment. Systolic blood pressure (SBP) at rest was significantly higher after MPH administration (without MPH 126.7±10.8, with MPH 131.9±12.7, p=.023). There were no significant differences in diastolic blood pressure (DBP), HR, or core temperature at rest or after the motor tests.
Conclusions: A single dose of MPH improved performance in the agility test without a ball but did not enhance balance or agility with a ball. These findings suggest that while MPH may enhance certain motor functions, its effects are selective and not universally beneficial across all motor tasks.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2094

Introduction: It is necessary to know how the pharmacokinetics of psychotropic drugs changes in the body of patients during their long-term use.
Objectives: To study the pharmacokinetic parameters of the anticonvulsant galodif in experimental rats at different times of drug administration.
Methods: Galodif (meta-chlorobenzhydryl urea, 100 mg/kg) was administered in rats (in suspension, intragastrically) for: 1, 5 and 15 days. Galodif was determined in the microsomal fraction of rat liver. Pharmacokinetic parameters were calculated by a model-independent method of statistical moments. The statistical significance of differences was assessed using the Kolmogorov-Smirnov λ-test at $p<0.05$.
Results: A single administration of galodif to rats is accompanied by a slowdown in its elimination from the body: the values of T1/2 (18.82±6.25h), MRT (22.41±7.07h), MET (10.64±2.84h), AUC (15.01±4.86 mcg/ml) increase, indicating the retention of galodif in the body tissues. A 5-fold administration of galodif stimulates the elimination of the drug: T1/2 (2.22±0.52*h), AUC (3.68 ±0.79*mcg/ml), MRT (2.95±0.73*h), MET (3.00±0.65*h) decrease. The pharmacokinetic parameters of the drug indicate a pronounced tissue availability of galodif molecules. With a 15-fold administration of galodif, the elimination of the drug from the body slows down somewhat, remaining accelerated relative to a single administration: T1/2 (10.79±2.90*h), MRT (3.97±1.03*h), MET (12.05±4.10*h), AUC (19.28±7.13*mcg/ml). The revealed changes in kinetic parameters during long-term administration of galodif to rats stimulate the elimination of the drug by inducing the microsomal liver oxidative system.
Conclusions: The choice of a drug that combines anticonvulsant and detoxifying properties is of great importance in long-term therapy of paroxysmal disorders, epilepsy and alcoholism.

Desvenlafaxine-a causative agent of extrapyramidal side effects

K. Anurag[1], H. Mohapatra[2*] and L. Dash[3]

[1]Psychiatry , Institute of Medical Sciences and sum hospital , baneswar uhB; [2]Psychiatry , Institute of Medical Sciences and sum hospital , neswar abuhB and [3]Psychiatry , Institute of Medical Sciences and sum hospital , aneswar buhB, India

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2095

Introduction: Extrapyramidal side effects due to antipsychotics is very common but antidepressants being the causative factor is very less studied. Among antidepressants escitalopram is the most commonly reported. SSRI's most commonly cause extrapyramidal side effects than other antidepressants. The major theories are changes in chemical, anatomical and physiological perspectives of neurological system. Reported cases shed light that akathisia occurs most commonly followed by dystonia, parkinsonism and tardive dyskinesia states in antidepressant induced extrapyramidal side effects. Desvenlafaxine (o desmethyl venlafaxine) inhibits reuptake of dopamine, serotonin and norepinephrine. EPS occurs due to inhibitory effect of serotonin on dopaminergic pathway in striatum. Females suffer from it more commonly than men. Increasing age in women,CYP2D6 inhibition by concomittently used drugs can increase the risk. SNRI's less frequently cause EPS than SSRI's. Although desvenlafaxine is very well tolerated this rare side effect increases noncompliance and chances of suicide. Drug induced parkinsonism also predicts future chances of parkinsonism. Usage of desvenlafaxine sometimes present to the emergency department as dystonia causing panic among care givers of the patients.

Objectives: To determine desvenlafaxine's role in causing extra-Pyramidal side effects

Methods: We report here 8 cases of desvenlafaxine induced extrapyramidal side effects. All follow up cases of depression coming for follow up to dept of psychiatry IMS & Hospital who were on desvenlafaxine was analysed.the patients developong extrapyramidal side effects were detected and detailed evaluation and appropriate management was done for those specific cases..all these cases were collected over a period of last 4 years.

Results: In our case series we bring into light rare occurences of extrapyramidal side effects due desvenlafaxine. 5 out of 8 cases were females.most of the symptoms of developed within 5 days of starting the medicine.4 of these cases resulted in secondary parkinsonism, 3 of them resulted in akathisia and one resulted in acute dystonia post adminstration of desvelafaxine. The average dose of desvenlafaxine in all the cases were within 50-100mg. When after extrapyramidal side effects desvenlafaxine was withdrawn replacement with mirtzapine, escitalopram, sertraline or duloxetine was used instead of it resulting in good symptom reduction of primary illness.

Conclusions: Extrapyramidal symptoms with desvenlafaxine is extremely rare. In our case series we highlighted the importance of a keen eye to check for Extrapyramidal side-effects even with the administration of Antidepressants. Future reasearch is needed to find predictors and exact mechanism of action for the same.

Lymphopenia without neutropenia in Clozapine treatment. A review and a case report

C. Munaiz Cossío[1,2*], I. M. Peso Navarro[1], N. M. Casado Espada[1], M. Ligero Argudo[1], R. K. Gonzalez Bolaños[1], C. Payo Rodriguez[1], C. Garcia Cerdan[1], P. Andres Olivera[1] and C. Puerta Vazquez[3]

[1]Psychiatry, Complejo Asistencial Sanitario de Salamanca; [2]Psychiatry, Hospital de Salamanca and [3]Hematology, Complejo Asistencial Sanitario de Salamanca, Salamanca, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2096

Introduction: In 1975 Clozapine was retired after 16 cases of severe neutropenia, with a mortality of 50%. It wasn´t until 5 years later when its effectiveness in treatment resistant schizorenia, with a mandatory hematological follow up.

In studies available we find that clozapine treatment is related to neutropenia and not leukopenia. In the case we present below neutrophils are within range, but it´s lymphocytes that are affected.

Objectives: We hope that our expirience, and review can help other professionals in the future who find themselves in this situation.

Methods: We used the Pubmed and Uptodate databases.

We present the following clinical case.

Male, 36 years old, with a diagnosis of Schizophrenia. Several admissions to the Acute Unit over the years, requiring treatment with ECT. Maintenance treatment with Olanzapine, with which he maintained some delirious ideation and tendency to isolation. He was admitted again in 2023 due to a destabilization of his pathology, presenting delusions of harm, persecution, self-referentiality, auditory hallucinations, imperative phonemes, etc. with important affective and behavioral repercussions. Several pharmacological treatments were tried (Olanzapine, risperidone, aripiprazole), finally the patient showed some improvement with Lurasidone although his functionality was still impaired.

It was decided to start treatment with Clozapine, to minimize the psychotic symptoms, after a hemogram study, which was normal.

Results: During the weekly follow-up of the treatment, a decrease in lymphocytes was observed, with normal neutrophils. The treatment was proving to be ineffective, so it was decided to continue in this line.

Seven months after starting the treatment, the patient suffered a catarrhal process, and once resolved, we observed in addition of the lymphopenia, anaemia and grade 2 neutropenia in the hemogram. Succeeding a consult with hematology specialist we decided to stop the treatment.

The week following the suspension of the treatment, the hemogram normalizes, but the psychotic symptomatology worsens (inability to relate to others, thought blocks, etc.). Taking into account that the blood alterations occured after a cold, and the mental deterioration that the patient presented, it is agreed with the family and the patient to restart the treatment. Wich resulted in improvement of the psychotic symptoms but a new leukopenia due to a slight lymphopenia is observed again.

Conclusions: The average time described for the resolution of severe neutropenia is 12 days. In our case, the hemogram started to improve by the fifth day following the suspensión of the treatment. As it is an infrequent side effect, we do not have studies on the effects of lymphopenia secondary to Clozapine.

We decided to mantein the Clozapine treatment due to the great improvement of the patients quality of life.
Currently he is taking Clozapine 75mg a day and remains stable.

Long-acting injectable antipsychotics vs schizophrenia: a descriptive study in a Greek university hospital

G. N. Porfyri[1], E. Kottaridou[2], V. Tarantili[3]* and A. Konsta[2]

[1]National and Kapodistrian University of Athens, School of Medicine, MSc "Global Health-Disaster Medicine", Athens; [2]1st Psychiatric Clinic, General Hospital of Papageorgiou, Thessaloniki and [3]General Hospital of Argos, Argos, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2097

Introduction: Antipsychotics' adverse effects in combination with patients' anosognosia, which is frequent among individuals with schizophrenia, lead to high rates of medication nonadherence. However, long-acting injectable (LAI) antipsychotics represent a veritable ally to the eyes of patients suffering from schizophrenia. Instead of the daily pill-taking required with oral antipsychotics, LAI antipsychotics are administered by injection at two- to four-week intervals, permitting patients to feel more independent, self-secure and free.
Objectives: To explore the sociodemographic profile of patients receiving LAIs and to highlight the positive and the negative impact this treatment had on their health.
Methods: The study sample consisted of 44 patients followed-up in the Depot Outpatient Department of Papageorgiou General Hospital in Greece. The research was conducted between 2023 and March 2024. The sample was divided into subgroups according to gender, diagnoses - according to the International Classification of Diseases (ICD-10)-, and type of long-acting antipsychotic treatment. A bivariate analysis was performed to examine relationships between variables, such as: (a.) age; (b.) family status (c.) BMI; (d.) number of lifetime hospitalizations; (e.) lifetime suicide attempts.
Results: 63.6% of patients were men, 36.4% were females.
90.9% were diagnosed with Schizophrenia (F20).
31% were between 31 - 40 years old, while 26.2% were between 51 - 60 years old.
61.4% were unmarried, while 13.6% were married and 13.6% were divorced.
81.8% were unemployed/receiving welfare benefits.
68.2% lived with a relative.
56.8% claimed not suffering from physical diseases. However, when physical disorders were reported, they mainly included dyslipidaemia, diabetes and hypertension.
Based on their BMI, 37.2% were in the 2nd degree of obesity, 25.6% were in the 1st degree of obesity and 30.2% had normal weight.
47.7% were on olanzapine, 22.7% were on paliperidone and 11.4% were on haloperidol or aripiprazole.
The average value of years on LAI treatment was 3.5 years, with a minimum of 1 month and a maximum of 12 years.
Prior LAI treatment, the average value of hospitalizations was 3.5, with a minimum of 1 hospitalization and a maximum of 21 hospitalizations. After receiving treatment, 95.5% of patients were never hospitalized.
Prior LAI treatment, 88.6% of patients had no history of suicide attempts, while 11.4% had one or two suicide attempts. After receiving treatment, no participant had any suicide attempt.
Conclusions: Long-acting injectable antipsychotics help patients to live their lives outside of a psychiatric ward, by drastically diminishing the number of hospitalizations as well as the number of suicide attempts. But when it comes to their physical health, patients face many adverse effects, such as obesity. Clinicians must stay vigilant to ensure the quality of physical health of their patients.

EPV1609

Pre-acceptance study of bi-monthly Aripiprazole in clinically stable patients

S. Sanchez-Alonso[1]*, S. Manchado[1], A. Loewen[1], L. Navio Garcia[1] and S. Ovejero[1]

[1]Psychiatry, University Hospital Fundación Jiménez Díaz, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2098

Introduction: Aripiprazole monthly (Ar1M) has been the first long-acting injectable (LAI) partial agonist antipsychotic. The benefits of long-acting injectables in terms of relapse reduction are well known.
Objectives: The aim of this study is to assess the level of acceptance and the doubts presented by patients before switching to 2-monthly Aripiprazole (Ar2M).
Methods: 25 patients diagnosed with schizophrenia and related disorders in symptomatic remission were asked consecutively whether they would switch to the new bimonthly formulation of aripiprazole and the doubts expressed were collected.
Results: The sample is composed of 25 patients (12 women and 13 men). The mean age is 52.64 years. All are being treated with Ar1M with a mean dose of 408 mg/monthly. Most of the patients present a diagnosis of affective psychosis (N=12 (42%)), 36% a non-affective psychosis (N=9) and 16% a delusional disorder (N=4). Presenting an average of 3.8 previous admissions.
Acceptance was mostly positive, with an initial acceptance rate of 76 % (N=19). Twelve percent (N=3) did not initially want the treatment. Another 12% had doubts and preferred to postpone the decision. 20% of the patients had doubts, related to possible appearance of side effects. 75% of the patients who do not want the treatment have doubts, as do the patients who prefer to wait. Of the patients who initially accepted the treatment, only 1 expressed doubts about it.
Conclusions: The level of acceptance of Ar2M is very high, exceeding 75%. Of the doubts expressed about the possible change, the appearance of side effects is a matter of concern. Given the high level of acceptance, the treatment proposal is important given the wide-ranging benefits it can bring to patients. The clarification of doubts and the successive proposals of the treatment can contribute to a greater acceptance.

Effect of clozapine and olanzapine on the production of malondialdehyde in reaction to free radical attack on deoxyribose

K. M. Sipowicz[1]*, T. B. Pietras[2] and M. K. Kosmalski[2]

[1]Department of Interdisciplinary Research in the area of Social Inclusion, The Maria Grzegorzewska University in Warsaw, Warsaw and [2]Department of Clinical Pharmacology, Medical University of Lodz, Lodz, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2099

Introduction: Clozapine and olanzapine are among the most effective antipsychotic drugs. However, their use is associated with the development of metabolic syndrome and lipid profile disorders. It is therefore interesting whether they can affect the level of oxidative stress associated with the Fenton reaction, which is a source of harmful hydroxyl radicals in the blood that damage DNA.
Objectives: The aim of our study was to test the in vitro antioxidant properties of two known neuroleptics – clozapine and olanzapine, which are commonly used in the treatment of schizophrenia and bipolar disorder.
Methods: The study was based on the ability of the hydroxyl radical to split deoxyribose into malondialdehyde (MDA). In the experimental system, the Fenton reaction was used as a source of the hydroxyl radical, in which the divalent iron cation reacts with hydrogen peroxide to form a highly toxic hydroxyl radical. For this purpose, deoxyribose was incubated under appropriate conditions with FeSO4 (0.5 mM), EDTA (1 mM), H2O2 (14 mM) and cloazpine or olanzapine at concentrations of 1, 5, 20 or 50 µmol/l. These concentrations corresponded to the concentration of drugs in the cerebrospinal fluid. A clean system (containing no drugs) was used as a positive control. Then, thiobarbituric acid (TBA) was added to the reaction mixtures in the presence of trichloroacetic acid.
Results: Both olanzapine and clozapine inhibited the formation of malondialdehyde (MDA) from deoxyribose under the influence of the Fenton reaction. At concentrations of 1 and 5 µmol/l, both neuroleptics did not inhibit the reaction. At concentrations of 20 µmol/l, olanzapine inhibited the reaction by 15%, and clozapine by 20%. At concentrations of 50 µmol/l, olanzapine inhibited the reaction by 30%, and clozapine by 37%. The difference between the two neuroleptics was not statistically significant.
Conclusions:

1. At concentrations of 1 and 5 umol/l, both neuroleptics did not inhibit the studied reaction.
2. At concentrations of 20 and 50 umol/l, both neuroleptics inhibited the reaction.
3. The difference in the degree of inhibition of the reaction between clozapine and olanzapine was not statistically significant.

The similar results of inhibition of the reaction by both neuroleptics probably result from a similar chemical structure. The fact that clozapine and olanzapine inhibit the Fenton reaction may have a beneficial effect in protecting tissues from oxidative damage.

Disclosure of Interest: None Declared

Clinical Pharmacist Recommendations for Rational Benzodiazepine and Zolpidem Use During Daily Ward Rounds in Inpatients with Mental Disorders: A Retrospective Pre-Post Study

M. Stuhec[1,2]*, A. G. Gazdag[3], Z. Cuk[3], R. Oravecz[4] and B. Batinić[5,6]

[1]Department of Pharmacology, University of Maribor, Medical Faculty Maribor; [2]Department of Clinical Pharmacy, Ormoz's Psychiatric Hospital, Maribor; [3]Clinical Pharmacy; [4]Ormoz's Psychiatric Hospital, Ormoz, Slovenia; [5]Department of Psychology, University of Belgrade, Faculty of Philosophy, Belgrade and [6]Clinic of Psychiatry, University Clinical Centre of Serbia, Belgra, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2100

Introduction: Benzodiazepines and zolpidem are commonly prescribed as long-term treatments for anxiety and insomnia, although recommendations generally do not support their extended use. These medications are often prescribed for longer durations than necessary, at inappropriate doses, and with potential drug-drug interactions. In this context, rational prescribing strategies are essential. One potential strategy is the integration of a clinical pharmacist into the inpatient team for daily interdisciplinary ward rounds. However, this approach remains under-researched in the context of inpatients with mental disorders.
Objectives: This study aimed to evaluate the impact of a clinical pharmacist on medication-related problems (DRPs) focused on benzodiazepine and zolpidem use during daily ward rounds within an interdisciplinary team in a Slovenian psychiatric hospital.
Methods: A retrospective observational pre-post study was conducted at Ormož Psychiatric Hospital in Slovenia, including patients treated between 2019 and 2020. During this study, clinical pharmacists provided recommendations focused on benzodiazepines and zolpidem. The primary outcomes assessed were the difference in the total number of DRPs observed at the time of hospital discharge compared to admission. The secondary outcomes evaluated adherence to existing treatment guidelines.
Results: The study involved 20 participants with a mean age of 57.2 years (SD = 17.1). A total of 23 recommendations related to DRPs associated with benzodiazepine and zolpidem use were performed (1.15 per patient). Of these, 19 DRPs (82.6%) were identified as potential issues, while 4 DRPs (17.4%) were already expressed. Most DRPs concerning benzodiazepines and zolpidem were classified as unnecessary treatment, with 18 recommendations (78.3%). The remaining five recommendations (21.7%) addressed treatment effectiveness. The most common recommendation was the discontinuation of benzodiazepine and zolpidem therapy, suggested in 12 cases (56.5%), followed by adjustments to the treatment regimen, predominantly dose reductions, in 9 cases (39.1%). In only one case (4.3%) was the recommendation to initiate benzodiazepine treatment. Initially, the acceptance rate of recommendations was 100.0% (N = 23) at the time of discharge, but this decreased to 82.6% (N = 19) three months after discharge. Adherence to treatment guidelines improved ($p < 0.05$).
Conclusions: The results indicate that this approach led to fewer DRPs, improved adherence to treatment guidelines, and a high

acceptance rate. This is the first retrospective pre-post study in the European Union to include this collaboration in daily rounds at psychiatric hospitals, focusing on these medications. However, the study has notable limitations (non-randomized design and small sample size), which should be addressed in future research.

EPV1613

MM120 demonstrates no evidence of abuse potential in rodent preclinical studies

J. Tripp[1]* and G. N. Smagin[1]

[1]Mind Medicine, Inc., New York, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2101

Introduction: Generalized anxiety disorder (GAD) is a chronic and disabling disorder with an estimated lifetime prevalence of up to 7.8% in the US. MM120 (lysergide D-tartrate), a tartrate salt of D-lysergic acid diethylamide (LSD), is currently under development as a potential treatment for GAD. The mechanism of action (MOA) by which MM120 may elicit profound lasting psychological changes is not fully understood. Studies suggest that it has significant effects on functional brain activity across several networks, likely a result of serotonergic agonism mediated by 5HT2A activity and subsequent changes in neural network connectivity.
Objectives: A series of Good Laboratory Practice (GLP) compliant studies were conducted to evaluate abuse potential of MM120.
Methods: In vitro assessments of MM120, and its main metabolite 2-oxo-3-hydroxy LSD, receptor binding activity were performed using Eurofins CEREP BioPrint. To examine single dosing effects, MM120 was administered by oral gavage to male Sprague Dawley rats (n=6/group) at doses of 0 (vehicle only), 0.5, 2.0, and 6.0 mg/kg. A Modified Irwin test evaluated shorter acting drug effects at 15, 60, 120, and 240 minutes post-dosing compared to pre-dose baseline, with long-term, single dose neurological effects studied in a functional observation battery (FOB) on the day of dosing and 24 hours post dose. To compare potential chronic MM120 effects, male and female Sprague Dawley rats were dosed daily for four weeks via oral gavage at 0 (vehicle only), 0.5, 2.0, and 6.0 mg/kg (n=10-15/sex/group) followed by a 4-week recovery phase. FOB was performed pre-dose, dosing day 27, and day 25 of recovery phase. Additional assessments included toxicological and toxicokinetic evaluations.
Results: Receptor binding assay confirmed MM120's MOA is mediated by the serotonin system and hallucinogenic effects are driven by agonism at 5-HT2A and 5-HT2C receptors. MM120 demonstrated agonist activity at 5-HT1A, 5-HT1B, 5-HT1D, 5-HT5A, 5-HT6, and 5HT7 receptors and only nanomolar affinity at D2 dopaminergic receptors. Single dose MM120 at 0.5 mg/kg, had no effects on behavioral or physiological states. Following 6 mg/kg MM120, vocalization was recorded in 1/6 rats 2-4 h post dose, and incidences of mild piloerection were recorded in 3/6 rats from 4 to 24 h post dose. In the chronic study, there were no MM120-related changes in basic or fine movements, total ambulation, total rears, or total distance traveled.
Conclusions: Binding studies suggest no indication for elements of abuse for MM120 even with binding at serotonergic and, to a smaller degree, dopaminergic receptors. in vivo studies with MM120 evaluated supratherapeutic doses and demonstrated no evidence of physical dependence or withdrawal after sustained, daily administration for four weeks.

EPV1614

Clozapine for the treatment of resistant psychosis – CLOZAPINE UNIT

D. Tsaklakidou[1]*, M. Selakovic[1], D. Kosmidis[1] and T. Pantazis[1]

[1]Psychiatric Clinic, Sismanoglio General Hospital, Athens, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2102

Introduction: Treatment resistant schizophrenia (TRS), according to HOWES et al. 2017, is defined as a patient's condition in which, despite two or more treatment cycles with adequate dosage and duration of antipsychotic treatment, the patient's condition does not improve to the extent expected with positive or negative or cognitive symptoms persisting. The heterogeneity of patients with resistant psychosis is high, and some may show the resistance in the course of the disease after years. However, several patients show resilience from the first psychotic episode.
Objectives: Treatment resistant psychosis is probably a distinct subtype of schizophrenia, with a different etiopathogenetic mechanism. Clozapine is currently considered the drug of choice with proven efficacy, whereas atypical antipsychotic drugs are inferior in efficacy in the treatment of resistant psychosis.
Methods: The mechanism of action of the drug is unknown and there is a potential for serious side effects to occur, which necessitates the adoption of a specific protocol for clozapine administration and patient monitoring in regular psychiatric clinical practice.
Results: The Adult Psychiatric Clinic of Sismanoglio General Hospital in Athens, Greece, in its effort to create a systematic and integrated treatment and monitoring of patients who take clozapine, has created, in collaboration with the cardiology and hematology department of Sismanoglio Hospital a special unit for paients with treament resistant scizophrenia.
Conclusions: The unit called "CLOZAPINE UNIT" will ensure the regular and continuous monitoring of patients receiving clozapine during and after their hospitalization in the psychiatric clinic.

EPV1615

Vitamin E and Clonazepam in the treatment of tardive dyskinesia secondary to atypical antipsychotic treatment: a case report

S. Uygun[1]*, H. Kaya[1] and E. Göka[2]

[1]Department of Psychiatry and [2]Ankara Bilkent City Hospital, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2103
Introduction: Tardive dyskinesia is a movement disorder mostly associated with long-term antipsychotic use. Patients may present

with a wide variety of clinical features such as stereotypic movements, dystonia, etc. There are many treatment approaches but the level of evidence is low. (Vasan et al. StatPearls Pub 2024)
Objectives: To draw attention to the clinical presentation of tardive dyskinesia and its treatment.
Methods: A detailed case report is documented.
Results: A 43-year-old woman, married, housewife, diagnosed with psychotic disorder. Last year, she admitted to our outpatient clinic for the first time. She was receiving Amisulpride 400 mg/g, Zuclopentixol deconoate 200 mg/month, Biperiden 4 mg/g, Propranolol 80 mg/g on admission. Her complaints were slowed movements and difficulty in doing housework. On examination, mouth puckering and periodic head movement were noticeable. She complained of contractions in her legs and numbness in her tongue. Her speech and walking were slow. In cerebellar tests she was clumsy. She stated that her complaints increased sometimes, the contraction in her neck and legs never stopped, but the mouth puckering movement ceased at night. Her AIMS scale point was 11.
It was learned that about 4 years ago she had started to complain of feeling that she was being spied on and hearing bad things. She had been hospitalized and diagnosed with psychotic disorder. Paliperidone and aripiprazole long-acting injections, olanzapine, quetiapine treatments had been tried during hospitalization and outpatient follow-up. She had been continuously switched to another treatment because of her suspicion. Lastly zuclopentixol deconoate had been started and combined with amisulpride. She stated all her complaints of movement appeared shortly after first hospitalization. Biperiden and propranolol were added to treatment, but her complaints didn't improve. During our follow-up she was consulted to neurology. Her current picture was evaluated as tardive dyskinesia. Her treatments were gradually stopped. Clonazepam was started and gradually increased to 2 mg/g and combined with vitamin E and its dosage was increased to 1200 mg/g. After discontinuation of antipsychotics during close follow-ups she had no psychotic complaints. Within 5 months, mouth puckering movement, stereotypic left-turning movement in the neck, numbness in the tongue and contraction in the leg completely resolved. Her speech and walking improved. Last AIMS scale point was 3.
Conclusions: Tardive dyskinesia is an iatrogenic movement disorder. Many methods have been proposed for treatment but no definite treatment is known. It's thought that vitamin E may be beneficial with its antioxidant effect and clonazepam may be effective above 2 mg. The case is important in terms of demonstrating the efficacy of the combination of vitamin E and clonazepam. (Cornett et al. *Ochsner journal* (2017):162-174.)

EPV1616

Exploring cholinergic dysfunctions in schizophrenia as targets for a new generation of antipsychotics- The current level of evidence

O. Vasiliu[1,2]*, A. M. Ciobanu[1,3], A. G. Mangalagiu[1,2] and B. M. Petrescu[1,2]

[1]Neuroscience Department, "Carol Davila" University of Medicine; [2]Psychiatry Department, "Dr. Carol Davila" University Emergency Central Military Hospital and [3]Psychiatry Department, "Prof. Dr. Alexandru Obregia" Clinical Hospital of Psychiatry, Bucharest, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2104

Introduction: The dopaminergic hypothesis of schizophrenia has been constantly revised and virtually all the antipsychotics currently available for the treatment of schizophrenia are based on this pathogenetic hypothesis. However, the involvement of cholinergic, glutamate, gamma-amino-butyric acid, serotonin, neurotrophins, and pro-inflammatory cytokines in the onset of psychotic disorders is attracting more and more interest. This interest is fueled by the high rates of treatment resistance in schizophrenia, which reaches 15-40% (Wong *et al* Transl Psychiatry 2024;50 14) and requires second-line treatment, frequently associated with significant adverse events. Finding new pharmacological agents that can be used either as monotherapy or as add-ons to the ongoing treatment in patients with schizophrenia is essential for improving the chances of functional recovery.
Objectives: To review the evidence supporting the modulation of cholinergic neurotransmission as a potential pharmacological target for treating schizophrenia.
Methods: Two clinical studies repositories (US National Library of Medicine- clinicaltrials.gov and WHO International Clinical Trials Registry Platform-https://www.who.int/clinical-trials-registry-platform) and the PubMed database were explored using "choline*" and "schizophrenia" or "psychotic disorders" or "schizophrenia spectrum disorders" for studies and reviews focused on cholinergic agents targeting symptoms of schizophrenia.
Results: Positive allosteric modulation of the α7 nicotine receptors and M1/M4 muscarinic receptor agonism are the two pharmacodynamic mechanisms explored for cholinergic-based antipsychotics. Other possible mechanisms of interest are positive allosteric modulation of the M5 muscarinic receptors, selective M4 positive allosteric modulation, and cholinesterase inhibition. Out of these preclinically explored options, only xanomeline, an M1/M4 muscarinic receptor agonist, has reached phase III of clinical research with significant antipsychotic effects. The currently explored formula is an association of a fixed dose of xanomeline (selective M1/M4 cholinergic agonist) and trospium (a cholinergic antagonist), the last agent being included to decrease the risks of peripheric cholinergic adverse events. Studies investigating cholinesterase inhibitors have not been associated with favorable results, and the tolerability was low. Positive allosteric modulators of the α7 nicotine receptors are investigated in preclinical studies, but in phase 1b such an agent, i.e., AVL-3288, failed to show efficacy versus placebo.
Conclusions: The association of xanomeline, an M1/M4 receptor agonist, and trospium, a peripheric cholinergic antagonist, led to favorable results in phase III trials. Other molecules with cholinergic mechanisms are also explored in schizophrenia, but the results are not yet clinically significant.

Disclosure of Interest: None Declared

EPV1617

Atypical antipsychotics as add-ons to antidepressants in the major depressive disorder – A risks and benefits analysis

O. Vasiliu[1,2]

[1]Neuroscience Department, "Carol Davila" University of Medicine and Pharmacy and [2]Psychiatry Department, "Dr. Carol Davila" University Emergency Central Military Hospital, Bucharest, Romania
doi: 10.1192/j.eurpsy.2025.2105

Introduction: Major depressive disorder (MDD) is associated with high rates of incomplete response during treatment, with only

one-third of the patients reaching remission after the first trial of antidepressants, according to the STAR*D trial. Based on the results of the same study, only 67% of the patients with MDD obtained remission after four trials of antidepressants, including a monoamine oxidase inhibitor, i.e., tranylcypromine, and various augmenting strategies. However, in STAR*D, no atypical antipsychotics (AAPs) were used, which is an important shortcoming of this trial. Exploring the efficacy of AAPs as add-on agents to antidepressants in the case of MDD with partial responsiveness may improve the prognosis of patients who did not remit during either antidepressant monotherapy or antidepressant therapy augmented with other psychotropic agents.

Objectives: To assess the available data on the efficacy and tolerability of atypical antipsychotic augmentation in patients with MDD who obtained only partial response to antidepressants.

Methods: This review included three databases (Google Scholar, PubMed, and EMBASE) that were searched from their inception until June 2024 for papers published in English corresponding to the keywords "major depressive disorder," and "partial response" and "atypical antipsychotics". Both primary and secondary reports were included.

Results: Systematic reviews dedicated to this topic reported significantly superior responses to placebo for ziprasidone, risperidone, aripiprazole, brexpiprazole, cariprazine, and quetiapine when added to antidepressants. The tolerability of these augmenting agents was low, with high rates of early treatment discontinuation reported. Only risperidone was reported in a systematic review as similar to placebo in terms of tolerability for this population. Network meta-analyses showed positive results for quetiapine, olanzapine, aripiprazole and brexpiprazole in terms of efficacy, but in terms of acceptability, no difference between these four antipsychotics and between each of them and placebo were found; tolerability was low for all antipsychotics vs. placebo, but the certainty of most evidence was evaluated as low and very low. Aripiprazole, quetiapine, olanzapine, brexpiprazole and cariprazine are approved by the FDA for the adjunctive treatment of MDD that does not respond to antidepressant monotherapy.

Conclusions: AAPs are an efficient option for augmenting antidepressants when MDD is only partially responsive to antidepressants, but careful monitoring of this strategy's tolerability is needed, and high rates of treatment discontinuation are reported.

Disclosure of Interest: None Declared

EPV1618

A case of dysphagia associated with an increase in antipsychotic dosage

M. Velasco Santos[1]*, M. A. Morillas Romerosa[1], P. Vázquez Giraldo[1], I. Diéguez De Juan[1], C. Serrano Fuentes[1], F. Mir Biribay[1], H. Rincón Reques[1] and G. García Cepero[1]

[1]Psychiatry, Hospital Universitario La Paz (Madrid), Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2106

Introduction: Dysphagia is a rare but significant side effect of antipsychotic medications, often associated with extrapyramidal symptoms. These adverse effects become particularly relevant when dosages are increased, as seen with various antipsychotics. This report describes a case involving a 57-year-old male with a long-standing diagnosis of schizophrenia who developed dysphagia following an increase in amisulpride dosage. The patient was admitted to the psychiatric unit due to psychotic decompensation after interrupting his treatment regimen of aripiprazole 30 mg/day and amisulpride 200 mg/day for two weeks. His psychotic relapse was also precipitated by the hospitalization of his critically ill mother. Following his admission, his previous treatment was reintroduced, and the amisulpride dose was increased to 600 mg/day, with diazepam 15 mg/day added. Subsequently, he developed bradykinesia, tremor, rigidity, and oral dysphagia, necessitating a liquid diet. Despite the introduction of biperiden 4 mg/day, symptoms persisted. Comprehensive physical and neurological examinations, blood tests, and a cranial computed tomography (CT) scan were performed, revealing no abnormalities other than the parkinsonian-like symptoms. An otolaryngological assessment indicated that the dysphagia was likely of neurological origin and probably related to the use of antipsychotic medications.

Objectives: To present a case of dysphagia and parkinsonian symptoms triggered by an increase in amisulpride dosage in a patient with schizophrenia, highlighting the importance of careful monitoring during dose adjustments.

Methods: This is a case report describing a single patient. The methodology involves a detailed examination of this unique case, including clinical evaluation, diagnostic testing, treatment modifications, and outcomes.

Results: Due to the persistence of symptoms and their temporal association with the increase in amisulpride dosage, amisulpride was discontinued and switched to olanzapine 10 mg/day. Gradual improvement in both parkinsonian symptoms and dysphagia was noted over the subsequent days. Dysphagia resolved within one week, and by the time of follow-up, the patient had resumed a normal diet and experienced significant improvement in motor symptoms.

Conclusions: This case highlights the potential for amisulpride to induce extrapyramidal symptoms, including dysphagia, particularly when doses are increased. The temporal relationship between the amisulpride dose increase and the onset of symptoms, along with the resolution of symptoms after discontinuation, supports this association. Clinicians should be vigilant in monitoring for such side effects, especially in patients requiring dose adjustments of antipsychotic medications.

Psychoplastogens – a risk-benefit analysis and perspectives for future research

V. A. Voicu[1,2,3]*, O. Vasiliu[1,4] and A. Ciobanu[1,5]

[1]Carol Davila University of Medicine and Pharmacy; [2]Romanian Academy of Medical Sciences; [3]Romanian Academy; [4]Psychiatry Dept., Dr. Carol Davila University Emergency Central Military Hospital and [5]"Prof. Al. Obregia" Psychiatry Clinical Hospital, Bucharest, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2107

Introduction: The continuous exploration of new treatments in the field of psychopharmacology has brought a new light on psychedelics, raising the provocative question of how these drugs of abuse (DOA) may become useful in clinical practice. Psychedelics are included in the category of "psychoplastogens", substances that are known for their effects of enhancing neuroplasticity in the nervous central system via the modulation of Brain-derived Neurotrophic Factor (BDNF) signaling. However, psychedelics were originally

known as DOA; therefore, ascribing them to therapeutic use for patients with psychiatric disorders may seem largely counterintuitive.
Objectives: To review the current data on the benefits and risks of psychoplastogens in patients with psychiatric disorders.
Methods: A literature review was conducted in four electronic databases (PubMed, EMBASE, Cochrane, and Clarivate/Web of Science) and the US National Library of Medicine database for clinical trials (www.clinicaltrials.gov) to find clinical and preclinical sources published between January 2000 and September 2024. The keywords used were "psychoplastogens," "neuroplastogens," "neuroplasticity," "psychoactive drugs," "drugs in the pipeline," and all the main psychiatric diagnosis categories. Both primary and secondary reports were allowed, but only those published in English were selected.
Results: Ketamine and each of its stereoisomers, as well as psilocybin, are the most extensively explored drugs in this class, but also MDMA, DMT, psilocin (ELE-101), CYB003 (a psilocybin analog), and lisuride have received increased attention in the last decade. Such agents are investigated for indications such as treatment-resistant major depression, posttraumatic stress disorder, binge eating disorder, and substance use disorders. One important direction of research is the evaluation of psilocybin in patients with cancer-related depression and/or anxiety. Hallucinations and altered states of consciousness that may receive mystical interpretations are typical for high doses of psychedelics, raising questions about the use of these drugs in clinical populations with already severe mood, thought and perceptual disturbances. Safety and tolerability aspects are extremely important in deciding when, to whom, and how much psychoplastogens may be recommended for different psychiatric disorders. Creating psychoplastogens with less or no psychotomimetic activity is expected to increase the interest of clinicians in the use of such agents for patients with psychiatric disorders, especially in treatment-resistant cases.
Conclusions: Although expected to be a paradigm-shifter in psychiatry, the exploration of psychoplastogens should consider not only the potential benefits, which require further and extensive studies, but also their adverse events. For this purpose, long-term studies are needed with both efficacy and tolerability outcomes carefully monitored.

European healthcare professionals' use and experience with aripiprazole once-monthly 400mg two-injection start initiation regimen in adult patients with schizophrenia

M. Yildirim[1]*, C. Beckham[2], A. Fagiolini[3], K. Leopold[4,5], W. J. Cottam[6], J. Hickey[6], O. Rogerson[6] and S. Pappa[7]

[1]H. Lundbeck A/S, Valby, Denmark; [2]Otsuka Pharmaceutical Europe Ltd., Berkshire, United Kingdom; [3]Università Di Siena, Siena, Italy; [4]Department of Psychiatry, Psychotherapy and Psychosomatics, Vivantes Hospital am Urban and Vivantes Hospital im Friedrichshain, Charite, Universitätsmedizin, Berlin; [5]Department of Psychiatry and Psychotherapy, Carl Gustav Carus University Hospital, Technische Universität Dresden, Dresden, Germany; [6]Real-World Evidence, OPEN Health and [7]Division of Psychiatry, Department of Brain Sciences, Imperial College London, London, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2108

Introduction: Aripiprazole once monthly 400mg (AOM400) is a long-acting injectable (LAI) available with a two-injection start initiation regimen (AOM400-TIS) for the maintenance treatment of adult patients with schizophrenia stabilised with oral aripiprazole.
Objectives: This survey sought to explore the perspectives and experiences of HCPs using AOM400-TIS across Europe.
Methods: HCPs who had prescribed and/or administered the AOM400-TIS regimen to ≥3 patients with schizophrenia were invited to participate in an online survey. The survey was launched in two waves across the target countries (wave 1: Italy, Germany, United Kingdom (UK); wave 2: Denmark, Italy, Sweden). The survey aimed to understand HCPs' perspectives and attitudes towards prescribing and/or administering AOM400-TIS according to the European label in clinical practice, including reasons for its use, potential benefits, and common barriers and/or concerns. Analysis was descriptive; data was collected between February 1–March 21, 2024 (wave 1) and September 16-October 28 (wave 2).
Results: 216 HCPs completed the survey (wave 1: 31 from Italy, 31 Germany, 32 UK; wave 2: 28 from Denmark, 64 Italy and 30 Sweden) including psychiatrists (67%) and psychiatric nurses (27%). HCPs estimated 30.0% (median; IQR: 20.0–50.0) of patients in their caseload were diagnosed with schizophrenia, and of these, 50.0% were treated with LAIs (median; IQR: 25.0–65.0). 46% of HCPs were primarily responsible for prescribing AOM400-TIS, 26% for administering it, and 28% were responsible for both. HCPs estimated that 42% of patients typically spent 14–28 days on oral aripiprazole prior to AOM400-TIS, with HCPs rating the severity of symptoms of patients initiated with AOM400-TIS as mild (18% of HCPs), moderate (65% of HCPs) and/or severe (53% of HCPs). The most common reasons for initiating AOM400-TIS after transitioning from oral aripiprazole were poor adherence (88%) and relapse(s) (52%), and the most reported goals for prescribing AOM400-TIS were to improve adherence (69%) and prevent relapses (64%). Common barriers to the use of AOM400-TIS were patient reluctance to receive two injections (55%), concerns about tolerability (34%) and safety of administering a high dose in a single day (35%). Prior treatment adherence (56%) and efficacy (46%) were the most cited factors influencing prescribing of AOM400-TIS. Overall, HCPs "agreed", or "strongly agreed", that AOM400-TIS was easy to administer (84%) and that it had a similar safety/tolerability profile to the single injection start regimen (60%), while the majority were satisfied with patient outcomes with AOM400-TIS (85%).
Conclusions: Overall, HCPs with experience of using AOM400-TIS reported that it is easy to administer, well tolerated, and improves treatment outcomes, while barriers to its use include patient reluctance and perceived safety concerns.

EPV1622

Oculogyric Crisis and Suicidal Ideations in a Patient with Schizophrenia: A Case Report with Pharmacogenetic Findings

D. Žujić[1]*, N. Božina[1], A. Mihaljević-Peleš[2], L. Ganoci[3], L. Šimićević[1,3] and M. Živković[1,2]

[1]School of Medicine, University of Zagreb; [2]Department of Psychiatry and [3]Department for Pharmacogenomics, University Hospital Centre Zagreb, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2109

Introduction: Suicidal ideations are severe and serious symptoms in the clinical presentation of schizophrenia, as well as adverse reactions such as oculogyric crises. In certain situations, they may be associated with specific pharmacogenetic factors, such as gene variations for the serotonin transporter (SERT) and the CYP2D6 enzyme.
Objectives: A 37-year-old patient with treatment-resistant schizophrenia, characterized by frequent suicidal ideations, is regularly treated with clozapine (100 mg/day). Additionally, during disease exacerbations, the patient is given haloperidol (10 mg/day) as supplemental therapy, resulting in the development of oculogyric crises.
Methods: Due to the lack of therapeutic response and a predisposition to side effects, a pharmacogenetic analysis revealed *CYP2D6* genotype *4/*9 and 5-*HTTLPR* genotype S_A/S_A. This indicates CYP2D6 intermediate enzyme activity and SERT low activity. Due to these findings, haloperidol was discontinued, and paliperidone palmitate was introduced at a dose of 75 mg monthly, after which the oculogyric crises no longer occurred. The pharmacogenetic results showed reduced SERT activity, which may be associated with the decreased therapeutic response to clozapine and the persistence of suicidal ideations.
Results: Haloperidol is metabolized via CYP2D6, and its intermediate activity can lead to higher plasma concentration, resulting in extrapyramidal side effects such as oculogyric crises. Paliperidone is a metabolite of risperidone, and the activity of CYP450 enzymes has a minimal impact on its therapeutic response and potential for adverse reactions. HTTLPR regulates the transcriptional activity of the 5-HTT gene, so genotypes with low expressions, such as S'/S' or S'/L', may exhibit a weaker response to clozapine, which may include the persistence of suicidal ideations.
Conclusions: The personalized antipsychotic treatment according to an individual's pharmacogenetic profile may prevent adverse reactions and potentially explain therapeutic resistance in such cases where clozapine is otherwise indicated. Effective modern psychopharmacological treatment requires understanding pharmacogenetic factors and their influence on therapeutic response and the development of adverse reactions.

EPV1623

Salivary Oxytocin as a Biomarker in Psychedelic Assisted Psychotherapy

L. Cazorla[1], S. Alaux[1], C. Mabilais[1], C. Amberger[1], A. Buchard[1], G. Thorens[1], P. Louise[1], Z. Daniele[1] and T. Aboulafia Brakha[1]*

[1]Psychiatry, Geneva University Hospitals, Geneva, Switzerland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2110

Introduction: One of the main mechanisms of action of LSD in psychedelic-assisted psychotherapy (PAP) is the activation of 5HT2A receptors. This triggers a cascade of neurochemical processes with the release of neurotransmitters and neurohormonal substances. The release of oxytocin in this process is well documented in pre-clinical studies, with recent evidence in healthy subjects. We have no data on oxytocin reactivity during LSD treatment in patients with psychiatric problems. It would be of great scientific interest to identify treatment biomarkers in this field.
Objectives: The main objective of this pilot study is to obtain preliminary data on the reactivity of salivary oxytocin during a single LSD intake as part of PAP for anxiety disorders or depression. The secondary objective is to establish preliminary correlations between variations in oxytocin levels, intensity of perceived effects, intensity of psychedelic mystical experience, and the overall clinical response to treatment (anxiety-depression symptoms).
Methods: Participants are recruited among patients with resistant anxiety-depressive disorders enrolled in the psychedelic-assisted psychotherapy (PAP) program of the Division of Addictology, Department of Psychiatry (Geneva University Hospital). Salivary oxytocin is measured at four different time-points: before LSD intake, then 60, 90 and 180 minutes after intake. Self-perceived intensity of effects is also measured at these time points and a self-report questionnaire of mystical experience (MEQ-30) is administered at the end of the LSD session. Of note, self-reported symptoms of depression (BDI-II) and anxiety (SATI-T) are measured when participants enroll the PAP program, then a few months later right before the treatment and three weeks after treatment. ClinicalTrials.gov:NCT06557239
Results: Six participants (out of 10 planned) have completed the entire protocol. Four additional participants will receive treatment within the next two weeks. Saliva samples are stored at -20.C and will be sent for analysis once recruitment will be over (November 2024). A significant effect of time (P= 0.02) of perceived intensity effects is observed across different time-points (30, 60, 90, 180, 360 minutes after treatment), with a peak effect at 180 minutes. We also observe a significant interaction (P=0.03) between self-perceived intensity of effects and the intensity of mystical experience measured with the MEQ-30. BECK and STAI-T scores will be analysed after post-treatment assessment.
Conclusions: Our preliminary data show a clear effect of self-perceived treatment intensity and a relation between this effect and self-reported mystical experience. It will be of great interest to include oxytocin data in this analysis as well as the evolution of self-reported symptoms of anxiety and depression. With the successful recruitment and easy adherence to the protocol, we will certainly have all data available by the end of 2024.

Disclosure of Interest: None Declared

EPV1624

Exploring neurophysiological indices in psychiatric disorders: Fronto-central beta oscillations as a potential biomarker

S. Costantini[1]*, L. Ghidetti[2], S. Garofalo[2], E. Ubaldini[3], S. Pecar[3], R. Raggini[1], M. Beghi[3] and R. P. Sant'Angelo[3]

[1]Mental Health, Ausl Romagna; [2]Psychology, University of Bologna and [3]Mental Health Department, Ausl Romagna, Cesena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2111

Introduction: Historically, psychiatric disorders are studied according to a strictly behavioral approach taking into account the manifest symptomatology.
Objectives: The present work aims to deepen the investigation of neural substrates through the use of neurophysiological recording techniques in an attempt to identify biomarkers related to these pathologies. Investigating whether neurophysiological indices are able to predict the symptomatic improvement and socio-relational functioning of the sample in a transversal manner with respect to the diagnostic category and the symptomatic severity of the psychiatric disorder. Further research is necessary.
Methods: The subjects were evaluated through the scale that measures psychopathological severity (BPRS, PANSS), global functioning (HoNOS) and cognitive (MMSE, CDT). The users were categorized based on the diagnosis and divided into the two Clusters, taking into account the number of hospitalizations of each user during the current year. The following neurophysiological parameters were detected using the Rehacor-T device: electroencephalographic (frontocentral brain oscillations), electrocardiographic (heart rate and HRV) and skin conductance (EDA). For a total procedure duration of 10 minutes (6 minutes of rest, 4 minutes in which the Stroop Test task was performed). Statistical analyses (Random Forest Clustering, Logistic Regression, ANOVA) were performed with the Jasp software (JASP 0.17.3.0).
Results: 83 users hospitalized at the Psychiatric Unit of the M. Bufalini hospital in Cesena were recruited and categorized according to the clinical diagnosis. Using a Random Forest Clustering algorithm the population was divided into two different Clusters based on the extent of improvement, assessed based on the low or high number of hospitalizations in the last year. Cluster 1 includes people with a higher number of hospitalizations, while Cluster 2 includes those with a lower number. From logistic regression analyses, a single neuropsychophysiological parameter was identified that was able to predict the classification of users within the two Clusters, namely the Beta oscillations (13-30 Hz) recorded in the fronto-central position in the resting state with eyes closed (resting state). Greater power was recorded in the group of subjects who reported a significant improvement in the symptomatic picture (Cluster 2). The variable of sex was not relevant, while the diagnosis, in Cluster 2, a greater concentration of people with depressive disorder was found.
Conclusions: This work highlights how the fronto-central Beta oscillations recorded in the resting state with eyes closed can be a predictive index of the improvement of the psychopathological conditions of the sample. The remaining neurophysiological indices taken into consideration (delta, theta, alpha and beta oscillations, ECG, EDA), did not show the same predictive capacity.

Disclosure of Interest: None Declared

EPV1625

Neurophysiological indices as predictive factors of clinical improvement

L. Ghidetti[1], S. Costantini[2]*, S. Garofalo[1], M. Beghi[3], E. Ubaldini[3], S. Pecar[3], R. Raggini[3] and R. P. Sant'Angelo[3,3]

[1]Psychology, University of Bologna; [2]Mental Health and [3]Mental Health Department, Ausl Romagna, Cesena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2112

Introduction: In recent years, scientific literature has focused on the study of neurophysiological indices, including parameters derived from electroencephalography (EEG), electrocardiography (ECG), and electrodermal activity (EDA), in order to identify potential biomarkers that could be useful in the assessment, monitoring, and prevention of psychiatric disorders.
Objectives: The aim of this work is to investigate whether some neurophysiological indices are able to predict the symptomatic improvement and the socio-relational functioning of people hospitalized in acute psychopathological conditions at the Psychiatric Unit of the Bufalini hospital in Cesena, in a transversal manner in regard to the diagnostic category and the symptomatic severity of the psychiatric disorder.
Methods: To assess treatment outcomes from both a psychopathological and functional perspective, the Health of the Nation Outcome Scales (HoNOS) and Brief Psychiatric Rating Scale (BPRS) were administered at the start and end of hospitalization. Neurophysiological parameters were measured using the Rehacor-T device, which recorded frontocentral cerebral oscillations in Delta, Theta, Alpha, and Beta frequency bands, as well as heart rate and skin conductance. Data collection involved two phases: initially, participants viewed a calming landscape with eyes open, followed by a phase with eyes closed where they aimed to maintain tranquility. The Stroop test was then conducted. Statistical analyses were performed using JASP software.
Results: The sample includes 112 patients (M = 57; F = 55), the average age of the participants is 44 years (SD = 16), while the average level of education is 11 years (SD =3).
The Beta frequency band in the eyes closed condition and the Delta frequency band in the eyes open condition show a positive regression with the changes in the HoNOS scale scores, indicating that an increase in Beta and Delta oscillations corresponds to an improvement in socio-relational functioning.
A positive regression was found between Delta oscillations in the Stroop test phase and changes in BPRS scores, suggesting that an increase in oscillations corresponds to an improvement in clinical symptoms.
Conclusions: Although several autonomic abnormalities are known in psychiatric disorders, our results did not show any prognostic ability from the ECG and EDA indices recorded in the sample.
In conclusion, in line with what has already been demonstrated in the literature, it is possible to confirm that EEG indices can reflect the adaptive resources of the person affected by psychiatric disorders in terms of the possibility of responding to treatment.
Deepen the research in this field could lead to the identification of new and more specific biomarkers for the prevention, diagnosis and treatment of psychiatric disorders.

Exploring Heart Rate Variability Changes Following Respiratory Training in Individuals with Panic Disorder

S. Daccò[1,2], D. Caldirola[1,2]*, A. Alciati[2,3], A. Spiti[3] and G. Perna[1,2]

[1]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele; [2]Humanitas San Pio X Hospital, Milan and [3]IRCCS Humanitas Research Hospital, Rozzano, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2113

Introduction: Studies reported an association between panic disorder (PD) and diminished heart rate variability (HRV) (Zhang *et al.* J Affect Disord 2020; 15, 267 297-306), potentially heightening their susceptibility to cardiovascular mortality and diminished quality of life. Preliminary research has demonstrated that HRV-biofeedback training can enhance the regulation of autonomic function in both healthy individuals (Schumann *et al.* Front Neurosci 202;15 691988) and patients with anxiety (Herhaus *et al.* Psychosom Med 2022; 84, 2 199-209).

Objectives: We examined the impact of HRV-biofeedback training intervention on autonomic activity modulation among outpatients with PD with or without agoraphobia (AGO).

Methods: We conducted a retrospective observational pilot study including 10 outpatients (five females and five males; median age = 35.5 years) diagnosed with PD (9 with comorbid AGO and 1 without). The clinician-administered Panic Associated Symptoms Scale (PASS) was used to assess PD and AGO severity. All the included patients underwent a physiological assessment to determine HRV parameters and breathing rate during a 5-minute resting condition at baseline (T0) and follow-up (T1) assessment. Between T0 and T1 assessments, all patients underwent HRV-biofeedback training. Pre-post comparisons were conducted using the Wilcoxon Signed Ranks Test. To evaluate the impact of psychotropic medications, we used the Mann-Whitney U test to compare HRV parameters and disorder severity between patients with and without medications, at T0 and T1. Significance level was set at $p<0.05$.

Results: HRV-biofeedback training among individuals with PD with or without AGO fostered notable enhancements in RMSSD ($Z = -2.08$; $p < 0.01$), SDNN ($Z = -2.5$; $p = 0.01$), and LF ($Z = -2.09$; $p = 0.04$) parameters at T1 compared to T0. Furthermore, a significant decrease in heart rate ($Z = -2.19$; $p = 0.03$) was shown. These enhancements didn't seem related to psychopharmacological medications and disorder severity.

Conclusions: Despite limitations (e.g., small sample, no control group, lack of comorbidity and T1-PD severity assessment, missing inclusion/exclusion criteria, and unaccounted confounding variables affecting HRV), our study suggests that HRV biofeedback training may improve autonomic regulation in PD patients, aligning with existing literature (Herhaus *et al.* Psychosom Med 2022; 84, 2 199-209). Further research is needed to determine to what extent bio-feedback training can help to reduce panic symptoms and disorder severity.

Analysis of interhemispheric EEG spectral variation at rest and after mental arithmetic task in schizophrenic patients compared to healthy controls

N. Smaoui[1], D. Jardak[1]*, R. Feki[1], S. omri[1], I. Gassara[1], N. Charfi[1], J. Ben Thabet[1], M. maalej[1], M. Bou Ali Maalej[1], L. Zouari[1] and L. triki[2]

[1]Psychiatry C, Hedi Chaker University Hospital and [2]Functional Explorations, Habib Bourguiba University Hospital, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2114

Introduction: Electroencephalogram (EEG) has emerged to be valuable for understanding the neurophysiological mechanisms underlying cognitive dysfunctions in psychiatric disorders. EEG mental arithmetic enables to assesse cognitive abilities in schizophrenic patients, by inducing brain activity that can be observed through frequency band analysis

Objectives: This study aimed to assess the absolute spectral density (ASD) of various EEG frequency bands in schizophrenic patients and healthy controls, at rest and during a mental arithmetic task, in order to identify specific neural differences

Methods: We conducted a cross-sectional, descriptive, and analytical case-control study involving 15 schizophrenic patients and 15 healthy controls. The study was carried out at the outpatient unit of Psychiatry Department "C" at Hedi Chaker University Hospital in Sfax, Tunisia. Participants underwent a standard wakefulness EEG with eyes closed at the Functional Explorations Department of Habib Bourguiba Hospital in Sfax, Tunisia. Each participant also performed a mental calculation test during the EEG recording

Results: The ASD of the different EEGs was studied for each frequency band in the different cerebral lobes (Table 1). At rest, in schizophrenic patients, a significant difference was found between the mean ASD of the delta, theta, and beta1 frequency bands in the right and left occipital regions. Also, frequency band activity was more diminished in the left occipital regions than in the right. After mental calculation, the interhemispheric asymmetry disappeared in schizophrenic patients. In the control group, no significant differences were found between the mean ASD for any frequency band in the right and left frontal, temporal, and occipital regions, either at rest or after mental calculation (Table 1)

Table 1 : Comparison of EEG absolute spectral density between hemispheres in schizophrenics and controls at rest and after mental calculation task

	Schizophrenics		*p=*	*Controls*		*p=*
	Right	*Left*		*Right*	*Left*	
At rest						
DELTA Occipital	30,44± 26,37	22,74±19,34	**0,021**	5127,7±19031	5111,41±18968	0,373
THET Occipital	58,17±47,67	45,67±44,88	**0,023**	3856,8±12450	3863,76±12458	0,721
BETA 1 Occipital	7,22±4,25	6,24±3,77	**0,002**	497,9±1854	498,26±1860	0,854
After mental calculation task						
DELTA Occipital	22,62±17,8	24,84±33,76	0,725	4970,14±15006	4979,39±15068	0,762
THETA Occipital	46,35±41,48	62,62±96,01	0,442	1895,46±5301	1849,43±5245	0,766
BETA1 Occipital	5,76±3,45	5,43±3,17	0,466	934,81±3152	919,04±3093	0,328

Conclusions: These results underline the importance of considering cerebral lateralization in the diagnostic and therapeutic approach to schizophrenia. It is important to note that mental

arithmetic involves complex cognitive processing, essentially working memory. Hence the importance of adopting a therapeutic approach incorporating not only pharmacological treatments, but also cognitive remediation therapies

Slow EEG potentials as predictors of cognitive impairment in patients with clinical high risk for schizophrenia

M. V. Slavutskaya[1,2], A. V. Pavlov[1], A. P. Dzhem[2], A. Y. Komarova[2]*, M. A. Omelchenko[3] and I. S. Lebedeva[2]

[1]Department of the highest nervouse activity, Lomonosov Moscow State University; [2]Laboratory of neuroimaging and multimodal analysis and [3]Department of adolescent psychiatry, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2115

Introduction: Cognitive deficits in schizophrenia are associated with impaired predictive processes, however, the neural mechanisms of these impairments at the early stages of the disease are poorly understood. A modified memory-guided saccade task can be informative for studies in this field. The contingent negative variation (CNV) slow negative potentials (SNP1, 2, 3 waves) in 1000-ms interval before a memory-guided response are considered to be neural correlates of attention, memory, motor, and inhibitory predictive processes.
Objectives: We aimed to assess the CNV-type slow negative event-related potentials (ERP) during the latent period before the signal to perform remembered saccades in patients with clinical high risk (CHR) for schizophrenia.
Methods: An electroencephalogram (EEG) from 24 electrodes and electrooculogram of horizontal eye movements were recorded in 16 patients with CHR and 18 healthy controls. The participants had to remember the location of a peripheral stimulus (PS, 150ms) and perform a saccade or antisaccade (50% probability) when the central fixation stimulus (CFS) was turned off after a delay period of 2800–3000 ms. The CFS shape (cross or circle) defined a motor response type: saccade or antisaccade.
Results: The task performance (assessed based on response latency and errors) was worse in CHR patients compared to controls. In the antisaccade condition, SNP1 was faster in CHR patients compared to controls possibly reflecting attention deficits in CHR patients. The SNP1 amplitude peaks were equally distributed across the EEG leads in CHR patients but were located predominantly in frontal and central leads in controls. Diffuse representation of the amplitude peaks may reflect a compensatory involvement of posterior temporal and parietal-occipital cognitive control networks at the early stages of schizophrenia. At the last 300 ms of the delay period, the late SNP3 wave was shorter before memory-guided antisaccades compared to saccades only in patients. This may reflect the violation of predictive attention processes as well as proactive inhibition deficits, that are well-known in schizophrenia, in CHR patients.
Conclusions: Based on our data we consider the SNP1 and SNP3 components in the memory-guided saccade task to be potentially significant neurobiological markers of cognitive control at the early stages of schizophrenia.
The research was carried out within the state assignment of Ministry of Science and Higher Education of the Russian Federation (theme No.121032500081-5 and No.AAAA-A19-11904049098-9).

Neuropsychiatric Circuitry and Receptor Dysregulation in the Pathogenesis of Bruxism

D. Patel[1]*, M. Murugappan[2] and B. Carr[2]

[1]Medicine, Nova Southeastern University, Davie and [2]Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2116

Introduction: Bruxism, characterized by the grinding and clenching of teeth, is often associated with psychiatric disorders such as anxiety and stress. Bruxism not only results in significant dental pathology but can also contribute to underlying neurophysiological disturbances.
Objectives: To elucidate the relationship between bruxism and psychiatric medication by focusing on the neurophysiological mechanisms involved and the resultant dental pathologies.
Methods: A comprehensive literature review was conducted using databases such as PubMed, PsycINFO, and Google Scholar, focusing on studies from the last decade that investigate the association between bruxism, psychiatric medications, and neurophysiological factors. The review included clinical studies, neuroimaging research, and behavioral analyses.
Results: The findings indicate a strong association between bruxism and the use of psychiatric medications, particularly antidepressants and antipsychotics. Neurophysiological studies reveal dysregulation in neurotransmitter systems, notably dopamine and serotonin, which play critical roles in both bruxism and the effects of psychiatric medications. This dysregulation affects motor control circuits and stress response pathways in the central nervous system, leading to involuntary teeth grinding and clenching.
Table 1: Neurophysiological Mechanisms

Mechanism	Description
Dopamine Dysregulation	Inhibition of dopaminergic neurons leads to dysregulation of motor control and contributes to spontaneous movement of jaw muscles.
Serotonin Imbalance	Excess serotonin enhances excitatory neurotransmission and disrupts dopaminergic pathways, contributing to increased anxiety and masseter muscle hyperactivity.
Autonomic Nervous System	Hyperactivity in the sympathetic branch, driven by chronic stress, leads to increased arousal and muscle tone causing bruxism.

Table 2: Dental Pathologies Resulting from Bruxism

Pathology	Description
Tooth Wear	Enamel erosion due to repetitive grinding, leading to dentin exposure.
Fractures	Microfractures in teeth from constant pressure, progressing to severe cracks.
TMJ Disorders (TMJD)	Chronic bruxism contributes to TMJD, characterized by pain and joint dysfunction.
Periodontal Damage	Excessive force on teeth exacerbates periodontal issues, leading to gum recession.

Conclusions: Bruxism is both a symptom and a potential side effect of various psychiatric medications, rooted in neurophysiological disturbances. The interplay between dysregulated neurotransmitter

systems, psychiatric medications, and resultant dental pathologies highlights the need for integrated dental and psychiatric care. Effective management of bruxism through targeted dental interventions and tailored psychiatric treatments can significantly improve both dental health and psychiatric well-being.

Exploring the Links Between Cognitive Deficits and EEG Spectral Density in Schizophrenia

N. Smaoui[1], D. Jardak[1]*, R. Feki[1], M. Bou Ali Maalej[1], I. Gassara[1], N. Charfi[1], J. Ben Thabet[1], M. maalej[1], S. omri[1], L. Zouari[1] and L. triki[2]

[1]Psychiatry C, Hedi Chaker University Hospital and [2]Functional Explorations, Habib Bourguiba University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2117

Introduction: The research revealed significant correlations between cognitive performance, assessed by psychometric scales, and variations in frequency bands in the electroencephalography (EEG), illustrating the link between electroencephalographic activity and cognitive functions in schizophrenic patients
Objectives: Our study aimed to explore the relationship between the electroencephalographic spectral power of slow frequency bands (delta and theta) and cognitive functions in patients with schizophrenia by comparing them to healthy subjects.
Methods: We conducted a cross-sectional, descriptive, and analytical study involving 15 schizophrenic patients and 15 healthy controls. The study was performed at the Psychiatry Department "C" outpatient unit at Hedi Chaker University Hospital in Sfax in Tunisia. We used the Arabic literary version of the Screen for Cognitive Impairment in Psychiatry (SCIP) scale to assess cognitive functions. Participants underwent a standard wakefulness EEG with eyes closed at the Functional Explorations Department of Habib Bourguiba Hospital in Sfax in Tunisia. Linear regression analysis was used to examine correlations between the total SCIP score and the absolute spectral density (ASD) values of EEG oscillations.
Results: Linear regression analysis revealed a negative correlation between the total SCIP score and the delta wave ASD at T5 (left temporal) ($r = -0.37$; $p = 0.025$) and theta wave ASD at Fp2 (right prefrontal) ($r = -0.131$; $p = 0.006$). A positive correlation was found between theta wave ASD at F3 (left frontal) ($r = 0.125$; $p = 0.02$) and the total SCIP score. It revealed a negative correlation between the total SCIP score and the age of onset of schizophrenia ($r = -0.647$; $p = 0.001$).
Conclusions: These results suggest that theta and delta power at rest, as measured by EEG, may serve as potential biomarkers for cognitive deficits in patients with schizophrenia. These findings could contribute to a better understanding of the neurophysiological basis of cognitive alterations associated with this condition.

Distinguishing Quantitative Electroencephalogram Findings between Panic Disorder and Generalized Anxiety Disorder

H. Suh[1]* and K.-S. Lee[1]

[1]Psychiatry, CHA University, School of Medicine, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2118

Introduction: It is important to have early diagnosis and early intervention for generalized anxiety disorder(GAD) and panic disorder(PD). However, it is difficult to distinguish GAD from PD. Neurobehavioral markers that differentiate GAD and PD would be helpful to refine classification schemes based on neurobiological measures.
Objectives: The aim of this study is to determine the distinguishing neurophysiological characteristics between generalized anxiety disorder and panic disorder using quantitative EEG.
Methods: The study included 36 patients with GAD and 25 patients with PD. Resting vigilance controlled EEG recordings were assessed at 64 electrode sites according to the international 10/20 system. QEEG were compared between GAD and PD groups by frequency bands (delta 1-3 Hz, theta 4-7 Hz, alpha 8-12 Hz, beta 12-25 Hz, high beta 25-30 Hz, gamma 30-40 Hz and total 1-40 Hz) made by spectral analysis.
Results: The absolute powers of theta and alpha bands at the frontal area differed between GAD and PD group. The absolute power of the theta activity was decreased in FP1 and FP2 ($p < 0.05$) and the absolute power of the alpha activity was decreased in F3 ($p < 0.05$) in cases with GAD compared to PD.
Conclusions: The differences in QEEG power suggest that underlying pathophysiologic mechanisms may be different between GAD and PD. The findings that the decreased absolute powers of the theta and alpha activity at the frontal area in GAD may be the main neurophysiological characteristics of the GAD and help to have early differential diagnosis between GAD and PD.

EPV1635

Two-Year Overview of Theta-Burst Stimulation for Treatment-resistant Depression: Assessing Efficacy and Outcomes

R. P. L. Andrade[1]*, C. P. Desport[2], C. Costa[2], C. Gomes[2], A. Dias[2], S. N. Martins[2], V. Covelo[2] and P. Valente[2]

[1]Serviço de Psiquiatria, ULS Viseu Dão-Lafões, Viseu and [2]Hospital de Magalhães Lemos, ULS de Santo António, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2119

Introduction: Major depressive disorder (MDD) is a very common and debilitating disorder. MDD accounts for 4.3% of the global burden of disease, is among the largest single causes of disability worldwide, and is an important cause of premature death. Depression expands its negative influence in all aspects of life, being estimate that 12 billion productive workdays are lost every year to depression and anxiety.
On top of that, non-response to first line pharmacological and psychotherapeutic treatments are substantial, with treatment-resistant depression (TRD) affecting approximately one third of these patients. These patients are thus candidates for non-invasive neuromodulation procedures such as repetitive transcranial magnetic stimulation (TMS), included in all major treatment guidelines.
Objectives: With this work we intend to present a descriptive analysis of the efficacy of the intermittent theta burst TMS (iTBS)

protocol in patients with TRD who underwent this treatment at Hospital de Magalhães Lemos, Porto, since July 2022.
Methods: We conducted an analysis of sociodemographic characteristics of patients who underwent treatment with iTBS. The primary outcome was the Beck's Depression Inventory (BDI) score difference between the first and last sessions. Secondary outcome included the Montgomery-Asberg Depression Rating Scale (MADRS) applied to a smaller cluster of patients.
Results: Since July 2022, more than 50 cycles of iTBS treatment have been performed.
More than 60% of the TRD patients enrolled scored positive changes with the treatment, on BDI. Improvements exceeded non-response in both sexes, irrespective of disease duration, and in nearly all age groups – except for the single patient under 25 years old. Positive changes were also observed with the MADRS, with more than 70% of this cluster of TRD patients scoring positive changes, including the patient under 25 years old who score non-response with BDI.
iTBS was also applied to a small number of patients diagnosed with treatment-resistant bipolar major depression, in whom positive changes outweighed non-response.
All iTBS cycles were performed without major adverse effects being reported.
Conclusions: TMs, represented here by the iTBS protocol, is safe and effective in improving depressive symptoms when first line treatments are not. The positive effects extend to patients diagnosed with BD, despite the small number of patients present in our patient pool.
Combined with the logistical ease of its use, not requiring general anaesthesia or induction of seizures like electroconvulsive therapy, TMS presents itself as an important alternative in the treatment of TRD.

Descriptive analysis of the Application of Electroconvulsive Therapy in patients with acute psychiatric pathology admitted to a Psychiatric Hospitalization Unit

M. F. Parada[1]*, R. Arias[1], I. Lizarraga[1], E. Chavarría[1], J. Jimenez[1], P. Fructos[1], C. Arranz[1], A. Ortiz[1], J. Bullard[1] and M. Vallejo[1]
[1]Psychiatry, Clinica Universidad de Navarra, Pamplona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2120

Introduction: Electroconvulsive therapy (ECT) is a recognized treatment for various psychiatric conditions (Bernardo et al., 2018). However, there is a lack of recent studies describing the clinical characteristics of patients undergoing ECT (Peltzman et al., 2020).
Objectives: To provide an updated evaluation of the clinical **characteristics, treatment parameters, and outcomes** of patients receiving ECT at Clinica Universidad de Navarra (CUN), focusing on its **effectiveness and evolution** over recent years.
Methods: This **cross-sectional descriptive study** examines patients who underwent electroconvulsive therapy (ECT) at CUN's Psychiatric Hospitalization Unit from **January 2019 to August 2023.** It focuses on those who received bifrontotemporal ECT, with stimulation power quantified using the DGx program on the Thymatron® machine. Collected data include age, sex, prior psychotropic medication use, ECT indication, comorbidities, Stimulus potency (% DGx), seizure duration (seconds on the electroencephalogram), and anesthetic induction type. Hamilton Anxiety and Depression Scales were recorded before and after treatment when clinically indicated.
Results: ECT was administered in 80 cases, constituting 8.62% of admitted patients, with 33.75% being male. Among these, 33% had **psychiatric comorbidities**, most commonly being pathological personality traits (16%) and generalized anxiety disorder (5.3%) (Image 1). **Non-psychiatric comorbidities** included endocrine-metabolic conditions 49% and cardiac conditions 34% (Image 2.)
Pre-ECT, the most **common psychotropic medications** included benzodiazepines (87.5%), atypical antipsychotics (76.5%), and dual antidepressants (47.5%). Propofol was used for **initial anesthetic induction** in 86.25% of cases, with 30.43% requiring a switch to thiopental due to the reduced efficacy. The average number of **ECT sessions** per patient was 8.9 (range: 3-13), with a **mean seizure duration** of 30.5 seconds. The **primary indications for ECT** were depressive disorders (85%) and psychotic disorders (11%) (Image 3).
Before ECT, the **average Hamilton Depression Scale** score was 25.3, decreasing to 5.3 post-treatment. Similarly, the **Hamilton Anxiety Scale score average** was 23.72 before ECT and 4.6 after.

Image 1:

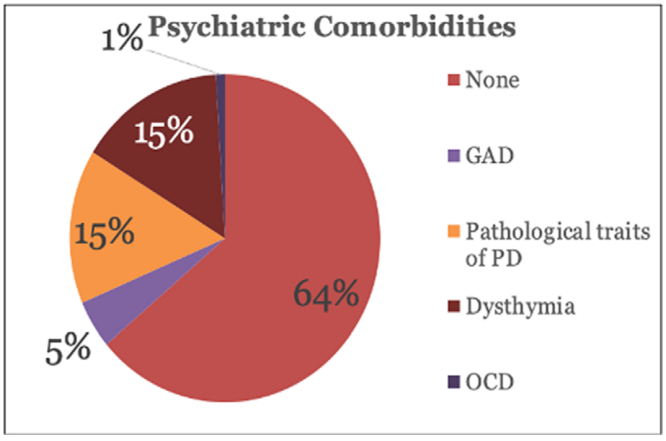

Image 2:

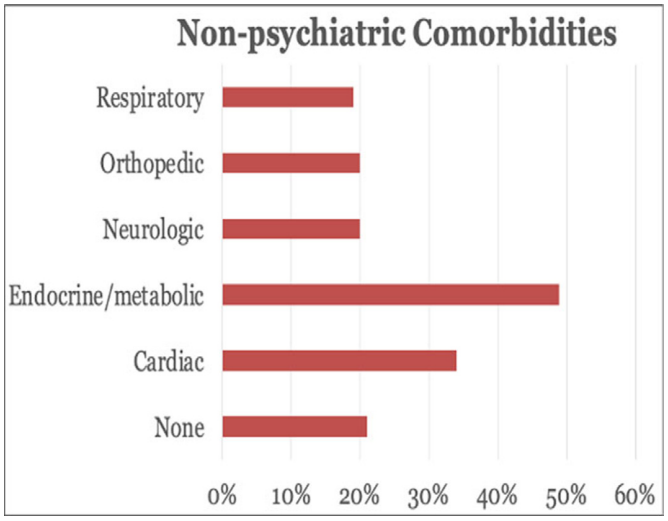

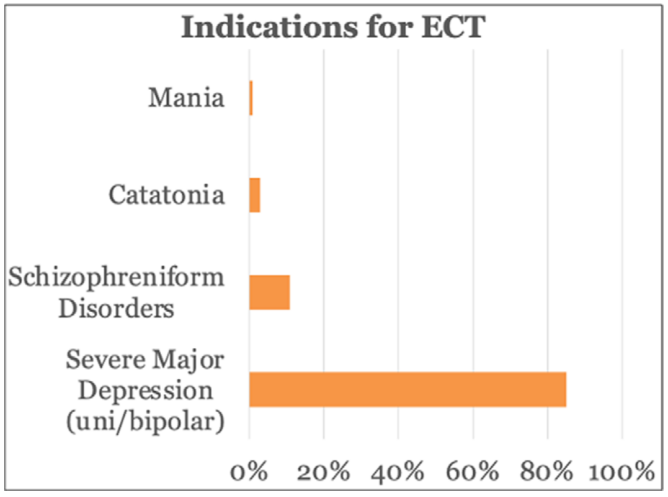

Image 3:

Conclusions: Our sample revealed that the **primary indications for ECT were affective and psychotic disorders**, with a predominant impact on **adult women**. This supports its role as a key intervention for **treatment-resistant conditions**, a finding consistent with existing literature (Leiknes et al., 2012). These **preliminary results** represent an initial evaluation in a broader study aimed at exploring additional aspects of clinical response and comparing ECT with other treatment modalities.

EPV1639

Repetitive Transcranial Magnetic Stimulation (rTMS) an an augmentation strategy in a sample of patients with treatment-resistant depression: a comparison of traditional and accelerated protocols

D. Conti[1], C. Bucca[1]*, N. Girone[1], L. Larini[1], M. Vismara[1], B. Benatti[1,2] and B. Dell'Osso[1,2,3]

[1]Department of Mental Health, Department of Biomedical and Clinical Sciences Luigi Sacco; [2]"Aldo Ravelli" Center for Neurotechnology and Brain Therapeutic, University of Milan, Milan, Italy and [3]Department of Psychiatry and Behavioral Sciences, Bipolar Disorders Clinic, Stanford University, Stanford, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2121

Introduction: Repetitive transcranial magnetic stimulation (rTMS) is a clinically validated treatment, included in international guidelines for managing treatment-resistant depression (TRD). The conventional daily administration of rTMS protocols over several weeks can pose challenges for patients, such as work interruptions and commuting difficulties. To enhance the antidepressant effects and minimize the duration of treatment, increasing the frequency of daily rTMS sessions has been proposed as a potentially more effective approach.
Objectives: This study aims to compare the efficacy and tolerability of standard versus accelerated rTMS protocols as supplementary treatments for patients with TRD
Methods: 24 patients diagnosed with major depressive episodes (either unipolar or bipolar) and classified as partial responders or non-responders to adequate pharmacological treatment were randomized into two groups. One group received standard rTMS (one session daily, five days a week, over four weeks; n=9), while the other underwent accelerated rTMS (two sessions daily, five days a week, over two weeks; n=15). Both groups were treated on the left dorsolateral prefrontal cortex with high-frequency stimulation (10 Hz) at 120% of the motor threshold, delivering 3000 pulses per session. Primary outcome measures included scores from the Hamilton Depression Rating Scale (HAM-D), Montgomery-Åsberg Depression Rating Scale (MADRS), and Clinical Global Impressions-Severity (CGI-S) at baseline (T0), post-treatment (T1), and during follow-ups at one month (T2) and three months (T3). Tolerability was assessed based on reported adverse effects. Paired Samples t-Test was employed for continuous variable comparisons, while t-Test was used to analyze differences between groups.
Results: Analysis of the overall sample revealed a significant reduction in HAM-D, MADRS, and CGI-S scores from T0 to T1 ($p<0.001$). These improvements were maintained at the one-month and three-month follow-ups (T1 vs T2: p=0.726, p=1.00, p=0.803; T2 vs T3: p=0.105, p=0.594, p=0.653). No significant differences were observed in response and remission rates between the two protocols (T1: p=0.722; T2: p=0.727; T3: p=0.979). The only reported side effect was mild, transient headaches during stimulation, with a minimal dropout rate (0.25%).
Conclusions: These preliminary findings align with previous literature, suggesting similar efficacy and tolerability between accelerated and standard rTMS protocols. Future studies with larger, controlled, and blinded designs are warranted to validate these results and explore treatment parameters for accelerated rTMS.

Disclosure of Interest: None Declared

EPV1640

Transcranial Magnetic Stimulation in Bipolar Depression: retrospective analysis and literature review

C. P. Desport[1]*, R. P. Andrade[2], C. Costa[1], C. Gomes[1], A. Dias[1], S. N. Martins[1], V. Covelo[1] and P. Valente[1]

[1]Psychiatry, Hospital de Magalhães Lemos, Unidade Local de Saúde de Santo António, Porto and [2]Psychiatry, ULS Viseu Dão-Lafões, Viseu, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2122

Introduction: Bipolar affective disorder (BD) affects approximately 2% of the population. It's an incapacitating condition that significantly impairs quality of life and functional capacity; depressive episodes in BD are highly debilitating and carry major suicide risk and treatment-resistant bipolar depression has been reported in about one-quarter of patients with bipolar disorders. Non-invasive neuromodulation procedures, such as repetitive transcranial magnetic stimulation (TMS), being an approved treatment for treatment-resistant unipolar depression, can also be an option for bipolar depression.
Objectives: with this work we intend to assess the efficacy and outcomes of the intermittent theta burst TMS (iTBS) protocol in patients with bipolar depression, who underwent this treatment at Hospital de Magalhães Lemos, Porto, since July 2022. We also conducted a literature review on the subject.
Methods: analysis of clinical and sociodemographic characteristics of the 4 patients who underwent treatment and of the treatment outcomes using Beck's Depression Inventory (BDI) score difference between first and last sessions and Montgomery-Asberg Depression Rating Scale (MADRS) as the secondary outcome, the last applied to only 2 of the patients. A computerized search was performed on PubMed, for articles published in the last 10 years, using the key-words "bipolar depression", "bipolar depressive episode" and "tms".
Results: since July 2022, 4 patients with bipolar depression were submitted to iTBS treatment, 3 women and 1 man. Of these, 3 had a diagnosis of bipolar type 1 disorder and 1 of bipolar type 2. One of the women had a comorbid diagnosis of dementia and was not able to answer BDI. All 4 of these patients were referred to this treatment after failure to reach sustained symptomatic remission with at least two different treatment trials, at adequate therapeutic doses. We found positive changes in BDI in all 3 patients that completed this questionnaire and in MADRS in the 2 that answered. One of the patients had an elevated mood and an increase in energy levels following treatment but did not meet criteria for hypomanic/manic episode. No major side effects were reported.
Conclusions: Our results and literature review suggest that TMS, in our study iTBS protocol, may well be an effective treatment for bipolar depression, with some studies showing even higher response rates for bipolar depression when compared with unipolar depression, suggesting that bipolar disorder is more likely a better biological target. Furthermore, the low side effect profile of TMS and the fact that it is a minimally invasive procedure, makes it even more appealing as a treatment option. Risk of psychomotor agitation and hypomania/mania must be closely monitored in these cases.

EPV1642

Effectiveness of Electroconvulsive Therapy in Postpartum Psychosis: A Systematic Review

O. Herrera-Barrón[1]*, X. Cors-Cepeda[1], C. López-García[1] and J. Paez-Mayorga[1]

[1]School of Medicine and Health Sciences at Tecnológico de Monterrey, Monterrey, Mexico
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2123

Introduction: Postpartum psychosis (PPP) is a psychiatric condition that arises shortly after childbirth. Electroconvulsive therapy (ECT) offers rapid symptom relief, particularly in severe cases. Despite reports of ECT effectiveness in PPP, its use remains limited and unstandardized.
Objectives: This systematic review aims to evaluate the clinical effectiveness of ECT in treating PPP.
Methods: The electronic databases PubMed/MEDLINE, Cochrane, SciELO, SCOPUS, and WOS were screened for studies reporting ECT outcomes in PPP following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. Studies published between 2004 and 2024, written in English, and focused on subjects up to 12 months postpartum were included. All studies were vetted by ≥ 2 reviewers. Bias was assessed with the JBI Critical Appraisal Tool.
Results: A total of 255 studies were identified and 7 met the inclusion criteria. ECT was exclusively used in severe PPP refractory to pharmacological intervention. Symptom improvement was reported in 100% of cases and most achieved total remission. Total ECT sessions ranged from 5 to 15, with symptom improvement after 1-6 sessions and remission after 5-11 sessions. ECT side effects were transient and included memory loss, mild cognitive deficit, and pain.
Conclusions: High remission rates on ECT were demonstrated where pharmacological intervention was insufficient, highlighting its effectiveness as a rapid and safe intervention for PPP. Adverse effects were transient and manageable, underscoring ECT safety. Small sample sizes and variability in ECT protocols limit the generalizability of the findings. Further evidence from prospective studies is needed to consider ECT as a first line treatment for PPP.

Deep brain stimulation for obsessive-compulsive disorder : A look back over 24 years of use

A. Karmous[1]*, H. Ghabi[2], A. Hajri[1], E. Khelifa[1], A. Maamri[1] and H. Zalila[1]

[1]Emergency and outpatient department and [2]Department G, Razi hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2124

Introduction: Deep brain stimulation (DBS) was first used in 1999 for the treatment of resistant obsessive-compulsive disorder (OCD), and it was not until 2009 that the Food and Drug Administration approved it for this purpose.

Objectives: The aim of our study was to investigate the safety and efficacy of DBS through a systematic review.
Methods: A systematic review was conducted. PubMed via Medline, Google Scholar and Semantic Scholar were used as search engines. The keywords used were ("Obsessive compulsive disorder" or "OCD") and ("Deep brain stimulation" or "DBS"). Clinical trials and observational studies assessing the efficacy of DBS for OCD, published from inception to December 2023 and written in English or Frensh were analysed. The inclusion criteria were a main diagnosis of OCD, DBS conducted for therapeutic purposes and a response to DBS assessed by the Yale-Brown Obsessive-Compulsive scale (Y-BOCS).
Results: Thirty four studies were included in the final analysis with a reported total of 316 cases. In 58.2% of cases, patients were female. The average age at the time of surgery of implanting the stimulation device was 40.9 ± 7.8 years. The mean time from onset of symptoms to surgery was 22.4 ± 4.6 years. The mean initial Y-BOCS score was 33 ± 3.7. The mean response rate, defined as a reduction in Y-BOCS score of more than 35 % was 70.7% ± 24.8. The maximum symptom reduction was reached between 12 to 14 months after implantation in most studies. Hypomania was the most frequent side effect reaching 45% in some studies. Intracranial hemorrhage secondary to surgery was the most serious complication and did not exceed 5 % in any study. No clear predictive factors for response to DBS were identified.
Conclusions: DBS appears to be a promising therapy for patients with resistant OCD. This innovative approach, combined with ongoing advancements in neurotechnology, offers hope for the future of OCD treatment. However, no predictors of response have yet been established.

Safety and efficacy of electroconvulsive therapy during pregnancy: A systematic review

A. Karmous[1]*, H. Ghabi[2], N. Karmous[3], R. Lansari[1], A. Larnaout[1] and W. Melki[1]

[1]Department D; [2]Department G, Razi hospital, Manouba and [3]Gynaecology and obstetrics department B, Charles Nicoles hospital, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2125

Introduction: Pregnancy and the immediate postpartum period are at high risk of decompensating or developing psychiatric disorders. Electroconvulsive therapy (ECT) is an effective treatment for severe and resistant mental disorders and could be a therapeutic option for psychiatric disorders during pregnancy.
Objectives: The aim of our study was to investigate the safety and the efficacy of ECT in pregnant women through a systematic review.
Methods: A systematic review was conducted. PubMed via Medline, Google Scholar and Semantic Scholar were used as search engines. The keywords used were ("Electroconvuslive therapy" or "ECT") and ("pregnancy" or "pregnant"). Clinical trials, case reports and case series assessing the efficacy and safety of ECT during pregnancy, published from inception to December 2023 and written in English or Frensh were included.
Results: A total of 30 articles were included for the final analysis with a total of 96 cases. The mean age of patients was 30.1 years. ECT was mostly performed during the first trimester of pregnancy with 45.3% of patients. The main psychiatric diagnoses were major depressive disorder with 47.6% of patients, followed by bipolar disorder with 19.3%. The average number of sessions performed was 10.4 with a maximum of 22. A partial improvement or a total resolution of symptoms were noted in 78.6% of cases. Transient fetal arrhythmia (not requiring drug intervention) was the most common complication, occurring in 6.25% of cases (n=6). Fetal death or abortion were observed in 4.1% of cases (n=4).
Conclusions: ECT appears to be an effective treatment for severe psychiatric disorders in pregnant women. However, it needs to be performed as part of a multidisciplinary care team to reduce the risk of serious consequences for both the mother and the fetus.

Comparison of the clinical efficacy of rhythmic transcranial magnetic stimulation protocols in patients with depression

A. N. Pomytkin[1] and A. Y. Komarova[1]*

[1]Laboratory of neuroimaging and multimodal analysis, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2126

Introduction: Transcranial magnetic stimulation (TMS) is a method of non-invasive stimulation of the cerebral cortex with an alternating magnetic field, used in the therapy of patients with depression, including cases where drug therapy is ineffective. The currently widely used high-frequency stimulation protocols with the application of an inductor to the projection of the left dorsolateral prefrontal cortex (LDLPC) have confirmed their effectiveness, while protocols with a significantly shorter procedure time are appearing in clinical practice. In this study, a clinical comparison of two protocols was conducted.
Objectives: To conduct a comparative assessment of the clinical effect of TMS using theta-burst stimulation and high-frequency (10 Hz) stimulation.
Methods: The study included 34 patients (mean age 27.2 ±2.1 years) with a diagnosis F31-F34 and clinical depression confirmed by psychometric assessment data (HDRS=21.7±5.6). Patients received stimulation in the projection of the left dorsolateral prefrontal cortex for 3 weeks: 17 patients (group 1) received high-frequency stimulation (10 Hz) and 17 patients (group 2) intermittent theta burst stimulation. Symptom reduction, according to psychometric assessment, corresponding to 50% or more, was chosen as the criterion for response to treatment.
Results: By the end of the study, the number of patients in the total sample who responded to treatment corresponded to 55.9% (n=19).

Comparison of the effectiveness of the protocols showed that the group statistically significantly differed in the number of responders (p<0.05; 0.01): in group 1 47.06% (n=8), in group 2 64.71% (n=11). Patients who received theta-burst stimulation had a faster rate of symptom reduction and demonstrated higher adherence to treatment.

Conclusions: Thus, a comparative study of the effectiveness of two TMS protocols demonstrated a higher effectiveness of theta-burst stimulation, however, it is worth noting the overall effectiveness of this method regardless of the stimulation parameters, as well as a fairly rapid development of the clinical effect.

The study was supported by RSF grant 22-15-00437.

High-Dose Accelerated Bilateral Theta Burst Stimulation for Depression and Anxiety: The Seville Protocol

M. Martín-Bejarano[1], Á. Moleón[1,2]*, P. Álvarez de Toledo[1], I. Pérez-Aquino[1], J. Narbona-Antúnez[1], J. Torres-Pereira[1] and M. García-Ferriol[1]

[1]Institulo Andaluz de Salud Cerebral and [2]Hospital Virgen del Rocío, Sevilla, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2127

Introduction: Treatment resistance affects 20-60% of patients, leading to substantial personal and economic impact. Repetitive transcranial magnetic stimulation (rTMS) is effective, with theta burst stimulation (TBS) providing similar benefits more efficiently.

Objectives: To assess high-dose TBS effectiveness and to explore how demographic and clinical factors influence treatment outcomes.

Methods: Accelerated high-dose (30 sessions) cTBS and iTBS was administered targeting the right and left dorsolateral prefrontal cortex (DLPFC) respectively (3600 pulses per session), with MRI-guided neuronavigation. Pre- and post-treatment HAM-D and HAM-A scores were analyzed with mixed-effects models. Response and remission rates were further examined using generalized linear models (GLM). All analyses were conducted using the R Studio.

Results: The study included a total of 101 participants, of whom 89 had data available for HAM-D (56 [38.8–65] years; 69.7% females), and 82 had data available for HAM-A (56 [39–65] years; 70.7% females). 29.2% achieved HAM-D remission, 22% achieved HAM-A remission, with response rates of 46.1% for depression and 50% for anxiety.

Mixed-effects models showed a highly significant reduction in both HAM-D and HAM-A scores after TMS treatment (HAM-D: $\beta = -12$, $p = 2.2e{-}15$; HAM-A: $\beta = -14.484$, $p = 1.1{\times}10{-}14$) (Fig. 1). For HAM-D, family history was associated with reduced treatment effectiveness ($\beta = 5.302$, $p = 0.011$). Sex also influenced HAM-D scores, with males showing a greater response than females ($p = 0.018$), although this trend was only marginally significant for HAM-A ($p = 0.073$).

Fig. 1. Pre- and post-treatment scores on the HAM-D and HAM-A showing significant reductions following rTMS.

The GLM analysis for HAM-D and HAM-A remission did not reveal statistically significant overall results. However, specific predictors were significantly associated with treatment response. A family history of mental health conditions was linked to a lower likelihood of response, based on HAM-D (OR = 0.058, p = 0.016) and HAM-A (OR = 0.074, p = 0.049). Age was a significant predictor for response on both HAM-D (OR = 1.1, p = 0.048) and HAM-A (OR = 1.115, p = 0.032) (Fig. 2). Additionally, regarding employment status individuals identified as "Housekeeper" or "Retired" had reduced likelihood of positive response ($p < 0.05$).

Figure 2. Influence of age on HAMA and HAM-D response outcomes in patients undergoing TMS treatment.

Image:

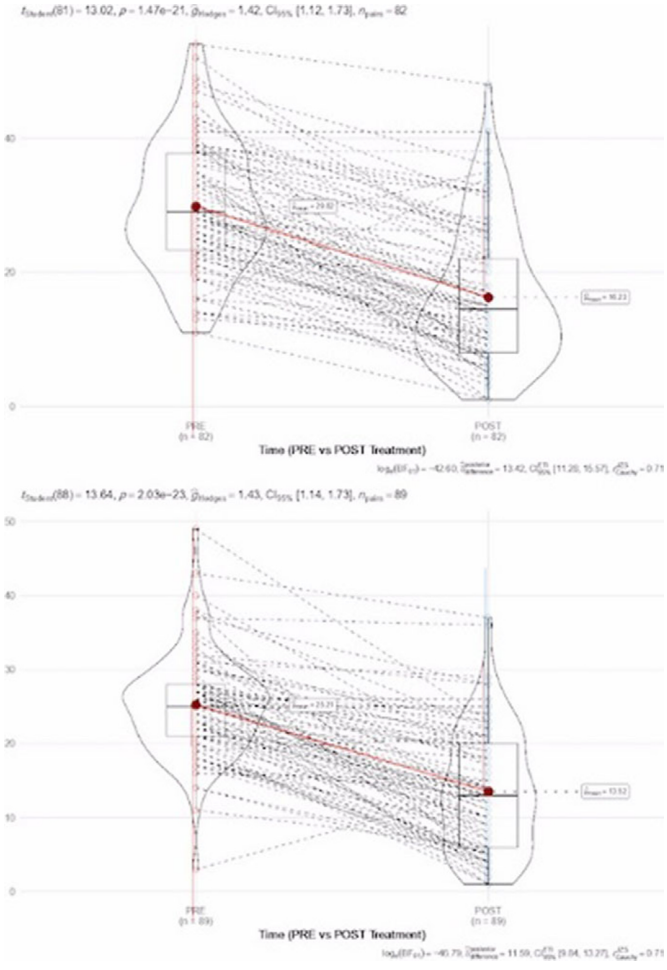

Image 2:

Conclusions: High-dose accelerated bilateral TBS using the Sevilla Protocol significantly reduced depression and anxiety symptoms in treatment-resistant patients, with notable response and remission rates. Family history, age, and certain employment statuses significantly influenced treatment response, suggesting that TBS may benefit from tailored approaches. Larger, balanced samples are needed to confirm these findings and improve prediction models.

Mechanisms and Efficacy of Transcranial Stimulation Technologies in Substance Use Disorders: A Focus on Prefrontal Cortex Stimulation

C. Pinheiro Ramos[1]*, A. F. Reis[1], M. J. Freire[1] and S. Mendes[1]
[1]Setúbal Hospital Center, Setúbal, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2128

Introduction: About 31 million people worldwide suffer from substance use disorders (SUDs), causing significant health and economic burdens.
SUDs are linked to reduced dopamine activity in the mesolimbic region of the brain, as well as dysfunction in the dorsolateral prefrontal cortex (DLPFC) and dorsal anterior cingulate cortex (dACC), which are responsible for decision-making and self-control. Additionally, the ventral prefrontal cortex (PFC), including the orbitofrontal cortex (OFC) and ventral anterior cingulate cortex (vACC), play a role in emotional processing and limbic arousal.
A promising approach to treating SUDs involves non-invasive neuromodulation techniques (NIBS), specifically repetitive transcranial magnetic stimulation (rTMS) and transcranial direct current stimulation (tDCS).
Objectives: To better understand the role of non-invasive neuromodulation techniques in substance use disorders.
Methods: A search was conducted in various databases, including PubMed.
Results: Many studies using rTMS to treat SUDs have targeted the DLPFC. When the left DLPFC is stimulated, the effects are generally positive, and the treatment produces clinically significant results for tobacco, stimulant, and opioid use disorders.
It has been found that the medial PFC (mPFC) could be a potential target for therapy, especially when using deep TMS, as demonstrated by studies involving alcohol and cocaine. Both the DLPFC and mPFC are promising targets for rTMS.
Regarding tDCS, it seems that right anodal DLPFC stimulation is the most effective method across all types of substances.
Conclusions: Much remains unknown regarding the mechanisms by which rTMS or tDCS induce therapeutic effects in SUDs. Further research is necessary to determine the clinical safety and efficacy of these treatments.

Efficacy of Electrostimulation in Treating Major Depressive Disorder and Generalized Anxiety Disorder: A Literature Review

J. R. Pinto Nasr[1]*, F. H. de Oliveira Bezerra[1], V. A. Masson[1] and L. R. Ambrósio Filgueiras[1]
[1]Universidade Paulista - Campus Campinas, Campinas, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2129

Introduction: Major Depressive Disorder (MDD) and Generalized Anxiety Disorder (GAD) are prevalent conditions that significantly affect quality of life. Many patients with MDD and GAD do not respond adequately to conventional therapies, such as psychotherapy and antidepressants, highlighting the need for alternative treatments. In this context, electrostimulation, particularly Transcranial Magnetic Stimulation (TMS) and Transcranial Direct Current Stimulation (tDCS), has shown promise by modulating brain activity to relieve symptoms.
Objectives: To assess the efficacy of TMS and tDCS in treating MDD and GAD.
Methods: This systematic literature review was conducted in SciELO, PubMed, covering the period from 2014 to 2024. After an initial selection of 15 articles, six studies were chosen based on relevance and reliability. The analysis focused on outcomes from controlled and randomized studies as well as systematic reviews and meta-analyses, involving TMS and tDCS.
Results: The reviewed studies demonstrated that TMS and tDCS significantly reduce symptoms in MDD and GAD compared to placebo. One study evaluated the combined effect of tDCS with

antidepressants, indicating a more pronounced clinical response and suggesting potential synergy between neuromodulation and pharmacotherapy in cortico-limbic circuits. However, larger sample sizes are needed to achieve robust statistical validation, clarifying the isolated impact of each modality and their combination.
Conclusions: Both TMS and tDCS represent effective therapeutic alternatives for patients with MDD and GAD, especially those refractory to conventional approaches. Although promising, implementing these techniques faces challenges, including high costs, the need for specialized professionals, and stronger scientific validation to enable widespread use. Expanding clinical knowledge and disseminating evidence-based guidelines can promote safe access to and usage of these therapies.

A historical overview on the rise and downfall of psychosurgery

G. N. Porfyri[1] and V. Tarantili[2]*
[1]National and Kapodistrian University of Athens, Athens and [2]General Hospital of Argos, Argos, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2130

Introduction: "Psychosurgery" is defined as the human brain surgery to treat psychiatric symptoms.
Objectives: This study aims to portray psychosurgery's historical evolution.
Methods: A review of 35 articles from 2000 to 2024 on PubMed and Google Scholar, regarding psychosurgery.
Results: The initial phase of psychosurgery dated in 1888, when Swiss psychiatrist Gottlieb Burckhardt, in en effort to control the symptoms of psychiatric patients, he performed the very first brain topectomies. Later on, in 1936, Portuguese neurologist Egas Moniz and neurosurgeon Almeida Lima, collaborated on performing the first lobotomy. After achieving 20 lobotomies, Moniz reported that 35% of patients showed complete remission of psychiatric symptoms, 35% of patients showed a mild improvement, and 30% of patients showed no improvement. It was Freeman's (a neurologist) and Watts's (a neurosurgeon) turn to perform in 1936 the first lobotomy on the USA ground, on a woman suffering from depression; Alice Hammatt. Unfortunately, six days post-operation, Hammatt experienced language difficulties, disorientation and agitation. However, the surgery was still considered a success. By 1942, Freeman and Watts had performed 200 lobotomies, declaring that 63% of patients improved, 23% of patients showed no relief, while 14% of patients suffered complications, including death. Freeman pursued with the development of a transorbital method which he tended to perform in outpatient departments, without any neurosurgical assistance, having patients anesthesized with a portable electroshock machine. Profoundly disapproving this method, Watts, decided to end their partnership. Further unsatisfactory outcomes like the lobotomy of Rosemary Kennedy (sister of President John F. Kennedy) shaped an additional negative image of Freeman's work. Rosemary who initially was subjected to lobotomy due to mild developmental delays, anxiety and epilepsy, was postoperatively left severely disabled, without autonomy, being institutionalized for the rest of her life. Finally, the approval of chlorpromazine's use in the US (1955) alongside public awareness over psychosurgery's complications, such as the "post-leucotomy syndrome" causing disinhibition as well as "lobotomy criteria" which included female gender, non-obeidance, hospitalization in overcrowed institutions, opposite political opinion, leaded to psychosurgery's dowfall.
Conclusions: Considering the dark history of psychosurgery, it is imperative to proceed to such treatments exclusively to diseases with a well decoded neurophysiology, always respecting human rights and protecting patients' dignity and self-will.

EPV1654

The role of electroconvulsive therapy in the treatment of aggression in psychiatry: A literature Review

A. Rami[1]
[1]Razi Hospital, Manouba, Tunisia
doi: 10.1192/j.eurpsy.2025.2131

Introduction: Electroconvulsive therapy (ECT) has gained increasing attention as a therapeutic option for managing aggressive behavior in psychiatric patients. Aggression is a common symptom in several psychiatric disorders, such as schizophrenia, bipolar disorder, and severe depression, which can be resistant to conventional pharmacological treatments.
Objectives: This literature review examines the efficacy and safety of ECT in reducing aggression across various psychiatric populations.
Methods: We have conducted a web resurch on Pubmed for articles published in the last ten years about the topic using key words like "agression" , "ECT".
Results: Evidence suggests that ECT can be particularly effective in cases where patients do not respond to medications or display dangerous behaviors. Significant reductions in aggression have been reported post-ECT, along with improvements in mood and overall functioning.
Conclusions: Although ECT remains controversial due to concerns about cognitive side effects, advancements in its application have enhanced its safety. This review emphasizes the need for further.

A case report of anticonvulsive effects of CBD under ECT treatment

M. Sánchez López[1]*, A. de Arriba Arnau[1,2], A. C. González Pezoa[1], R. Obrador Font[1] and M. Urretavizcaya Sarachaga[1,2]
[1]Psychiatry, Hospital Universitari de Bellvitge and [2]Universitat de Barcelona, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2132

Introduction: Cannabidiol (CBD) is a non-psychoactive cannabinoid with therapeutic potential in various fields, such as its effect on mental health or antiepileptogenic, among others. For this reason, the interest in research on the potential effects of this substance is booming and the sale and consumption by the general population is increasing.

Objectives: To describe the observed effects of CBD use during treatment with electroconvulsive therapy (ECT).
Methods: To describe in detail the clinical case and to correlate the changes observed in the seizures and the electroencephalogram (EEG) of the ECT sessions when the patient performed concomitant consumption of CBD, in addition to the changes at the clinical level that he experienced during this period.
Results: The subject is a 47-year-old man who required admission for a psychotic decompensation of his schizoaffective disorder bipolar subtype. In recent years, he had no adherence to psychopharmacological treatment or follow-up, and reported self-medicating with CBD cigarettes in varying amounts (he reported 5 to 15 units/day). During admission, pharmacological treatment was instituted with poor response and an acute course of ECT was performed due to a history of good response in a previous episode 10 years ago and the patient's preference. He remained abstinent from CBD during hospitalization and it was agreed to remain non-consuming at discharge. He presented progressive improvement in the clinical signs from the 4th session, with remission in the 7th session. Upon discharge, it was agreed to perform consolidation ECT on an outpatient basis, initially with weekly sessions and then every two weeks.
From the 2nd outpatient session, a worsening of motor and electroencephalographic seizures was observed in the ECT sessions. A possible relapse into CBD use, which the patient denied, was explored. After the 3rd outpatient session, the patient recognizes relapse into CBD consumption with occasional consumption. During the following 2 sessions, the deterioration in the quality of the EEG pattern progresses and it is decided to interrupt ECT treatment due to the absence of seizures in EEG recording, coinciding with an increase in the daily amount of CBD consumed.
Conclusions: There is little literature on the management of the effects of CBD in ECT treatment. The observations in this clinical case provide valuable information about the combination of CBD and ECT that can be useful to other professionals with similar cases.

EPV1658

Increasing the Utilisation of Transcranial Magnetic Stimulation for Treatment-Resistant Depression

Y. H. Tay

Psychological Medicine, Khoo Teck Puat Hospital, Singapore, Singapore
doi: 10.1192/j.eurpsy.2025.2133

Introduction: Transcranial magnetic stimulation (TMS) has been consistently recommended in international guidelines as first-line for treatment-resistant depression, due to its superior efficacy over the next antidepressant, with minimal side effects. However, owing to its high cost, lack of insurance coverage, the need for daily time commitment over a period of 4 to 6 weeks and its relative novelty, TMS is still not being offered to many eligible patients with MDD including at our hospital, leading to an under-utilisation of the service.
Objectives: We aim to determine the rate at which TMS is being offered to eligible patients with MDD at our hospital in Singapore, explore the root causes behind why it is not being offered and utilised more often, and implement new models of care to increase this rate by at least two-fold over 6 months.
Methods: All patients who registered at our outpatient clinics from June to November 2024 were screened for the eligibility criteria for TMS. Flow charts, affinity diagram and fishbone diagram were drawn. Multi-voting was conducted to arrive at the top root causes for the low rate at which TMS was being offered to eligible depressed patients, determined on a Pareto chart. 5 Plan, Do, Study, Act cycles were carried out. Key interventions included: (a) Adopting evidence-based, shorter TMS protocols that reduced time to remission from 6 weeks to 2-3 weeks, (b) initiating a novel, nurse-led TMS counselling service, (c) improving promotional materials, and (d) using simple yet effective strategies to improve familiarity with TMS and encourage psychiatrists to consider it more often.
Results: The rate at which TMS was offered to eligible patients with MDD increased from 15% to 80% over June to November 2024. 31% of these eligible patients took up TMS, and 100% of those who started TMS eventually completed the course. Patients who completed the course had a 69% reduction in clinician-administered depression rating scales. Psychiatrists were more inclined to offer TMS via the TMS counselling service run separately by TMS nurses, as this otherwise often took up substantial time in busy clinic settings. The increased awareness of TMS through promotional materials empowered patients such that they were bringing up TMS during consultations before they were being offered. The evidence-based, shorter TMS protocols involved conducting multiple sessions a day with adequate intervals, without compromising on efficacy and safety. Patients enjoyed the option of having less interruptions from work or school, and the quicker times to remission. Direct cost savings were observed.
Conclusions: We observed better quality of clinical care, increased patient, staff and stakeholder satisfaction, cost and time savings to patients, and increased productivity in both patients and staff, through effective and sustainable interventions which can be replicated in TMS clinics elsewhere.

Disclosure of Interest: None Declared

EPV1659

Unraveling Reality : Complaints that became delusions aligned to Ehlers-Danlos Syndrome ended up with ECT - a case report

D. Uslu[1]*, R. E. Dindar[1], E. E. Bestepe[1] and H. Kolsuz[1]

[1]Psychiatry, Istanbul Erenköy Mental and Nervous Diseases Training and Research Hospital, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2134

Introduction: Ehlers-Danlos Syndrome (EDS) is a group of hereditary connective tissue disorders that primarily involve skin hyperelasticity, hypermobility of joints and fragility of blood vessels.This syndrome shows heterogeneous features.Recent studies have shown that patients with EDS have a higher risk of psychiatric conditions such as depression, suicide and schizophrenia.The existing literature on safe administration of ECT defines several case reports which incorporates connective tissue disorders.
Objectives: This case report aims to define a rare case of EDS related psychosis including the clinical presentation and management.Furthermore, to show the administration of ECT in patients suffer from this medical condition after their assessment.

Methods: Comprehensive presentation of patient's case and review of systematic literature using database, in regards to connective tissue disorders and psychiatric conditions.
Results: A 42-year-old female patient,diagnosed with anxiety disorder 7 years prior, who has shown no remission and has experienced multiple hospital admissions over the past year due to various psychotic and depressive episodes, presented to our hospital with complaints that a "sorcerer" had cast spells on her.She reported delusions of mystical and somatic nature, describing that as a result of these spells, supernatural entities had caused her teeth to shrink, her skull to shift, the brightness in her eyes to diminish, her internal organs to decay and her physical presence to fade away.Additionally, she expressed paranoid-persecutory delusions that these entities would ultimately lead to her death.Treatment history included multiple SSRIs, antipsychotics and 6 sessions of TMS therapy, all with limited response.Her family history revealed that her father had died by suicide and her siblings were also diagnosed with depression/anxiety disorders.
The patient was admitted with a preliminary diagnosis of psychotic depression.Physical examination findings included hyperflexibility and hyperlaxity, suggestive of EDS.As the patient was at increased theoretical risk for complications; several consultations were requested to assess fitness for treatment prior to ECT.Based on these evaluations, ECT was deemed safe to proceed.Bifrontal ECT was successfully administered, resulting in marked improvement in the patient's psychotic symptoms.
Conclusions: Even delusions are remarkably indicative for psychosis, it is crucial to recognize the underlying medical conditions may contribute to its onset and/or exacerbation.Psychiatric evaluations should be performed during EDS patients' routine follow-ups.Additionally, as is already shown in other case reports, administration of ECT in patients with EDS should be considered.However, further research is required to understand the eligibility of ECT on connective tissue disorders also to expand our repertoire in the treatment.

EPV1661

Electroconvulsive therapy in patients with cranial metal implants

P. Sulic[1], P. Viskovic[2]*, M. Zivkovic[3,4] and A. Mihaljevic-Peles[3,4]

[1]Department of Psychiatry, General Hospital "Dr. Ivo Pedišić" Sisak, Sisak; [2]The Child and Adolescent Psychiatry and Psychotherapy Unit, University Hospital Centre Zagreb; [3]Clinical Department of Psychiatry and Psychological Medicine, University of Zagreb School of Medicine and [4]Clinical Department of Psychiatry and Psychological Medicine, University Hospital Centre Zagreb, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2135

Introduction: Electroconvulsive therapy (ECT) is a widely recognized and effective treatment for severe psychiatric conditions, including major depressive disorder, treatment-resistant depression, and some psychotic disorders. Although ECT is highly effective, administering it to patients with cranial metal implants—such as plates, screws, clips, or electrodes—presents potential safety challenges. Metal implants, particularly those made of ferromagnetic materials, may interact with the electrical currents in ECT, which can lead to heating, shifting of the implant, or other adverse effects, thereby raising safety concerns.
Objectives: To review the safety and clinical considerations of electroconvulsive therapy in patients with cranial metal implants. This literature search aims to identify evidence on risks, contraindications, and guidelines to support safe and effective treatment in this population.
Methods: We conducted a literature search on PubMed to investigate the application of ECT in patients with cranial metal implants. The search included keywords "electroconvulsive therapy" and "ECT" combined with the terms "cranial metal implants," "head metal implants," and "metallic skull plate" interchangeably. We included only case reports. We used this approach to gather relevant studies addressing the safety, efficacy, and considerations of electroconvulsive therapy in individuals with metal implants in or near the skull.
Results: The literature search identified 11 case reports documenting the successful administration of ECT in patients with cranial metal implants. Across these cases, ECT was performed without adverse events related to the implants, and treatment outcomes were reported as effective in managing psychiatric symptoms. Most reports emphasized careful planning and individualized assessment to minimize risks, particularly regarding implant location and material composition. Safety measures included conducting pretreatment imaging to evaluate implant positioning.
Conclusions: The connection between cranial metal implants and ECT necessitates careful consideration of safety protocols to prevent potentially hazardous interactions. While metals such as titanium are generally not problematic for this therapy, it is essential to consider the type of metal, its location, and its magnetic properties before applying this technique. Our clinical experience also shows positive outcomes in patients with cranial metal implants, demonstrating safe and effective administration with proper evaluation and precautions. Further research and establishing safety guidelines will be crucial for optimizing treatment and minimizing risks for patients with metal implants.

Interpersonal Psychotherapy (IPT) for Eating Disorders: A Literature Review

M. L. Aires[1]*, J. Barreira[1], D. Stolnik[1] and M. Pinto[1]

[1]Unidade Local de Saúde Tâmega e Sousa, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2136

Introduction: Interpersonal Psychotherapy (IPT) has been recognized as an effective treatment for various eating disorders, particularly Binge Eating Disorder (BED) and Bulimia Nervosa (BN). IPT focuses on addressing interpersonal difficulties, such as role transitions, interpersonal disputes, and social deficits, which are common in individuals with eating disorders. While evidence supports its use for BED and BN, its effectiveness for Anorexia Nervosa (AN) remains limited. Group-based IPT has also shown promise by targeting interpersonal deficits that perpetuate disordered eating behaviors.
Objectives: This literature review aims to evaluate the efficacy of IPT in treating eating disorders, with a focus on BED and BN. Additionally,

it explores the role of interpersonal deficits as a central focus of IPT and compares the outcomes of individual and group-based IPT formats.
Methods: A review of peer-reviewed studies, clinical trials, and meta-analyses published between 2000 and 2024 was conducted. The review assessed the effectiveness of IPT in reducing disordered eating behaviors, improving interpersonal functioning, and maintaining long-term treatment gains. Studies on both individual and group IPT formats were included, with a focus on binge eating reduction, interpersonal relationship improvements, and relapse prevention.
Results: The literature consistently shows that IPT is effective in reducing binge eating behaviors and improving interpersonal relationships in individuals with BED. Group IPT, in particular, has been shown to effectively address interpersonal deficits, providing social support and improving interpersonal skills, which contributes to sustained treatment outcomes. IPT has demonstrated comparable short-term efficacy to Cognitive Behavioral Therapy (CBT), with studies indicating superior long-term maintenance of treatment effects. However, evidence for IPT's use in AN remains sparse.
Conclusions: IPT is a promising treatment for eating disorders, particularly for individuals with BED and BN who exhibit significant interpersonal deficits. Group IPT appears to be especially effective in addressing these interpersonal issues, providing long-term benefits. While CBT remains the most widely used therapy, IPT offers a valuable alternative, particularly for individuals who do not respond to CBT. Future research should focus on exploring IPT's mechanisms and expanding its application to other eating disorders, including AN, where evidence is currently lacking.

Disclosure of Interest: None Declared

EPV1664

Integration of Ego-States Therapy into a Day Clinic Approach for Addictive Disorders: A Case Report

U. Altunoez

Department of General Psychiatry and Psychotherapy, KRH Wunstorf Psychiatric Hospital, Wunstorf, Germany
doi: 10.1192/j.eurpsy.2025.2137

Introduction: The relationship between childhood traumatic experiences and substance use disorders (SUD) has been the subject of considerable discussion in the literature. The development of efficacious therapeutic models for the treatment of these comorbidities remains an ongoing area of research. In particular, trauma-related disorders accompanied by dissociative changes and SUD may be effectively treated with ego-states therapy, which employs a combination of psychoanalytic and hypnoanalytic methods with other systemic approaches.
Objectives: The objective of this presentation is to illustrate a case study from an interdisciplinary day clinic that employs an integrated approach to the treatment of substance use disorders (SUD) and other comorbidities. Furthermore, we will propose an innovative naturalistic method for addressing complex phenomenological manifestations of trauma-related disorders in individuals with SUD.
Methods: In this presentation, we will introduce a psychotherapeutic method from a day clinic in Lower Saxony, Germany, through a comprehensive case study.
Results: Case:
A 40-year-old woman was referred to the day clinic following a period of ward treatment following the death of her father. This period led to an increase in her cannabis consumption and a concomitant increase in depressive symptoms. In her history, she revealed that her elder sister had committed suicide when the patient was in primary school. Consequently, she was tasked as a child with the responsibility of handling all bureaucratic matters with her parents, as she was the only member of her family who could speak German due to their migration background.
During the psychotherapeutic treatment, various ego states were identified and addressed through a combination of psychoanalytic, systemic-milieu therapeutic, and family therapeutic interventions. Particular attention was paid to those aspects that had been functional during childhood but were now manifesting in a destructive manner. The adult ego-states were activated to bring those processes into conscious awareness and promote psychological stabilization. By the end of the 6-week day clinic process, cannabis levels were no longer detected in the urine, and a significant reduction in depressive symptoms was observed.
Conclusions: Complex phenomenological presentations require multidisciplinary, holistic, and integrative therapeutic approaches. Further evidence-based evaluations are necessary to optimize treatment outcomes for such cases.

Cognitive Behavioral Therapy for Obsessive-Compulsive Disorder with Comorbid Schizophrenia: A Case Report

S. Laabidi[1], O. laabidi[1], U. ouali[1], A. Aissa[1]* and R. jomli[1]

[1]psychiatry A, Razi hospital, manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2138

Introduction: In the general population, the lifetime prevalence rates for obsessive-compulsive disorder (OCD) range between 1.9% and 3.3%. In patients with schizophrenia, the prevalence rates of OCD range between 7.8% and 26%. Accurate diagnosis has prognostic and treatment implications.The empirical basis regarding the optimal treatment for comorbid OCD in patients with schizophrenia is almost nonexistent.
Objectives: We report a successful treatment course of intensive CBT for a patient with OCD comorbid with schizophrenia and reflect on the difficulties in the management and treatment of these cases.
Methods: We describe a case report in which OCD emerged gradually after the remission of positive symptoms of schizophrenia. The CBT involved psychoeducation, case formulation, cognitive restructuring, and exposure and response prevention.
Results: The case is a 24-year-old male, single, with no comorbid somatic diseases. He was admitted to our psychiatric ward for self-muttering activity and delusion of thought broadcasting from the past year. A diagnosis of schizophrenia was made. We started risperidone gradually titrated to 6 mg/day. During his follow-up period, he reported having repetitive and intrusive thoughts of blasphemous nature despite well-controlled psychotic symptoms. He acknowledged these thoughts as originating in his own mind but was unable to stop them on his own accord. He also reported obsessions related to contamination and disgust. This led to

compulsive hand washing and avoidance behaviour of some objects, which was both distressing and time-consuming. The diagnosis was revised to comorbid schizophrenia and OCD. Antipsychotic was changed from risperidone to amisulpride 800 mg daily in combination with paroxetine up to 60 mg/d. Since paroxetine was already optimized, the next step taken was to substitute it. He was then medicated with amisulpride, and clomipramine slowly increased up to 225 mg/d. There was no significant clinical improvement, regardless of the dose. Cognitive behavioural therapy (CBT) was commenced later. Medication was kept stable during the baseline, treatment, and follow-up period. Fourteen 1-hour sessions of CBT, including exposure and response prevention, were delivered each week over a period of 14 weeks. At the end of the intensive treatment, he reported a significant reduction in obsessions and compulsions. His score on the Y-BOCS dropped from 34 to 8 (76%) before treatment to 4-month follow-up.He reported that the decrease in OCD symptoms was associated with a significantly higher quality of life.
Conclusions: CBT appears to offer a valuable opportunity to reduce symptom severity in patients with OCD comorbid with schizophrenia.Further research within this field and systematic clinical evaluations are highly desirable.

Families stuck in a trauma loop: a systemic approach to address vicarious trauma and enhance mental health treatment adherence in 2nd and 3rd generation offsprings of psychiatric patients

S. Andrei[1]* and B. Raz[2]

[1]Psychiatry and Psychotherapy, Private Practice, Challans and [2]Family Therapy Center, CH Roanne, Roanne, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2139

Introduction: Vicarious trauma (VT) was first described by Pearlman and McCann as the therapists' internal experience that is "impacted as a result of empathic engagement with client's traumatic material". (JTS 1990. 3: 131–149). Furthermore, the authors used a constructivist framework to differentiate it from other forms of secondary trauma. In the context of mental illness, family elements of VT are be more subtle than primary trauma, but can remain identifiable across generations.
Objectives: The primary focus of our study was to develop a theoretical framework for understanding severe mental illness (SMI) and its traumatic long-term consequences on the family. Our secondary aim was to explore the impact of SMI and of psychiatric stigma on 2nd and 3rd generation offsprings.
Methods: To begin with we conducted a narrative review of the scientific literature using Pubmed search engine. This was followed by a qualitative study with psychiatric patients who declared a family history of SMI in a first degree relative who received medical care in France. The methodology involved conducting 11 structured interviews, which were audio recorded, transcribed and thematically analyzed.
Results: When family trauma develops, it is a complex phenomenon, seemingly infinite loop. It further impacts every aspect of the family's communication and relational style, attachment and regulation.
On an individual level, the consequences can be viewed as a continuum from adverse childhood experiences and primary trauma to secondary traumatic responses. This study aims to advocate for identifying specific VT subtypes. Some specific complaints are often encountered in the initial presentation of psychiatric patients, even with adults as young as 18yo. Exploring family psychiatric history through the vicarious "trauma lens", can allow us to have a better appreciation and understanding of the patient's suffering: their system of meaning and beliefs regarding psychiatric diagnosis, treatment and case management are often disrupted, the nocebo effect is increased (by increased sensitization to all other trauma and by modified emotion control). When the sense of safety is disturbed on a family basis multi-generational level, the consequences could lead to extreme anti-psychiatry attitudes and predict negative mental health outcomes.
Conclusions: Current understanding of vicarious trauma is limited to specific job-related contexts. What has not been studied yet is the vulnerability of children to vicarious trauma due to perceived traumatizing treatment, or the way in which medical stories are recounted to children. Therefore, additional research is needed on this topic. For psychiatrists, the vicarious trauma approach can be one of the key entry points to building the therapeutic alliance, which further enhances patient adherence to the treatment.

Impact of Acceptance and Commitment Therapy (ACT) on Psychological Flexibility in Medical Students

E. Cetintas[1]*, M. E. Karadere[1] and F. Cetinkaya[1]

[1]Istanbul Medeniyet University, Department of Psychiatry, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2140

Introduction: Medical school is known for high levels of anxiety, and mental health challenges. Psychological flexibility - the ability to accept difficult thoughts and emotions while acting in alignment with one's values- can protect against these challenges. ACT has been shown to enhance psychological flexibility and reduce mental health symptoms in various populations. However, its impact on medical students has not been extensively explored.
Objectives: This study aimed to assess whether a brief ACT intervention could improve psychological flexibility and related psychological outcomes in medical students.
Methods: Forty-two medical students from Istanbul Medeniyet University participated in a four-day ACT program. Inclusion criteria included active enrollment in a medical program and willingness to participate. Exclusion criteria were severe psychiatric disorders or ongoing psychiatric treatment.The intervention involved four days of ACT-based activities, including mindfulness, cognitive defusion, and value-based exercises. Each session lasted 90 minutes and was conducted in a group format. To assess the impact of the intervention, we measured psychological flexibility and related factors at baseline and after the program using the following tools: the Multidimensional Experiential Avoidance Questionnaire (MEAQ-30), AAQ-US, SF-25, Valuing Questionnaire (VQ) and the DASS-21. Paired t-tests were used to compare pre- and post-intervention scores, with statistical significance set at $p < 0.05$.

Results: The ACT intervention led to significant improvements in psychological flexibility and related factors. The ACT intervention led to significant improvements in psychological flexibility and related factors. Specifically, Distress Aversion (MEAQ-30, subscale B) decreased significantly ($p = 0.010$), while Distress Endurance (MEAQ-30, subscale F) increased significantly ($p = 0.008$). Additionally, Anxiety (DASS-A) decreased significantly ($p = 0.004$), and Stress (DASS-S) also decreased significantly ($p = 0.004$). No significant changes were observed in other subscale scores, including those for SF-36, depression (DASS-D), and scores for AAQ-US and VQ . These results suggest that ACT may be particularly effective in reducing anxiety and stress while enhancing cognitive flexibility and acceptance.
Conclusions: This study suggests that even a brief, four-day ACT intervention can significantly improve psychological flexibility and reduce anxiety and stress in medical students. These findings highlight ACT's potential as an effective tool for supporting mental health and resilience in medical students. Further research with larger sample sizes and longer follow-up periods is needed to explore the long-term impact of ACT interventions in academic settings.

Insight into psychosis in patients in the early stages of psychotic disorders and their parents

L. Gorsic[1]*, S. Caratan[1], H. Gorsic[1], M. Krevatin[1], S. Kocijan[1,2], V. Grosic[2,3] and I. Filipcic[3,4]

[1]Day Hospital for non psychotic disorders, University Psychiatric Hospital Sveti Ivan, Zagreb; [2]Department of Psychiatry and Neurology, Faculty of Dental Medicine and Health JJStrosmayer, Osijek; [3]Integrative Psychiatry, University Psychiatric Hospital Sveti Ivan, Zagreb and [4]Department of Psychiatry and Neurologyiy and Neurology, Faculty of Dental Medicine and Health JJStrosmayer, Osijek, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2141

Introduction: Clinically insight is a multifaceted phenomenon related to acceptance of one's condition as being psychiatrically ill, recognition of symptoms as pathological, recognition of the social consequences of illness and treatment acceptance. The common features of psychotic disorders are symptoms classified through several dimensions: positive symptoms, negative symptoms, cognitive symptoms, affective symptoms and psychomotor symptoms. These symptoms often cause impaired reality testing and poor insight. Impaired insight is common during early stage of psychosis with its prevalence ranging from around 30-50% and may cause treatment delays, more severe symptoms, poorer treatment adherence, involuntary admissions, potentially aggressive behaviour, poorer social functioning and outcomes. Insight is directly related to the severity of psychotic symptoms and inversely related to depression score. Enviromental factors such as family beliefs and stigma can influence on insight level. Considering that the first symptoms of psychosis often appear in young adulthood while the affected still live with their parents, we believe that the role of parental insight is important in recognizing the signs and treating psychosis.
Objectives: Aim of this study was to investigate level of patient's and parent's insight into early psychosis.
Methods: We performed a cross-sectional study on 105 diads parents - children suffering from early stage of the psychotic disorders, during disease < 5 years, diagnoses from the spectrum F20-F29 , both sexes, aged 18-35 years who were hospitalized at "Sveti Ivan" Psychiatry Clinic. The purpose and objectives of the research were explained to all participants, and they signed informed consent. The instruments used: sociodemographic questionnaire, The Scale to Assess Unawareness of Mental Disorder - Abbreviated version (SUMD), The Positive and Negative Syndrome scale (PANSS) – The Five factor models, Clinical Global Impression-severity scale (CGI-s). The research was conducted in accordance with Helsinki declaration.
Results: Among the patients, the male gender is slightly more represented, with a good level of education, mostly with the F23 diagnosis, while in the group of parents, mothers are significantly more represented. On the PANSS Five Factor scale, the patients showed significant improvement in all domains. The patients were more aware of their disorder than their parents. The fathers were more aware of their children's disorders than mothers.
Conclusions: The research has contributed to clarifying the complexity of the issue of insight and complex relationships between parents and children, pointing to the necessity of family psychotherapy and psychosocial interventions in the treatment of patients in the early stages of psychotic disorders.

EPV1673

Impact of Therapist Breaks on Patients with Borderline Personality Disorder: A Review

I. Gözel[1]* and I. İnan[2]

[1]Psychology, Ankara Bilim University and [2]Psychology, Hacettepe University, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2142

Introduction: Borderline Personality Disorder (BPD) is characterized by abandonment schemas, impairments in emotion regulation, and attachment issues. The literature shows significant evidence that psychotherapy is effective in the treatment of BPD in addition to pharmacotherapy. The therapeutic relationship established with the patient is a crucial component of psychotherapy processes and plays a vital role in the prognosis of the disorder. Working on the therapeutic relationship is essential to maintain an effective psychotherapy process in BPD treatment. The therapeutic alliance is at the core of the treatment's success. When a therapist takes a break from the therapy process (due to reasons such as vacation, childbirth, or loss), ruptures may form in the therapeutic relationship with patients diagnosed with BPD.
Objectives: This review compiles and synthesizes findings from empirical and case studies on the effects of breaks in psychotherapy treatment for BPD patients.
Methods: PsycArticles, Web of Science, PubMed, and Google Scholar were reviewed.
Results: Immediately following a therapy break, BPD patients often experience intense feelings of anger, anxiety, and frustration. At the same time, in the long term, this can lead to distrust in the therapist and weaken the therapeutic relationship. Moreover, acting-out behaviors tend to increase during this period. For inpatient patients, this can be observed as non-compliance with clinic rules

or using verbally inappropriate expressions.This break in the therapy process activates the abandonment schema, which is a core characteristic of BPD. Patients with borderline personality organization return to the dysfunctional coping strategies they had previously developed.
Conclusions: These results highlight several important areas of discussion for clinical practice and research. Firstly, BPD patients should be informed about upcoming therapy breaks and prepared for the absence, and expectations should be discussed openly. Secondly, after the break, working on the therapeutic relationship, mistrust, the activated abandonment schema, and negative emotions directed toward the therapist will contribute to the healing process. Thirdly, given the risk of suicide linked to impulsivity and acting out, the therapist should develop an action plan. Fourthly, maintaining the therapeutic framework is one of the most critical steps in the recovery of BPD patients, so it is crucial to preserve the framework even during therapy breaks. Lastly, due to the gap in the literature on this subject, there is a need for more empirical studies and research on how to repair potential ruptures in the therapist-patient relationship that occur during breaks.

Psychodynamic group psychotherapy for family members of patients with psychoses

M. Grah[1,2]*, B. Restek-Petrovic[1] and V. Grosic[1,2]

[1]University Psychiatric Hospital Sveti Ivan, Zagreb and [2]Faculty of Dental Medicine and Health, Osijek, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2143

Introduction: As part of our comprehensive early intervention program for psychotic disorders (RIPEPP), we have been conducting psychodynamic group psychotherapy for family members since 2005. This type of therapy intended for family members of patients that are motivated for psychological work and the correction of maladaptive forms of family interactions. The 90-minute sessions are held every two weeks under the guidance of a psychiatrist – group analyst.
At the beginning of this new experience, we applied group analytical principles in the group. Due to the large drop out and specific dynamics, we gradually changed the therapeutic technique and became more flexible and supportive.
During the years of therapy, with the strengthening of group cohesion, it was gradually possible to switch again from a more flexible and supportive method to the classic group analytical technique.
In this presentation, we will show vignettes from the therapeutic process.
Objectives: An overview of the need to modify the group-analytic technique in the treatment of family members of individuals with psychotic disorders.
Methods: Following the protocol of group sessions.
Results: Over the course of the therapeutic process, the group members become more ready for group analytical work, which is adapted and applied in sessions in which they openly talk about themselves, their feelings and partner relationships. The modification of the group analytic technique is still at work with a continuously present psychodynamic understanding.
Conclusions: A group-analytic approach is applied in the treatment of family members of individuals with psychotic disorders. The frequent occurrence of dropouts among group members highlighted the need to modify the group-analytic technique, with the potential to revert to the classical method by strengthening group cohesion and improving family dynamics.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2144

Introduction: Numerous studies indicate that caregivers of patients with schizophrenia experience significant burden and exhibit depressive symptoms as measured by the CES-D scale. Specific psychoeducational programs like the multifamilal CBT based Profamille program may help alleviate these symptoms. However, it is yet to be established the extent to which these caregivers meet the criteria for clinical depression as defined by the DSM-5, as well as whether the interventions employed in this program can effectively reduce the prevalence of depressive disorder among caregivers.
Objectives: Assess the prevalence of major depressive disorder among caregivers at the start and end of the Profamille psychoeducational multifamily program.
Methods: Caregivers were referred to the program by family organizations, welfare services or healthcare providers, or found out about the program through the local press.
A group consists of twelve caregivers of approximately ten patients, participating in 14 structured weekly sessions of Profamille program version V3.2, each lasting 4 hours. These sessions provide information about schizophrenia, develop coping strategies for caregivers, and employ behavioral and cognitive techniques to address depressive symptoms.
Mood was assessed using the PHQ-9, a self-report questionnaire consisting of nine items aligned with diagnostic criteria for major depressive disorder. Responses were analysed using an algorithm

based on DSM-5 criteria to classify participants as having or not having major depressive disorder.
Given the paired nominal data, McNemar's test was employed for analysis
Results: A total of 507 caregivers were recruited, including 349 women. The average age of the participants was 58.0 years (SD = 9.0). At the beginning 14.6% of participants had a diagnosis of major depressive disorder. Fourteen sessions later this rate decreased to 5.7% (McNemar's test, p-value < 0.00001)
Conclusions: The annual prevalence of depression in the general population is approximately 5%, indicating a threefold over-representation among caregivers participating in the program. This rate of over-representation is consistent with other studies utilizing the CES-D, which also captures subclinical depression. Given the implications of depression for participants' physical health, this underscores the need for systematic investigations aimed at providing support. The Profamille program, which employed specific cognitive behavioral techniques in a group setting, resulted in a significant reduction in depression rates over 14 sessions, bringing the final rates more in line with those of the general population. These findings suggest that the program effectively normalized the prevalence of depression. However, the absence of a control group limits our ability to assess the natural progression of depressive symptoms without program participation

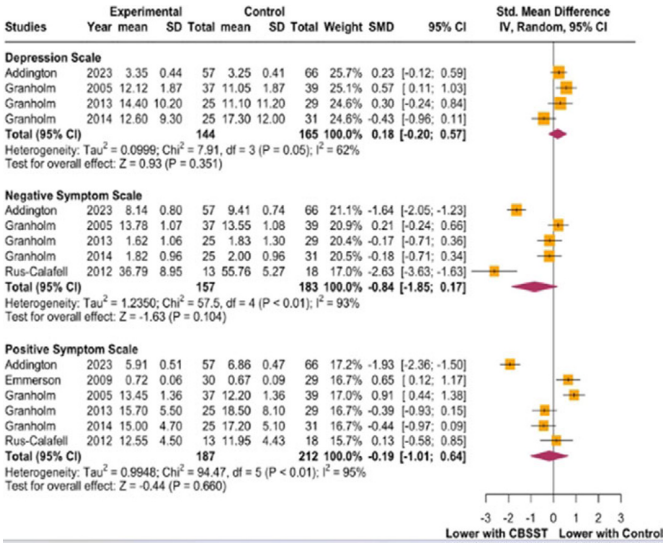
Systematic Review and Meta-Analysis of Cognitive Behavioral Social Skills Training for Schizophrenia

D. F. Holanda[1]*, D. V. S. Cavalcante[2], F. V. Zamora[3], L. K. C. S. Galvao[4], A. C. F. D. F. Santos[5], A. V. Zamora[3], N. Y. D. S. Balio[6], T. L. S. Barreiro[7] and G. P. Simões[8]

[1]Medicine, Federal University of Amazonas, Manaus; [2]Pharmacy, Federal University of Maranhao, São Luiz; [3]Medicine; [4]Federal University of Minas Gerais, Belo Horizonte; [5]Pharmacy, City University of São Paulo, São Paulo; [6]Universidade Cruzeiro do Sul, Cruzeiro do Sul; [7]Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre and [8]Faculdades Integradas do Vale do Ivaí, Paraná, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2145

Introduction: Schizophrenia is a major cause of severe global functional disability with negative symptoms that greatly affect functional outcomes. These symptoms are divided into expressive (e.g., facial affect and voice tone) and experiential (e.g., amotivation and asociality) dimensions.
Objectives: This study assessed the effectiveness of Cognitive Behavioral Social Skills Training (CBSST) in enhancing functioning in individuals with schizophrenia. It examined the link between defeatist performance attitudes and functional changes post-CBSST.
Methods: We conducted a comprehensive search of PubMed, Embase, and Cochrane databases up to September 2024 for studies comparing CBSST with standard treatments for schizophrenia. We calculated the mean or standardized mean differences (MDs and SMD) for continuous outcomes along with 95% confidence intervals (CIs). Heterogeneity was evaluated using the I^2 statistics.
Results: Our review included 7 studies with 462 patients, of whom 219 (47.4%) received CBSST. There were no significant differences between the groups regarding positive symptoms (SMD 0.19, 95% CI -1.01 to 0.64, I^2 = 95; Figure 1A), negative symptoms (SMD -0.84, 95% CI -1.85 to 0.17, I^2 = 93; Figure 1B), Depression Scale scores (SMD 0.18, 95% CI -0.20 to 0.57, I^2 = 62; Figure 1C), or the Independent Living Skills Scale (MD 0.05, 95% CI 0.04 to 0.06, I^2 = 0; Figure 2). However, the independent living skills scores were significantly lower in the control group.

Image 1:



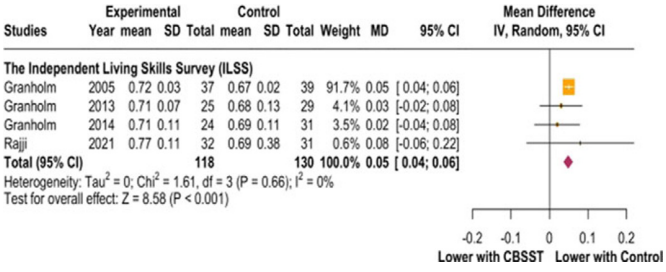


Image 2:

Conclusions: CBSST is effective in enhancing functioning in individuals with schizophrenia. Along with other supportive goal-oriented interventions, it can alleviate symptom distress, boost motivation and self-esteem, and enhance life satisfaction. Individuals with severe defeatist performance attitudes may experience the greatest benefit from cognitive-behavioral approaches that target functional improvements.

Tone of mood in new mother and attachment to her partner

I. S. Lancia[1]*, G. M. Festa[2,3], A. Attouchi[3], F. De Pasquale[3], M. Manganozzi[3], M. Civino[1] and L. M. Colone[1]

[1]Interdisciplinary Institute of Advanced Clinical Training; [2]Pontifical Faculty of Educational Sciences «AUXILIUM and [3]Interdisciplinary Institute of Advanced Clinical Training «IACT», Rome, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2146

Introduction: Mood in puerperium is a subject of great interest since it can undergo variations in such a significant period of a woman's life as motherhood. It is equally true that the presence of a partner with a secure attachment style can constitute a stable base for a woman to lean and to rely, while it is more likely to hypothesize cracks in mood in absence of effective support in the relational context.
Objectives: The aim of this research is to analyse the trend of puerperal mood in women in the period immediately following the delibery and after a few months. The study also examines the attachment styles of the partners of these women and the relationship between mood in women and the attachment of their partners.
Methods: The study was conducted on a sample of women and their partners.
The women were administered 2 administrations of the Edinburgh Peripartum Depression Scale (EPDS): the first within 24 hours of delivery and the second four months after delivery.
The Relationship Questionnaire (RQ) was administered to the male partners immediately after the evnt of delivery.
The data were analyzed from a statistical point of view, with analysis of variance (ANOVA) and post hoc tests.
Results: A 2-way ANOVA with repeated measures was performed using the different attachment styles as emerged from the RQ (secure attachment and insecure attachment) in the partner group as the independent variable and the EDPS scores in the 2 times (EPDS1, EPDS2) of the women themselves as the dependent variable. The ANOVA described the main effect of Time as significant ($F(1, 14) = 5.79$; $p < .05$). The post hoc (LSD - Least Significant Difference test) highlights how there is a significant decrease in the EPDS score of women in the before-after comparison ($M = 8.71$ vs $M = 4.93$; $p = .005$) considering, as an independent variable, the secure attachment group of partners. While this decrease is not significant in the group of partners with insecure attachment.
Conclusions: The initial data of this study suggest that security in the attachment style of the partner can favor an increase in the mood of the woman after a delivery. In particular, the research data tend to highlight a significant improvement in the mood of women 4 months after giving birth. The proximity of a partner with secure attachment therefore seems to favor a good mood in the woman in pueperium.

EPV1678

Wisdom psychotherapy in adjustment disorders. Results of a randomized controlled study

M. Linden

Department of Psychosomatic Medicine, Charité University Medicine Berlin, BNerlin, Germany
doi: 10.1192/j.eurpsy.2025.2147

Introduction: Wisdom is a capacity which is needed to cope with difficult situations in life. Wisdom can be trained like other capacities. Wisdom psychotherapy has been developed as a method of cognitive behavior therapy to help patients who are stuck in negative life experiences, or confronted with unsolvabale dilemmas.
Objectives: Test the efficacy of wisdom psychotherapy in patients with adjustment disorders.
Methods: patients with adjustment disorders (>18 on the ADNM8 scale) were randomly assigned to group wisdom therapy (WT: N=114), or group behavioral activation therapy (BA: N=109). Additionally a matched group of patients was build, which were not included in any study procedures but underwent routine treatment only (RT: N=114). Wisdom was measured with the Multidimensional Wisdom Competency Scale (MWC15).
Results: There was an increase on the MWC15 of 5.3 in the wisdom group as compared to 0.4 in the activation group and 0,2 in the routine group. This is statically sigificant in the pre-post comparison and in the time/goup interaction (F4,42, p=0,13). The ADNM8 score, the SCL90 GSI, the BDI score decreased, with a trend for more side effects in the wisdom than the activity group.
Conclusions: The results confirm that wisdom psychotherapy can make a difference in the improvement of wisdom capacities. Wisdom therapy, different from other psychotherapies, does not aim at increasing hedonic or symptom free wellbeing but rather eudaimonic wellbeing in order to teach patients to live a decent and successful life.

EPV1681

Evaluation of the Psychosocial Treatment of Psychosis

L. Mehl-Madrona[1,2]* and B. Mainguy[3]

[1]Native Studies, University of Maine, Orono; [2]Psychiatry Residency, Northern Light Acadia and [3]Wabanaki Health and Wellness, Bangor, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2148

Introduction: Some people with a diagnosis of psychosis wish to minimize or avoid medications. A literture exists that intensive psychosocial treatment can mitigate psychotic symptoms with lilttle or no medication being used.
Objectives: We provided services to people who wishers to reduce or avoid medications within the context of a private psychiatric practice and wanted to assess their outcomes. We wondered what factors led to success.
Methods: We report on a series of 62 patients, age 18 years or older, who engaged in psychotherapy, medication, and lifestyle management over at least six months, aiming to minimize or eliminate medication. An additional 217 patients who consulted us did not continue for six months. An anonymous, matched comparison group of 62 patients of the same age, socioeconomic status, diagnosis, and severity of illness was generated from electronic health records at another clinic where LMM also worked. We used the Brief Psychiatric Rating Scale, the Positive and Negative Symptom Scale, the MADRS depression scales, and the Clinical Global

Inventory. Narrative interviews generated qualitative data. We compared patients who met their goals to those who did not.
Results: Forty-one people eliminated medication. Another 16 managed well on low-dose medications. Five patients had psychotic episodes that led them to return to higher levels of medication. This group functioned at higher levels than the comparison population with much lower doses of medications. The five readmissions to hospital were signnificantly lower than the number of readmissions in the comparison and the control groups. The cost for one year of care was higher for our people; the costs over subsequent years were less related to fewer hospitalizations, crises, and diminished suicidality.
Conclusions: The results suggest the need for individualized client-centered psychosocial approaches that build upon the person's previous successes, enroll family and friends in a community effort, and collaborate with those communities to apply those approaches desired by the people themselves. In this dialogical approach to psychosis, lived experience is granted full ontological reality, which appears to facilitate recovery. Lifestyle management and embeddedness in a community facilitate recovery.

Disclosure of Interest: None Declared

EPV1682

Correlations between Psychopathological Symptoms and Self-stigmatization of Patients with Bipolar Affective Disorder at the Initial Stage of the Disease

V. Mitikhin[1]*, G. Tiumenkova[1] and D. Oshevsky[1]

[1]Mental Health Research Centre, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2149

Introduction: It was demonstrated in the number of studies that patients with bipolar affective disorder (BD) at the initial stage of the disease are characterized by the high level of self-stigmatization (Latalova K., Kamaradova D., Prasko J., 2014; Solokhina T.A., Oshevsky D.S., Barkhatova A.N., et al., 2023). However, relationship of patients' self-stigmatization with their psychopathological symptoms wasn't analyzed, what determined the theoretical and practical significance of our study.
Objectives: To reveal correlations between psychopathological symptoms and self-stigmatization of patients with BD at the initial stage of the disease and to work out the integrated approach to their psychosocial treatment.
Methods: Questionnaire for assessing the phenomenon of self-stigmatization of mentally ill people (Mikhailova et al., 2005), SCL-90-R were used. A group of 17 patients (12 women and 5 men) with diagnosis of bipolar affective disorder (BD, F31.xxx according to ICD-10) was examined. The average age of the patients was 25.52±4.55 years. The duration of the disorder varied within 0.5 -3 years.
Results: Patients with BD demonstrated high overall level of self-stigmatization (1.22±0.73 points). This parameter was significantly higher than average values. As a result of correlation analysis, multiple dependable ($p<0.01$) moderate relationships between SCL-90-R indicators and parameters of several scales of the self-stigmatization questionnaire were established. So, perception of changes associated with the disease as irreversible, depriving opportunities in various spheres of life (scales «Overestimation of self-realization», «Overestimation of internal activity») leaded to somatization of patients and the formation of hypochondriac experiences (SOM, r=0.58 and r=0.54, respectively). In turn, this reduces self-esteem and causes an increase in the overall level of experienced distress (GSI, r=0.61 and r=0.53, respectively). Self-doubt, the expectation of a negative attitude towards oneself (the scale «De-identification from others in the social sphere») leads to increased anxiety (ANX, r=0.64), hostility (HOS, r=0.53), vulnerability in communication and restriction of social contacts (INT, r=0.51).
Conclusions: The obtained results permitted to work out proposals on psychosocial treatment of patients with BD at the initial stage of the disease. It is necessary to carry out psychoeducation programs as well as trainings aimed at forming a positive self-perception, activating personal resources, increasing communicative competence and maintaining social interaction.

Fake Therapists: How Short Courses Lead to Long-Term Mental Health Issues

E. Molchanova

Psychology, American University of Central Asia, Bishkek, Kyrgyzstan
doi: 10.1192/j.eurpsy.2025.2150

Introduction: In Kyrgyzstan and other Central Asian countries, there has been a surge in advertisements for psychological services from underqualified practitioners. These individuals, often with only short-term training, market themselves as professionals while the cost of their services has risen dramatically. Vulnerable populations may be exploited financially without receiving effective care, leading to worsened outcomes.
Objectives: This paper explores how the rise in underqualified practitioners and unchecked price increases for psychological services in Kyrgyzstan lead to harmful mental health outcomes. It also compares the regulatory frameworks in neighboring countries, highlighting Kazakhstan's more structured approach.
Methods: This study utilizes a comparative analysis of the regulatory frameworks for psychological services in Kyrgyzstan, Tajikistan, Uzbekistan, and Kazakhstan. Data is sourced from governmental reports, academic studies, and analyses of online advertisements for psychological services. The focus is on licensing systems, training requirements, and the impact of rising consultation prices.
Results: Kyrgyzstan, Tajikistan, and Uzbekistan lack adequate regulatory systems for licensing psychologists. The surge in online advertisements by underqualified practitioners has flooded the market, with many offering their services at increasingly inflated rates. These individuals often charge exorbitant prices while lacking the proper training, exacerbating mental health challenges for vulnerable populations. In contrast, Kazakhstan has introduced a structured National Qualifications Framework (SQF), which ensures that psychological services are provided by properly trained and certified professionals.
Conclusions: The unchecked rise of advertisements by unqualified therapists and the unlimited escalation of consultation fees in Kyrgyzstan and neighboring countries pose serious risks to public mental health. Without proper licensing and price regulation, individuals seeking help may face harmful consequences. Adopting a regulatory system similar to Kazakhstan's, with strict licensing and certification requirements, would help ensure that psychological services are both safe and affordable. Such reforms are

essential to protect the public from the exploitation and risks posed by untrained "therapists."

Unconscious processes in psychotherapy and supervision: Difficulties in the supervisory relationship

L. Mustoo Başer

Psychology, International University of Sarajevo, 71210, Bosnia and Herzegovina
doi: 10.1192/j.eurpsy.2025.2151

Introduction: Supervision is recognized as having a vital role in the professional development of psychotherapists. The way it is implemented has a direct impact on the quality of the educator's learning process, as well as on the quality of psychotherapy provided to clients. Supervision is a complex and dynamic practice, requiring supervisors to conceptualize the thoughts, feelings and behavior of their educators and the educator's clients, as well as selective attention to the complexly layered interpersonal dynamics between clients, educators and themselves.
Objectives: Emphasizing the possibility of the appearance of difficulties and their aspects and increasing awareness of these concepts can greatly help supervisors and educators in the formation of ways and approaches that can facilitate better communication and the formation of a more professional relationship as significantly influencing the main result of the quality of psychotherapy and the process of professional development.
Methods: During the training of mental health professionals, it is crucial to ensure that the supervision process is carried out according to a legal, ethical and competent approach, such as informed consent and a supervision contract, and it is necessary to take into account elements such as supervisor and educator competencies, awareness of the challenges of diversity and multiculturalism, personal and professional boundaries, multiple contexts of relationship between supervisor and educator, evaluation and feedback. Through the supervisor's dilemmas, ambiguities in the perceptions of supervision educators, success is reflected through the analysis of personal contribution, of unconscious interpersonal and developmental dynamics, and access to one's own limits.
Results: The importance of clinical supervision is evidently recognized by almost all licensing boards and accrediting bodies for the mental health professions, requiring that educators receive psychotherapeutic, clinical supervision as part of their training, and ongoing supervision is often necessary to maintain professional licensure. An integrative approach of incorporating innovative research results, as well as consolidating them with already established factors, is key in leading psychotherapeutic training, research, supervision, as well as the client's treatment itself towards increased effectiveness. A significant contribution to the literature would be enabled by future research dealing with issues of difficulties in supervision through the prism of educators.
Conclusions: This paper focuses on understanding the significance of the supervision process thorugh the theoretical perspective, approaching the concept of difficulties by the prism of supervisors and educators, and the practical implications of successful supervision.

EPV1685

Gilles de la Tourette Syndrome and Habit-Reversal: A Case Report

D. Patel[1]* and H. Tyagi[1]

[1]Department of Neuropsychiatry, University College London Hospital NHS Foundation Trust, London, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2152

Introduction: Gilles de la Tourette Syndrome (GTS) is characterised by tics which appear as sudden, rapid, purposeless motor movements and vocalisations. In contrast to other movement disorders, temporary and purposeful suppressibility for a few minutes at a time can be achievable. However, this is ineffective over time. Apart from the physical consequences incurred, tics and their associated neuropsychiatric symptoms can diminish individual quality of life.
Objectives: To present an adult single case study of the implementation of Habit Reversal Training (HbRT) for the treatment of a motor tic and to determine the clinical efficacy of the intervention over time (i.e., post-intervention and at a one-, three- and six-month follow-up).
Methods: A twenty-six-year-old male patient with a well-established diagnosis of GTS was referred to a tertiary-care neuropsychiatry outpatient clinic. Prior to the HbRT intervention, the patient had well-tolerated a continuous tetrabenazine prescription (25mg twice a day). His tic consisted of twitching of his nostrils and sudden and repeated head nods. The tic was reported to being experienced throughout the day and almost always being preceeded by a premonitory sensation. The patient's history was unremarkable with respect to pre, peri-, and postnatal development. There was no family history of tics nor any other movement disorders. Formal measures revealed the following: Clinical Outcomes in Routine Evaluation-Outcome Measure (**11**), Frost Multidimensional Perfectionism Scale (**117**), Autism-Spectrum Quotient (**2**), Adult Attention Deficit Hyperactivity Disorder Scale (**1**), and Yale-Brown Obsessive Compulsive Scale (**15).**
Results: By the end of a five-week fifty-minute one-to-one intervention window and at a one-, three-, and six-month follow-up appointment, the following main results are reported: [i] at post-intervention, a self-reported tic improvement score (measuring effectiveness of competing response on tic management since the first appointment) of eighty percent was achieved, [ii] self-reported tic improvement scores carried over to all three follow-up appointments, and [iii] week-to-week monitoring revealed that tic management improved by fifty percent by the third week of the intervention.
Conclusions: This study has accomplished its objectives of offering additional support for the implementation of HbRT for the treatment of a motor tic and to establish the clinical efficacy of the intervention over time. With these objectives in mind, TD and GTS continues to provide clinicians, clinician-scientists, and researchers with an abundance of possibilities for future research. For instance, on a clinical level, it is essential to further characterize variations in motor tic phenotype so that the factors that modify tic behaviour can be clarified. It would also be fascinating to longitudinally study and explore changes in tic frequency and intensity over time following a behavioural intervention such as HbRT.

Feasibility of metacognitive interpersonal therapy treatments in European public services

M. Pinotti[1]*, F. Inchausti[2], G. Dimaggio[3], R. Popolo[3] and P. Ottavi[3]

[1]South Psychiatric Operating Unit, Mental Health Department, Mental Health Center Rovereto, Trento, Italy; [2]University of La Rioja, La Rioja, Spain and [3]MIT Center, Rome, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2153

Introduction: Metacognitive Interpersonal Therapy (MIT) is a third wave orientation psychotherapy, based on the understanding that severe mental illness features a combination of poor capacity to make sense of mental states or metacognition, maladaptive interpersonal schemas and dysfunctional coping procedures.
Objectives: MIT is gathering increasing empirical support in both individual and group formats, in adults and adolescence in populations with personality disorders and early psychosis (Dimaggio et al., 2017; Fioravanti et al., 2024; Gordon-King et al., 2018; Pasetto et al., 2022; Inchausti et al., 2022; Popolo et al., 2018).
Methods: The group format has been empirically tested in different countries (Italy, Spain and Norway).
Results: Here we present the results of a series of RCT delivered in public mental health units (Ichausti et al., 2017; 2018; 2024; and Pinotti et al., 2024; Popolo et al., 2021; 2022).
Conclusions: Overall results show that MIT in group can be successfully delivered in the context of public mental health facilities with evidence for its efficacy, feasibility and effectiveness.

EPV1688

Cognitive and Emotional Regulation for High-Performance Poker Players: A Multidisciplinary Therapeutic Approach

M. Ribeiro[1]*, E. de Lanna[2,3] and L. S. Ribeiro[4]

[1]Private Practice, Delray Beach, United States; [2]Psychology, Universidade Federal Fluminense, Volta Redonda; [3]Psychology, Pontifical Catholic University of Rio de Janeiro and [4]Psychology, Private Practice, Rio de Janeiro, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2154

Introduction: High-performance players in sports, poker, or other competitive fields share traits that support them to excel under pressure. Exceptional players show mental resilience, staying focused, and adaptability skills in high-stress situations. However, many players struggle with consistency and discipline when emotional influence occurs over their routine and decision-making on tables. This work addresses common challenges for high-performance poker players and explores therapeutic techniques that improve decision-making and overall well-being.
Objectives: High-performance poker players, particularly cash game players, encounter unique cognitive and emotional challenges due to high-stakes, financial volatility, and emotional dysregulation. This work addresses common therapeutic demands and multidisciplinary approaches to support high-performance poker players.
Methods: Players who received therapeutic support benefited from a combination of cognitive-behavioral strategies and positive psychology, particularly focusing on emotional regulation and goal-setting to enhance their sense of control, motivation, decision-making, psychological well-being, and overall performance. The therapeutic interventions specifically targeted cognitive distortions and behavioral patterns that undermine decision-making and contribute to emotional dysregulation. Techniques such as cognitive restructuring, mindfulness, and problem-solving skills training through deliberate practice, promoting practical tools to manage the unique cognitive and emotional challenges faced in poker.
Results: The findings show that integrating cognitive-behavioral techniques into daily routines improves consistency, making daily strategies more automatic. Mental exercises like mindfulness and cognitive reframing strengthened skills while monitoring emotional states and helped players detect early signs of "tilt" and regulate emotions, diminishing impulsive decisions and heightening emotional responses. Addressing cognitive distortions, such as confirmation bias, through journaling and stress management techniques like deep breathing, helped players maintain composure under pressure. Therefore, these approaches assisted poker players in improving their adaptability skills without sacrificing consistency, leading to better performance and long-term success.
Conclusions: The cognitive and emotional demands of high-stakes poker require a comprehensive mental regulation approach. Combining cognitive-behavioral techniques, psychodynamic strategies, and mindfulness improves emotional stability, decision-making, and performance. Addressing cognitive distortions and using emotional regulation techniques help players avoid emotionally-driven decisions and maintain focus under pressure. By integrating these strategies into their routines, poker players can enhance consistency, optimize cognitive function, and achieve long-term success.

Kintsugi, Mending with Gold - A Psychotherapeutic Technique

P. I. Santos[1,2,3]* and A. B. Costa[3]

[1]Hospital das Neurociências, Hospital Trofa Saúde, Vila do Conde; [2]HPG, VNG and [3]Psichology, Psicobodycare, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2155

Introduction: Psychotherapy, when supported by an appropriate set of techniques, has a high impact on the patient's psychological well-being, self-knowledge and self-growth.
Objectives: This study aimed to determine the clinical utility of the therapeutic tool "Kintsugi," developed by the corresponding author, through two assessment phases.
Methods: To a total of 200 participants, aged between 18 and 70 years (M = 44.3, SD = 12.5), were administered a semistructured interview, the Hamilton Anxiety Scale, and the Échelle de Mesure des Manifestations du Bien-Être Psychologique. The assessments occurred before and after the application of the techinique, with an interval of about two months (approximately 4 to 6 sessions).
Results: Findings indicate that, in the first moment of assessment, participants showed lower levels of psychological well-being (M = 78.0, SD = 15.0) and, consequently, more anxious symptoms (M = 32.0, SD = 9.0). After the use of the "Kintsugi" technique, regardless of the participant's age or gender, an increase in psychological well-being (M = 96.5, SD = 12.0; F-test = 77.65, $p < .001$, $\eta^2 = 0.28$) and a decrease in anxiety (M = 21.0, SD = 7.0; F-test = 87.50, $p < .001$, $\eta^2 = 0.31$) were observed.

Conclusions: This therapeutic tool proves to be useful, beneficial, and clinically effective in a psychotherapeutic context, as its high contribution to the mental health of individuals becomes evident.

Closing the Gap: Integrating Science and Practice in Psychotherapy

N. Schwarzbach[1]*, M. Pijnenborg[1], R. Hoekstra[1], A. Poppe[1] and T. Bouman[1]

[1]University of Groningen, Groningen, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2156

Introduction: The science-to-practice gap in psychotherapy is a prominent topic of discussion that hinders the seamless integration of research findings into clinical settings. This divide seems, among others, to stem from conflicting views on the practical relevance of evidence-based mental health (EBMH).
Objectives: This study aims to provide a comprehensive overview of the existing narratives that define the science-to-practice gap, develop an inclusive definition that reflects the complexities of this issue, and identify the factors influencing and strategies for mitigating this gap.
Methods: We conducted a systematic literature review with a qualitative, thematic synthesis approach including 131 articles. Themes were identified and synthesized to outline the science-to-practice gap. Additionally, we included a historical analysis to examine how the prevalence of certain codes and themes has evolved over time, reflecting shifts in the academic and clinical landscape.
Results: Based on our findings, we refined the definition of the science-to-practice gap, capturing its multifaceted nature. Key themes influencing this gap include the educational background of psychotherapists, orientation towards specific psychotherapeutic schools, and personal inclinations of psychotherapists. Contextual factors such as institutional support and incentives for employing EBMH were also found to be positive influences. However, critiques regarding the rigidity of research methodologies and their applicability to diverse clinical scenarios were prevalent, with observable variances in thematic emphasis over the decades. Strategies identified for bridging the gap emphasized increased dialogue and collaboration between researchers and practitioners.
Image 1:

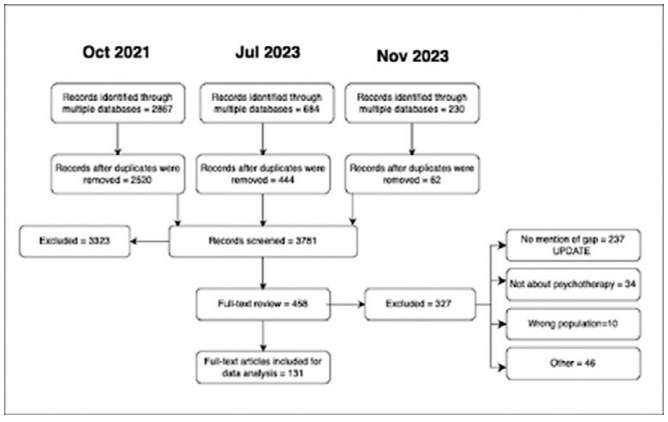

Image 2:

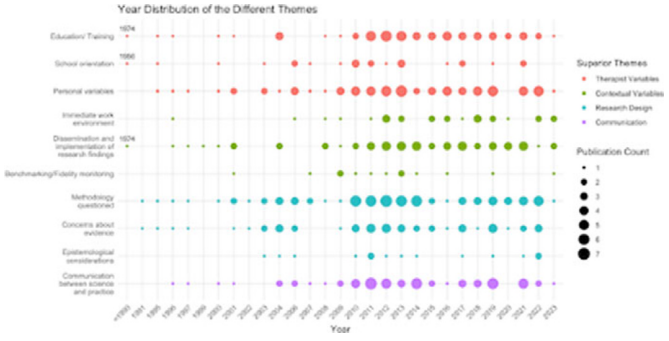

Table 1

Summary of the Reasons for the science-to-practice gap as Mentioned in the Literature

Therapist Variables	Contextual Variables	Research Design	Communication
Education/Training Insufficient education: • critical thinking, research training • scientific theories • practical training on application of EBMH **School orientation** • EBMH more favorable in CBT in contrast to psychoanalytic, humanistic, existential, and eclectic approaches **Personal variables** EBMH is associated with • younger therapists • openness towards EBMH • knowledge about EBMH • confidence about EBMH use • believes about effectiveness, importance and usefulness of EBMH Less EBMH is associated with • no access to interventions or literature • evaluation fear when using EBMH • cultural preferences of not using EBMH • mismatch of intervention with patient culture • difficulties understanding EBMH • dislike/resistance towards EBMH • placing much value on clinical expertise or artistry	**Immediate work environment** Influences at the workplace: • supervisors • colleagues • social environment • practical support • technical support • providing materials • providing infrastructure • employer attitudes **Dissemination and implementation of research findings** Influences: • implementation guidance • implementation planning • context specificity of implementation • lLack of incentives for EBMH implementation for therapists to • implement EBMH • engage with research	**Methodology questioned** • rigidity of RCTs • difficulty applying research results • rigidity in diagnostic and inclusion criteria • rigidity of manuals • nomothetic results applied to individual cases • overreliance on efficacy studies • overreliance on outcome research **Concerns about evidence** • EBMH interventions ineffective or harmful • variability not represented • limited awareness of ineffective treatment • publication bias **Epistemological considerations** • differences in thinking between positivism/empiricism and	**Communication between science and practice** • insufficient • lacking • unidirectional • little opportunity for exchange

Note: RCT = randomized controlled trials; EBMH = evidence-based mental health; CBT = cognitive-behavioral therapy.

Image 3:

Conclusions: This work sets the stage for future research that should prioritize the clinical perspective on evidence usefulness, broaden the research focus beyond intervention efficacy, and validate diverse methodologies. By proposing practice-focused research guidelines and emphasizing the need for robust dialogue between science and practice, we aim to enhance the applicability of research findings in clinical settings. Ultimately, our findings advocate for policies that facilitate the exchange of ideas and experiences, aiming to bridge the gap between scientific evidence and psychotherapeutic practice effectively.

Navigating the Intersection of Autism and Gender Fluidity: A Case study of psychotherapy in a Neurodivergent Adult

A. Vuk

Department of integrative psychiatry, University psychiatric hospital Sveti Ivan, Zagreb, Croatia
doi: 10.1192/j.eurpsy.2025.2157

Introduction: Autism Spectrum Disorder (ASD) is a developmental condition that modifies how a person perceives their surroundings, communicates and interacts with others. Autistic individuals often experience executive dysfunction, impaired social cognition, likewise differences in perception and information processing that can make it challenging to describe their internal sense of gender and gender-related needs. This case report presents the therapeutic journey of a young man diagnosed with Asperger Syndrome who entered dynamic supportive psychotherapy to address social and emotional challenges, likewise identity issues.
Objectives: This poster aims to explore the clinical complexities arising from the presence of gender neurodivergence in individuals with ASD and its impact on their presentation, assessment and management. It seeks to highlight the unique challenges faced by autistic individuals in navigating gender identity, emphasizing the need for tailored clinical approaches.
Methods: A descriptive case report of a patient with ASD and gender neurodivergence, drawing on clinical records, patient interviews and psychotherapy sessions, psychological assessment and a non-systematic review of relevant literature.
Results: A case report presentation of a 29-year-old man diagnosed with Asperger syndrome during adolescence. Due to adaptation difficulties and anxiety he started seeing a child's psychiatrist and then transferred to an adult setting. He had intermittent visits to a community mental health service initially and, over the last two years, attended biweekly psychotherapy sessions at our hospital. Early psychological assessments revealed challenges with social interactions, confused and bizarre thinking patterns, identity diffusion, and a tendency for ruminative self-reflection. Treatment was interrupted at the end of 2023 due to a psychotic episode with dissociative phenomena, leading to the introduction of antipsychotics. After stabilization, psychotherapy resumed. During the course of therapy, conversations revealed a complex narrative around gender identity, including reflections on multiple genders and gender fluidity.
Conclusions: This case highlights the intersection of neurodiversity and gender identity, illustrating how individuals on the autism spectrum may experience and navigate gender in unique ways. The therapeutic process explored gender fluidity as an evolving self-concept, emphasizing the importance of inclusive approaches in psychotherapy. The report underscores the need for mental health professionals to be attuned to diverse expressions of gender identity within neurodivergent populations and advocates for flexible therapeutic frameworks that accommodate both neurodiversity and gender diversity.

Improvements in self-efficacy and attachment security during the psychodrama group process among young women: A mix-methods study

I. G. Yilmaz-Karaman[1]*, N. Kalkan-Oguzhanoglu[2], O. ÖNER[3] and T. GUNDUZ[1]

[1]Psychiatry, Eskişehir Osmangazi University, Faculty of Medicine, Eskişehir; [2]Psychiatry, Pamukkale University, Faculty of Medicine, Denizli and [3]Bergama State Hospital, İzmir, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2158

Introduction: Mental illnesses are more common in women than men, and common illnesses such as anxiety and depression often begin in youth. Young women are disadvantaged both in terms of developing mental illnesses and in terms of gender-based discrimination. In this respect, protective, preventive, and empowering interventions targeting young women can be a good investment in terms of protecting their mental health. The youth period is the focus of protective and preventive interventions due to its nature as the initial period of frequently seen mental illnesses. Empowerment can reduce vulnerability during this period.
Objectives: This study aimed to examine quantitatively and qualitatively whether the self-efficacy and attachment dimensions of the participating young women changed as a result of an empowerment-themed psychodrama group therapy.
Methods: The study has a longitudinal design with mix methods. After the local ethics committee approval, an announcement was made online, and the participants were included in the study after face-to-face meetings. Young women between 18 and 25 years who do not have a current psychiatric diagnosis, without suicide attempts and alcohol or substance use disorder, were recruited. Seventeen psychodrama sessions, each lasting three hours, were conducted. Role reversal, pairing, and mirror techniques were mainly used in the sessions. Warm-up games and group games were selected following the theme of empowerment. The General Self-Efficacy Scale (GSS) and Experiences in Close Relationships- Revised (ECR-R) were applied to the group members before starting the psychodrama sessions and after the sessions ended. In addition, the group members' processes were investigated using qualitative methods after the sessions had ended.
Results: Thirteen young women completed the psychodrama group sessions without more than 20% absence. Statistically significant increases were observed in the initiation ($z=-2.310$ $p=0.021$), resilience ($z=-1.973$ $p=0.049$), maintenance effort sub-dimensions ($z=-2.355$ $p=0.019$), and GSS total score ($z=-2.357$ $p=0.018$) of general self-efficacy after the intervention. When the sub-dimensions of ECR-R were evaluated, statistically significant decreases were observed in both avoidant attachment ($z=-2.831$ $p=0.005$) and anxious attachment ($z=-2.864$ $p=0.004$). Qualitative analysis showed themes of self-confidence, modeling, and universality.
Conclusions: Psychodrama group psychotherapy is suitable for developing self-efficacy and increasing secure attachment in young women as a preventive psychiatric intervention.

Psychotherapy of women victims of domestic violence: Ukrainian practice

M. Markova[1]*, I. Romanova[1], A. Avramenko[1], S. Martynenko[1], V. Pliekhov[1] and T. Aliieva[1]

[1]Sexology, Psychotherapy and Medical Psychology, Kharkiv National Medical University, Kharkiv, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.818

Introduction: According to the press service of the National Police of Ukraine, the number of domestic violence complaints in 2023 amounted to 291,000 statements from victims, which is almost 2 times more than in 2022. This trend determines the relevance of improving the model of comprehensive assistance to victims of domestic violence in Ukraine.
Objectives: To develop and study the effectiveness of a comprehensive system of psychotherapy for women victims of domestic violence.
Methods: We have been examined 85 women victims of domestic violence during 2022-2023; 59 % of them were suffered from physical violence, 100 % – psychological violence, 6 % - economic violence. The following methods were used: Spielberger-Y.L.Khanin scale of reactive and personal anxiety (STAI), Eysenck Personality Questionnaire (EPQ) to determine the level of neuroticism, The Thomas–Kilmann Conflict Mode Instrument (TKI), The Hamilton Depression Rating Scale (HDRS).
Results: The most common form of psychological violence against women was manipulation of the child's interests during divorce proceedings, when men tried to insult and humiliate the authority of their wives, displaying aggressive forms of behavior. Most aggressors are characterized by emotional instability, irritability and cruelty. An aggravating psychological factor in conflicts in such families was the abuse of alcohol by men.
Women who suffered from domestic violence showed psychopathological personality changes not only in the form of victim character traits, but also in the form of aggression. Other women, on the contrary, were passive, conformist, and could not protect themselves. We used the following methods of psychotherapy: telephone and online counseling, psychological counseling, behavioral psychotherapy, systemic family psychotherapy, and rational psychotherapy. Psychological counseling solved the problems of resolving the difficulties of women victims by creating conditions for expressing strong emotions and helping them gain a sense of control over themselves. The comprehensive system of psychotherapy was aimed at assessing the psychotraumatic situation of a case of violence and forming new ideas about family life and developing new reactions and forms of behavior, forming victim personality traits in women.
Conclusions: The comprehensive system of psychotherapy for women victims of domestic violence was developed. As a result, 82% of women who received the indicated therapy experienced a decrease in manifestations of neurotic and somatoform syndromes, an increase in self-esteem, self-confidence, an improvement in the well-being of women, and an improvement in the psychological climate in these families.

The Impact of Sedentary Lifestyle on the Psychological Well-being of Hospital Administrative Staff

K. Imen[1], R. Nakhli[1], L. S. Chaibi[2]*, M. Bouhoula[1], A. Chouchane[1], M. Maoua[1], H. Kalboussi[1], O. El Maalel[1], S. Chatti[1], A. Aloui[1] and N. Mrizak[1]

[1]Occupational Medicine Department, University of Sousse, Faculty of Medicine Ibn Al Jazzar, Sousse and [2]D Psychiatric Department, Razi Hospital, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2159

Introduction: Sedentary behavior, a leading cause of preventable mortality in developed nations, has been linked to a range of health problems, including cardiovascular disease and depression. While the benefits of leisure-time physical activity are well-established, the impact of sedentary behavior within the workplace, particularly in the healthcare sector, remains under-explored.
Objectives: To study the relationship between sedentary behavior and mental health among.
Methods: A cross-sectional study was conducted among administrative staff at Farhat Hached University Hospital, Sousse, from March 2024 to June 2024. Data were collected through an anonymous, self-administered questionnaire written in French and distributed to the administrative staff of Farhat Hached University Hospital. It included six sections covering sociodemographic characteristics, lifestyle habits, medical data, physical activity. Mental health, was assessed using the Hospital Anxiety and Depression Scale (HAD) and the Perceived Stress Scale (PSS).
Results: A total of 85 questionnaires were completed by administrative staff at Farhat Hached University Hospital. The majority of participants were female (sex ratio of 0.42), with an average age of 47.1 ± 8.2 years. Higher education levels were represented by 66 participants, and only 24 engaged in professional physical activity (<30 minutes per day). The average seniority at the institution was 19.91 ± 9.2 years. Administrative managers (25.9%) and administrative staff (20%) were the main professional categories. A significant proportion of participants exhibited signs of anxiety (25.8%) and depression (32.9%). The average perceived stress score was 17.75 ± 4.95. A significant association was found between anxiety and low levels of physical activity at work ($p<0.001$). However, no significant association was observed between perceived stress and physical activity at work.
Conclusions: Sedentary behavior at work is associated with a high prevalence of anxiety and depressive disorders among hospital administrative staff, highlighting the importance of promoting physical activity to improve mental health.

Can a modified resuscitation course in a national psychiatric hospital improve medical provider confidence in medical emergency response

Y. Y. Chew[1]*, N. Y. W. Lee[1], E. Seow[2] and F. Yao[1]

[1]Institute of Mental Health and [2]Khoo Teck Puat Hospital, Singapore, Singapore
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2160

Introduction: Institute of Mental Health (IMH) is the only tertiary psychiatric hospital in Singapore and does not provide acute medical care. The on-call doctors, who are Advanced Cardiac Life Support (ACLS) certified, respond to medical emergencies. Resuscitation skills are expected to decay with time when not used frequently and thus can pose an important challenge to maintain the doctors' skills in settings with low volumes of code blue situations (Au *et al.* Resuscitation 2009;138:284-296). Our code blue aduits revealed significant competency gaps. IMH introduced a biannual resuscitation training program which includes a video demonstration of the optimal code blue response, hands-on session to review airway management techniques, operation of the defibrillators used in IMH, recognition and management of cardiac arrest rhythms including a pre-course ECG worksheet, familiarisation with the emergency drugs used in IMH, and a code blue drill. Due to COVID-19, the original course was shortened by removing the video demonstration and code blue drill, augmenting the home-based question paper with IMH-specific clinical vignettes.
Objectives: We aimed to determine the common conditions resulting in code blue activations and whether the modified course was equivalent to the original course or ACLS in maintaining resuscitation currency and doctors' confidence in responding to emergency scenarios.
Methods: Data was collected from June to August 2023 with consent via an electronic feedback form, to reduce non-response bias, from doctors who have responded to code blue activation in IMH. Qualitative justification on the responses were collated. Efforts were made to collect at least 25 responses from doctors with different levels of experience to minimize sampling bias. Surveys were anonymised, questions were vetted by 2 senior doctors and the survey was kept short to reduce response bias. Binary responses were tabulated for analysis and content analysis was done for feedback obtained.
Results: Of 28 respondents, most were Psychiatry trainees (60.7%) with 1-2 years of experience working in IMH (36.7%) and more than 30 overnight duties (53.6%). The most commonly encountered emergency scenarios were hypotension (31%) and desaturation (20%). 92.9% of participants agreed that the modified course was useful for emergency scenarios faced. 53.6% of participants attended both the full and modified course, amongst whom, 60% reported that the modified course was equivalent to the full course. Only 50% felt that ACLS alone would suffice. Qualitative feedback obtained from participants reiterated that it was a context-specific and timely refresher course.
Conclusions: IMH doctors were satisfied with the modified resuscitation course and found it effective for frequently encountered emergency scenarios suggesting it as a valuable training adjunct in low code blue volume settings.

EPV1697

An Audit of Compliance with Trust Guidelines for Post-Incident Medical Reviews of Patients who have Ligatured on Acute Inpatient Psychiatric Wards in CWP NHS Foundation Trust, using a Sample of Data from the period between January 2022 and May 2024

A. Brown[1], K. Clark[1]*, Z. Wrightson[1], M. Godsiff[1] and S. Button[1]
[1]Psychiatry, Cheshire and Wirral Partnership NHS Foundation Trust, Cheshire and Wirral, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2161

Introduction: Immediate physical assessment and management of patients on psychiatric wards who have been ligaturing is not standardised across the UK. There is little published research or literature on what is needed in terms of medical input and these incidents are usually initially assessed/managed by non-medical staff who are on site at the time of any such incidents. Within CWP NHS Foundation Trust, we have local guidelines (SOP 13 'The Management of ligatures in Mental Health and Learning Disability Services') advising that any inpatient on the adult/older adult psychiatry wards who has ligatured should be seen by a doctor for a medical review,
Objectives: To review a sample of recorded inpatient ligature incidents to see if Trust guidelines were being adhered to. We hope to use the findings from this audit to review the current guidelines and assess whether or not the additional medical reviews add to or change clinical management already instigated by ward staff. This may be more of an issue when medical staff cover is limited e.g. out of hours.
Methods: We accessed recorded ligaturing incidents on adult and older adult inpatient psychiatry wards across our Trust (accessing the 'Datix' reporting system) from the period starting 1st January 2022 to 31st May 2024. In total, there were 1127 and we took a sample of 112 picked using a random number generator. We reviewed the documentation from the incident to confirm how many had had a medical review after the incident, how long after the incident they were seen and whether or not the medical review had changed management following the incident.
Results: Approximately 50% of patients had had a medical review post ligature incident. Approximately 4% of patient ligaturing (5/112) or 9% of those who received a medical review (5/55) had new management instigated as a result of the medic review. On review of these cases, there was limited medical input needed including application of steristrips for wound care and asking for ambulance transfer to acute hospital for CT head following seizure after ligaturing. There were no serious harm outcomes from the patients we reviewed in our sample.
Conclusions: Whether or not the we can review guidlines can be reviewed in light of the data is to be discussed following presentation of our results to the Trust. It appears that the initial managment plan, instigated by ward staff, has usually been appropriate and when additional input has been given by the medic on site at review, this has not been felt to have been critical in optimising patient safety. It would still be possible for a medic to review patients when felt by ward staff to be necessary even if guidelines were changed to suggest it was not mandatory for patients to be seen by a medic.

EPV1698

Risk assessment tools for sexual assault: a scoping review

E. Doody[1,2]*, D. Flynn[1,2] and S. Nolan[1]
[1]Psychiatry, University Hospital Waterford, Waterford and [2]Psychiatry, RCSI, Dublin, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2162

Introduction: Risk assessment tools are used to enhance patient safety and promote quality care by limiting adverse outcomes to the greatest extent possible. In the Republic of Ireland, risk is monitored and regulated by the Mental Health Commission (MHC). A 2023 report by the MHC identified high numbers of recorded episodes of sexual assault on the acute inpatient unit in the Department of Psychiatry (DOP), University Hospital Waterford (UHW). Standard risk assessment tools are used in the DOP, however, these risk assessment tools failed to identify those who were at high risk of perpetrating a sexual assault.
Objectives: The purpose of this research was to determine if there were risk assessment tools with a higher predictive value of identifying risk of sexual assault in an acute adult inpatient psychiatric setting. I also wanted to establish whether there were risk assessment tools available which assess risk of sexual assault in those with no history of perpetrated sexual assault.
Methods: This scoping review was prepared according to the PRISMA-Scr guidelines. Databases including Embase, Medline, CINAHL, UptoDate, TRIP, Cochrane and PsychINFO were searched. Keywords included inpatient, psychiatry, mental health, risk assessment tools, risk assessment scales, risk management, sexual assault and sexual offense. There was no limit on the date of publication or country of origin of articles. Only articles that used risk assessment tools on adults, who were inpatients in an acute psychiatric setting, in the English language were included. Only risk assessment tools that included assessment of risk of sexual assault were included.
Results: A total of 15 articles were identified. There was a dearth of literate that compared risk assessment tools in this population with regards to risk of sexual assault. Most articles exploring risk of sexual assault focused on the study of those who were offenders and explored the risk of recidivism through the use of risk assessment tools.
Conclusions: Risk cannot be accurately predicted or eliminated. However, determining the most appropriate and comprehensive risk assessment tools, with the highest probability of identifying risk of sexual assault has the potential to enhance patient safety and improve the quality of care provided. There is a lack of risk assessment tools that assess sexual assault, especially in those with no prior history of perpetrating a sexual assault.

Examining the Correlation between Emotional Intelligence and Burnout: A Study on Mental Health in the Workplace

R. Galea[1]*, A. Zahra[1], E. Cassar[2], K. J. Farrugia[1], C. Busuttil[1], B. Gatt[1], R. Micallef[1] and M. Micallef[1]

[1]Mount Carmel Hospital, Mental Health Services and [2]Mater Dei Hospital, Health Services, Attard, Malta
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2163

Introduction: Mental Health (MH) in the workplace profoundly influences employee well-being. Burnout, Emotional Exhaustion (EE), depersonalization and diminished personal accomplishment are prevaling concerns among healthcare professionals. Left unchecked these facets can impinge on professionals' MH and productivity.
Objectives: This study explores the relationship between Emotional Intelligence (EI) and burnout among staff at Mount Carmel Hospital by assessing the degree of EE, depersonalisation and personal accomplishment before and after the EI training.
Methods: 121 participants from four hospital wards were recruited. An anonymized questionnaire assessed EI, burnout and demographics including the Schutte Self Report EI Test and the Maslach Burnout Inventory. EI training was provided by professionals from within the hospital service. Post-training measures were reassessed to determine the training's impact on improving the constructs of occupational burnout.
Results: Gender analysis revealed higher EI scores among females (125.4±11.2) compared to males (117.0±13.9, p=0.026). EE was significantly higher among Maltese staff (20.4±8.3) compared to EU (17.2±4.8) and third-country nationals (12.3±4.9, p=0.027). Longer ward tenure (11-25 years) correlated with higher EE (32.7 ±6.8) compared to <1 year (16.6±8.1) or 1-5 years (17.6±5.7, p=0.0087). Negative correlations between EI and depersonalization (r=-0.32, p<0.01) emerged, indicating higher EI is associated with lower levels of depersonalization. A significant positive correlation between EI and personal achievement (r=0.54, p<0.01) suggested that higher EI is associated with higher levels of personal achievement. No correlation was found between EI and EE. Phase two revealed a significant difference in post-training EI. Other measures showed no significance; suggesting that other corporate fundational aspects impinge on employee MH.
The findings have important implications for MH professionals and organisations. The correlation between EI and burnout highlights the importance of promoting EI. Specific correlations need further testing, as the higher degree of EE in participants with higher scores of EI effects training development. Training programs focusing on EI should be incorporated into continous professional development. Significant variations in EE were observed among participants from different nationalities and those with varying years of experience in the ward; underscoring the importance of tailored interventions enhancing EI and mitigating burnout.
Conclusions: This study provides evidence for the correlation between EI and constructs of burnout among staff at Mount Carmel Hospital. Further corporational functional aspects potentially impact employees' professionals outlook, perception and MH. Training programs aimed at enhancing EI can be used to reduce and mitigate burnout levels while improving well-being in the workplace.

Exploring healthcare provider's views on potential causes and solutions of waiting lists in mental health services in Ireland

J. Khan[1]*, M. whitty[2] and M. Nadeem[2]

[1]Psychiatry, Connolly Hospital Blanchardstown Dublin, Dublin and [2]Psychiatry, South Meath Mental Health service, Ashbourne, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2164

Introduction: This study focused on one of the key components of mental healthcare provision: waiting lists in the community mental health service in County Louth and Meath, Ireland. The background context addresses the increasing demand for healthcare,

shortage of resources, administrative hindrances, and the impact of waiting time on patient outcomes and satisfaction.
Objectives: The objectives of the research were to Identify the primary causes of waiting lists in the community mental health services of County Louth and Meath in healthcare provider's opinions and their views on potential solutions to reduce waiting lists and improve service delivery.
Methods: A mixed-methods approach was applied to conduct a comprehensive assessment of waiting list causes and potential solutions based on the combination of qualitative and quantitative methods. The main qualitative methods encompassed semi-structured interviews with healthcare professionals and thematic analysis of their perceptions. The quantitative part of the study consisted of a survey distributed among members of the multidisciplinary mental health teams to collect information regarding perceptions, challenges, and potential solutions to the waiting list problems.
Results: The study showed a variety of issues in the human factor of waiting lists, including insufficient staffing, high demand for services, administrative delays, limited resources, and communication failures between mental health and primary care teams. The mental healthcare professionals in County Louth and Meath voiced their apprehensions concerning patients' wait times, resource scarcity, and the effect of these problems on the performance of services and patient outcomes. The general findings uncovered that 89.3% of respondents recognized insufficient staffing as the essential challenge in waiting list management, with 82.1% likewise featuring the higher demand for services as a significant variable adding to waiting lists.
Conclusions: Carefully assessing these issues is vital, and evidence-based steps are to be employed in managing the waiting lists in the community mental health services in County Louth and Meath, Ireland. Suggestions on increased staffing, resource investment, technology leveraging, process optimization, and enhanced communication between primary care and psychiatry are the essence of potential solutions. Undertaking these suggestions will enable mental health services to increase efficiency, provide a better patient experience, and subsequently improve overall service delivery while reducing the consequences of long waiting times.

Disclosure of Interest: None Declared

EPV1701

Qualitative Needs Assessment study of Mental Health Service Networks

I. Makivic[1]*, A. Žurga[1], A. Prijon[1], N. Ropret[1] and M. Vinko[1]
[1]Nacionalni inštitut za javno zdravje, Ljubljana, Slovenia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2165

Introduction: Assessing the needs within the field of mental health is crucial for the effective allocation of resources and the development of tailored interventions. A well-functioning network of services plays a vital role in addressing the complexities of mental health issues, which range from mild anxiety to severe psychiatric disorders. Understanding the local context and the diverse needs of the population can enhance the delivery of mental health services and improve overall community well-being.
Objectives: The primary objective of this study was to assess the needs related to mental health services in two Slovenian regions. We aimed to identify the challenges faced by individuals with mental health issues, their families, and different professionals involved in their care. Furthermore, we sought to evaluate the existing service networks and the gaps in mental health support, highlighting the necessity for a coordinated approach in addressing these challenges. By understanding, the specific needs and different services available in both regions, we aim to inform policymakers and stakeholders about potential improvements and strategies for enhancing mental health service network.
Methods: A semi-structured guided conversation was conducted with individuals and professionals working in mental health services. Coordinators that guided the conversation used specific questions. The data collected was analyzed to identify prevalent mental health issues within the local communities, potential solutions for the identified challenges, and the quality of collaboration among various stakeholders and services in the field of mental health.
Results: Both regions reported significant mental health challenges, including high rates of anxiety, social isolation, and dual diagnoses among users. Common issues included long waiting times for services and stigma surrounding mental health. Service providers faced challenges like staff shortages, lack of training, insufficient time for treatment, and excessive administrative tasks. Both environments highlighted the need for improved inter-sectoral collaboration and community support programs. Systemic issues included lack of continuous funding, and inadequate living arrangements for people with mental health problems.
Conclusions: The findings underscore the importance of a coordinated approach to mental health services that fosters collaboration among stakeholders. A robust service network is essential for addressing the diverse needs of individuals with mental health challenges. Future efforts should emphasize enhancing multisectoral collaboration, clarifying roles within the network, and involving families in care processes. By prioritizing these elements, we can create a more supportive environment for those affected by mental health issues and facilitate their recovery.

EPV1704

Psychotropic medication use and its metabolic consequences: advocating for a patient-centred approach

L. Young[1]* and R. Rasheed[1]
[1]Chapel street surgery, Rigg Milner Medical and Corringham health centre, and Collingwood Surgery, Essex, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2166

Introduction: There exponential rise in prescribing SSRIs and antipsychotic medication have highlighted the paucity of shared decision making, holistic therapies and weight management programmes. Guidelines are vague about checkpoints and deprescribing, seeming to ignore the metabolic consequences, failing to advocate for physical health monitoring.
Objectives: We undertook a retrospective analysis of (n =492) patients initiated on psychotropic medication to understand the physical consequences, assessing the metabolic consequences of long-term prescribing of psychotropic medication in a rural primary care population.
Methods: Electronic patient records were analysed from depression and serious mental health registers across three primary care sites.

Data collected included the start date of treatment, BMI measurements before and after treatment.
Results: Among the 220 patients studied, 150 (67.7%) experienced weight gain, while 70 (31.8%) lost weight. The average treatment duration was 11.5 years. Weight gain was more prevalent among males (71.6%) compared to females (66.7%). Patients who gained weight were, on average, prescribed cumulatively more psychotropic medications (3.21) than those who lost weight (2.89).
Conclusions: Shared decision making and acknowledgement of the metabolic consequences of these medications at the point of initiation, and identification of pre-existent metabolic risks, monitor weight gain, and ensure adequate life-style changes to mitigate side effects. These methods should continue throughout the duration of treatment, and when possible, the option of deprescribing should always be available to the patient. It is time care bundles for patients with mental health illness are resourced for primary care.

Improving Cognition in Severe Mental Illness by Combining Cognitive Remediation and Transcranial Direct Current Stimulation: Study Protocol for a Pragmatic Randomized Sham-Controlled Multi-Center Trial (HEADDSET+)

N. C. Buist[1,2*], A. Poppe[1,2], B. Ćurčić-Blake[3], G. H. M. Pijnenborg[1,4] and L. van der Meer[1,2]

[1]Clinical and Developmental Neuropsychology, University of Groningen, Groningen; [2]Department of Rehabilitation, Lentis Psychiatric Institute, Zuidlaren; [3]Department of BSCS Neuroscience, University Medical Center Groningen, Groningen and [4]Department of Psychotic Disorders, GGZ Drenthe, Assen, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2167

Introduction: Individuals with severe mental illness (SMI) frequently experience challenges in daily life, often attributable to cognitive impairments. Cognitive rehabilitation interventions can be implemented to enhance thinking abilities and improve functional outcomes. Transcranial direct current stimulation (tDCS) is a non-invasive brain stimulation technique that may promote neural plasticity and therefore, may enhance learning.
Objectives: This trial aims to determine whether individuals with SMI who need supported housing can improve cognitive and daily functioning after following cognitive remediation (CR). Next, this trial evaluates whether CR combined with tDCS will enhance the effect of CR alone. Lastly, this trial will investigate the subjective experience of the CR intervention. We expect that participants will improve in goal attainment and cognitive and daily functioning.
Methods: In this pragmatic, triple-blinded, randomized, sham-controlled multi-center trial, we will compare the experimental group (CR + active tDCS) with the control group (CR + sham tDCS). 126 participants with SMI will receive 16-20 weeks of twice-weekly CR (32-40 sessions of 30-45 minutes) combined with active (N = 63) or sham tDCS (N = 63), separated over five cohorts. We will recruit participants aged between 18 and 65 with SMI residing in supported living facilities. Functional, cognitive, and clinical outcome assessments will be performed at baseline, post-16-week waiting period, post-treatment, and 6-month post-treatment. Additionally, post-treatment participants will be asked to engage in an in-depth interview to evaluate their meta-cognitive skills and subjective experience of the treatment.
Results: Preliminary results from the post-treatment effects, along with insights from in-depth interviews conducted in the first cohort (N = 15) as well as post-16-week waiting period effects for goal attainment (including the second cohort, N ≈ 40) will be presented.
Conclusions: This randomized controlled trial will investigate the efficacy of CR and tDCS in enhancing recovery in people with SMI. If the intervention proves to be effective, it has the potential to be implemented into standard care for service users requiring long-term support.

The efficacy of LIFESTYLE behavioral intervention in improving healthy eating and reducing alcohol consumption in patients with severe mental disorder: one year of follow-up

B. Della Rocca[1*], P. Catapano[1], C. Toni[1], M. Di Vincenzo[1], E. Mancuso[1], F. Lucci[1], G. Sampogna[1], M. Luciano[1] and A. Fiorillo[1]

[1]Università della Campania "Luigi Vanvitelli", Napoli, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2168

Introduction: Patients with severe mental disorders (SMD) often report unhealthy dietary patterns, including low intake of fruits and fiber, high consumption of junk food, and alcohol misuse, leading to poor nutritional status and increased oxidative stress, which negatively impacts physical and mental health. Psychoeducational interventions focusing on dietary habits and alcohol consumption have shown promising results, but long-term data is currently scarce.
Objectives: The main objective was to evaluate the LIFESTYLE intervention's one-year effectiveness in helping individuals with SMD improve their eating habits. Secondary objectives included evaluating the impact of psychiatric symptoms on lifestyle behaviors and the reduction of alcohol consumption.
Methods: The study included 401 patients with SMD from 7 university centres in Italy. Participants were randomized to either the control group, which received general health education, or the experimental group, which received a 5-month psychoeducational intervention. The intervention featured group sessions focused on diet, physical activity, and behavior modification. Univariate analysis was performed to investigate the correlation between psychiatric symptoms and changes in lifestyle behaviours, such as eating habits, physical activity, and alcohol consumption.
Results: Univariate analysis showed significant improvements in lifestyle behaviors among the experimental group. There was an increase in fish consumption (OR: 1.67, 95% CI: 1.45-1.97; $p < 0.05$), fresh fruit intake (OR: 1.36, 95% CI: 0.80-2.31; $p < 0.05$), and vegetable consumption (OR: 1.91, 95% CI: 1.56-1.96; $p < 0.05$). Moreover, there was a reduction in junk food consumption (OR: 0.814, 95% CI: 0.53-1.25; $p < 0.05$) and daily alcohol intake (OR: 0.70, 95% CI: 0.42-1.15; $p < 0.05$).
Conclusions: The results of this study support the efficacy of structured lifestyle intervention for enhancing physical activity and eating behaviors in patients with severe mental disorders. They also support the translation of similar interventions into clinical practice and illustrate the necessity of physical activity

and dietary advice in patients with SMD as part of their treatment schedule. Psychoeducational interventions can greatly improve the long-term health outcomes for those with SMD.

Work Performance Challenges and Needs of Adults with ADHD: Exploring Lived Experiences

N. Grinblat[1]* and S. Rosenblum[1]

[1]Department of Occupational Therapy, University of Haifa, Haifa, Israel
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2169

Introduction: Attention-deficit hyperactivity disorder (ADHD) significantly impacts adults' work performance, yet their lived experiences and perceptions of their work challenges remain underexplored. Understanding these subjective viewpoints is crucial for capturing the complexities of this population's daily work challenges and needs, serving as a foundational step in developing targeted intervention to enhance work performance and participation.
Objectives: This study aimed to explore the work performance experiences, challenges, and needs of adults with ADHD.
Methods: Twelve adults (ages 20-46) diagnosed with ADHD participated in three separate online focus groups, each comprising four participants.
Results: Participants reported key challenges in executive functions, including difficulties with time management (lateness, missing deadlines), planning (prioritizing tasks, multitasking), working memory (forgetting instructions and names), maintaining focus, managing distractions, and emotional regulation (struggles in relationships with colleagues and employers). These challenges often led to frustration, stress, and low occupational self-efficacy. Identified needs included psychoeducation, self-regulation strategies, work and environment accommodations, and personalized interventions.
Conclusions: The study highlights the unique executive challenges and emotional consequences faced by working adults with ADHD. Hence, it emphasizes the need for personalized interventions to enhance work performance, participation, and overall well-being in this population.

Disclosure of Interest: None Declared

EPV1711

The comparison of labor work training performances for the patients with mental illness in a public psychiatric center

F.-Y. Gu[1,2]*, A.-L. Liu[1] and W.-C. Lue[1]

[1]Occupational Therapy, Taipei City Hospital, Songde Branch and [2]Taipei City Hospital Songde Branch Psychiatric Nursing Home, Taipei City, Taiwan, Province of China
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2170

Introduction: Mental illness is a kind of change in mental health status which affected thought, feeling, emotion, behaviors, and so on. Labor work training is one of common rehabilitation programs in psychiatric medical institutes in Taiwan. This rehabilitation program has been implemented for many years, being an important indicator of psychiatric hospital accreditation. However, we couldn't analysis and apply effectively.
Objectives: We aim to investigate different labor work training performances of the patients with mental illness in a public psychiatric center in Taipei City. Furthermore, we can apply in shared decision making and modifying the labor work training project according to the data results.
Methods: In this cross-sectional study, 89 participants with mental illness who were stably engaged in labor work training for at least 1 month were included in Taipei City Hospital Songde Branch. Descriptive statistics will be used in characteristic of population, incentive record and score of the comprehensive occupational therapy evaluation scale (COTES). We used one-way ANOVA to test the difference of work behavior scores in different labor work training.
Results: This study results showed that the percentage of participants in the cleaning labor group, manual group, and sales & delivery group were 15% (N=13), 49% (N=44), and 36% (N=32) respectively. The most people engaged in the manual group. The average total score of psychiatric patients' work behavior was highest in the sales & delivery group (p<.05). There were significant differences at scores of work behavior items, including motivation (p=.006)、duration (p=.001), responsibility (p=.002), comprehension (p=.002), technique (p=.005), and fine motor coordination (p=.005).

Image 1:

Table 1 The work behavior mean scores for cleaning labor group, manual group, and sales & delivery group.

items	cleaning labor group	manual group	sales & delivery group	F	p
Motivation	3.27±1.18	3.43±0.94	4.03±0.67	5.373	.006*
Duration	3.62±0.87	3.16±1.01	4.02±0.85	7.829	.001*
Responsibility	3.54±0.66	3.34±0.77	3.92±0.57	6.637	.002*
Frustration tolerance	3.08±1.04	3.25±0.72	3.53±0.76	1.949	.149
Self-expectation	3.00±0.58	3.11±0.55	3.38±0.60	2.803	.066
Comprehension	3.04±0.85	2.90±0.75	3.52±0.63	6.870	.002*
Technique	2.69±0.72	2.77±0.80	3.31±0.72	5.616	.005*
Fine motor coordination	2.54±0.97	2.05±1.07	2.84±0.99	5.717	.005*
Total score	24.77±4.86	24.01±4.78	28.55±4.26	9.305	.000*

Image 2:

Table 2 Demographic characteristics.

		Cleaning labor group	Manual group	Sales & delivery group
People (percentage)		13 (15%)	44 (49%)	32 (36%)
Gender	Male	9	24	16
	Female	4	20	16
Diagnosis	F20	13	42	31
	F31	0	1	1
	Other	0	1	0
Education (years)		11.31±2.81	10.91±3.72	12.75±2.72
Course of disease (years)		31.36±10.28	25.45±9.26	23.44±9.59
Age(years)		54.38±6.67	49.80±8.48	48.91±8.69
	20-29	0	1	0
	30-39	0	5	7
	40-49	4	9	9
	50-59	5	28	12
	60-65	4	1	4
Marital status	Single	9	31	28
	Married	2	4	1
	Divorced	2	7	3
	Others	0	2	0
Content of work training		Cleaning, laundry, meal delivery, etc.	Agriculture, craft, manual processing, broadcasting.	Ward assistant, internship of convenience store

Conclusions: In comparison, the patients with mental illness in the sales & delivery group are better at work behavior. According to the analysis of the result data, when the therapist and the patient make shared decisions, they can discuss appropriate labor work training based on the patient's work behavior.

Development of a carer psychoeducational group in an early intervention in psychosis service

A. Gutierrez Vozmediano[1]*, M. Carter[1] and J. Lodge[1]

[1]South West London and St George's NHS Mental Health Trust, London, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2171

Introduction: One of the quality statements for the treatment of psychosis in adults refers to the provision of education programmes for carers (NICE QS 80 2015). Our Early Intervention in Psychosis Service (EIS) in South London offered individual support for carers, but there was a need for a structured psychoeducational group for carers.

Objectives:

1. The development of a psychoeducational and support programme for carers. 2. A reduction on carers' experience of burden, as measured by a reduction on the Brief Experience of Caregiving Inventory (BECI). 3. An improvement on the carers' wellbeing, as measured by an increase on the Warwick-Edinburgh Mental Well-being Scale (WEMWBS).

Methods: The team used the materials created by the University of Lancaster in REACT (Lobban *et al.* BJPsych; 2013 203 366-72), and further amended them to reflect the local services, and expand peer support discussions. Sessions were further co-produced with input from team members, and following feedback from participants. Quantitative feedback was obtained before the group and in the end. Qualitative feedback about the group's experience was elicited at each session.

Results: The group was attended by 7.1 participants on average, with a drop out of 3 participants after the first session. For those participants that completed the group, it was elicited an improvement on the experience of burden associated to caregiving and on wellbeing; please see Table 1 for details. The improvement on BECI included its four subscales: Stigma/Effects on Family, Positive Personal Experiences, Problems with Services and Difficult Behaviours. Qualitative feedback elicited that the participants felt listened to, their knowledge about psychosis and management had increased, and they felt less lonely.

Table 1

Table 1	BECI average score	WEMWBS average score
Before the group	36.6	41.3 indicative of possible/mild depression
After the group	30.4	47.1 indicative of average wellbeing

Conclusions: A psychoeducational group for carers was well received by participants, and on average they experienced an improvement on the burden associated to caregiving and their wellbeing. Analysis of results was limited due to drop outs, but their feedback included that they did not feel the need anymore for this intervention. Further feedback from participants has contributed to change the sessions' content based on co-production, and the time of the group to enable attendance.

EPV1713

Personal recovery in psychosis: neurobiological basis

J. J. M. Jambrina[1]*, N. Á. Alvargonzález[1], L. P. Gómez[1] and M. A. R. Cortina[1]

[1]Psychiatry, Hospital Universitario San Agustín, Avilés, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2172

Introduction: Personal recovery in psychosis is one of the fields where research and clinical activities are growing faster. But the concept lacks conceptual clarity and internal consistency. As a result, most of the studies evaluating its efectiveness may be biased. As in any other intervention, great improvement in clinical evolution of the users has been claimed. And so, neurobiological changes should be described.

Objectives: This study finds to develop a systematic review of studies describing changes surrounding the recovery process from a neurobiological level.

Methods: Keywords hev been selected in order to find all studies focussing on personal recovery in psychosis from its neurobiological basis. Qualitative studies of personal recovery will be excluded. Cross-sectional, longitudinal as well as intervention studies will be included.

Results: The systematic review is underway. The study protocol will be registered at PROSPERO database.

Conclusions: Most studies researching about personal recovery have been developed taking "personal recovery" as an outcome marker. But this is not enough. We need to clarify the neurobiological basis underlying this concept.

Barriers against implementing assertive community treatment teams in Spain: a qualitative exploration of the staff, users and general population experiences

J. J. M. Jambrina[1]*, A. D. Rivas[2], J. M. Vela[3] and C. O. Roldán[1]

[1]Mental Health, Hospital Universitario San Agustín, Avilés; [2]Mental Health, Hospital Universitario Arquitecto Marcide, Ferrol and [3]Mental Health, Hospital Universitario Central de Asturias, Oviedo, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2173

Introduction: Three years after having been approved the Spanish Strategy for Mental Health, the creation of Assertive Community treatment teams is getting slower.

Objectives: The current study seeks to investigate the reasons of and barriers to implementation of this approach. Findings will aim at serving to inform mental health policy about legislative changes.

Methods: Qualitative expert interviews and focus groups were led with team members and users, families and general population from the cities where four of this teams have been developing theirs activities, at least during 15 years A thematic analysis was developed.
Results: Four main topics were identified: 1. Stigma: when economical situation is not good enough, people with psychiatric severe illnesses are not the first in the queue 2. Fear and distrust about breaking the CMHCenters policies; 2. Team development: a hard task more than a challenge; 3. Regardless of profession, finding well trained staff is difficult;
Conclusions: Further research is needed to convince politicians and health authorities. Randomized controlled trials examining the efficacy and efficiency of ACT teams are needed

Disclosure of Interest: None Declared

doi: 10.1192/j.eurpsy.2025.2174

Introduction: Diabetes mellitus is the most common endocrine disease that occurs as a result of an absolute or relative lack of insulin and is accompanied by a number of different somatic, neurological and mental disorders. The aim of the study is to investigate the clinical, psychopathological and pathopsychological features of cognitive and emotional disorders in patients with type II diabetes mellitus.
Objectives: In the course of the study, a comprehensive examination of 109 patients with type II diabetes mellitus of moderate to severe forms of disease (52 females and 57 males), aged 35.9 ± 10.1 years was conducted.
Methods: MMSE, Addenbrooke's Cognitive Examination, Luria's Memory Words Test-Revised, Symptom Check List-90-Revised, HAM-A, HAM-D, The State-Trait Anxiety Inventory Scale. It has been established that patients with diabetes mellitus have mild to moderate cognitive impairment, which is manifested by a reduction in verbal memory, a decrease in the speed of counting operations, minor difficulties in orientation and a slight drop in the perceptual and diagnostic sphere, a decrease in concentration and memorization of the information received, and a pronounced reaction of mental fatigue.
Results: Presence of mild (51.2% of men and 49.8% of women) or moderate (49.8% and 50.3%, respectively) cognitive impairment according to MMSE and Addenbrooke's Scale; decreased ability to concentrate and impaired working memory in patients with type II diabetes mellitus was noted.
Emotional disorders in patients with diabetes mellitus are represented by anxiety (33.4% of men and 35.2% of women), depression (26.6% and 33.1% of patients, respectively), asthenohypochondriacal (27.3% of men and 19.1% of women), and hysteroform (12.7 and 12.6%, respectively) variants of psychopathological syndromes.
Conclusions: A comprehensive, personalized system for correction of cognitive and emotional disorders associated with diabetes mellitus has been developed and tested. System comprises four stages: diagnostic, therapeutic, rehabilitation and dynamic monitoring. It employs a range of therapeutic modalities, including pharmacotherapy, psychotherapy and psychosocial programmes.
The implementation of the developed system for correction and prevention of emotional and cognitive disorders in patients with type II diabetes mellitus contributes to an improvement in the quality of medical care for patients with type II diabetes mellitus, as well as an improvement in their quality of life and psychosocial functioning.

Cast off instead of setting anchor: A project to promote housing and work integration for users of integration assistance

J. Krieger[1]*, K. Friedrich[1], C. A. Penkov[1], V. Rößner-Ruff[1], W. Wilkening[2], I. T. Graef-Calliess[3] and M. Ziegenbein[4]
[1]Research and Development; [2]Head of the Residential and Day Care Center division, Klinikum Wahrendorff, Sehnde; [3]Medical Director, ZfP Südwürttemberg, Ravensburg and [4]Medical Director, Klinikum Wahrendorff, Sehnde, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2175

Introduction: 80% of users of inpatient integration assistance facilities prefer to live in their own home. Access to training opportunities on the labor market is also difficult for people with severe mental illness. Permeability within the care system remains low, meaning that external orientation on the residential or labor market is associated with numerous hurdles. In a dissertation, 18 people from an inpatient integration support facility were followed in a qualitative longitudinal design on their way into their own home.
Objectives: Based on these findings, a project is now being established to support people on their way to greater participation and independence from inpatient facilities. It consists of a multi-stage group program that combines psychoeducational elements with peer-oriented interventions. In addition, an information team of social workers, psychologists and peers is being set up to advise interested users. The project is rounded off by an aftercare program that provides users with advice and is primarily intended to bridge any difficult situations that may arise and build up a support network.
Methods: Users of inpatient integration assistance at a facility in Lower Saxony with an interest in external orientation in the area of living or working. Expected sample size approx. 50 users in a naturalistic longitudinal design. Accompanying evaluation with three measurement points on the development of perceived social support (F-SozU), quality of life (OxCAP-MH) and the subjective benefits of the project to strengthen the participants' opportunities for participation and the use of further support services.
Results: The project with the individual modules and initial experiences during the implementation phase will be presented.
Conclusions: Possible adjustments to the offer are derived and discussed on the basis of the initial results.

Is Animal-assisted intervention (AAI) a feasible treatment in a recovery-oriented psychiatric rehabilitation program ?

A. Litta[1,2*], D. Benazzi[3], P. Carbutti[3], A. Vacca[2], A. M. Nannavecchia[4], A. Morelli[5], A. M. Sisto[6], E. Attolino[3], P. Manigrasso[3] and M. Nacci[2]

[1]Department of Precision and Regenerative Medicine and Ionian Area (DiMePRe-J) University of Bari "Aldo Moro", Bari; [2]Mental Health Department, ASL Taranto, Taranto; [3]EPASSS Foundation; [4]AReSS Puglia- Regional Strategic Agency for Health and Social, Bari; [5]Third Sector Organization "La coda di Ulisse" and [6]Third Sector Organization "La coda di Ulisse", Massafra, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2176

Introduction: Physical contact with the animal appears, on the basis of the latest research, acts as powerful calming factor on heart rate and breathing (Nose et al., 2022). Moreover, taking care of an animal stimulates a sense of responsibility and promotes empathy and kindness (Walsh et al., 2009). Studies have suggested that animals may serve as "social catalysators" involving feelings of safety and facilitation of interpersonal interactions. These effects are related to biophilia hypothesis which describes the affinity of humans to other living species (Tyssedal et al., 2023).
Objectives: Our project aimed to assess effectiveness and feasibility of animal assisted intervention (AAI) in patients with psychotic spectrum disorders following a recovery-oriented psychiatric rehabilitation program.
Methods: In the present study ten patients from psychiatric residential facilities belonging to the EPASSS Foundation were approached to participated in this study. Patients followed a rehabilitation project named "Animal-Mente" and originated from the collaboration of the psychiatric residential facilities belonging to the EPASSS Foundation with "La coda di Ulisse", a Third Sector Organization (ETS) which represents the Apulian reference centre for AAI. An observational study design was followed in which the new intervention based on AAI was added to treatment as usual (usual rehabilitation intervention and/or psychopharmacological treatment). All sessions were performed following the Italian National Guidelines for animal assisted interventions and required a multidisciplinary team capable of managing the complexity of the human-animal relationship. Outcome assessments were conducted at recruitment (time 0) and after animal-assisted intervention (time 1). Outcome assessments were conducted at recruitment (time 0) and after animal-assisted intervention (time 1). They included : Personal and Social Functioning Scale (FPS of the V.A.D.O.), Brief Rating Psychiatric Scale (BPRS), Recovery Evaluation Scale (RAS), Quality of Life Index (Q-Index), S.T.A.I.-Y questionnaire.
Results: All patients followed a psychosocial rehabilitation intervention and all but one had psychopharmacological treatment in the last six months. BPRS (p-value = 0.022) and RAS scale (p-value = 0.006) showed a significant variation at time 1 compared to time 0. No one reported worsening of psychotic or other symptoms during entire program.
Conclusions: Our data highlighted the feasibility of Animal-Assisted Interventions (AAI) in community mental health services. Moreover, our study underlined the opportunity of AAI in an integrative recovery oriented psychiatric rehabilitation program involving mental health department, psychiatric residential facilities and third sector organizations in a network activity.

Game On: Assessing the Therapeutic Benefits of Board Games in Schizophrenia Management

R. M. Lopes[1*], A. F. Silva[1], A. C. Rodrigues[1], A. C. Matias-Martins[1], F. M. A. Santos[1], P. M. F. Coelho[1], T. A. A. Vieira[1] and V. S. Melo[1]

[1]Psychiatry and Mental Health Department, Unidade Local de Saúde do Médio Tejo, Tomar, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2177

Introduction: Schizophrenia is a complex psychotic disorder characterized by positive symptoms (such as delusions, hallucinations, and disorganized speech and behavior), negative symptoms, and cognitive impairment. Cognitive deficits, including impairments in executive function, memory, and social cognition, are particularly persistent and significantly impact daily functioning and overall quality of life. While cognitive remediation has proven effective, recent research has explored the potential of board games as a therapeutic tool.
Objectives: This study aims to assess the therapeutic benefits of board games on cognitive function, specifically executive function, in patients with schizophrenia.
Methods: A literature review was conducted using articles from PubMed, focusing on the terms "board game", "schizophrenia" and "cognition".
Results: Cognitive deficits in schizophrenia contribute significantly to poor functional outcomes and daily functioning. Improving cognitive function and social behaviors has been a major focus of psychiatric rehabilitation techniques. Board games have been found to improve various aspects of cognitive function, including attention, working memory, speed of processing, verbal learning, visual learning, reasoning and problem solving, as well as social cognition. They are expected to enhance knowledge, interpersonal interactions, and increase participant motivation. Ideally, an effective board game for this population should be behaviorally oriented, emphasize positive reinforcement and shaping, and be sensitive to cognitive limitations through repetition and procedural learning. Additionally, they should be engaging and fun to address negative symptoms.
Conclusions: Board games present a promising therapeutic avenue for managing schizophrenia, particularly in enhancing cognitive function and social skills. While cognitive remediation programs have already demonstrated efficacy, board games offer a more accessible and engaging alternative. Despite these positive findings, the limited number of studies and inconsistent long-term data highlight the need for further research. Future studies should evaluate the durability of cognitive and functional improvements from board game interventions and explore their integration into comprehensive treatment programs for schizophrenia.

The impact of spiritually-oriented therapy on the rehabilitation of mentally ill patients with a religious worldview

A. Magay

Mental Health Research Centre, Moscow, Russian Federation
doi: 10.1192/j.eurpsy.2025.2178

Introduction: Spirituality and religiosity have a significant effect on mental health. Biopsychosocyospiritual model in psychiatry is used in multiple researches in Europe and Russia as well (Hefti 2013; 24(2) 119-129). Many patients use religious beliefs and actions to cope with mental disease (Tepper et al., 2001; *2*(5) 660-665). The pathological religiosity phenomenon determining the severity of mental disease is described (Borisova 2020; 120(1) 103-110). Spiritually-oriented therapy methods are aimed at pathological religiosity correction and assist in mental well-being achievement.
Objectives: To assess the effect of spiritually-oriented therapy on mental health of religious patient during comprehensive rehabilitation.
Methods: 42 patients with endogenous mental schizophrenic and affective spectrum disorders who participated in comprehensive rehabilitation using spiritually-oriented therapy (26 women and 16 men) were examined. There were used psychometrical (SF-36, PIL, Schwartz Value Survey – SVS, B-RCOPE) and statistical methods.
Results: In a therapeutic environment in the religious community, 42 patients received psychopharmacological treatment and participated in multimodal rehabilitation throughout the year. Psychoeducational, art-therapeutic, spiritually-oriented modules were used in rehabilitation. 13 (31%) ceased the rehabilitation early, 29 (15 women and 14 men) underwent the entire rehabilitation. 73% of them had a pronounced improvement in quality of life indicators, 84% had a meaningfulness of life increase, a transformation of value system with the dominance of "security," "kindness" and "traditions", a higher cohesion of values. Rehabilitated patients had a more harmonious religiosity structure with a predominance of inner religiosity, they used religious behavior to cope with the disease which correlated with a decrease in the intensity of pathological religiosity manifestations.
Conclusions: The use of spiritually-oriented therapy methods in the rehabilitation of mentally ill patients with a religious worldview promote to correct the manifestations of pathological religiosity and to cope with mental disease. Patients have a qualitative and quantitative change in value system and religious beliefs, mastering adaptive styles of religious behavior. Spiritually-oriented therapy methods are not an alternative to natural religious life, but complement it, taking into account the existing mental disorders.

Social and Independence Skills Dynamics in Adolescents with Developmental Disorders Comprehensive Intervention Program Results

A. Portnova[1,2,3], N. Maltseva[3]* and K. Reitsen[3]

[1]Department of Psychiatry, Psychotherapy and Psychosomatic Pathology, Patrice Lumumba Peoples' Friendship University of Russia; [2]Association of Psychiatrists and Psychologists for Evidence-Based Practice and [3]Center for Curative Pedagogics, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2179

Introduction: Adolescents with developmental disabilities and their families face significant challenges in the transition to adulthood. Comprehensive interventions that include psychological support, daily living skills training, and vocational guidance are crucial. This pilot study tests a program aimed at developing independence and adaptive skills in adolescents with developmental disorders.
Objectives: The study aimed to evaluate the dynamics of adaptive and independence skills in adolescents with various developmental disorders who participated in a comprehensive intervention program.
Methods: 10 adolescents (5 boys and 5 girls, mean age 15,11, SD 2,4) were included in the study. Participants were mainly diagnosed with the following primary DS: F70.xx, F84.xx. Also, participants had additional DS such as F48.xx, F80.xx, G40.xx, Q37.xx, Q74.xx. IQ of the participants was measured by the Leiter-3 Performance Scales (mean 62.8, SD 26.9). Comprehensive intervention program lasted the 2022/2023 academic year 3 d/week, 2-3 h/day. The intervention included individual and group sessions, several home visits and the parent groups led by a team of psychoeducational professionals (neuropsychologists, special educators, speech pathologists). The training outcomes were measured by the Vineland Adaptive Behavior Scales (VABS-2). Statistical analysis was performed using the paired samples t-tests and d-Cohen effect size (d).
Results: Significant improvements were observed in all four VABS subscales. Communication improved from 56.1 to 59.6 ($t=-3.42$, $p=0.008$, $d=-1.08$), Daily Living Skills from 59.9 to 66.4 ($t=-5.57$, $p<0.001$, $d=-1.76$), Socialisation from 58.6 to 65.1 ($t=-3.84$, $p=0.004$, $d=-1.21$), and General Adaptive Behaviour Index from 56.9 to 62.0 ($t=-5.31$, $p<0.001$, $d=-1.68$). The largest improvements were seen in Daily Living Skills and General Adaptive Behaviour Index which highlight the program's effectiveness in fostering independence and adaptive capacities in adolescents.
Conclusions: The pilot study demonstrated the promising effectiveness of the program in developing independence and adaptive skills, suggesting it as a valuable intervention for preparing young people for independent living in adulthood. Following research plans include follow-up analysis of current participants' outcomes, an increase in sample size, and the implementation of between-group designs.

EPV1722

Speech therapy stimulation program for social skills of adolescents victims of mistreatment

M. M. N. Matsumoto[1]*, A. A. Carneiro[1] and D. R. Molini-Avejonas[1]

[1]University of Sao Paulo, Sao Paulo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2180

Introduction: The United Nations Children's Fund defines mistreatment as any act that causes harm to the health, dignity or development of an individual. The aim of this study was to quantitatively analyze the effect of speech therapy stimulation on the development and quality of social skills in adolescents victims of childhood mistreatment. The hypothesis is that after the intervention

program the subjects will show improvement in relation to the performance of these skills.
Objectives: To quantitatively and qualitatively analyze the effect of speech therapy stimulation on the development and quality of social skills in adolescents victims of childhood mistreatment. The hypothesis is that after the intervention program the subjects will show improvement in relation to the performance of these skills.
Methods: 10 adolescents, between 12 and 16 years old, have participated in the research. The following inclusion criteria were used: 1) being between 7 and 17 years old; 2) having experienced mistreatment in childhood; 3) be treated in a highly complex health service. The intervention programs consisted of 12 follow-up sessions, carried out in person. The main focus was on stimulating communicative and pragmatic skills, also covering theory of mind skills, personal problem solving and paralinguistic skills. After the 12 sessions, patients underwent reevaluation and the results were tabulated and analyzed by the researcher.
Results: Participants had considerable difficulties with social skills before speech therapy intervention, the initial difficulties was mainly in self-control and assertiveness skills. After the 12 intervention sessions, a significant improvement in the social skills was observed, especially in empathy and assertiveness.
Conclusions: The participants progressed after the intervention in all areas evaluated, with more significant improvements in empathy and assertiveness. These results demonstrate the positive impact of speech-language therapy intervention for the stimulation of social communication and pragmatic skills.
It is important to emphasize that this population has many specificities, making it difficult to work with isolated variables. Therefore, more studies involving speech-language therapy, particularly speech-language therapy intervention, with adolescent victims of abuse are needed.

Disclosure of Interest: None Declared

EPV1723

Features of Self-stigmatization of Patients with Schizophrenia Spectrum Disorders at the Initial Disease Stage

V. Mitikhin[1]*, T. Solokhina[1] and D. Oshevsky[1]

[1]Mental Health Research Centre, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2181

Introduction: Patients with schizophrenia spectrum disorders (SSD) are the most vulnerable category in terms of formation of self-stigmatization (Rayan A., Aldaieflih M., 2019). However, clinical and psychological features of their self-stigmatization were studied mainly at the longer stages of the disease. Self-stigmatization- of patients at the initial stages of the disease rarely got to the attention of researchers, what determined the relevance of the study.
Objectives: To identify characteristics of self-stigmatization patients with SSD at the initial stage of the disease; to determine their needs in psychosocial treatment.
Methods: Questionnaire for assessing the phenomenon of self-stigmatization of mentally ill people (Mikhailova et al., 2005) and PANSS were used. A group of 39 patients (23 women and 16 men) with SSD (F20.xxx, F23.xxx, F25.xxx according to ICD-10) were examined. The average age of the patients was 28.95 ±8.53 years. The duration of the disorder varied within 0.5-3 years.
Results: Patients at the initial stages of SSD demonstrated relatively low level of self-stigma. The indicator «General level of self-stigma» was slightly lower than the average values and constituted 0.86±0.53 points. Patients believed that mental disorder and associated changes will not limit their education and work (0.80±0.57 points), social activities (0.78±0.49 points) and self-realization (0.60±0.48 points). Rejection to restrictions caused by mental illness, underestimation of possible social and interpersonal problems and desire to distance from people with mental disorders (0.74±0.56 points) were identified. Correlation analysis of the named Questionnaire on self-stigmatization and PANSS scales revealed the strongest correlations across parameters «Readiness to distance oneself from mentally ill people in the sphere of internal activity», characterizing the rejection of changes that have occurred as a result of the disease, with scales: P2 - judgment disorders, G-12 - decreased criticality to one's condition and N-1 - dullness of affect (r=0.61 at p=0.003, r=0.54 at p = 0.003, r=0.52 at p=0.006, correspondingly). Thus, relatively low level of self-stigmatization of patients with SSD at the initial stage of the disease is associated with insufficiently critical self-assessment of their state, underestimation of possible social and interpersonal problems, and desire to distance from people with mental disorders.
Conclusions: It is necessary to carry out psychoeducation programs for patients with SSD, aimed at developing an adequate perception of mental disorder and prevention of possible consequences of self-stigmatization, as well as social and communication skills' development trainings.

Disclosure of Interest: None Declared

EPV1724

Effectiveness of a social cognition remediation intervention for patients with schizophrenia: a randomized-controlled study

P. Pezzella[1]*, L. Giuliani[1], A. Mucci[1], D. Palumbo[1], E. Caporusso[1], G. Piegari[1], G. M. Giordano[1], P. Blasio[1], S. Torriero[2], C. Mencacci[2] and S. Galderisi[1]

[1]University of Campania "Luigi Vanvitelli", Naples and [2]Department of Psychiatry and Addiction, ASST Fatebenefratelli-Sacco, Milan, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2182

Introduction: Individuals with schizophrenia often experience significant deficits in social cognition, including emotion processing, social perception, and theory of mind (ToM). These deficits have a greater impact than symptoms on occupational and social functioning.
Objectives: The present randomized controlled trial aimed to evaluate the effectiveness of a new integrated and personalized social cognition rehabilitation intervention, the Social Cognition Individualized Activity Lab (SoCIAL), in improving performance in social cognition and consequently the clinical and functional outcome of subjects with schizophrenia (SCZ).
Methods: SoCIAL, consisting of 10 weekly sessions, was compared with treatment as usual (TAU). Two recruitment centers (Naples and Milan) were involved. Repeated measures MANOVA was used to investigate between-group differences in changes from baseline to follow-up in terms of psychopathology, cognitive performance, and functioning.
Results: Twenty people with schizophrenia were blindly assigned to SoCIAL and twenty to TAU. After 10 weeks, SoCIAL significantly

improved disorganization, emotion recognition, functional capacity and real-life functioning. As compared to TAU, the SoCIAL group showed a significant improvement in minimal and enriched social inference domain of theory of mind, and in key domains of real-life functioning (interpersonal relationships, everyday life skills, and work skills).
Conclusions: SoCIAL improved social cognition and real-life functioning of people with schizophrenia. These results highlight the importance of social cognition deficit treatment in schizophrenia and the necessity for these interventions to be multifaced and personalized. Such an approach ensures that improvements in social cognition translate into enhanced functional outcomes.

The Singapore Inpatient Psychiatric Rehabilitation Experience

T. Teoh[1]
[1]Rehabilitation Service, Institute of Mental Health, Singapore, Singapore
doi: 10.1192/j.eurpsy.2025.2183

Introduction: Stepping Stones Rehabilitation Centre(SSRC) is a one-year old psychiatric rehabilitation centre in the Institute of Mental Health Singapore.
SSRC was initially created as a 100-bed inpatient ward to address a treatment gap and fast-track the psychiatric rehabilitation of patients admitted for acute psychiatric conditions. SSRC serves as the 'stepping stone' for acutely unwell inpatients as they transcend the hospital back to the community. To do so, SSRC actively engages our upstream partners (teams managing acutely unwell patients) as well as downstream partners (social service agencies) to continually assess the treatment gap between acute and community psychiatric care and evolve our programme and processes to close this gap and smoothen the transition.
Objectives: The overall objective is to provide patients with the relevant levels of rehabilitation by training and equiping them with the necessary skills to intergrate back to society at the level for which they have set their goals on.The levels of rehabiliatation range from intermediate rehabilitation following acute illness to regain their functional status to perform their daily activities to tertiary rehabilitation which provides higher intensity rehabilitation programmes to help patients return to their daily function and to work and life as much as possible. This is achieved via a multi-disciplinary team comprising of patient, psychiatrists, doctors, nurses, occupational therapists (OT), medical social workers (MSW), psychologists, peer support specialists (PSS) and case managers(CM) to derive a bespoke rehabilitation programme for each patient over their course of stay in the ward.
Methods: Patient are referred to the SSRC from the acute inpatient wards of IMH or from the outpatient setting. Upon acceptance to the ward, patients are reviewed and a timetable is created based on the goals the patient would like to achieve. Patients are reviewed at weekly MDT (multi-disciplinary team) meetings at frequencies which commensurate to their rate and intensity of rehabilitation. Measures obtained to assess the progress of each patient and the programme are:
1. CGI-I (Clinical Global Impression - improvement) scale
2. GAF (Global Assessment of Functioning)
3. RAS-DS (Recovery Assessment Scale - Domains and Stages)
4. SLOF (Specific Level of Functioning)
5. Acceptance rates to stepdown care
6. 30-day readmission rates

Results: At the latest tabulation of data, there has been 117 patients successfully discharged from SSRC. The other data are currently being tabulated and analysed and updated results will be shared at the meeting.
Conclusions: SSRC is one of few psychiatric rehabiliatation entities that reside in an acute psychiatric hospital. It was assessed that patients who present with acute decompensation in their mental state could benefit from intense fast-tracked rehabilitation measures before stepping down to community provided services.

Psychoeducation for caregivers of patients with first psychotic episode

A. Magay[1]* and M. Kuzminova[1]
[1]Mental Health Research Center of Russian Academy of Medical Sciences, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.559

Introduction: Caregivers of patients with first psychotic episode (FPE) are under considerable stress. The onset of schizophrenia results in significant limitations for the relatives, and resulting maladaptive behavior. It is crucial to provide psychoeducation to those caring for a patient with FPE.
Objectives: To assess the impact of psychoeducation on the psychological state of caregivers of patients with FPE.
Methods: A total of 48 caregivers of patients with FPE (40 women and 8 men) were assessed before and after psychoeducation. Psychometric and statistical methods were used.
Results: Analysis of functioning in interpersonal roles of relatives of FPE patients using the SAS-SR scale before the intervention showed significant distress in various domains (above 66 T-scores). 32.9% of relatives had impaired social interactions (withdrawal, conflicts, sensitivity to criticism). 25.4% of caregivers had strained family relationships (conflicts, guilt), and 12.4% reported difficulties in intimate relationships. 10.8% of relatives experienced problems in their relationship with the patient (overprotection combined with emotional coldness, distancing). After psychoeducation distress decreased in most areas, but some relatives still had problems of social functioning and deterioration in marital relationships. According to the SCL-90 questionnaire, distress decreased after the intervention. GSI (General Symptomatical Index) dropped from 0.69 to 0.38 (with a norm of 0.31). Anxiety and hostility also approached normal levels (from 0.68 to 0.33 and from 0.59 to 0.28, with a norm of 0.30, respectively). However, scores for paranoia (from 0.72 to 0.40, with a norm of 0.34) and depression (from 0.79 to 0.43, with a norm of 0.36) remained elevated, reflecting ongoing stress. PSDI (Positive Distress Symptomatical Index) dropped from 1.53 to 1.44. PST (Positive Symptomatical Index) dropped from 37.06 to 23.56.
After psychoeducation caregivers members' stress coping strategies improved. Confrontation decreased (from 9 to 8 points), while social support-seeking increased (from 13 to 14 points). Avoidance behavior and distancing also decreased. Medication adherence

improved: before psychoeducation 63% of caregivers had moderate adherence and 35% had low adherence. After the intervention 90% of relatives showed moderate adherence and 2% showed high adherence, and none denied the necessity of treatment.
Conclusions: Psychoeducation for caregivers of patients with FPE helps them develop stress management skills, constructive communication with the patient and problem-solving strategies. The intervention reduces anxiety, stigma and improves medication adherence. The study demonstrates that psychoeducation is effective intervention that reduces the risk of relapse during the early years, contributes to the patient's recovery.

Saccade latency can indicate temporal attention differences in ADHD

L. R. R. Carreiro[1]*, T. O. dos Santos[1], B. C. Guedes[1] and L. C. V. Pereira[1]

[1]Universidade Presbiteriana Mackenzie, São Paulo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2184

Introduction: Temporal attention (TA) is the ability to allocate attention to specific periods in time. Temporal processing is often impaired in individuals with ADHD, but additional studies are needed to expand knowledge about these deficits compared to control groups.
Objectives: To analyze the performance of adults in TA tasks based on ADHD symptoms using eye-tracking to measure saccade latency.
Methods: Forty young adults (20 meeting ADHD criteria and 20 in the control group - CG) performed an attentional task in which a fixation point (FP) was presented at the center of a computer screen; 1000 ms later, an arrow indicating right or left appeared. The task consisted of two blocks, one with a higher frequency of targets at a 400 ms interval and the other at a 1000 ms interval, among shorter and longer intervals. Participants were instructed to focus on the FP, prepare to respond to the higher frequency interval, and only move their eyes after the peripheral target appeared. Saccade latency—defined as the time between target appearance and the initiation of eye movement—was recorded using a Tobii eye-tracker. A repeated measures ANOVA was conducted for the analysis. Ethical approval was obtained.
Results: For longer intervals, saccade latency was significantly different between the ADHD and control groups ($p = .009$). While the CG showed reduced latency, the ADHD group exhibited increased latency, demonstrating a diminished ability to control attention over time.
Conclusions: Young adults with ADHD exhibit a reduced capacity to sustain attention over longer periods of time. **Grant:** CNPq process number: 408084/2021-9

The impact of involuntary-to-voluntary hospitalization transitions on psychiatric decompensation: A protocol for a retrospective cohort study

M. Castro[1], J. Coelho[2,3]*, A. R. Ferreira[3,4] and H. Salgado[2,3]

[1]Faculty of Medicine, University of Porto; [2]Psychiatry Service, Unidade Local de Saúde São João; [3]Department of Clinical Neurosciences and Mental Health, Faculty of Medicine, University of Porto and [4]CINTESIS@RISE, Faculty of Medicine, University of Porto, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2185

Introduction: Involuntary hospitalization of a patient with a mental disorder is defined as admission to an inpatient unit without consent. Literature suggests that severe involuntarily admitted patients often present in crisis situations, receive less pharmacologic intervention and therapy, and exhibit poorer prognostic outcomes, such as an increased risk of readmission. Despite being a lifesaving treatment, involuntary admissions can also be stigmatizing, undermine the long-term therapeutic relationship and reduce adherence to care. In this context, little research has been conducted to evaluate how switching a patient's hospitalization from involuntary to voluntary may impact health outcomes, such as psychiatric decompensation.
Objectives: To compare the risk of hospital readmission of patients who switched to voluntary hospitalization with those who remain under involuntary hospitalization, and to analyze their sociodemographic characteristics and prognostic outcomes.
Methods: An observational retrospective study will be conducted using administrative and clinical data of patients who were involuntary admitted to inpatient psychiatry of Unidade Local de Saúde São João. All involuntary hospitalizations spanning from January 1, 2022, and December 31, 2022, will be categorized into two groups: patients who switch to voluntary hospitalization or patients that maintained involuntary hospitalization. Data registered in medical records within one year after the index hospitalization will be assessed (whether structured data or free-text). Descriptive, univariate, and multivariate analyses will be performed.
Results: For both groups, sociodemographic and clinical variables will be described and compared, as well as the number of previous admissions, their legal status and the presence of previous ambulatory involuntary treatment. Administrative data on patient's hospitalization, such as the length of stay, medical treatment and procedures performed, and the orientation received after discharge will also be compared. Additionally, prognosis outcomes, including readmissions, length of stay of readmissions and legal status of readmission will be analyzed.
Conclusions: We expect to elucidate the impact of switching involuntary hospitalized patients to voluntary status on prognosis outcomes. Through this comparative analysis, we hope to provide evidence supporting the prioritization of voluntary treatment whenever feasible.

Revolving door plagiarism in medical research: breaking the vicious cycle

R. K. Gupta[1]*, J. Yadav[2] and R. Gupta[3]

[1]Institute of Mental Health, Senior Professor and Director-cum-CEO; [2]Institute of Mental Health, Senior Resident, Rohtak and [3]Central Institute of Psychiatry , Junior Resident, Ranchi, India
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2186

Introduction: The basic purpose of any research is to encourage and develop original thinking, critical analysis, and inculcate spontaneity and creativity. However, the online availability of a plethora of resources, sophisticated software, and artificial intelligence has opened floodgates to plagiarism, which is having adverse effect on developing minds for original research.
Objectives: To comprehensively understand the current state of postgraduate research training, the challenges faced by students, and potential areas for improvement, particularly in fostering an environment conducive to original and unimpeded research.
Methods: A cross-sectional web-based survey was conducted among medical students pursuing postgraduate courses in various specialties to address potential gaps in postgraduate research training. It comprised four sections with a total of twenty-seven items; Section one: Personal Data and Demographics; Section two: Exposure to Research Principles during Undergraduate Studies; Section three: Perception of postgraduate students towards Plagiarism Checks and Linguistic Barriers faced during dissertation writing; Section Four: An open-ended question inviting participants to suggest ways to promote the free flow of research ideas among young researchers. Survey data were exported to Microsoft Excel and analysed using descriptive statistics. Key themes and insights were derived from the suggestions provided in the fourth section of the questionnaire.
Results: The survey questionnaire was completed by 130 respondents. The majority of the students were in their first or second year of postgraduate studies and represented various medical specialities. The majority of participants reported "low exposure" (n=86, 66%) to research methodology during undergraduate studies. 80% participants reported that they conducted a background research on the topic of their thesis and the most common challenge faced by them was lack of credible content in the online arenas. Almost one-third of the respondents reported that their original idea was blocked because of the "plagiarism checks". Our survey participants represented linguistic diversity and 70.8% considered plagiarism as a marker of "linguistic proficiency". 77.2% believed that conducting literature reviews exclusively in English, without considering texts available in other languages, hampers comprehensive research on a given topic.
Conclusions: It is imperative to expose undergraduate students to "Practical aspects of research", such as "Good research Practices". Further, mentors should allow free flow of ideas, linguistic liberty, and encourage for in-depth discussion over these ideas, ensuring alignment with current scientific standards. An institutional level "Research integrity support" should be provided, including access to authentic plagiarism checking software and workshops focussing on research publication ethics.

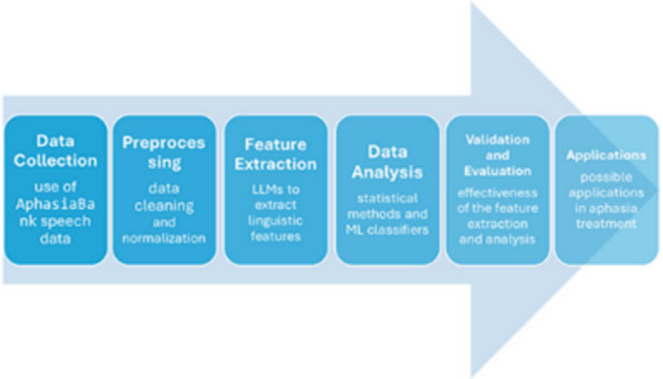
Linguistic Fingerprints in Aphasia: Exploring Speech Patterns Through LLM-Based Analysis



E. Gutierrez[1,2], C. Quesada[1], M. Navas[1] and P. Cano[3]*

[1]Universidad Politécnica de Madrid - NEBULA group, Madrid, Spain; [2]MIT LinQ - Massachusetts Institute of Technology, Cambridge, United States and [3]Universidad Politécnica de Madrid, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2187

Introduction: Aphasia, a language disorder resulting from brain damage, presents significant challenges in assessment and treatment. Traditional evaluation methods often lack precision and efficiency. This study introduces a novel framework for feature extraction in aphasia speech data, leveraging the power of state-of-the-art Large Language Models (LLMs) to enhance assessment, classification, and treatment planning. We used the AphasiaBank database (https://aphasia.talkbank.org/) to test our methods.
Objectives: Our primary objectives were to:

1. Develop a comprehensive set of LLM-based feature extractors for aphasia speech analysis.
2. Evaluate the effectiveness of these features in assessing aphasia types and severity.
3. Explore the potential of AI-assisted speech analysis in clinical settings for aphasia management.

Methods: We developed a novel framework focusing on content analysis of transcribed aphasia speech. Our approach utilizes the embedded knowledge of language usage in LLMs to evaluate speech disfluencies. The advanced set of features derived from LLMs includes, but is not limited to: 1) Lemma similarities for vocabulary diversity assessment, 2) Syntactic structure analysis, 3) Use of linkers and connectors, 4) Degree of abstraction in word usage, 5) CEFR framework-based word complexity analysis, 6) Maze type identification, 7) Semantic field variability, 8) False start analysis. This content-focused feature set is designed to complement existing phonetic features derived from audio files and other potential data sources, such as MRI.
Results: Our evaluation demonstrates that current SOTA LLMs show significant potential in aphasia assessment and group differentiation. The novel feature set provides detailed insights into various aspects of language use affected by aphasia, offering a more comprehensive evaluation than traditional methods.
Image 1:

Conclusions: This study presents an advancement in applying AI to aphasia assessment and treatment. Our novel LLM-based framework offers a more nuanced and efficient approach to analyzing aphasia speech, potentially leading to more accurate diagnoses and personalized treatment plans. The findings lay the groundwork for integrating AI-assisted tools into clinical workflows, complementing rather than replacing human expertise. Future research could explore combining this framework with immersive technologies for enhanced language rehabilitation. This work contributes to a future where AI augments the quality and accessibility of care for individuals with aphasia, while maintaining the central role of human clinicians in the therapeutic process.

About value systems and religious orientations among family sobriety club members

A. Magay[1]*, Z. Zoricic[2], A. Baburin[1] and A. Nemtsev[3]

[1]Mental Health Research Centre, Moscow, Russian Federation; [2]University Hospital "Sestre Milosrdnice", Zagreb, Croatia and [3]Tomsk State University, Tomsk, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2188

Introduction: For over 50 years, there has been based on Vladimir Hudolin method a family preventive program for the addicted of psychoactive substances and actions (Zoricic 2006; 42(1) 35). Family therapeutic communities (family sobriety clubs) exist in many countries in Europe and the world, in Russia there are over 50 clubs. In Russian clubs, a change in the lifestyle of rehabilitants is accompanied by a transformation of value systems and semantic formations into traditions of religious worldview.
Objectives: To study the dynamics of changes in value systems and religious beliefs among family sobriety club members during rehabilitation, which includes a spiritually-oriented component.
Methods: 50 Russian patients with alcohol addiction who participated in rehabilitation in a community setting were examined: 25 ("participants" group) - with remission from several months to two years, 25 ("leaders") – with remission over two years were also the heads of family sobriety clubs. There were used psychometrical (Schwartz Value Survey – SVS, Religions Orientation Scale - ROS) and statistical methods.
Results: Leading values among "participants" are "kindness", "safety" and "conformality", the most significant values among "leaders" are "kindness", "traditions" and "universalism" ($p<0,05$). Benchmarking: *self-transcedence* values prevail among "leaders", high levels of *self-raising* among "participants". Analysis of variance (ANOVA): increasing the significance of values of *kindness* ($p = 0.025$) and *tradition* ($p = 0.009$) at the level of ideals, *tradition* ($p = 0.0003$) and *safety* ($p = 0.04$) at the level of priorities at remote stages of rehabilitation. The cohesion of values among "leaders" is higher than among "participants" (*conformity* ($p = 0.03$) and *kindness* ($p = 0.09$)). Over time a detailing of spiritual ideas takes place, rehabilitants identify themselves as believers and aim to change their lifestyle according to religious Faith values. According to ROS, there is a more meaningful religiosity among "leaders" than among "participants," the predominance of internal religiosity over external religiosity at long stages of assistance.
Conclusions: Change in value orientations correlates with the duration of rehabilitation, their greater cohesion is noted, values are more consistent with the normative for the population as a whole. Religious idias become more harmonious, a transformation of dysfunctional manifestations of external religiosity into adaptive forms of internal religiosity is noted, which is associated with the increase of overall meaningfulness of life.

Cognitive impairments and their impact on daily life in persons with severe mental illness in long-term care: an explorative study using electronic clinical files

L. Sanders[1]*, T. Van Brouwershaven[1], S. Piening[2] and L. Van der Meer[1,3]

[1]Department of Rehabilitation, Lentis Psychiatric Institute, Zuidlaren; [2]Department of Youth Mental Health and Autism Jonx, Autism Team Northern-Netherlands, Lentis Psychiatric Institute and [3]Department of Clinical and Developmental Neuropsychology, University of Groningen, Groningen, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2189

Introduction: In persons with severe mental illness (SMI) in long-term care, cognitive impairments may be severe and pervasive. However, it remains unclear how cognitive impairments specifically impact daily life and how these effects are reflected in their everyday functioning. Collection of such data is complicated by the fact that these individuals are often excluded from scientific research and tend to drop out more frequently due to the severity and complexity of their mental health issues. This calls for a different approach, one that makes greater use of the available structured and unstructured data from electronic patient records (EPRs).
Objectives: The goals of this research are to assess how cognitive impairments and their impact on daily life in persons with SMI are qualitatively addressed in EPRs and to assess whether and how such data may be systematically evaluated.
Methods: We will conduct an explorative, retrospective EPR study focused on persons with SMI who use long-term care services within Lentis Psychiatric Institute, Department of Rehabilitation. EPRs contain qualitative (such as written reports) as well as quantitative (such as Routine Outcome Measures) data. To ensure patient privacy, the data in the obtained files will be de-identified. Indicators of cognitive impairments and their impact on daily life will be operationalized in collaboration with health care professionals and clustered in the domains of working memory, attention, verbal learning and memory, reasoning and problem solving, processing speed and social cognition. Using these operationalizations, natural language processing, an innovative machine-learning technique used to understand and interpret human language, will be used to identify patterns (such as, potentially, gender differences) with respect to cognitive impairments and their impact on daily life functioning from the qualitative EPR data.
Results: As the study is work in progress, preliminary results are currently not yet available and will be presented at the conference.
Conclusions: EPRs are a potentially vital but underused source of data for persons with SMI in long-term care. By analysing data from EPRs we may gain a broader insight into cognitive impairments and their impact on daily life in persons with SMI. Such insights are essential to aid recovery for persons with SMI in long-term care.

Assessment of the SABAS cutoff point based on studies in problematic smartphone use

C. Sándor[1]*, N. Pirwani[2], M. Csibi[3] and A. Szabo[2]

[1]Faculty of Psychology, Department of Sciences and Letters, George Emil Palade University of Medicine, Pharmacy, Science, and Technology, Targu Mures, Romania; [2]Institute of Health Promotion and Sport Sciences, Faculty of Education and Psychology, ELTE Eötvös Loránd University, Budapest and [3]Institute of Special Education, Faculty of Pedagogy, Eszterházy Károly Catholic University, Eger, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2190

Introduction: The SABAS is a single-factor measure of problematic smartphone use, with higher scores indicating a potential addictive tendency. Some researchers (Peng et al., 2023) suggest a cutoff point of 23 out of a maximum available score of 36. Other researchers consider a high mean a guideline without suggesting a possible threshold. This score will indicate the presence of the problematic factor under investigation, regardless of age.

Objectives: Our study aims to identify a score for problematic smartphone use that may already indicate vulnerability to addiction. The research investigates the proposal of a possible cutoff point for problematic smartphone use based on several SABAS surveys over 9 years.

Methods: In our research, 1228 participants completed four online surveys between 2015 and 2023. The age distribution was 9-73 years, with 41.2% male and 58.8% female. Our research instrument was the Smartphone Application-Based Addiction Scale (Csibi et al., 2018) questionnaire, a 6-question questionnaire designed to detect problematic smartphone use. We hypothesized that SABAS scores that show a significant relationship with cutoff scores of clinical questionnaires with convergent validity (NMP-Q, SPAI, SHAI, FNPQ) could be as cutoff scores within the measure.

Results: Our results showed a significant correlation between SABAS and NMP-Q scores ($r(238) = .63$, $p = .001$), with the mean of the moderate-severity nomophobia score (88.5 points) being the mean of the SABAS 23 score. For the response distribution corresponding to the NMP-Q prevalence of severe nomophobia (100 points or more), the SABAS score mean was 29 points. The mean scores on the SPAI questionnaire were 85.82 (*SD*=22.76) and 97.17 (*SD*=31.65), respectively, for the subscales Functional Impairment 22.47 (*SD*=8.41) and 27.29 (*SD*=9.59), Compulsive Behaviour 29.48 (*SD*=9,03) and 34.41 (*SD*=11.64), Withdrawal 21.77 (*SD*=6.41) and 23.41 (*SD*=8.55), and Tolerance 12.10 (*SD*=3.61) and 12.05 (*SD*=4.64). The correlation was also evident for the SHAI ($r(439) = .67$, $p = .001$), its subscales, and the FNPQ scale ($r(398) = .27$, $p = .001$).

Conclusions: The mean SABAS score indicating problematic smartphone use was 23 points, with scores above this point indicating increasingly severe use of analyzed behavior. Those with a score of severe nomophobia scored 29 or higher on the SABAS scale. The SABAS shows a significant relationship with the cutoff scores of the convergent validity questionnaires along the mean scores indicated above (23,29), so we suggest using these scores as cutoffs.

Gone with the Protocol: Searching for unpublished documents from unregistered clinical trials

G. Tomei[1]*, F. Visconti[1] and I. A. Cristea[1]

[1]Department of General Psychology, University of Padova, Padova, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2191

Introduction: Trial protocols and manuals are critical documents outlining core elements of a clinical trial, such as theoretical background, recruitment strategies, intervention structure and components, and control comparators. Availability of these documents is essential as it prevents trial duplication, helps detect or avoid research misconduct, and facilitates tracking of trial results. Moreover, a detailed description of intervention components is crucial for the methodological rigor of advanced meta-research approaches, such as component network meta-analysis (cNMA). However, clinical trials often fail to make these documents publicly accessible, either before or after the trial ends, for instance as supplementary materials to publications. Attempts to obtain these documents by contacting researchers directly are frequently unsuccessful. Therefore, alternative avenues for retrieving these materials must be explored.

Objectives: This study aims to assess the feasibility of retrieving trial protocols and manuals through alternative sources, such as ethics committees/IRBs, funding bodies, and sponsors.

Methods: In the context of a cNMA on psychotherapeutic interventions for eating disorders, we identified 34 published studies (12 on anorexia nervosa and 22 on bulimia nervosa); for each, we reviewed the full-text publications to identify potential sources to retrieve trial protocols and manuals. To this end, we adopted a systematic, stepped approach, investigating: 1) explicit mentions of published trial protocols; 2) trial registration details, including ethics committees/IRBs; 3) institutions or clinics whose ethics committees approved the protocol; 4) specific trial sites or study sponsors/funders; 5) first author's affiliation.

Results: Of the 34 publications analyzed: 1) 2 studies had published trial protocols; 2) 11 studies were registered in trial databases and reported ethics committee or IRB details; 3)16 studies identified the ethics committee or IRB that approved the protocol; 4) 26 studies reported one or more specific trial sites or funding bodies/sponsors; 5) 31 studies provided the first author's institutional affiliation.

Overall, 26 studies had at least one contact associated with organizations that would have reviewed the trial documents, and 31 studies had at least one institutional contact potentially connected to the trial's documentation. For 3 studies no information on ethics committees, trial site, or author affiliation was available.

Conclusions: Despite the recognized importance of making trial protocols publicly available, spontaneous dissemination remains rare in clinical trials on psychotherapeutic interventions. In the absence of published protocols or trial registration details, our feasibility study highlights that full-text publications of trial results can offer multiple potential points of contact that may provide access to such documentation.

Early Warning Signs of Schizophrenia: Effective Strategies and the Benefits of Early Treatment

A. H. I. Abu Shehab[1]*, A. Baltă[2], A. B. Ciubară[3], S. L. Burlea[4], V. Doina Carina[5], M. Grigoraş[6] and A. Ciubară[7]

[1]Psychiatry, "Elisabeta Doamna" Psychiatry Hospital of Galati; [2]Clinical; [3]orthopaedics and traumatology, Faculty of Medicine and Pharmacy, "Dunărea de Jos" University, Galati; [4]Oral and maxillofacial surgery, 7University of Medicine and Pharmacy "Grigore T. Popa", Iaşi; [5]Rheumatology; [6]Psychology and [7]Psychiatry, Faculty of Medicine and Pharmacy, "Dunărea de Jos" University, Galati, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2192

Introduction: Schizophrenia is a severe mental condition marked by a progressive onset of symptoms. Early evaluation and proper management are necessary for improving long-term outcomes and reducing the disorder's severity. Early detection of prodromal symptoms and the prompt initiation of treatment can substantially influence the evolution of the condition, resulting in improved prognoses and a better quality of life.
Objectives: The paper examines methods for recognizing early indicators of schizophrenia and evaluates the effects of early intervention. The emphasis encompasses comprehending the prevalent prodromal symptoms linked to schizophrenia, assessing diverse early detection techniques, and analysing the advantages of prompt intervention on long-term results.
Methods: A comprehensive examination of existing literature and clinical investigations was performed to identify and delineate prevalent prodromal symptoms of schizophrenia, including social disengagement, cognitive impairments, and atypical thought processes. The assessment examined various early detection instruments, encompassing structured clinician interviews, self-report questionnaires, and neuroimaging methodologies. Furthermore, data from longitudinal studies was examined to ascertain how early intervention may impact the disorder's course and enhance patient outcomes.
Results: The review realized multiple significant prodromal signs, including social isolation and cognitive impairments. Multiple early detection instruments, including structured interviews and neuroimaging, proved helpful in identifying persons at elevated risk for developing schizophrenia. Timely intervention measures, integrating pharmacological therapies and psychosocial assistance, correlated with a substantial decrease in symptom severity and improved long-term results.
Conclusions: The management of schizophrenia necessitates early identification and intervention. The severity of the disorder and the prognosis can be significantly reduced by recognizing prodromal symptoms and administering effective treatment. In order to enhance recovery and mitigate the effects of schizophrenia on individuals and their families, clinicians should prioritize early detection and early treatment.

Religious activity and religious delusions in schizophrenia/schizoaffective disorder

N. Ait Bensaid[1]*, M. Sabir[1] and F. El Omari[2]

[1]arrazi psychiatric hospital, Sale, Morocco and [2]HAS, arrazi psychiatric hospital, Sale, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2193

Introduction: Religious delusions are a common symptom in patients with schizophrenia. They can be more difficult to treat than other delusions because they are usually held with more conviction [1], which makes them of great clinical relevance. Religious delusions occur in between one-fifth and two-thirds of patients with delusions [2].
Cross-cultural differences may provide a partial explanation, but it seems likely that individual socio-demographic variables, particularly the extent of personal religiosity, as well as genetic factors, may also play a role.
Objectives: To assess the relationship between sociodemographic characteristics and religious activity in patients with schizophrenia/schizoaffective disorder with religious delusions followed and hospitalised at the Arrazi psychiatric hospital in Salé.
Methods: This was a descriptive cross-sectional study using a questionnaire including socio-demographic criteria, clinical criteria and questions about religious activity by grouping patients into 5 categories: (1 = no religious affiliation, 2 = religious affiliation, but not actively religious, 3 = religious affiliation, somewhat active activity, 4 = religious affiliation, moderately active activity, 5 = religious affiliation, very active activity) to assess the relationship between sociodemographic characteristics and religious activity in patients with schizophrenia/schizoaffective disorder with religious delusions followed and hospitalised at the Arrazi psychiatric hospital in Salé.
The inclusion criteria were as follows: both sexes with a diagnosis of schizophrenia/schizoaffective disorder according to DSM 5 criteria and having a mystico-religious delusion.
The exclusion criterion was severe intellectual disability.
Results: A total of 109 patients were collected.
Approximately 85% were male. Most had an average socio-economic status. 67% lived with their families and 15 were homeless. About 89% were unemployed.
About 78% of the patients were hospitalised and most had poor compliance. All patients had mystico-religious delusions, most thought they were prophets or angels, 10 believed they were God. Fourteen patients thought they were Al Mehdi AL montadar, 2 said they were the Holy Spirit. 22 had a delusion of possession.
77% had Islam as their religion, 12% Christianity and 11% no religious affiliation. About half of the patients had a religious affiliation but were not actively religious. Very active religious subjects were 3 times more likely to suffer from religious delusions than subjects with no religious affiliation.
Conclusions: Our data suggest that a high level of personal religious activity appears to be one of the risk factors for the onset of religious delusions. A high level of religiosity appears to increase the risk of developing religious delusions.
Further research is needed to examine the relationship between religiosity and religious delusions.

Disclosure of Interest: None Declared

EPV1742

Constipation in patients with schizophrenia admitted to the Arrazi psychiatric hospital in Salé

N. Ait Bensaid[1]*, F. Laboudi[2,3] and A. Ouanass[4]

[1]arrazi psychiatric hospital; [2]HAS, SALE; [3]HAS, arrazi psychiatric hospital in sale, rgoiRRabaRrat and [4]arrazi psychiatric hospital in sale, sale, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2194

Introduction: Constipation is a common side effect of antipsychotic drugs [1] that has not received much attention.
In patients treated with clozapine, constipation may be the most common side effect, affecting one in three patients [2, 3].
Cases of delayed detection of symptoms of constipation or inadequate treatment of constipation have resulted in paralytic ileus, faecal impaction, intestinal obstruction and even death [4,5].
However, other risk factors for constipation are also common in people with schizophrenia, such as low socio-economic status, a sedentary lifestyle, and illnesses and medications associated with constipation.
Translated with DeepL.com (free version)
Objectives: To assess constipation in patients with schizophrenia hospitalised at the Arrazi psychiatric hospital in Salé and to study the factors associated with these symptoms: socio-demographics, lifestyle, psychotropic drugs, other drugs and co-morbidities such as diabetes and obesity.
Methods: This was a descriptive cross-sectional study using a questionnaire including sociodemographic and clinical criteria as well as questions on the lifestyle of hospitalised patients with schizophrenia to assess constipation in these patients and study the factors associated with these symptoms.
Exclusion criteria: intellectual disability.
Results: A total of 167 patients admitted to the psychiatric hospital for management of schizophrenia were collected. Approximately 69% were male. Adherence to antipsychotics was poor in most patients. 53% were on haloperidol, 25% on olanzapine and 12% on clozapine. Diabetes was present in 21% of patients. Constipation was present in 57% of patients. Most participants had a lifestyle without physical exercise and a balanced diet.
Conclusions: Constipation is common in patients with schizophrenia on antipsychotics, with the risk of complications sometimes severe. It is recommended that clinicians assess antipsychotic-induced constipation and manage it effectively.

Comprehensive Management of Severe Mental Disorders: The Synergy between Multifamily Groups and Psychopharmacology

R. Albillos Pérez[1]*, S. Castelao Almodóvar[2], R. González Núñez[1], A. Castelao Escobar[1], P. Sanz Sánchez[1] and C. Alguacil Núñez[1]

[1]Psiquiatría, Hospital Universitario Puerta de Hierro Majadahonda and [2]Psiquiatría, Hospital Universitario El Escorial, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2195

Introduction: The treatment of severe mental disorders benefits significantly from a multidisciplinary approach that integrates, among others, psychopharmacology and psychotherapy. The intervention with multifamily groups (MFG) shows multiple benefits for this patient profile. Its positive effects include reducing relapse rates, increasing treatment adherence, improving socio-occupational and family functioning, and reducing stress and family burden. When implemented optimally, it can be an effective tool that complements other treatment options, such as psychopharmacology and other psychosocial interventions.
Objectives: To describe a clinical case of severe mental disorder, emphasizing the special relevance of a comprehensive approach.
Methods: The case of a 46-year-old woman, with no prior mental health history, is described. She began follow-up after experiencing several psychotic episodes induced by substance use (cannabis). It was agreed with the patient to start psychopharmacological treatment and a psychotherapeutic approach by incorporating her into the center's Multifamily Group (MFG). Initially, she received treatment with olanzapine 15 mg maximum daily dose (MDD), but it was discontinued due to the metabolic syndrome that appeared as a side effect. Treatment with lurasidone 74 mg MDD was then started, but it was also eventually discontinued due to intense akathisia. During the three years of follow-up, the patient remained abstinent from cannabis, without psychopharmacological treatment, and received intensive therapy in the MFG. Over time, her delusional ideation of persecution and self-referential clinical symptoms progressively subsided until resolution.
Results: During a session of the MFG, in the context of several stressful situations (her son moving out of the family home, personal experience with the stigma of mental illness after a reading in the MFG, and frequent arguments with her husband), the patient reported delusional ideation and self-referentiality again, predominantly affecting her emotional state. In agreement with the patient and considering the side effects previously experienced with other antipsychotics, it was decided to initiate treatment with Brexpiprazole at progressively increasing doses until reaching 4 mg MDD, with good tolerability and clinical efficacy.
Conclusions: This case highlights the particular importance of adopting a multimodal approach for the effective management of severe mental disorders, which can optimize clinical outcomes, promote more sustainable recovery, and improve the quality of life for patients.

An Assesment of The Long-Term Effects of Electroconvulsive Therapy On Cognitive Functioning İn Patients With Schizophrenia

B. Alpuğan[1]* and D. İpekçioğlu[2]

[1]Republic of Türkiye Ministry of Health Bitlis Tatvan Public Hospital, Bitlis and [2]Psychiatry, Istanbul Bakırköy Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2196

Introduction: In schizophrenia, cognitive symptoms emerge in the early period and are among the core symptoms. This study aimed to investigate the long-term effect of electroconvulsive therapy on the cognitive functions of schizophrenia patients.
Objectives: In schizophrenia, cognitive symptoms emerge in the early period and are among the core symptoms. This study aimed to

investigate the long-term effect of electroconvulsive therapy on the cognitive functions of schizophrenia patients.
Methods: In this study, 25 patients diagnosed with schizophrenia according to DSM-5 criteria and treated with only pharmacotherapy (FT), 25 patients treated with pharmacotherapy plus electroconvulsive therapy (ECT) those who are inpatients in the psychiatry clinics of Istanbul Bakırköy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital 28 healthy controls were included. Patients were evaluated clinically with tests during the acute exacerbation period and 3 months later.
Results: During the acute exacerbation period, schizophrenia patients were identified to present poor cognitive performance compared to healthy controls. After three months of treatment, significant clinical improvement was observed in both patient groups. MoCA total scores increased for both groups after treatment. After treatment, TMT-A and TMT-B performance improved in the pharmacotherapy group and TMT-A performance improved in the pharmacotherapy + ECT group. With treatment, there was a significant positive change in the number of categories completed in the WCST in the pharmacotherapy group. In the Stroop Test, the pharmacotherapy group showed significant positive changes in the duration values of all cards and in the interference effect, while the pharmacotherapy + ECT group showed significant changes in the duration values of Stroop 1, 2, 4 and 5 and in the interference effect. In the pharmacotherapy + ECT group, there was a statistically significant positive correlation between the change in PANNS negative subscale scores and the duration of TMT-B and the number of completed categories, perseverative responses and perseverative errors in WCST.
Conclusions: It was observed that treatment modalities are not superior to each other on cognitive functioning in the long term. The improvement in cognitive areas with treatment may be due to a decrease in symptom severity and increased patient compliance with treatment. In this field, prospective, multicenter studies with larger sample sizes, including different drug groups and different ECT modalities are needed.

Cycloid psychosis: revisiting the concept through a case report

C. Alves e Cunha[1]*, R. M. Cabral[1], P. Pires[1], I. Santos[1], F. Cunha[1] and N. Cunha[1]

[1]Departamento de Psiquiatria e Saúde Mental, ULS Viseu Dão-Lafões, Viseu, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2197

Introduction: The term cycloid psychosis was first introduced by Karl Kleist in 1926 to describe cases that did not meet the typical presentations of schizophrenia or manic-depressive illness. The concept was later developed by Karl Leonard, who proposed three distinct types of cycloid psychoses. Perris and Brockington established the first operational diagnostic criteria for the condition. Cycloid psychosis is characterized by its acute onset, brief duration, polymorphous and shifting symptomatology, a tendency for periodic recurrence, and full inter-episode recovery, with no residual functional impairment following the episodes. Despite its distinct characteristics, cycloid psychosis is not included in the current international psychiatric classification systems.
Objectives: We aim to present a case report and conduct a literature review.
Methods: A narrative review of the literature was conducted, with data collected from the PubMed database. Only English-language studies published in peer-reviewed journals were included in the selection.
Results: Case: A 35-year-old female patient has been presenting, over the last seven years, with episodes characterized by a sudden onset of agitation, acute anxiety (described by the patient as 'an inexplicable sense of fear'), and frequently accompanied by persecutory delusions and auditory commanding hallucinations. Upon observation, the patient typically presents with confusion and perplexity and exhibits a lack of recollection of some previous events. Following the initiation of antipsychotic treatment, a complete recovery is always observed within a few days, with no residual symptoms remaining. In the most recent episode, the patient drove for a few hours to a different city from the one where she lives and had to ask for help from a fire department, as she felt lost and confused and had no memory of the previous events. According to reports from her family, the patient exhibited disorganized behavior, increased irritability, and a reduction in sleep duration during the week preceding the episode. The patient later acknowledged discontinuation of antipsychotic medication. These episodes occurred without any prior substance use, cognitive decline, or underlying medical conditions. The patient had no previous psychiatric complaints or family history of psychiatric disorders. Although the patient was a smoker, there was no history of substance or alcohol abuse. A comprehensive evaluation, including laboratory tests, imaging studies (head CT and brain MRI) and electroencephalography (EEG), revealed no abnormal findings. Considering the range of symptoms and characteristics observed in this clinical case, the patient meets Perris's criteria for cycloid psychosis.
Conclusions: Our case report highlights that cycloid psychosis exhibits a distinctive symptom pattern and clinical outcome, which can support its validity as a nosological construct distinguishable from other disorders in classification systems.

Schizophrenia: can I be a normal person despite my diagnosis?

N. Navarro[1], P. Martínez Gimeno[1], B. Rodríguez Rodríguez[1], M. Fernández Lozano[1], P. Marqués Cabeza[1], A. Rodríguez Campos[1], M. Calvo Valcárcel[1], M. Andreo Vidal[1], M. P. Pando Fernández[1], A. Monllor Lazarraga[1], G. Guerra Valera[1], M. Rios Vaquero[1], G. Lorenzo Chapatte[1], L. Rojas Vázquez[1] and M. B. Arribas Simón[1]*

[1]Hospital clínico universitario de Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2198

Introduction: Schizophrenia is a mental disorder characterized by hallucinations, typically auditive ones, delusions, disorganized thinking and behavior, and flat or inappropiate affect. Symptoms develop gradually and usually begin during young adulthood and are never resolved completely. There is no objective diagnostic test; diagnosis is based on observed behavior, a holistic psychiatric history that includes the person's reported experiences, and reports of others familiar with the patient.

Objectives:
- Explore what schizophrenia is, its main characteristics and how it differs from other mental disorders.
- Analyze how schizophrenia affects families and interpersonal relationships.

Methods: Middle-aged man who resides with his adoptive parents in a town near the municipal seat, unemployed and longitudinally with few social relationships and a lover of technology. He has attended psychiatric consultations on specific occasions and irregularly without a clear diagnosis. a single admission to a city psychiatric hospital for psychotic symptoms that subsided with medication. Since then, monitoring has been erratic and he has been given medication disguised by his parents during meals. In the last two weeks he has been especially distrustful and suspicious, even with his parents, so he has barely been able to sleep and does not eat properly for fear of being poisoned. He has confined himself to his room and refuses to be evaluated by a doctor and his anguish and emotional lability are increasing. For this reason, he is taken to the emergency room, where he is evaluated and it is determined that he is going through an episode with psychotic characteristics, which is why it is necessary, given the repercussion of the condition and the patient's lack of cooperation, to be involuntarily hospitalized for treatment and stabilization.
Results: During admission, he experiences episodes of intense agitation and serious behavioral alterations that require important pharmacological adjustments. In addition, work is done on awareness of the disease and acceptance of the diagnosis. Although he is initially reluctant to take any type of intervention, he progressively accepts taking medication and understands the nature of his problem, as well as the need to continue monitoring his disorder at an outpatient level. We were also able to provide psychoeducation to the family, thus achieving commitment and support on their part as well, since at first they were reluctant that their son could suffer from schizophrenia, for fear of the stigma and rejection that this could cause.
Conclusions: People with schizophrenia often face social stigmatization, which can lead to further marginalization, isolation and discrimination. This affects their emotional and mental well-being, contributing to a decrease in quality of life. Lack of adequate understanding of the disorder reinforces these myths and perpetuates discrimination.

Efficacy of Xanomeline-Trospium (KarXT) in Reducing Schizophrenia Symptoms: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

V. Astori[1]*, B. Pandolfi Arruda[1], B. Westphalen Pomianoski[2], D. Lopes Vieira[3], M. Prätzel Ellwanger[4], M. Frizzo Messinger[5] and D. Fernandes Holanda[6]

[1]Escola Superior de Ciências da Santa Casa de Misericórdia de Vitória, Vitória; [2]Universidade Nove de Julho, São Paulo; [3]Universidade Federal de Minas Gerais, Belo Horizonte; [4]Universidade do Contestado, Mafra; [5]Universidade Federal do Rio Grande do Sul, Porto Alegre and [6]Universidade Federal do Amazonas, Manaus, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2199

Introduction: Schizophrenia is a severe mental disorder often diagnosed in early adulthood, significantly impacting quality of life and increasing mortality risk. Xanomeline-trospium (KarXT), a combination of a muscarinic cholinergic receptor agonist and a peripheral antagonist, offers a potential new approach.
Objectives: We aimed to perform a systematic review and meta-analysis to assess the efficacy of KarXT compared to placebo in reducing the symptoms of schizophrenia.
Methods: We systematically searched PubMed, Embase, and Cochrane for randomized controlled trials (RCTs) enrolling patients with schizophrenia treated with KarXT versus placebo. Our outcomes included the overall improvement in schizophrenia symptoms, measured by the Positive and Negative Syndrome Scale (PANSS) total score, as well as specific symptom domains assessed by the PANSS positive and PANSS negative subscales. Additionally, the Clinical Global Impressions-Severity (CGI-S) score was used to measure the overall severity of the disorder. We computed mean difference (MD) with 95% confidence intervals (CIs) using R version 4.3.2. Heterogeneity was assessed using I^2 statistics.
Results: Three RCTs were included with 640 patients, of whom 314 (49.1%) received KarXT. There were 509 males (79.5%) and 131 females (20.5%). The average body mass index (BMI) was slightly higher in the KarXT group (29.1) compared to the placebo (28.8). KarXT resulted in a greater decrease in the PANSS total score (MD: -9.74; 95% CI -12.40 , -7.08 ; p<0.001; I^2=0%; Figure 1A), PANSS positive (MD: -3.20; 95% CI -4.04 , -2.36; p<0.001; I^2=0%; Figure 1B), PANSS negative (MD: -1.55; 95% CI -2.28 , -0.81; p<0.001; I^2=22%; Figure 1C) and CGI-S score (MD: –0.60; 95% CI -0.75 , -0.45 ; p<0.001; I^2=24% ; Figure 2).
Image 1:

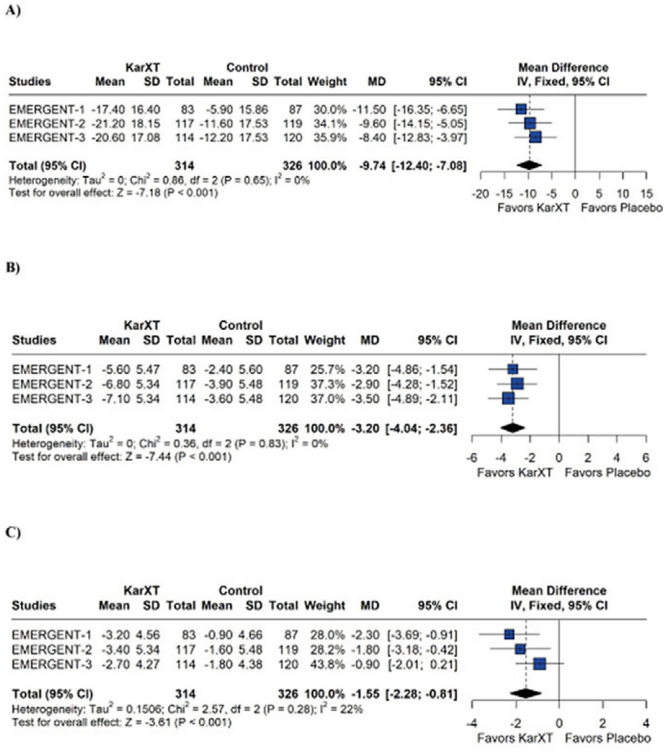

Figure 1 - A) KarXT resulted in a significantly reduced in the PANSS total score (P < 0.001), as well in their subcategories B) PANSS positive (P < 0.001) and C) PANSS negative (P < 0.001).

Image 2:

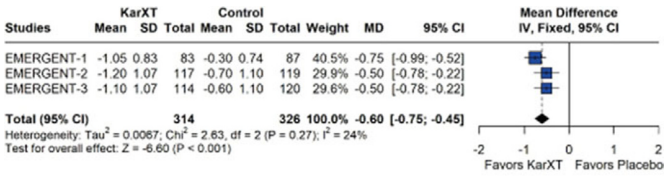

Figure 2 - CGI-S scores were significantly reduced in those receiving KarXT ($P < 0.001$).

Conclusions: Our systematic review and meta-analysis of RCTs showed that KarXT is significantly more effective than placebo in reducing schizophrenia symptoms.

Views on help-seeking for psychosis in South and Southeast Asia: A systematic mixed studies review

G. E. Aurizki[1,2*], R. Griffiths[1] and L. Renwick[1]

[1]Division of Nursing, Midwifery and Social Work, The University of Manchester, Manchester, United Kingdom and [2]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2200

Introduction: Psychosis is a condition characterised by hallucinations or delusions, which can cause distress and burden for both the individuals experiencing it and their caregivers. Seeking help can reduce the distress and burden, improve symptoms, and prevent adverse outcomes. However, many people still do not seek help or delay help-seeking. The reasons for this are not yet fully understood, especially in South and Southeast Asian settings.
Objectives: To explore the views and experiences of key stakeholders in South and Southeast Asia towards help-seeking for psychosis.
Methods: This systematic review included 'views' studies using qualitative, quantitative, and mixed-method designs. Systematic searches were conducted in several databases, including CINAHL, MEDLINE, PsycINFO, Embase, ASSIA, and Scopus from inception to September 2023. Each article was screened in duplicate by at least two independent reviewers. Popay et al.'s (2006) narrative synthesis was used to synthesise the data.
Results: This review included 51 studies from 10 South and Southeast Asian countries. The synthesis revealed that people with psychosis and their caregivers sought help from various sources. Factors that facilitate or hinder help-seeking behaviours include the ability to recognise problems, the alignment between illness and treatment perceptions, the attainability of help providers, the roles of social networks and support systems, and perceived stigma. Further, people also considered the outcome of each help-seeking process to determine their subsequent behaviours.
Conclusions: Interventions to improve help-seeking behaviours among people with psychosis should consider these multiple factors and address not only the help-seekers but also a wider range of key stakeholders, including social networks and potential help providers.

EPV1755

Impact of early administration of LAIs on socioeconomic status of patients with long term schizophrenia

U. M. Battelino[1*], A. Rojs[2], U. Ogrizek[1] and A. Čelofiga[2]

[1]Faculty of Medicine University of Maribor and [2]Maribor University Medical Centre, Maribor, Slovenia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2201

Introduction: Schizophrenia is a chronic psychiatric disorder with a complex and diverse pathology (Owen et al. 2016). Currently, the main form of treatment is antipsychotic therapy (AP), which involves the use of either oral antipsychotics (OAP) or long-acting injectable antipsychotics (LAIs) (Stępnicki et al. 2018). Although it affects only about 1% of the population, schizophrenia represents an important socioeconomic problem. The employment rates among individuals with schizophrenia are notably low, with only 10–30% maintaining employment, while approximately 80% are reliant on disability pensions (Holm et al. 2021).
Objectives: The aim of the study was to analyse the association between early administration of LAIs and the socioeconomic status in patients with long lasting schizophrenia and compare the differences between female and male patients.
Methods: This is a retrospective clinical study. We collected socioeconomic and sociodemographic data on all individuals and reviewed each patient's medical history from their first hospitalization up to the study period. Then we analysed the data. The inclusion criteria were ages from 18 up to 65 years, the diagnosis of schizophrenia or other psychotics disorders for at least 5 years, use of AP therapy for at least 5 years and current use of LAIs for at least 6 months. Exclusion criteria included the diagnosis of treatment-resistant schizophrenia, or the diagnoses classified under F70–79 in the ICD-10 classification.
Results: From the sample of 100 patients, the ones with early initiation of LAIS, within 2 years of onset of disease, had statistically higher rates of employment than those with late initiation of LAIs (p=0,04). We could not prove that the rate of employment was higher among early initiation female patients (p = 0,825), but we could for the male patients (p = 0,005) (Image 1). Meanwhile we couldn't prove the same for financial independence (p = 0,398), also there was no statistically significant result based on sex (p = 0,367, p = 0,692).

Image 1:

Contingency Tables

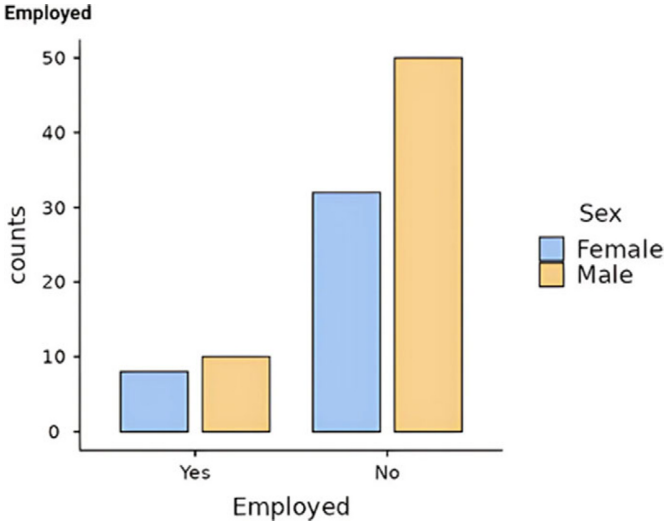
Contingency Tables

Sex	Time from Dx to LAI – 2 Yr cutoff	Employed		
		Yes	No	Total
Female	Early	1	5	6
	Late	7	27	34
	Total	8	32	40
Male	Early	5	6	11
	Late	5	43	48
	Total	10	49	59
Total	Early	6	11	17
	Late	12	70	82
	Total	18	81	99

χ^2 Tests

Sex		Value	df	p
Female	χ^2	0.0490	1	0.825
	N	40		
Male	χ^2	7.8049	1	0.005
	N	59		
Total	χ^2	4.0402	1	0.044
	N	99		

Image 2:



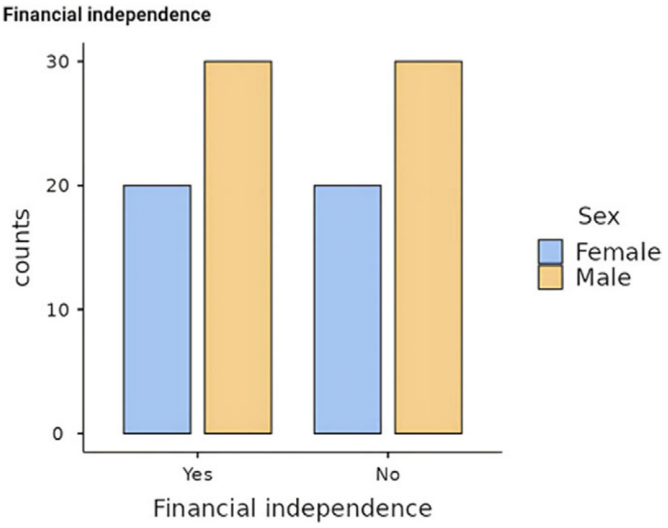


Image 3:

Conclusions: Results suggest that patients with earlier initiation of LAIs have higher rates of employment. The difference between sexes (Image 2 and 3) is also an interesting part of the study as it shows that female patients have a later onset than male patients and therefore receive the first does of LAIs at a much older age than men, which could be influencing the higher rate of unemployment and insufficiency among female patients.

EPV1756

Medication Compliance in Schizophrenia: The Role of Sociodemographic Factors and Depression

S. Ben Aissa[1]*, R. Khouloud[1], N. Chaima[1], L. Amine[1] and M. Wahid[1]

[1]Psychiatry D, Razi Hospital, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2202

Introduction: Non-adherence to prescribed medications in schizophrenia is a primary factor leading to relapse and repeated hospitalizations, posing a significant challenge in psychiatric care. Understanding and enhancing medication adherence is crucial for improving outcomes in schizophrenia treatment.

Objectives: This study aimed to estimate the prevalence of medication non-adherence among schizophrenia patients and to explore the impact of depression and other sociodemographic factors on adherence levels. Recognizing these influences is essential for developing targeted interventions to improve patient outcomes.

Methods: A cross-sectional analysis was conducted involving 350 individuals with schizophrenia, encompassing both outpatients and inpatients. A comprehensive questionnaire was employed to collect data on sociodemographic characteristics, clinical history, and therapeutic interventions.

To assess medication adherence and depressive symptoms, the study utilized the Medication Adherence Rating Scale (MARS)

and the Calgary Depression Scale for Schizophrenia (CDSS), both of which are validated tools designed for psychiatric evaluations.
Results: Data analysis revealed that 21.3% of the participants exhibited poor medication adherence as measured by MARS. Further statistical testing using a logistic regression model identified employment status and level of depression as significant predictors of non-adherence.
Patients who were unemployed and those exhibiting higher scores on the CDSS indicating more severe depressive symptoms were more likely to be non-compliant with their medication regimen (p=0,001). This highlights the intricate relationship between mental health symptoms and treatment adherence.
Conclusions: The results of this study illuminate the importance of considering depression and employment status when addressing medication adherence in individuals with schizophrenia. These factors play a pivotal role in the adherence behavior and overall treatment outcomes of patients.
Emphasizing comprehensive care that includes management of depression alongside routine antipsychotic treatment could enhance adherence and improve the prognosis for individuals living with schizophrenia. Ongoing research is needed to further elucidate the pathways that influence medication adherence and to develop strategies that effectively address these challenges.

The craziness in losing weight. A systematic review and case report of sibutramine's psychosis

E. I. Benítez Sánchez[1]*, L. Montesinos Almarcha[2] and J. López Álvarez[1]

[1]Servicio de Psiquiatría, Complejo Hospitalario Universitario de Badajoz, Badajoz and [2]Servicio de Psiquiatría, Complejo Hospitalario de Mérida, Mérida, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2203

Introduction: Sibutramine is an anorexigenic drug that has been used to treat obesity. After its commercialization, FDA ordered the suspension of its prescription in USA because of the adverse effects. It has structural similarities to amphetamine and is a serotonin-noradrenaline reuptake inhibitor. The primary metabolites are responsible for the activity and inhibit the reuptake of noradrenalin and serotonin from the synaptic cleft. This substance can interfere with one of the known mechanisms of psychosis increasing dopaminergic transmission and leading to potential psychomimetic effects.
Objectives: The main objective in this paper is to obtain a critical evaluation of the literature regarding psychosis and sibutramine. There has been done a bibliographic review in databases such us SCOPUS, Web of Science, UptoDate and PubMed. This review was realized under certain criteria and keywords. The motivations behind this research were generated after an unusual clinical case (in symptomatology's presentation). Sibutramine is a compound, which is not commercialized in the UE, so the diagnosis of the toxic psychosis was more complicated than the average psychedelics drugs.
Methods: To develop this review, numerous databases were chosen: PubMed, Scopus, UpToDate and Web of Science. However, only in PubMed we have obtain relevant results. For descriptors we have used two terms: "psychosis" and "sibutramine". In this database, 27 results were obtained. With the criteria previously designed, which were free text access and works published in the last 20 years, only ten of them met all the criteria. With these ten articles, a systematic and qualitative analysis has been done, focusing on the ones which described similar cases.
Results: The sibutramine psychosis is difficult to identify. Frequently is mixed up with other substances in dietary supplements, which can appear as harmless. So, as clinics, we need to be careful, always considering this information in the clinical records. This case was peculiar; a 24 years old woman was consuming sibutramine as a compound in one supplement she was taken for losing weight. Three weeks prior to the consult the symptons started with an erotomaniac delusions, accompanied by disruptive behaviour, mood swings (dysphoria) and irritability. She was hospitalized and treated with antipsychotic medication (aripiprazole) showing a full recovery in five days.
Conclusions: Sibutramine can cause severe mental health disorders. As a compound of dietary supplements, can be easily acquired through online stores. Our work as clinics is to be vigilant of this kind of substances because of the danger that can generate. More studies should be done, to acquire knowledge of the psychobiological mechanisms involved in these cases. The prognosis seems to be positive, but there are certain risks in patients with unknown vulnerability factors.

Disclosure of Interest: None Declared

Delusion of pregnancy in males and hyperprolactinemia: a case report and review of the literature

I. Besbes[1]*, A. Hakiri[1], C. Bey[1], K. Mahfoudh[1], A. Bouallagui[1], G. Amri[1] and R. Ghachem[1]

[1]Department B, Razi hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2204

Introduction: Delusion of pregnancy is not common among patients suffering from schizophrenia, especially males. The reports in literature regarding this delusion are rare and not conclusive, particularly about its mechanisms. The psychopathology behind this particular condition may involve hormonal and biological ways.
Objectives: Illustrate through a case report and a review of literature the causal relationship between delusion of pregnancy and hyperprolactinemia in a male with schizophrenia.
Methods: This case report involved a comprehensive evaluation of a patient presenting with delusion of pregnancy and hyperprolactinemia. We compared the clinical findings with the existent research after conducting a literature review on different databases such as Pubmed and the national library of medicine using the key words "delusion of pregnancy" "males" and "hyperprolactinemia"
Results: A 30-year-old Tunisian man with a history of schizophrenia who has been of treatment for 6 months, presented to our department with auditory hallucinations, incoherent speech, and a delusion of pregnancy. The patient reported feeling fetal movements and believed a uterus had been implanted in his abdomen after receiving stem cell injections. Since it is the first time that our patient presents this delusion of pregnancy unlike his other

relapses, we asked for a prolactinemia test and complete hormonal panel. His prolactin levels were elevated at 59.33 ng/ml (normal range: 15-25 ng/ml), compared to normal baseline levels in previous admissions. The hormonal screening revealed hypogonadotropic hypogonadism. The patient was treated with antipsychotics (haloperidol initially, then switched to clozapine) and sedatives to manage his symptoms and agitation. His prolactin levels were successfully managed with medication, returning to within the normal range (the second measurement being done 8 weeks after the switch to clozapine). The delusion of pregnancy resolved after several weeks of treatment with clozapine. The patient was discharged with ongoing outpatient care to monitor his schizophrenia and prolactin levels.
Conclusions: This case report highlights the association between delusion of pregnancy and hyperprolactinemia in a male patient with schizophrenia. The findings suggest the potential link between these two conditions. Further research is necessary to elucidate the underlying mechanisms and develop evidence-based clinical management.

EPV1760

Hostility and negative expectations about the future in mental disorders

T. I. Medvedeva[1], S. N. Enikolopov[1], O. Y. Vorontsova[1] and O. M. Boyko[1]*

[1]Clinical psychology, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2205

Introduction: Studies shows a connection between hostility and the severity of psychopathological symptoms. When psychopathological symptoms (mainly depressive) are expressed, hostility towards one's own "I", other people, and generalized impersonal hostility in the form of a sense of injustice, ill will of the surrounding world, and a negative assessment of the subjective future are combined. the connection between hostility and a negative assessment of the future requires empirical confirmation.
Objectives: The **aim** of the study was to analyze the connection between hostility and a negative assessment of the future.
Methods: N=37 people hospitalized in the clinic of the *Mental Health Research Center* (16 men and 21 women) with a diagnosis of schizophrenia and affective spectrum. Methods: SCL-90R, BPAQ-24 (Buss, Perry), All the subjects wrote a short essay "Me, others, the world", attitude to the future was assessed by a group of answers in the modified Sentence Completion Test (Sacks, Levy). The subjects were divided into three subgroups: "positive expectations of the future" (N=16, mean age 24.87±8.20), "neutral future" (N=10, mean age 21.89±8.08), "negative assessment of the future" (N=11, mean age 21.45±4.82). The presence of a trend in changing parameters depending on the attitude to the future - Jonckheere-Terpstra Test, comparison of subgroups by parameters of qualitative assessment of the essay - Chi-Square Tests were used.
Results: The analysis showed an increase in "hostility" (BPAQ-24) with a change in attitude to the future from negative to neutral and positive. With a negative attitude towards the future, there were the highest rates of "hostility" (24.82 ± 4.26, 17.60 ± 5.58, 16.40 ± 4.63, Std. J–Tstat. = -3.44, p = .001). It was revealed that negative expectations of the future are associated with the presence of problems in interpersonal relationships in the present, "Interpersonal Sensitivity" (SCL-90) is increased (10.82 ± 7.37, 7.00 ± 6.88, 4.87 ± 6.81, Std. J–Tstat. = -2.348, p = .019), individuals with high rates are distinguished by negative expectations regarding interpersonal interaction and any communications with other people. The analysis of the parameters of the qualitative analysis of the essays in the subgroups showed that only with a negative attitude towards the future there is a mention of the fragility and instability of the world (36%, p=.007), statistically more often mention the topic of suicide, death, "no place in this world" (80% compared to 16% and 22%, p=.049), the topic of "rejection" (p=.025), the frequency of expectation of a negative assessment of oneself by other people (, p=.004).
Conclusions: Results confirm the hypothesis about the relationship between hostility and a negative attitude towards the future and allow to assume that a common factor for both hostility and a negative attitude towards the future in mental pathology are problematic interpersonal relationships.

EPV1761

The theme of death in texts written by patients with endogenous mental disorders

T. I. Medvedeva[1], S. N. Enikolopov[1], O. Y. Vorontsova[1] and O. M. Boyko[1]*

[1]Clinical psychology, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2206

Introduction: A specific attitude towards death is an important marker of suicidal risk. A freely written text can be considered as a variant of a projective test and can assess implicit attitudes toward death and suicide.
Objectives: The **objective** was to identify the psychological characteristics of the subjects using the theme of death in the texts.
Methods: 91 patients with schizophrenic and affective spectrum disorders (43 men and 48 women). The control N=98 (40 men and 58 women). All the subjects wrote a short essay "Me, others, the world", the presence of words from the thematic group "death" was assessed, Big Five Inventory (BFI) and SCL-90R were used. The question about the presence of suicidal thoughts was measured on a Likert scale.
Results: Control and clinical groups did not differ in the frequency of the topic of death (13.3% of the control and 16.5% in clinical group). However, patients wrote more often about themselves, while in control «death» was more often encountered when discussing problems of humanity, ecology, loneliness. The subjects from the clinical group showed low: "Extraversion" (48,86±10,07 and 44,72 ±10,44 for the control and clinical groups) (due to low "Activity", "Excitement seeking" and "Gregariousness"), "Conscientiousness" ("Neat" and "Decisiveness"), "Emotional Stability" (50,58±12,21 and 54,88±11,42) (due to "Tension", "Depression" and "Self-punishing"). Ccomparison of the subgroups that mentioned «death» (control and clinical subgroups) revealed no statistical differences in BFI (clinical subgroup demonstrated a more pronounced "insensitivity"). In general, all subjects (both healthy and clinic patients) with the topic of death differed from the group of subjects who did not touch death vocabulary: "Introversion" (47.66±9.77 and 40.58±13.45

for the subgroup without «death» and with the topic of death), "Attachment" (53,25 ±10,06 and 60,25± 7,03), high "Emotionality" (48,85±11,87 and 56,91± 10,88). A similar pattern is observed when comparing the subgroups "control without the theme of death" and "control with the theme of death". In the clinical group, it was shown that the topic of death is associated with a higher suicidal risk (the question about the severity of the intention to commit suicide, the average values are 0.30±0.57 and 1.16±1.60 for the "clinical subgroup without the topic of death" and "clinical subgroup with the topic of death", respectively).

Conclusions: The topic of death in control group indicates a conflict between introversion and social orientation, as well as an inability to control their emotions and impulsive drives and low self-esteem. In the clinical group, almost all of whose subjects differ from the healthy group by increased introversion and emotionality, mentioning the topic of death may be a marker of increased suicidal risk.

Disclosure of Interest: None Declared

Association between Schizophrenia and Violence: The Cage of Psychosis

A. Castelao Escobar[1]*, C. Peláez Fernández[2], P. Sanz Sánchez[1], R. González Nuñez[1], C. Alguacil Núñez[1] and R. Albillos Pérez[1]

[1]Psiquiatría, Hospital Universitario Puerta de Hierro Majadahonda and [2]Psiquiatría, Hospital Universitario El Escorial, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2207

Introduction: In Spain, approximately 4% of the prison population suffers from severe mental disorders, with schizophrenia being more prevalent in this group compared to the general population. Although violent behavior is infrequent among individuals with schizophrenia, it holds significant clinical importance. Reoffending rates are low, and crimes are typically less severe. Comorbid substance abuse is also common.

Objectives: This study examines the case of a man with schizophrenia who committed homicide under the influence of drugs, highlighting the complex relationship between schizophrenia and violence.

Methods: We present the case of a 30-year-old man with no prior medical or legal history, sentenced to five years and nine months in prison for homicide (of his sister), resisting arrest, and minor injuries. The homicide occurred after the consumption of MDMA. The initial forensic report revealed no severe psychopathy and a preserved sense of reality, while the defense argued moderate impairment of cognitive and volitional faculties due to intoxication and extreme fatigue.

Results: After spending a few months in prison, he attempted suicide by hanging, which did not require admission and was considered reactive to a stressful life situation. During his incarceration, the patient exhibited progressive thought disorganization, eccentric behaviors, hallucinations, and delusional ideation unrelated to substance use. He also engaged in severe self-harm, requiring bilateral orchiectomy. Following this, he was diagnosed with schizophrenia and treated in a psychiatric unit. Since 2022, he has been included in the Integrated Care Program for Severe Mental Illnesses in Prison (PAIEM) and treated with extended-release paliperidone. After release, he was incorporated into the Continuity of Care Program, maintaining regular consultations with psychiatry, nursing, and social work. He has integrated well into the psychosocial rehabilitation center, showing no behavioral disturbances. He reports almost complete amnesia of the offenses for which he was convicted and exhibits some indifference towards them. He continues to receive treatment and is diagnosed with schizophrenia, predominantly with negative symptoms.

Conclusions: This case underscores the need to adequately assess negative symptoms of schizophrenia and their impact on violent behavior. The successful transition of the patient from prison to a specialized center highlights the importance of continuous treatment and monitoring in cases of severe mental disorders. Effective management of treatment and post-prison follow-up is crucial for minimizing risks and promoting successful community integration.

Shared psychosis at a distance: a case of telephone-induced Folie à Deux

S. Castelao-Almodovar[1]*, A. Arce de la Riva[2], R. Albillos Perez[2], A. Pérez Balaguer[1] and E. Gil Benito[1]

[1]Centro de Salud Mental El Escorial, El Escorial and [2]H. U. Puerta de Hierro, Majadahonda, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2208

Introduction: Shared psychotic disorder (*Folie à Deux*) is a phenomenon in which one person adopts the delusions of another with whom they have a close relationship. This case is particularly interesting because the delusions primarily developed through telephone conversations between two sisters and were notably exacerbated when they reunited in person. The telephone-based relationship between the sisters raises questions about the psychological influence from a distance in the development of shared psychosis.

Objectives: To describe a clinical case of *Folie à Deux* in which delusion transmission occurred predominantly through telephone communication, highlighting the role of physical contact in the exacerbation of psychotic symptoms.

Methods: We present the case of a 59-year-old woman hospitalized for shared psychosis. Her sister, with whom she maintained a close relationship through frequent phone calls, had previously developed persecutory delusions related to a complicated divorce. Over the course of five years, the patient began to share the same delusions of persecution and surveillance that her sister transmitted over the phone. However, following a visit from her sister to Madrid in July 2024, the patient's psychotic symptoms intensified, leading to psychiatric hospitalization in the brief hospitalization unit (UHB), where antipsychotic and antidepressant treatment was initiated.

Results: The patient was admitted with persecutory delusions centered on alleged surveillance related to her sister's divorce, delusions that her sister initially developed and which they shared after years of phone conversations. During hospitalization, antipsychotic treatment was effective, leading to remission of the active psychotic symptoms. The patient demonstrated insight into her delusions, linking them to her sister's influence. As contact with her sister decreased and treatment was introduced, the psychotic

symptoms subsided. Since discharge, the patient has remained stable, though a medication adjustment was required due to reported side effects.
Conclusions: This case of *Folie à Deux* highlights how a telephone relationship can be sufficient to transmit and maintain shared psychotic delusions. While physical contact exacerbated the symptoms, emotional exchange from a distance can also be a potent medium for perpetuating delusions. This case suggests that proximity, whether physical or emotional, directly influences the severity of shared psychosis.

Antidepressant-Induced Psychosis: A non-common Case Report

S. Castelao-Almodovar[1]*, A. Arce de la Riva[2], R. Albillos Perez[2], A. Pérez Balaguer[1] and E. Gil Benito[1]

[1]Centro de Salud Mental El Escorial, El Escorial and [2]H. U. Puerta de Hierro, Majadahonda, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2209

Introduction: The emergence of psychotic symptoms induced by antidepressants is an uncommon phenomenon, though it has been documented in isolated cases. Psychosis induced by serotonin-norepinephrine reuptake inhibitors (SNRIs), such as Venlafaxine, is particularly rare. This case presents a patient who developed psychotic symptoms after starting treatment with Venlafaxine, highlighting his capacity for self-criticism and the egodystonic nature of his delusions.
Objectives: To describe a case of a depressive episode with psychotic symptoms secondary to antidepressant treatment, emphasizing the importance of differential diagnosis, therapeutic management, and the patient's notable awareness of the unreality of his psychotic symptoms.
Methods: A 40-year-old male with a history of depressive disorder and substance abuse experienced high levels of anxiety following the death of his father, with whom he had a conflicted relationship. He started treatment with Venlafaxine, which he had previously taken with good results. Shortly after, he developed euphoria, persecutory thoughts, and delusions, such as the belief that there were cameras watching him, that his food was poisoned, and that he was being followed. No substance use was reported during this period, although he had a history of significant abuse in the past. Due to the worsening of his symptoms, he voluntarily admitted himself for further evaluation at a hospital in Barcelona.
Results: During his hospital stay, Venlafaxine was discontinued due to its association with the psychotic symptoms. Antipsychotics such as Olanzapine, Invega, Aripiprazole, and Depakine were introduced, but these were poorly tolerated. After being transferred to Madrid, Cariprazine was reintroduced, leading to partial improvement, although referential thinking persisted. In private follow-up care, Anafranil was later added, which further improved his mood, although residual psychotic symptoms, particularly referential thinking, remained. A key aspect of this case is the patient's good insight and egodystonic experience of his psychotic symptoms from the onset. He has recently started group therapy in a Multifamily Psychotherapy Group.
Conclusions: This case highlights the importance of differential diagnosis between antidepressant-induced psychosis and primary psychotic disorders. It also underscores the patient's egodystonic experience of his delusions, with good insight, which facilitated clinical management. The literature on antidepressant-induced psychosis, particularly with drugs like Venlafaxine, is limited, indicating the need for further study of this rare but significant side effect.

Exploring conversation coordination in patients with schizophrenia

M. Champagne-Lavau[1]*, C. Petrone[1], A. Poulet[2], C. Faget[3] and C. Lançon[3]

[1]CNRS, LPL, Aix-Marseille University, Aix-en-Provence; [2]Department of speech language pathology, Claude Bernard Lyon1 University, Lyon and [3]Department of Psychiatry, AP-HM: La Conception University Hospital, Marseille, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2210

Introduction: Individuals with schizophrenia (SZ) are known to be impaired in their social and communication abilities. However, these impairments are not well characterized. More specifically, little is known about how SZ individuals take into account their interlocutor during conversation. Verbal backchannels (e.g., okay, yes) have been described as crucial cues that contribute to conversation coordination by allowing the updating of knowledge shared between interlocutors (Gravano & Hirschberg, 2011, Comput. speech lang., *25*, 601-634). They could reflect the ability of interlocutors to take into account their partner's perspective during conversation.
Objectives: The aim of the present study was to explore how SZ individuals manage conversation coordination with their interlocutor.
Methods: Thirty-one SZ participants and 30 healthy control (HC) participants matched for age and educational level performed a referential communication task with a partner (i.e., a collaborative game; Champagne-Lavau et al., 2009, Cogn. Neuropsychiatry, 14, 217-239.). During this game, they played either the role of Director (condition 1) or the role of Addressee (condition 2) with an experimenter. In condition 1, we performed prosodic analyses on the cues known to predict the production of a backchannel (i.e., backchannel-inviting cues, Gravano & Hirschberg, 2011) by the Addressee (e.g., duration and intonational contour of the Director's utterance produced before the backchannel). In condition 2, we performed phonetic analyses (e.g., f0min, f0max, pitch span, duration) on the backchannels (i.e., yes) produced by the Addressee. SZ participants' severity of symptoms was measured using the PANSS. Participants were also assessed on their theory of mind abilities with the Hinting task.
Results: Data from 22 SZ and 17 HC participants were analyzed. The main results did not show any difference between SZ and HC participants regarding the production of backchannel-inviting cues (condition 1) and regarding the number of backchannels produced (condition 2). However, phonetic analyses in condition 2 showed that SZ participants produced backchannels with a shorter duration (222 ms ± 85) and a reduced pitch span (0.443 ± 0.301) compared to HC participants (duration: 265 ms ± 91; pitch span: 0.586 ± 0.367). We also found a correlation between pitch span and PANSS (general score) ($r = -0.467$, $p = 0.029$) and a correlation marginally

significant between pitch span and theory of mind abilities (r = 0.395, p = 0.069).
Conclusions: This exploratory study seems to show that SZ participants' production of backchannels (reflecting their role in conversation coordination) is related to their theory of mind abilities and to their symptoms.

Efficacy and safety of brexpiprazole in early-episode schizophrenia: post hoc analysis of clinical trials in adults and adolescents

C. Correll[1,2,3]*, B. Pflug[4], Z. Zhang[4], A. M. Palma[4] and P. Such[5]

[1]Department of Psychiatry, The Zucker Hillside Hospital, Glen Oaks, NY; [2]Department of Psychiatry and Molecular Medicine, The Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY, United States; [3]Department of Child and Adolescent Psychiatry, Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Berlin, Germany; [4]Otsuka Pharmaceutical Development & Commercialization Inc., Princeton, NJ, United States and [5]H. Lundbeck A/S, Valby, Denmark
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2211

Introduction: For patients with schizophrenia, effective treatment of early episodes may improve long-term outcomes, reduce the risk of relapse, and limit functional impairment.
Objectives: To evaluate the efficacy and safety of brexpiprazole versus placebo in adult and adolescent patients with early-episode schizophrenia.
Methods: Data were analyzed from four Phase 3, 6-week, randomized, double-blind, placebo-controlled trials: three in adults (Clinical Trials.gov: NCT01396421 [Vector], NCT01393613 [Beacon], NCT01810380 [Lighthouse]), and one in adolescents (NCT03198078 [Study 331-10-234]). For the trials in adults, patients aged 18–65 were randomized to placebo (total N=531), brexpiprazole (total N=1,093; 0.25, 1, 2 or 4 mg/day, or 2–4 mg/day, depending on the trial), or quetiapine extended-release (N=154; active reference in one trial). For the trial in adolescents, patients aged 13–17 were randomized to placebo (N=104), brexpiprazole 2–4 mg/day (N=110), or aripiprazole (N=102; active reference). Mean baseline Positive and Negative Syndrome Scale (PANSS) Total scores indicated that adult and adolescent patients were of similar disease severity. In all four trials, the primary efficacy endpoint was change from baseline to Week 6 in PANSS Total score. In this *post hoc* analysis, early-episode schizophrenia was defined as age 13–35, and ≤5 years' duration of illness. Data from the four trials were pooled and compared between brexpiprazole 2–4 mg/day (FDA-recommended target dose in adults and adolescents) and placebo. Efficacy outcomes were analyzed using least squares (LS) mean change from baseline (mixed model for repeated measures). Safety was also evaluated.
Results: The *post hoc* early-episode schizophrenia sample comprised 292 patients treated with brexpiprazole 2–4 mg, and 190 treated with placebo (analyzed for safety), of whom 289 and 187 were analyzed for efficacy, respectively. The *post hoc* efficacy sample comprised 19.3% of the corresponding efficacy sample of the adult trials (pooled), and 98.1% of the corresponding efficacy sample of the adolescent trial. In the *post hoc* efficacy sample, mean (standard deviation) baseline age was 22.4 (6.6) in the brexpiprazole group and 20.5 (6.6) in the placebo group, and baseline PANSS Total scores were 97.9 (13.5) and 100.4 (14.2), respectively. The LS mean (standard error) change from baseline to Week 6 in PANSS Total score was -21.4 (1.1) with brexpiprazole, and -17.8 (1.4) with placebo (p=0.042). The overall incidence of treatment-emergent adverse events (TEAEs) was 50.7% with brexpiprazole, and 46.3% with placebo. The TEAE with the highest incidence in the brexpiprazole group was akathisia (6.5%; placebo, 2.1%).
Image 1:

Conclusions: In this *post hoc* analysis of patients with early-episode schizophrenia, brexpiprazole was associated with greater improvement in schizophrenia symptoms than placebo. No new safety observations were made.

Disclosure of Interest: None Declared

EPV1767

Preliminary evaluation of the psychometric properties of the Italian version of the Psychotic Symptom Rating Scales (PSYRATS)

S. Costantini[1]*, A. Di Lisi[3], L. Ghidetti[2], F. Cappella[3], L. Orlando[4], F. Catalano[3], M. Benassi[2] and R. P. Sant'Angelo[5]

[1]Mental Health, Ausl Romagna; [2]Psychology, University of Bologna, Cesena; [3]Psychiatry, University of Bologna, Bologna, Italy; [4]Psychiatry, South London and Maudsley NHS Foundation Trust, London, United Kingdom and [5]Mental Health Department, Ausl Romagna, Cesena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2212

Introduction: Most of the validated Italian scales for assessing psychotic symptoms don't analyze specific symptoms like delusions and hallucinations in detail, but rather measure a wide range of experiences and behaviors in a general way. Scales such as PANSS, SAPS, and Sistema3 include only a few items on delusions and hallucinations, without considering the multidimensional characteristics of these symptoms, such as the degree of conviction, distress, duration, and perceived reality of the hallucinations. The Psychotic Symptom Rating Scales (PSYRATS) is the most widely

used scale globally for measuring the severity of hallucinations and delusions through a semi-structured interview, but it has never been translated into Italian.
Objectives: The aim of this study is to conduct a preliminary evaluation of the psychometric properties of the Italian version of the PSYRATs.
Methods: The participants were recruited from among adult patients who were able to communicate fluently in Italian and were admitted to the Psychiatry Department of the Cesena Hospital. Eligibility depended on the presence of persistent delusions or auditory hallucinations in the week prior.
The hospitalized patients were assessed using the Italian version of the PSYRATS, the Positive And Negative Syndrome Scale (PANSS), and the Brief Psychiatric Rating Scale (BPRS). The reliability of the scales was assessed using Cronbach's Alpha, and the relationship between the variables was analyzed using Spearman's correlation.
Results: The sample consisted of 25 participants (5 female, 20 male), with a mean age of 43 years and an average educational level of 11 years. A good internal consistency was observed for the "Auditory Hallucinations" scale (Alpha = .92) and for the "Delusions" scale (Alpha = .97). Spearman's correlation analysis revealed that the "Total PSYRATs" scale has strong correlations with the "Auditory Hallucinations" scale (Rho = .93; p = .001) and the "Delusions" scale (Rho = .45; p = .02). Valid correlation indices were also noted between the "Total PSYRATs" and "Total BPRS" scales (Rho = .62; p = .001) and the PANSS scale (Rho = .45; p = .02).
Image 1:

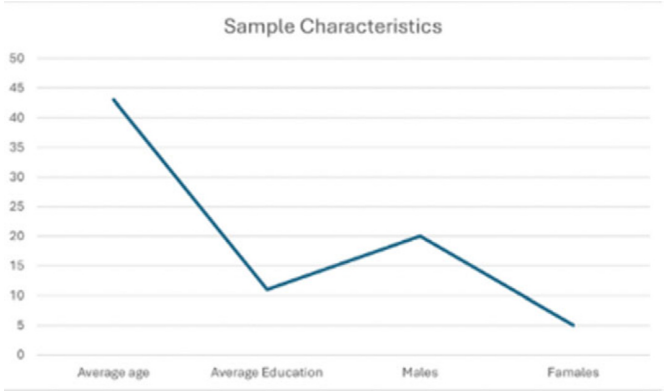

Image 2:

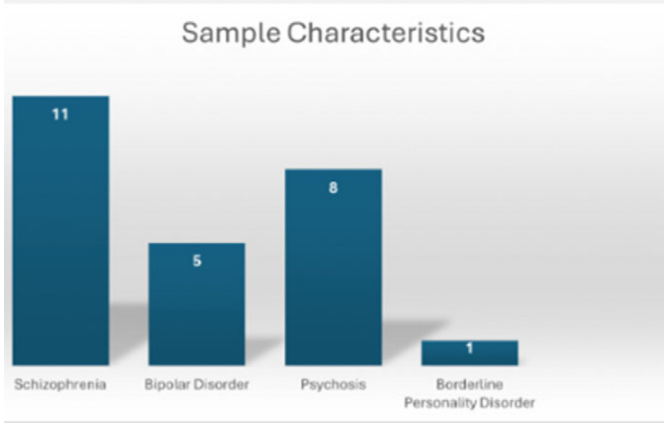

Image 3:

Correlation

			PANS TOT	BPRS TOT	PSYRATs
Rho by Spearman	Panstot	Correlation coefficient	1,000	,679**	,453*
		Significance (Two- tailed)	.	<,001	,023
		N	25	25	25
	BPRS TOT	Correlation coefficient	,679**	1,000	,617**
		Significance (Two- tailed)	<,001	.	,001
		N	25	25	25
	PSYRATs	Correlation coefficient	,453*	,617**	1,000
		Significance (Two- tailed)	,023	,001	.
		N	25	25	25

**. The correlation is significant at the 0,01 (two- tailed).
*. The correlation is significant at the 0,05 (two- tailed).

Conclusions: The preliminary data demonstrate good internal consistency and convergent validity of the Italian version of the PSYRATS; therefore, this instrument appears to be a valid measure for the assessment of hallucinations and delusions. The results of this study are limited by the relatively small sample size, making it essential to repeat the analyses on a larger population.

EPV1770

Shared Psychosis in Family Dynamics: Two Cases of Schizophrenia in Close Relatives

L. Demiraj[1]* and E. Sotiri[1]
[1]"Mother Teresa" UHC, Tirana, Albania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2213

Introduction: Shared psychotic disorder (folie à deux) is a rare mental health condition where delusions are transmitted from one person to another within a close relationship. Understanding these complex dynamics is crucial for effective diagnosis and treatment.
Objectives: To present two cases of shared psychosis involving close relatives diagnosed with schizophrenia, aiming to open discussion on the complex dynamics of familial relationships and their impact on mental illness.
Methods: 2 case reports.
Results: We present two cases of shared psychosis involving close family members. The first case involves two sisters, aged 43 and 48, both diagnosed with paranoid schizophrenia. The 43-year-old sister was admitted following a suicide attempt and exhibited active psychosis with paranoid delusions. During her hospitalization, the older sister displayed identical delusions and refused her sibling's treatment, leading to her own admission. Both sisters, previously untreated and highly educated, were managed with antipsychotic medications. While the delusions were encapsulated during treatment, concerns remain about their shared living environment and its potential influence on their ongoing recovery.
The second case involves a 33-year-old woman with a decade-long history of schizophrenia who was brought to the emergency room malnourished and uncommunicative, having not eaten for over a

week. She was fed via a nasogastric tube during her lengthy hospitalization and placed on a regimen of Clozapine. The patient exhibited severe negative symptoms and behaviors suggestive of auditory hallucinations. Her mother, also of low educational and socioeconomic status, was present throughout her stay but displayed delusional beliefs that interfered with her daughter's treatment. Following restrictions on the mother's access to the patient, the daughter showed slight improvement and began eating independently.
Conclusions: These cases highlight the significant impact that familial relationships and shared psychosis can have on the progression and management of schizophrenia. The challenge in treating shared delusions lies not only in addressing the symptoms but also in mitigating the interpersonal dynamics that may perpetuate them. Further investigation into family-based psychosis and its treatment is warranted.

Circadian rhythm melatonin in acute and stabilized schizophrenic patients

E. DIAZ MESA[1]*, A. Morera-Fumero[2], I. Zebenzui-Moreno Gonzalez[1], R. de Leon Hernandez[1], P. Abreu-Gonzalez[3], M. D. R. Cejas-Mendez[1] and L. Fernandez-Lopez[2]

[1]Psychiatry, University Hospital of the Canaries; [2]Department of Internal Medicine Dermatology and Psychiatry, School of Medicine and [3]Physiology, University of La Laguna, La Laguna, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2214

Introduction: Melatonin is a neurohormone plays a role in the development and course of schizophrenia.Melatonin also has an important role in regulating circadian rhythms, so melatonin secretions have been suggested as markers for circadian dysfunctions in schizophrenic patients. Some studies have assessed the circadian profiles of melatonin secretion in schizophrenic patients, showing that the nocturnal circadian rhythm of plasma melatonin secretion was disrupted in medicated chronic schizophrenics (Jiang H. K. & Wang J. Y. Diurnal melatonin and cortisol secretion profiles in medicated schizophrenic patients. *Journal of the Formosan Medical Association. Taiwan yi zhi 1998 97*(12), 830–837). Nocturnal plasma melatonin secretion was also reduced in the drug-free schizophrenic patients (Monteleone P. et al. Depressed nocturnal plasma melatonin levels in drug-free paranoid schizophrenics. *Schizophrenia research* 1992;*7*(1), 77–84). These findings could suggest the presence of abnormal melatonin rhythm in schizophrenics, which may be related to the pathophysiologic process itself. However, it is not known whether there are melatonin secretion significant differences in acute phase and clinical stabilization phase of schizophrenic patients.
Objectives: The aim of this study is to assess the melatonin secretion profile in acute phase and clinical stabilization phase of schizophrenic patients to know if exists circadian rhythm and to compare both measures.
Methods: Our sample consists in 48 patients that have been study in two clinic phases: acute phase and after discharge,clinically stabilized. Blood samples were collected in the morning (12:00 hours) and at night (00:00 hours) by venipuncture in reclined position with mask that covers the eyes. Serum levels of Melatonin were measured in acute phase and stabilized phase, after discharge. Melatonin was measured by means of ELISA (Enzyme-linked immunosorbent assay) techniques. The relationship between quantitative variables at two times of the same marker were analyzed by T-Student test.
Results: All comparisons reach a degree of statistical significance, which we can interpret as meaning that there is a circadian rhythm at the two moments measured. Furthermore there significant difference between acute phase of the schizophrenia respect control phase, three months after discharge.
Conclusions: In this study we can hypothesize that Melatonin has circadian rhythm when the patients are in acute psychosis and when are stabilized. MLT levels increase at control, a fact that we can interpret as there is an increase in antioxidants levels in the clinical stabilization phase, this increase being even greater at the three-month control, which may be attributable to the treatment due to its antioxidant properties or to the disease itself. The results of this biomarker could be interpreted as is useful variable for the prognosis.

The ability to interpret courtship signals in patients with schizophrenia

P. Biedkova[1,2]*, O. Vaníček[1,2], K. Ständer[1,2], E. Kolářová[1,2] and R. Androvičová[2,3]

[1]Charles University; [2]Centre for sexual health and interventions, National Institute of Mental Health, Prague, Czech Republic and [3]Amsterdam Medical Centre, Amsterdam, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2215

Introduction: Numerous studies have highlighted the unmet needs in intimate and sexual relationships among patients with schizophrenia. Although research shows that patients with schizophrenia express a desire for romantic and sexual connections, they encounter difficulties in forming and sustaining these relationships. However, the underlying causes of deficits in sexual and romantic functioning remain unknown and unexplored.
Objectives: The study aims to assess whether difficulties in forming intimate relationships could be connected to a decreased ability to interpret courtship signals.
Methods: 49 male participants (36 patients, 13 controls) and 27 female participants (14 patients, 13 controls) were exposed to our experiment „Does she like me?" task. The task involves a video stimuli that depicts a woman/man displaying different nonverbal behaviors (rejection, courtship, and neutral attitude). Each participant evaluated the woman's sexual interest/ man's sexual interest on a nine-point scale. In addition, eye movements and pupil dilation were measured using the eye-tracking device Eyelink 1000plus. Patients and controls were compared on subjective report and psychophysiological eye tracking markers. For data analysis, we used Repeated measures ANOVA.
Results: There was no statistically significant difference between the control group and patients in their assessment of women´s interest ($F(2, 94) = 1.28$, $p = 0.28$, $\eta_p^2 = 0.03$) or men's interest ($F(2,50) = 0.24$, $p = 0.79$, $\eta_p^2 = 0.01$). Also, there was no difference in average pupil size. However, while both groups correctly identified the nonverbal cues and responded accordingly (with the greatest assessments of interest for positive stimuli, lesser for neutral stimuli, and the least for negative stimuli), male patients on average tended to overestimate women's interest in all conditions (positive, neutral, negative) compared to the control group.

Conclusions: According to our results, the ability to interpret courtship signals does not differ significantly between patients and controls. However, male patients tend to overestimate women's sexual interest on average, which may be one of the reasons why they face challenges in intimate relationships. Further research is needed to explore this.
The study was supported by the Czech Health Research Council, no. NU21J-04-00024 and by the Charles University, Fac Med1, GAUK no. 56123.

EPV1775

Antipsychotic treatment for epilepsy-related psychosis: hope from a newcomer

V. Ferreira Amador

PSYCHIATRY, CENTRO HOSPITALARIO PADRE MENNI, SANTANDER, Spain
doi: 10.1192/j.eurpsy.2025.2216

Introduction: Psychosis has long been known to have an association with epilepsy. Slater's 1963 descriptive case series provided the first modern definition of epilepsy-related psychosis, described as psychotic symptoms developing after the onset of epilepsy and occurring in clear consciousness, not exclusively during or right after a seizure. Up to 7% of individuals with epilepsy have a co-morbid psychotic illness. Consensus guidelines by the International League of Epilepsy recommend treating epilepsy-related psychosis similarly to other categories of psychosis. Despite the widespread consensus that the prescription of an antipsychotic is possible without risk in an epileptic patient treated with AEDs, there have always been special considerations about prescribing antipsychotics for seizure-related psychosis. Furthermore, a review article by Adachi et al. specifically warns that concerns regarding seizure threshold can lead to the undertreatment of this particular type of psychosis.
Objectives: Case report.
Methods: Case report.
Results: Case presentation: Our patient has generalized epilepsy, with several incomes due to generalized tonic-clonic seizure and mild diffuse encephalopathy since childhood. By the age of 15 years, he started developing suspicion, self-reference, persecutory and damage delusions, visual hallucinations and episodes of aggressiveness towards people surrounding him. He had been treated with multiple antiepileptics and antipsychotics drugs, without achieving a long-term stabilisation until now. While the seizures were controlled in his early ages; ever since the onset of the psychosis both the psychotic symptoms and the seizures got impossible to handle, mainly because of his lack of tolerance to almost every antipsychotic used. Our primary hypothesis is that these antipsychotics lowered the seizure threshold, triggering new episodes of tonic-clonic seizures and arousing the patient's desire of abandon the treatment -the latter has been confirmed by the patient-. At this point, we considered the recently released brexpiprazol as a potentially efficient treatment. After a proper explanation of our clinical reasons to prescribe this new drug, especially its unique pharmacodynamics, we adquired the patient's consent to start with it. So far, the response is being excellent, which is particularly impressive given the fact that he is taking the maximum daily dose of brexpiprazol (4mg). Not only the psychotic symptoms are restrained, but also he has not experienced any seizure since the introduction. As a key outcome, the patient has developed a significant insight regarding his condition and the need of treatment.
Conclusions: The treatment of epilepsy-related psychosis is a really delicate subject. Brexpiprazol is a modern drug, with an innovative pharmacodynamics and an excellent side-effect profile, and should be taken into consideration in every patient with seizure-related psychosis.

EPV1777

Case Report: A Rare Case Example Of Charles Bonnet Syndrome

S. Göktaş[1]*, F. Monshizadeh Tehrani[2], E. Ilgın[1,3] and A. Sakallı Kani[3]

[1]Department of Psychology, Yeditepe University, Istanbul, Türkiye; [2]Child and Adolescents Mental Health Center, Mental Health Services in the Capital Region of Denmark, Copenhagen, Denmark and [3]Department of Psychiatry, Marmara University, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2217

Introduction: Charles Bonnet syndrome, first described by Charles Bonnet in 1760, is characterized by visual hallucinations in cognitively normal patients who are typically elderly and often visually impaired.
Objectives: This case has been evaluated as a typical Charles Bonnet syndrome characterized by multisensory hallucinations (visual, auditory, olfactory hallucinations) observed in a patient with NF-2 diagnosis. In this respect, this case analysis might make an important contribution to the literature, as it might expand the understanding of CBS in the context of complex neurological disorders. Consideration must be put into the possibility of associating the patients' multisensory hallucinations with organic pathology due to the presence of occipital and temporal meningiomas.
Methods: In this section, data obtained from our own case will be included. Additionally, a literature review was conducted using PubMed, restricting the search to studies published between 2014 and 2024. The search term "Charles Bonnet Syndrome" was used to identify relevant articles. Furthermore, a detailed anamnesis of the disease process was obtained from the patient's mother.
Results: A 31-year-old female first presented to our psychiatry outpatient clinic in July 2024, with her relative reporting a diagnosis of neurofibromatosis type 2. It was documented that the patient underwent surgery in November for diffuse meningiomas (both supra- and infratentorial, involving the temporal and occipital regions). Also, the patient experienced total hearing loss due to vestibular schwannomas in the right region and suffered from visual loss during the pre-operating period. She reported a distressing increase in the acute perception of the smell and taste of food and beverages. Her first psychiatric examination was conducted postoperatively. Olanzapine 2.5mg/day was commenced as a treatment for relative auditory and olfactory hallucinations, and the dose of the drug was gradually increased to 10mg/day. The final examination was conducted on August 26, 2024. According to reports from the patient's relatives, there was a noted decrease in the frequency and intensity of the hallucinations. Throughout the medical examinations, communication with the patient was partially facilitated using tactile cues.

Conclusions: A typical Charles Bonnet syndrome is a disorder characterized by visual loss accompanied by visual hallucinations. In this case, olfactory, auditory and alpha-factor hallucinations that developed after visual and hearing loss were detected and resulted in the involvement of more than one sensory organ, shedding light on the current literature. In this case, the fact that the person already had neurofibromatosis type 2 disease further complicates the etiology of these symptoms and requires detailed follow-up and treatment.

Negative Symptoms of Schizophrenia: Contribution of IL-1β, IL-4, and IL-10 Gene Polymorphisms and Adverse Childhood Experiences

V. MIKHAILOVA[1], V. Golimbet[1]*, M. Alfimova[1], V. Plakunova[1] and T. Lezheiko[1]

[1]Clinical Genetics Laboratory, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2218

Introduction: Schizophrenia is a severe mental illness manifested by various symptoms. Negative symptoms (NS) are associated with disability and poor function of patients. The study of NS neurobiology is complicated by their heterogeneity. Factor analysis revealed two distinct NS subdomains with different pathophysiological mechanisms: volitional pathology, including avolition and apathy (AA), and diminished expression (DE). Inflammation is one mechanism that may underlie NS, including their heterogeneity.
Objectives: To investigate the differentiated associations between polymorphisms of interleukin genes IL-1β (rs16944), IL-4 (rs2243250), and IL-10 (rs1800872, rs1800896) and adverse childhood experiences (ACE) with NS of schizophrenia, specifically the factors of AA and DE. We hypothesize that genetic variants, which may aggravate the inflammatory response, are associated with higher NS and NS factors scores.
Methods: Data from 564 patients diagnosed with schizophrenia or schizoaffective disorder were included in the study. NS factors were calculated based on the Positive and Negative Syndromes Scale. The two-way ANOVA (sex, genotype) with Bonferroni post hoc test was used to examine the effect of the genotypes on the PANSS-derived NS subdomains.
Results: The high-expressive allele of IL-1β and low-expressive alleles of IL-4 and IL-10 are associated with more severe NS. However, a differentiated association with the AA and DE factors was found only for the IL-10 rs1800872 polymorphism. Among carriers of the low-expressive AA allele with ACE, there is a trend towards increased ED scores, but not AA scores.
Conclusions: The findings confirm that the imbalance between pro-inflammatory and anti-inflammatory cytokines may be a key mechanism influencing the severity and heterogeneity of NS.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2219

Introduction: The efficacy of yoga as an adjunctive treatment for schizophrenia spectrum disorders (SSD) has garnered interest, however, meta-analytic findings exhibit heterogeneity. While yoga may positively influence various symptom domains, further investigation is needed due to the limited number, quality, and generalizability of studies. Yoga-based Group Intervention (YoGI) was specifically developed together with persons with SSD through a participatory approach and its mechanisms and processes were explored within qualitative studies.
Objectives: This pre-registered randomized controlled trial (RCT) assessed the acceptability and feasibility as well as preliminary outcomes of YoGI compared to a commprehensive treatment as usual (TAU) in an inpatient setting.
Methods: Fifty inpatients with SSD received either treatment as usual (TAU, n = 25) or YoGI+TAU (n = 25) for four weeks. Preliminary analyses examined rater-blinded positive and negative symptoms, self-rated depressive and anxiety symptoms, body mindfulness, mindfulness, psychological flexibility, subjective cognition, social functioning, quality of life, and medication regime at baseline and post-intervention.
Results: Outcomes showed a 95% protocol adherence, feasibility and retention rates of 91% and 94%, respectively, and a dropout rate of 6%. ANCOVA revealed significant between-group post-intervention improvements for YoGI+TAU in positive symptoms, depression, cognitive fusion, and a mindfulness subscale. Medium-to-large pre-to-post intervention effects were found for body-mindfulness, positive, negative, and general symptomatology, depression, anxiety, stress, cognitive fusion, attention, and quality of life in YoGI+TAU, while within-group changes were consistently smaller in TAU. No severe adverse events were reported.
Conclusions: This trial contributes to the growing evidence supporting the feasibility and acceptability of yoga for persons with SSD in an inpatient setting. Furthermore, preliminary evidence suggests that YoGI may provide additional benefits beyond TAU alone, across various self- and rater-based outcomes. These outcomes include improvements in body mindfulness, mindfulness, and psychiatric symptomatology, including positive and negative symptoms, subjective cognition, depression, anxiety, stress, social functioning, and quality of life. Additional fully powered RCTs are warranted to further elucidate the efficacy and potential mechanisms of action of YoGI for SSD, which should also assess the cost-efficiency of YoGI and explore longitudinal changes associated with the intervention. Such comprehensive research endeavours will not only enhance our understanding of the therapeutic potential of YoGI but also inform clinical practice and intervention strategies for persons with SSD.

Vortioxetine as an Adjunctive Treatment in Schizophrenia: A Systematic Review of Effects on Quality of Life, Anhedonia, Cognitive Function, and Symptom Domains

D. F. Holanda[1]*, F. R. de Lima[2], B. S. Pinto[1], T. N. Vianez[3], J. H. P. Raid[1] and E. C. Barbosa[4]

[1]Medicine, Federal University of Amazonas, Manaus; [2]Independent practice, São Paulo; [3]Neurology, Federal University of Amazonas, Manaus and [4]Medicine, Evangelical University of Goiás, Anapolis, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2220

Introduction: Schizophrenia is a severe psychiatric disorder characterized by disturbances in perception, thinking, affect, behavior, and negative symptoms. Depression in patients with schizophrenia worsens disease outcomes by increasing suicide risk, complicating the clinical picture, and reducing social functioning quality. Treatment is challenging, as monotherapy with modern antipsychotics is not always successful. Adding antidepressants may improve outcomes, but the effectiveness of such augmentation often requires further evidence.
Objectives: This study aimed to examine the effects of combining second-generation antipsychotics (SGA) with vortioxetine, a novel multimodal serotonergic antidepressant, on various aspects, including quality of life, anhedonia, cognitive function, and overall symptom improvement in schizophrenia patients.
Methods: We conducted a comprehensive search of PubMed, Embase, Cochrane and Web of Science databases up to September 2024 for studies using Vortioxetine with standard treatments for schizophrenia.
Results: We screened 371 studies and our review included six studies gathering 508 patients. Study type, sample sizes, and follow-up time varied across studies (Figure 1). All studies involved adding Vortioxetine to existing antipsychotic treatments, with dosages ranging from 5-20 mg/day. Study durations varied from eight to 48 weeks. Common scales across multiple studies included: PANSS (Positive and Negative Syndrome Scale), WHOQOL-BREF (World Health Organization Quality of Life Assessment), CDSS (Calgary Depression Scale for Schizophrenia), and various cognitive function tests (e.g., WCST, Verbal Fluency Test, Stroop Task). Overall, the studies reported positive effects of vortioxetine in schizophrenia patients (Figure 2): Improved quality of life, Reduced anhedonia, Enhanced cognitive function, Improved depressive symptoms, Reduced negative symptoms. Most studies reported good tolerability of vortioxetine with minimal side effects.
Image 1:

Study	Study design	Sample	Therapy (additionally to SGA)	Follow-up
Bruno et al. 2020	Non-randomized open-label clinical trial	20 patients with schizophrenia and comorbid depression	Vortioxetine 10 mg/d until 12th week; 20 mg/d from 12th to 24th week	24 weeks
Gres et al. 2024 a	Randomized controlled trial	120 stable patients with schizophrenia	Vortioxetine 10 mg/d, compared to placebo	12 weeks
Gres et al. 2024 b	Randomized controlled trial	120 patients with schizophrenia in remission	Vortioxetine 10 mg/d, compared to placebo	12 weeks
Kotzalidis et al. 2021	Prospective cohort	30 patients with schizophrenia	Vortioxetine 5-20 mg/day compared with other antidepressants	12 weeks
Moazen-Zadeh et al. 2020	Randomized controlled trial	78 patients with schizophrenia and predominant negative symptoms	Vortioxetine 10 mg 12/12h compared to placebo	8 weeks
Redaelli et al. 2022	Retrospective cohort	40 patients with schizophrenia or schizoaffective disorder	Vortioxetine 5-20 mg/d	48 weeks
Reznik et al. 2023	Case-control	78 patients with schizophrenia and depression	Vortioxetine 5-20 mg/d, compared to SGA alone	25 weeks

Figure 1 - Basic characteristics of the included studies

Image 2:

Study	Summary of Results
Bruno et al. 2020	Vortioxetine supplementation significantly improved Stroop test (P = 0.031) and Semantic Fluency (P = 0.002) at the end point. Moreover, a significantly reduction of PANSS domains "positive" (P = 0.019) at week 12 and of PANSS domains positive (P = 0.019) and total score (P = 0.041) and of depressive symptoms (Calgary Depression Scale for Schizophrenia, P = 0.032) at end point.
Gres et al. 2024 a	There is a statistically significant effect of treatment with vortioxetine in General quality of life (F=32.333 , p <, 001). The main effect of vortioxetine treatment is low to moderate (η 2 = .234).
Gres et al. 2024 b	Significant effect on physical anhedonia with a relatively small effect (F = 3.17, p < 0.05; η^2 = 0.061) and had a particularly strong effect on the level of social anhedonia (F = 5.04, p < 0.01; η^2 = 0.091).
Kotzalidis et al. 2021	Patients on vortioxetine improved similarly to those on other antidepressants on all measures. Significant improvements in cognitive function tests (p < 0.05); improvement in negative symptoms.
Moazen-Zadeh et al. 2020	Significant improvements in PANSS negative subscale (p < 0.001, Cohen's d = 0.97) and total scores (p <0.001; Cohen's d = 0.95)
Redaelli et al. 2022	At CGI-S assessment, 15 of the 35 evaluated subjects reported at least a 1-point improvement, from 5 at baseline to 4 after 3 months of treatment. Due to the sample size, we could not evaluate the impact of vortioxetine dose or the effect of specific antipsychotics on the effectiveness of the combination.
Reznik et al. 2023	There were significant differences between the SGA + vortioxetine and SGA groups in terms of the mean CDSS (p < 0.001), NSA-5 (p=0.003), PDQ-20 (p < .001), and PSP (p=0.004) scores after 3 months

Figure 2 - Summary of Results of the included studies

Conclusions: The findings suggest that Vortioxetine may be a promising adjunctive treatment for schizophrenia, potentially improving various domains including quality of life, cognitive function, negative symptoms, and depressive symptoms. However, larger and more robust studies are needed to confirm these findings.

What does Kombucha Tea Improve the Stool Passage in Patients with Schizophrenia? A Preliminary Results of A Randomized, Double-blind Placebo-controlled Clinical Study

A.-Y. Hong[1]*, Y.-J. Shih[2,3] and Y.-J. Yang[1]

[1]Department of General Psychiatry; [2]Department of Nursing, Tsao-Tun Psychiatric Center, Nantou county and [3]Department of Healthcare Administration, Asia University, Taichung, Taiwan, Province of China
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2221

Introduction: Patients with schizophrenia frequently have difficulties in defecation which may lead to adverse health consequences. Many interventions have been proposed to resolve the problems but not usually effective. Kombucha tea has been advocated for their effects on gut microbiota and thought to improve the stool passage in healthy population. However, the relevant evidence was insufficient in patients with schizophrenia. In this study, the research team tried to evaluate the effectiveness of Kombucha tea in the clinical settings.
Objectives: This study aimed to evaluate both subjective and objective amelioration of stool passage in constipated patients with schizophrenia.
Methods: Schizophrenic inpatients who took laxative medications or had subjective difficulties in stool passage were eligible for the study. The protocol was approved by the IRB of Tsao-Tun Psychiatric Center and registered on the trial registry of Clinicaltrial.gov. After obtaining consents and initial screening, the recruited participants were randomly allocated into either the control or intervention groups. Participants in the control group were provided

with flavored lemon tea while those in the intervention group drank commercial Kombucha tea. Every morning during 8-week period, participants in both groups were provided with the drinks bottled in opaque plastic bottles filled with the same volume (200ml) and similar taste.
The multidisciplinary team collected the demographic profiles, clinical details, kinesiological data, cognitive condition (measured with the MoCA) and psychiatric status (measured with the BPRS). The outcome data were collected through interview and medical record review by the researchers independent from allocation of the groups, and were computed with the statistical software JASP with the statistical significance at the 5% level ($p<0.05$).
Results: 79 schizophrenic patients were enrolled in the study, and the key data were illustrated at the attached Table. All the variables at the baseline showed no statistical significance between groups. In terms of the outcomes, the means of objective measurement of stool passage showed no statistical significance between groups. In contrast, the subjective measurement showed the ease of defecation difficulties, trending towards 'smoother and easier defecation' ($p<0.05$).
Image 1:

Table: Baseline demographic variables

Variable	*Controlled group (N=39)*	*Intervention group (N=40)*	*p-value*
Sex (F/M)	19/20	21/19	p=1.000
Age	53.82±9.72	51.75±9.42	p=0.339
BMI	21.29±2.65	21.33±3.39	p=0.955
Education years	11.08±2.61	10.60±2.51	p=0.410
Disease years	31.56±8.45	29.75±8.89	p=0.356
BPRS	32.05±9.58	33.55±10.63	p=0.513
MoCA	19.59±7.59	17.70±7.05	p=0.255

Continuous variables are illustrated with mean±SD

Conclusions: Our preliminary analyses indicated that Kombucha tea improved the subjective outcome of stool passage in schizophrenic patients with constipations after taking Kombucha tea drinks while no statistical significance was observed in the objective measurements. To the best of our knowledge, this study is one of the very few studies exploring the effectiveness of Kombucha tea in ameliorating difficulties in stool passage in the patients with schizophrenia and it shed the light of future research.

Unmet financial needs of people with psychosis - a cohort study of people with psychosis, parents, siblings, and controls

J. L. Jansen[1]*, J. Hao[2], R. Bruggeman[1,3], G. Investigators[4,5], J. Koerts[1] and L. Krabbendam[6]

[1]Department of Clinical and Developmental Neuropsychology, University of Groningen; [2]Department of Epidemiology; [3]University Center for Psychiatry, University Medical Center Groningen, Groningen; [4]Department of psychiatry, Amsterdam University Medical Center; [5]Institute for mental health, Arkin and [6]Department of Clinical, Neuro- and Developmental Psychology, Vrije Universiteit Amsterdam, Amsterdam, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2222

Introduction: Psychotic disorders have a negative impact on people's lives, including their financial situation. Limited studies indicate that people with psychosis also have lower subjective evaluations of their financial situation, such as perceived financial needs.
Objectives: This study aimed 1) to examine differences in unmet financial needs between people with psychosis, parents, siblings, and controls, 2) to examine whether family clustering contributes to unmet financial needs, and 3) to examine to what extent substance use, demographic, economic, psychiatric, functional, and cognitive characteristics predict unmet financial needs in people with psychosis.
Methods: Data of the first assessment of people with psychosis (n=956), siblings (n=889), parents (n=858), and controls (n=496) of the Genetic Risk and Outcome of Psychosis study were used. Group differences were assessed with Kruskal-Wallis tests (aim 1). We performed mixed-effect logistic regression analysis and explorative and confirmative ordinal logistic regression analyses for aim 2 and 3, respectively.
Results: People with psychosis reported significantly higher levels of unmet financial need (24%) compared to siblings, parents, and controls (all <10%; table 1). We found no evidence of familial clustering in unmet financial needs. Cannabis and tobacco use significantly and consistently predicted higher levels of unmet financial needs in people with psychosis. Demographic, economic, psychiatric, functional, and cognitive characteristics were no significant predictors.

Table 1. Levels of meeting financial needs of people with psychosis, siblings, parents, and controls.

	People with psychosis (n=956)	Siblings (n=889)	Parents (n=858)	Controls (n=496)
Mean (Standard Deviation)	3.2 (1.2)	3.8 (1.0)	4.0 (0.9)	3.9 (.9)
Not at all, % (n)	7.4 (71)	1.5 (13)	1.3 (11)	1.2 (6)
Almost not, % (n)	16.6 (159)	6.9 (61)	2.8 (24)	6.7 (33)
Unmet financial needs total, % (n)	24.1 (230)	8.3 (74)	4.1 (35)	7.9 (39)
Average, % (n)	36.9 (353)	29.7 (264)	26.0 (223)	25.8 (128)
Considerable, % (n)	23.6 (226)	35.2 (313)	33.0 (283)	38.3 (190)
Completely, % (n)	15.4 (147)	26.8 (238)	36.9 (317)	28.0 (139)

Conclusions: Relatively high levels of unmet financial needs occur in a heterogeneous group of people with psychosis, especially when they use cannabis or tobacco. Unmet financial needs can have serious consequences for mental health, leisure time, and social activities. Thus, it is pivotal to recognize unmet financial needs, especially combined with substance use, as a stressor for people with psychosis.

Impact of cannabis decriminalization on selected psychotic disorders: a retrospective analysis at "Center for Mental Health and Prevention of Addiction" (2013-2023) in Tbilisi

N. Jibuti[1]*, L. Jishkariani[1], K. Jmukhadze[1], K. Gigolashvili[2], D. Zurabashvili[3] and G. Lejava[4]

[1]Tbilisi State Medical University; [2]Tbilisi Center for Mental Health and Prevention of Addiction; [3]Tbilisi Center for Mental Health and Prevention of Addiction and [4]Scientific-Expert Council on Psychiatry and Narcology, Tbilisi Center for Mental Health and Prevention of Addiction, Tbilisi, Georgia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2223

Introduction: Correlation between cannabis decriminalization and some psychotic disorders, specifically Acute and transient psychotic disorders (ATPD), Schizophrenia, and Psychotic disorder with delusions due to known physiological condition. It will cover overview of these disorders, challenges in differential diagnoses and the effects of drug abuse on mental health.
Objectives: Impact of cannabis decriminalization on selected psychotic disorders: Acute and transient psychotic disorders (ATPD), Schizophrenia, and Psychotic disorder with delusions due to known physiological condition.
Methods:
- **Quantitative, Retrospective Analysis:** Analysis of archived medical records from 2013 to 2023 at "Center for Mental Health and Prevention of Addiction" in Tbilisi.
- **Examination of Prevalence Changes:** Focus on ATPD, Schizophrenia, and Psychotic Disorder with Delusions due to Known Physiological Condition.
- **Statistical Comparisons:** Comparison between pre-decriminalization (2013-2018) and post-decriminalization (2019-2023) periods.
- **Analysis of Drug User Patient Cases:** Assessment of the increase in drug user cases within the mentioned diagnoses.

Results:
- **ATPD Cases:** Increased significantly by threefold (from 195 to 594).
- **Schizophrenia Cases:** Decreased slightly by 21% (from 2068 to 1627).
- **Psychotic Disorder with Delusions due to Known Physiological Condition:** Remained relatively stable with a 14% decrease (from 473 to 408).
- **Drug User Patients:** Increased dramatically by about 3.5 times following cannabis decriminalization.

Conclusions:
- The findings suggest a potential link between increased substance use, including cannabis, and the rise in ATPD cases.
- Decriminalization may have indirectly influenced accessibility and use of various narcotics.
- The lack of public education about the potential mental health risks of narcotic use could be a contributing factor.
- The observed decrease in Schizophrenia and Psychotic Disorder with Delusions due to Known Physiological Condition cases might be due to other factors requiring further investigation.
- These findings highlight the need for comprehensive research on the long-term consequences of cannabis decriminalization on mental health.
- Targeted public health interventions and mental health support services are crucial to address the challenges of rising narcotic use in Georgia.

Disclosure of Interest: None Declared

EPV1786

Anti NMDA receptor encephalitis manifested as acute psychosis- case report

M. Kasjaniuk[1]* and M. Urban-Kowalczyk[1,2]

[1]Central Teaching Hospital of the Medical University and [2]Department of Affective and Psychotic Disorders, Medical University , Łódź, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2224

Introduction: The rapid change a variety of the clinical picture in case of autoimmune encephalitis remain a diagnostic challenge.
Objectives: Diagnostics and therapeutic process as of the atypical psychosis.
Methods: A 40-year-old woman, since 2 weeks she expressed catastrophic delusions and dysphoria. Next she revealed tinnitus, psychosensory disturbances, disorganization of thinking and behavior and the first grand mal seizure occurred. In the neurology ward were described psychogenic disorders and she was referred to the psychiatric ward, where catatonic schizophrenia was diagnosed. She was disoriented, with periodic episodes of arousal and freezing, negativism and command automatism. She was hallucinating visually, auditorily, olfactorily, and cenesthetically, expressed delusions of catastrophe, influence, and persecution. Despite modifications of treatment (aripiprazole, haloperidol, olanzapine, quetiapine, clozapine, valproate) she didn't improve. In the 4th week of hospitalization, an episode of fever of unknown etiology occurred and she was transferred to a higher referral psychiatric ward. Next fluctuating disturbances of consciousness, myoclonus, bilateral palmomental and Babinski's sign and swallowing disorders were observed. Due to the lack of therapeutic effect tiapride was administer with slight improvement.
Results: Laboratory tests: CRP, VDRL, anti-HIV antibodies - absent, ceruloplasmin, ANA, anti-TPO, anti-TSHR antibodies, tumor markers – normal range.
No changes in contrast-enhanced MRI head. In EEG moderate-grade, extensive changes in the fronto-central and frontotemporal leads bilateral.
CSF examination – normal range, negative result for 14-3–3 protein
In a panel for antibodies typical of autoimmune encephalitis - presence of anti-NMDA antibodies. Then autoimmune encephalitis was diagnosed. She was initially treated with immunoglobulins, with slight effects. Subsequently, effective immunosuppressive treatment with mycophenolate mofetil and methylprednisolone was administered. Further, the psychosis resolved, with the normalization of the neurological signs. The patient's in stable mental and somatic condition was discharged without further psychopharmacology.

Image 1:

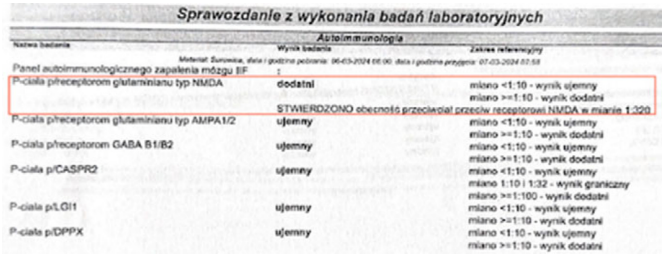

Image 2:

Conclusions: In anti NMDA receptor encephalitis affective symptoms, psychosis, catatonia, consciousness disorders, as well as neurological symptoms occurred. In majority of cases no changes are observed in brain imaging. EEG examination shows non-specific changes in 90% of cases. About 80% of patients recover without functional impairment, but in 7% disease is lethal. Crucial is to determine the etiology of atypical symptoms in order to implement adequate therapy as soon as possible.

Disclosure of Interest: None Declared

EPV1787

The Relationship Between Metabolic Syndrome and Psychological Resilience in Schizophrenia Patients in Remission

Ö. Kaya Tuncel[1]*, D. İpekçioğlu[2] and S. Uysal Atasoy[2]

[1]Psychiatry, Republic of Turkey Ministry of Health Ordu State Hospital, Ordu and [2]Psychiatry, Bakırköy Mazhar Osman Mental Health and Neurological Diseases Education and Research Hospital, İstanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2225

Introduction: Comprehending metabolic syndrome (MetS) risk factors in schizophrenia patients is pivotal for devising effective treatment strategies.
Objectives: This study aims to explore the relationship between MetS and psychological resilience in schizophrenia patients.
Methods: A total of 140 schizophrenia patients with no hospital admissions or treatment changes in the last 6 months were enrolled in the study. For metabolic syndrome screening, patients' blood pressure, height, weight, waist circumference, and hip circumference measurements were taken; these data, along with blood lipid levels and fasting glucose, were recorded on the sociodemographic and clinical data form. Patients were categorized into two groups based on the presence or absence of MetS. The Positive and Negative Syndrome Scale (PANSS) and the Resilience Scale for Adults were applied cross-sectionally.
Results: MetS was identified in 33.6% of the included patients, with 88.6% exhibiting abdominal obesity. There were no statistically significant differences between groups in terms of gender, marital status, education level, employment status, type of antipsychotic, and use of single or multiple antipsychotics. In the MetS group, PANSS negative symptom scores were significantly higher. No significant differences were observed in psychological resilience between the groups.
Image 1:

Table 1. Comparison of PANSS scores between metabolic and non-metabolic groups

n=140	Non MetS (n=93)		MetS (n=47)			
	Avg	Sd	Avg	Sd	t-value	p-value
PANSS positive symptoms scores	7,89	1,77	7,89	1,52	t=0,004	p=0,997
PANSS negative symptoms scores	9,69	3,18	11,02	4,18	**t=2,100**	**p=0,038**
PANSS general psychopathology scores	18,87	3,02	19,30	3,74	t=0,728	p=0,468

Avg=Average, SS=Standart Deviation , t= t test, Z=Mann Whitney U test
PANSS: Positive and negative syndrome scale, MetS: Metabolic syndoreme, p<0,05

Conclusions: The demonstration of the relationship between the presence of MetS and the severity of negative symptoms is one of the significant outcomes of our study. These outcomes may contribute to formulating personalized treatment approaches.

Disclosure of Interest: None Declared

EPV1788

The interaction between cognitive biases, intolerance of uncertainty and anxiety sensitivity in schizophrenia spectrum disorder

I. Keleş Altun[1]*, S. A. Korkmaz[2], I. Açar Duran[2] and M. I. Atagün[2]

[1]Department of Psychiatry, University of Health Sciences Bursa Yüksek İhtisas Training and Research Hospital, Bursa and [2]Department of Psychiatry, Çanakkale Onsekiz Mart University, Çanakkale, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2226

Introduction: The cognitive model of psychosis suggests that psychotic symptoms may arise due to biases in information processing. Cognitive biases such as jumping to conclusions (JTC), belief inflexibility (BI), selective attention to threat (AT), and external attribution (EA) are dysfunctional ways of thinking in which distortions are observed in data collection, processing and interpretation. Cognitive biases are known to be associated with the occurrence of positive psychotic symptoms, but evidence for the influence of other cognitive processes on this relationship remains lacking.
Objectives: This study aimed to examine the relationship between cognitive biases and psychotic symptoms in schizophrenia spectrum

disorders and the cognitive factors hypothesized to influence this relationship, such as intolerance of uncertainty and insight.
Methods: 65 patients with schizophrenia spectrum disorder were included. Sociodemographic data form, Davos Assessment of Cognitive Biases Scale (DACOBS), Intolerance of Uncertainty Scale (IUS) Anxiety Sensitivity Index-3 (ASI-3), and Beck Cognitive Insight Scale (BCIS) Positive and Negative Syndrome Scale (PANSS) and Beck Anxiety Inventory were applied. Ethics committee approval was obtained (no: 2023-40). Statistical analysis was performed with SPSS 25.
Results: The mean age of the participants was 39.27 ± 12.21 years. 63.1% were male (n: 41) and 36.9% (n: 24) were female. Disease duration was 16.95 ± 12.80 years. Hierarchical regression analysis determined that PANNS positive scores were predicted by DACOBS external attribution subscale and IUS, ASI-3 and BCIS scores had a moderator effect (F: 3.51 p<0.001).
Conclusions: Our results showed that external attribution bias is the only cognitive bias associated with positive psychotic symptoms. Intolerance of uncertainty and anxiety sensitivity also play a role in the prediction of positive psychotic symptoms. Targeting intolerance of uncertainty and anxiety sensitivity with cognitive interventions may be useful in the treatment of positive psychotic symptoms in schizophrenia spectrum disorders.

EPV1790

Development of addiction to nicotine with patients suffering from schizophrenia

M. Wadoń[1] and K. Krysta[1]*
[1]Department of Rehabilitaction Psychiatry, Medical University of Silesia, Katowice, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2227

Introduction: Symptoms of schizophrenia are associated with dysregulation of the dopaminergic systems of the central nervous system. Negative symptoms, including those related to emotions and mood, result from reduced activity in the mesocortical system, while positive symptoms result from increased activity of the mesolimbic system. Disorders in the reward system, composed of dopaminergic neurons, play an important role in the pathogenesis of addiction development. Nicotine activates the presynaptic parts of the neurons that make up the system to secrete dopamine, which translates into a feeling of pleasure and stimulates the development of addiction.
Objectives: The aim of the study was to demonstrate the relationship between the degree of development of nicotine and the severity of symptoms related to emotions and mood with patients suffering from schizophrenia.
Methods: The study involved 75 patients diagnosed with schizophrenia (F.20 according to ICD-10). The study was conducted from October 2023 to September 2024 in CZPiLU in Gliwice. During the study, the Frankfurter-Bejindlichkeits-Skala was used to assess the appearance and severity of symptoms related to emotions and mood. The analysis of the development of addiction was made possible by the Fagerström Test for Nicotine Dependence.
Results: Based on statistical analysis, a significant relationship was noted between the severity of addiction to nicotine and the presence or absence of symptoms related to well-being. In addition, a correlation (p<0,001) was noted between the degree of nicotine and the severity of symptoms related to emotions and mood. Patients with strong negative symptoms of schizophrenia developed a high level of addiction to nicotine (p=0,001), while those with mild (p=0,001) or moderate symptoms (p=0,005) related to well-being achieved lower scores on individual addiction scales. All patients included in the study had at least a mild level of addiction to nicotine.
Conclusions: The presence of schizophrenia symptoms related to well-being has a significant impact on the initiation of addiction development to nicotine. Furthermore, the level of advancement of symptoms related to emotions and mood translates into the severity of nicotine, especially in the group of patients in whom strong negative symptoms translate into a high level of addiction advancement. Patients suffering from schizophrenia require psychological and psychiatric care and diagnostics for addictions and appropriate prevention before their development.

Disclosure of Interest: None Declared

EPV1791

Assessing the Relationship Between Schizophrenia Symptom Severity and Insight Using the Frankfurt Complaint Scale (FBS) and "My thoughts and feelings" Questionnaire

W. Chojna[1], S. Rusinek[1], M. Laskowska[1], M. Bezeg[1], D. Piłat[1] and K. Krysta[1]*
[1]Department of Rehabilitation Psychiatry, Medical University of Silesia, Katowice, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2228

Introduction: Schizophrenia remains a complex psychiatric disorder characterized by varying symptoms and levels of insight. The Frankfurt Complaint Scale (FBS) and the "My thoughts and feelings" questionnaire provide quantitative measures of symptom severity and insight, respectively. Previous literature has emphasized the importance of these tools in both clinical assessment and therapeutic planning.
Objectives: Exploring the Relationship Between Schizophrenia Symptom Severity and Insight based on the Frankfurt Scale and the "My thoughts and feelings" Questionnaire.
Methods: The study utilized data extracted from an Excel dataset comprising demographic information and specific scores from the FBS and the Insight questionnaire. The sample was divided into four subgroups based on their FBS scores, and the average Insight score for each subgroup was calculated.
Results: The study found the following average Insight scores across FBS-defined subgroups: Mild symptoms: 9.67, Moderate symptoms: 8.25, Severe symptoms: 8.22, Very severe symptoms: 9.29. The correlation analysis revealed a weak and non-significant correlation between FBS scores and Insight scores (r = -0.017, p = 0.925). The demographic analysis showed a prevalence of male patients (n=20), with the most common age group being 36-45 (n=11). Most participants resided in large cities (n=16), with the highest educational attainment being a Bachelor's/Master's degree (n=12), and the majority were single (n=21). The study group displayed diverse demographic characteristics,
with a significant male predominance and a concentration in urban environments. This demographic distribution may influence the generalizability of the findings and provides a context for interpreting the varied experiences and perceptions of illness within the group.
Conclusions: This study underscores the complexity of schizophrenia, where symptom severity does not straightforwardly correlate with insight into the illness. It highlights the importance of

using a range of assessment tools to fully capture the multifaceted nature of patient experiences. Future studies should explore these relationships further to refine the tools used for assessments and to tailor intervention strategies effectively.

EPV1792

the relationship between childhood sexual abuse and the developement of schizophrenia, ptsd and substance abuse among men through life

M. Kupchik[1]*, S. mustafa[1] and N. SINAI[1]

[1]MERHAVIM MENTAL HEALTH CENTER BEER YAAKOV-NESS ZIONA, NESS ZIONA, Israel
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2229

Introduction: Background and aims: There is a lack of research regarding the topic of childhood sexual abuse trauma on men population. Childhood experiences and traumas can have a great impact on various life domains, including mental state and addictions.
This study examines the impact of childhood sexual abuse on men diagnosed with schizophrenia – regarding the age of the disease's appearance, the appearance of additional PTSD diagnosis and substance use throughout life.
Objectives: This study can contribute to the development of more effective treatment and prevention strategies for men who have experienced childhood sexual abuse and are diagnosed with schizophrenia.
Methods: Participants: 60 Male patients hospitalized in the closed wards for men, aged 18-50 at 'Merhavim' - Mental Health Center. Data Collection: A one-time meeting with the research team, which included completing several questionnaires regarding their current state and childhood experiences.
Results: The influence of childhood sexual abuse was significant in all subjects we examined. Patients of suffered from sexual abuse in their childhood were more likely to develop PTSD or develop schizophrenia at a much younger age. Also, they were more likely to suffer from substance abuse throughout their life.
Conclusions:
- Childhood sexual abuse has a significant impact on the onset of schizophrenia symptoms (age of first hospitalization), PTSD symptoms and substance abuse throughout life.
- Traumatic childhood experiences have a significant impact on mental symptoms that appear in adulthood as well as on various behaviors throughout life.

Inverse dose-dependent effects of aripiprazole on sexual dysfunction and prolactin levels in patients with schizophrenia

M.-L. Lu[1]* and K. K. Goh[1]

[1]Department of Psychiatry, Taipei Medical University-Wan Fang Hospital, Taipei, Taiwan, Province of China
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2230

Introduction: Aripiprazole, a novel antipsychotic drug with partial agonist activity at dopamine D_2 and serotonin 5-HT_{1A} receptors, as well as antagonist activity at 5-HT_{2A} receptor, has demonstrated fewer side effects, including extrapyramidal symptoms, hyperprolactinemia, and metabolic disturbances, compared to other antipsychotic drugs.
Objectives: The aim of this study was to examine the dose-dependent impact of aripiprazole on sexual dysfunction and prolactin levels in patients with schizophrenia. Patients with schizophrenia under aripiprazole monotherapy were recruited into this study.
Methods: Patients with schizophrenia under aripiprazole monotherapy were recruited into this study. Psychopathology and sexual dysfunction were evaluated using the Positive and Negative Syndrome Scale and the Arizona Sexual Experiences Scale (ASEX), respectively. Fasting blood samples were analyzed to measure metabolic parameters and prolactin levels.
Results: We recruited 128 patients with schizophrenia, comprising 86 females and 42 males. The prevalence of hyperprolactinemia, hypoprolactinemia, sexual dysfunction, and metabolic syndrome was 12.5%, 47.6%, 39.1%, and 36.7%, respectively. Patients with sexual dysfunction exhibited higher prolactin levels and a higher prevalence of hyperprolactinemia compared to those without sexual dysfunction. The ASEX scores showed a positive correlation with prolactin levels and a negative correlation with aripiprazole dose. Multivariate analysis revealed that prolactin levels and age were associated with ASEX scores. Prolactin levels were negatively correlated with aripiprazole dose and metabolic parameters. Multivariate regression analysis indicated that aripiprazole dose was associated with prolactin levels.
Conclusions: Aripiprazole exhibited inverse dose-dependent effects on prolactin levels and ASEX scores in patients with schizophrenia. Regular monitoring of prolactin levels and sexual function is recommended for patients with schizophrenia receiving aripiprazole treatment.

EPV1795

High risk of psychosis, condition or diagnosis? About a case

M. L. Maria Del Carmen[1]

[1]Psychiatric, Hospital General Universitario Gregorio Marañon, Madrid, Spain
doi: 10.1192/j.eurpsy.2025.2231

Introduction: A person with "high-risk mental status (HRMS)" indicates that the person, usually young people between the ages of 14 and 25, is more likely to develop psychosis. These people have attenuated psychotic symptoms without reaching the intensity or frequency of a frank psychotic episode. It is suggested that psychological trauma could favor neurochemical and psychopathological changes in a vulnerable individual. It would be interesting to study the role of psychotherapeutic interventions in the course of high-risk mental states and their possible evolution to a psychotic disorder.
We present the case of an 18-year-old adolescent whose diagnosis was high risk of psychosis.
Objectives: This work has several objectives. On the one hand review current information on high-risk mental status (EMAR). On the other hand, develop a discussion about whether the EMAR category should be a diagnostic entity or just a condition.
Methods: A bibliographic search has been carried out in the main sources of medical information such as Pubmed, Uptodate as well

as in national and international journals. Likewise, the knowledge and clinical experience of the team has been reviewed in order to expose its own experience in this field, defining specific interventions as well as results.
Results: The case presented is of an 18-year-old female patient. She states that the main reason for consultation is something that happened last Sunday, at which time he had "an identity crisis" in which he did not know if he was a girl or a boy. The reasoning behind this fact is that "as Pablo Alborán likes him, perhaps he is a boy". Given the bizarreness of the explanation and the patient's particular contact, I explore a previous psychopathological situation. She says that since last year she feels more insecure, with diffuse fear that it is difficult to specify or nominate something specific: "in class and that is very difficult for me, public presentations", she says that "everything scares me", she says that she has a non-specific fear that has been maintained even increasing over the months and that has led him to have greater anguish. Even though the patient dates the beginning of the picture on Sunday, it is noteworthy that the previous Thursday she had requested a consultation with psychology in the private circuit that although she does not know how to specify the reason "because of fears" it seems that the anguish resulting from this fear had been increasing, having greater difficulties for the presentations in class. The contact is psychotic and the situation that the patient describes is typical of a "treme" situation, cataloged in the current literature as a High-Risk Mental State.
Conclusions: High-risk mental states are not a diagnostic category according to current classifications, although it is necessary to reach a consensus on what the diagnosis implies and what would be the way to proceed when a patient presents these symptoms.

Group weight management program for people with schizophrenia or bipolar disorder: an Italian experience

V. Martiadis[1]*, F. Raffone[1], E. Pessina[2], E. Favaretto[3], A. Martini[2], P. Matera[4] and C. I. Cattaneo[4]

[1]Department of Mental Health, Asl Napoli 1 Centro, Naples; [2]Department of Mental Health, Asl Cuneo 2, Bra; [3]Department of Addiction, South Tyrol Health Care, Bressanone and [4]Department of Mental Health, Asl Biella, Biella, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2232

Introduction: Obesity and weight gain are major clinical problems for people with severe mental illness (SMI), such as schizophrenia and bipolar disorder. While psychopharmacological treatment, particularly with atypical antipsychotics and mood stabilisers, is the 'core' of treatment for these disorders, it can increase the risk of overweight/obesity, metabolic and cardiovascular disease. Most guidelines on how to manage overweight and obesity in these patients share an initial conservative approach. These guidelines include diet, physical activity, lifestyle coaching and behaviour modification. Only then are pharmacological or, eventually, surgical treatments added.
Objectives: This study evaluated the effectiveness of a group behavioural weight management program in a real Italian outpatient setting.
Methods: 100 patients diagnosed with schizophrenia or bipolar disorder who participated in a group weight management program were followed up for 12 months. The intervention consisted of 8-week training in which patients received nutritional and lifestyle coaching in groups of 10. Weight, BMI, waist circumference, blood glucose and blood pressure were measured at 0, 6 and 12 months.
Results: Mean body weight (kg) decreased from 98.01±18.30 at baseline to 93.29±17.36 at 6 months ($p>0.001$) and to 90.35 ±17.90 at 12 months. There were also statistically significant reductions in BMI, waist circumference, blood glucose and systolic blood pressure. There was no significant reduction in diastolic blood pressure. After segmenting the patients at baseline according to their initial body weight (normal weight, overweight and obese according to the World Health Organisation), a statistically significant difference in weight only occurred between baseline and the first 6 months of follow-up, suggesting that the programme was successful in the short term and that the results were maintained over the following 6 months.
Conclusions: Despite the study's limitations, the intervention demonstrated feasibility in an outpatient setting, a high retention rate with no drop-outs during the programme, and significant weight loss in the first six months, followed by long-term maintenance at the end of the study. Current NICE recommendations suggest that people with SMI, particularly those receiving antipsychotic treatment, should receive integrated diet and exercise programmes. Future research should focus on the cost-effectiveness of this type of intervention and its reliability in the medium and long-term in different health care settings.

Depression in psychosis: where does it come from?

M. A. Andreo Vidal[1], M. Calvo Valcárcel[1], M. P. Pando Fernández[1], P. M. Gimeno[1], M. Fernández Lozano[1], B. Rodríguez Rodríguez[1], N. Navarro Barriga[1], M. J. Mateos Sexmero[1], A. Monllor Lazarraga[1], L. Rojas Vázquez[1], G. Lorenzo Chapatte[1], M. Ríos Vazquero[1], F. J. González Zapatero[1], L. del Canto Martínez[1], C. Rodríguez Valbuena[1] and O. Martin Santiago[1]*

[1]Psychiatry, Hospital Clínico Universitario de Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2233

Introduction: Many patients suffering from schizophrenia have symptoms suggesting depression during the course of their illness. It can appear both in the prodrome of a psychotic decompensation and in the acute phase, as well as after its resolution. But is it part of the disease itself? Is it an experiential reaction to the assumption of the sickness or is it an independent entity? Can it be produced or exacerbated by antipsychotics?
Objectives: This case study aims to analyze the clinical presentation of depressive symptoms in a patient with schizophrenia.
Methods: A review of the literature on affective symptomatology which may occur in psychosis.
Results: A 34-year-old male with a history in Mental Health since the age of 16, with diagnosis of paranoid schizophrenia. He has presented at least 5 depressive episodes and several severe self-harming attempts. He is on treatment with olanzapine, clonazepam, quetiapine and aripiprazole.
During a follow-up, he reports intensification of low mood in the last few weeks due to sentimental break-up, clinophilia and social isolation. He spends the day in his room with the curtains lowered, he has

neglected his personal hygiene, and verbalizes thoughts of death. He shows poor functioning, slowed thinking and lack of energy.
His mother reports that he has had self-aggressive behaviors, such as hitting his face and eating his faeces. Sensory and perceptual disturbances are not excluded. Given the current depressive affective state and risk of commiting suicide, it is decided to admit him to the hospital and to start treatment with fluoxetine.
A few weeks after hospital discharge, he continues with poor functioning and isolation, but his mood is better and his thoughts of death have disappeared.
Conclusions: Although clear differentiation between depressive and psychotic symptomatology has been classically described, both symptoms are often associated. Affective symptoms can be part of different stages of the disease, secondary to medication, due to insight phenomena or part of schizoaffective disorder and psychotic depressions.
Depressive symptomatology can also be confused with the presentation of negative symptoms. They both share clinical manifestations such as anergy, social isolation and lack of interest; but while in depression there is a sad mood, in negative symptons there is emotional flattering. Also, positive symptomatology can simulate social withdrawal, usually seen in depression.
Depression in an acute phase has historically been related to a better prognosis, although several studies indicate that depression in a chronic phase causes a higher risk of suicide and relapses. Therefore, early diagnosis and treatment are essential.
In our case, the patient suffers from major affective symptoms regarding his life situation, which may be overlapped by isolation due to a likely positive symptomatology, without dismissing possible negative symptomatology as a result of many years of evolution of his disease.

Ekbom Syndrome: A case report and literature review

P. Martínez Gimeno[1], L. Rodríguez Andres[1]*, C. Alario Ruiz[1], O. Martín Santiago[1], B. Arribas Simón[1], M. P. Pando Fernández[1], M. Andreo Vidal[1], M. Calvo Valcarcel[1], B. Rodríguez Rodríguez[1], M. Fernández Lozano[1], M. D. L. Á. Guillén Soto[1], A. Aparicio Parra[1], M. Ríos Vaquero[1], G. Lorenzo Chapate[1], A. Monllor Lazarraga[1], L. R. Vazquez[1], F. J. Gonzalez Zapatero[1] and L. Del Canto Martínez[1]

[1]Hospital Clínico Universitario Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2234

Introduction: Ekbom's syndrome is a clinical term for delusional parasitosis, a condition characterized by the belief that one's skin is infested by invisible parasites. Delusional infestation is a rare psychiatric disorder, is more common in the elderly, particularly in postmenopausal females. Psychiatric interventions are usually rejected by these patients and long-term treatments are frequently abandoned, they usually seek care from dermatologists. It is advocated to form a liaison between dermatology and psychiatry to ensure a full range of differential diagnoses, in order to form the most suitable management plan.
Objectives: The objetive of this case is to illustrate the severity of Ekbom's syndrome, providing detailed clinical information and highlighting the challenges in treatment.
Methods: The following patient will be presented, doing a thorough systematic bibliography review.
Results: A 54-year-old female patient describes a clinical history of three years of visual hallucinations and generalized pruritus since a family weekend at a countryside house. She reported that, for the past three years, she has experienced itching all over her body and has occasionally seen "bugs" on her body that she believes to be fleas. She mentioned having been diagnosed with "scabies" and "seborrheic dermatitis".Despite these diagnoses, her father noted that for the past year, the patient has been extremely anxious, spending hours examining her hair and skin, washing repeatedly, and searching for "bugs." In recent weeks, she refused to eat.Throughout her stay in the unit attended therapy regularly, and participated actively. A psychopharmacological adjustment was made, starting with Abilify at 15 mg/day, which was well-tolerated and effective. A dermatology consult ruled out dermatological pathology. Over the days, a reduction in anxiety and partial improvement in somatic complaints were observed. As the patient's condition improved, she committed to continuing with the treatment and attending mental health team consultations with her referring psychiatrist.
Conclusions: Delusional infestation is a serious and uncommon disorder that endangers the patients and the people around them, and can be complicated with secondary somatic complications, often requiring involvement of different medical specialists.The treatment is long and complicated, the effectiveness of pimozide, aripiprazol or risperidone for the Ekbom syndrome has been documented in the literature. In our case, we decided to introduce aripiprazol. The management of these patients requires a multidisciplinary approach between dermatologists and psychiatrists, as they often refuse treatment. Consultation and collaboration between both specialties are essential to ensure timely referral. Additionally, it is crucial for general physicians to have greater awareness of these conditions, perform early recognition, maintain good rapport with patients, and provide empathetic treatment.

Brief Episodes, Lasting Impact: A Case Series on Acute and Transient Psychotic Disorder

C. Martins[1]*, M. Sant'Ovaia[1], J. M. de Castro[1], S. Martins[1] and L. A. Fernandes[1]

[1]Psychiatry, Unidade Local de Saúde Amadora/Sintra, Amadora, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2235

Introduction: Psychotic disorders with acute onset and remitting course have been described by 19th and 20th-century European psychiatrists under various terms, such as "amentia," "cycloid psychosis," "bouffée délirante". In modern taxonomy, brief psychotic episodes are classified as "acute and transient psychotic disorder" (ATPD) in ICD-11 and "brief psychotic disorder" in DSM-5. The lack of continuity between earlier nosological concepts and current descriptive categories, along with frequent changes in definitions across DSM and ICD versions, has hindered empirical research, limiting our understanding of these conditions. As a result, ATPDs have been marginalized in textbooks and training programs, leading to a lack of evidence-based treatments, despite their clinical relevance. Our work aims to renew interest in these "forgotten" disorders.
Objectives: To examine the epidemiological and clinical aspects of ATPDs through the description of clinical cases.

Methods: We selected a convenience sample of 8 patients with a first diagnosis of ATPD (F23, ICD-10), currently or previously treated at Unidade Local de Saúde Amadora/Sintra. Data was collected from electronic health records, including demographic information, clinical presentation, treatment, and disease course. Additionally, we conducted a non-systematic literature review.
Results: The sample consisted of 6 females and 2 males, with a median age at diagnosis of 44.5 years (min=24, max=64). Fifty percent (n=4) were migrants, with 25% (n=2) coming from lower-middle- and low-income countries. Sixty-two point five percent (n=5) received inpatient care (mean stay of 8.6 days). Most patients (87.5%, n=7) were treated with dopamine D2 receptor antagonists/partial agonists, risperidone being the most common (n=4); one patient achieved spontaneous remission. All patients had a sudden onset of symptoms; the clinical picture was primarily marked by delusions, hallucinations, confusion, psychomotor abnormalities (including catatonia signs) and mood disturbances (mainly anxiety). The mean duration of the episode was 23.2 days. All patients fully remitted and returned to their premorbid functional status. Sixty-two point five percent (n=5) experienced a second episode after a mean of 33.2 months, and 25% (n=2) had a change in diagnosis (bipolar disorder and unspecified psychosis).
Conclusions: Despite the small sample and follow-up variability, our findings highlight ATPDs' clinical heterogeneity and high recurrence rates. A renewed research effort is necessary to refine diagnostic criteria and investigate treatment responses, risk factors, and long-term prognosis of this disorder, in order to improve therapeutic strategies and patient outcomes in clinical practice.

Beyond clozapine – what options do we have in clozapine resistant schizophrenia?

A. C. Matias[1]*, T. Vieira[1], A. Ferreira Silva[1], R. Machado Lopes[1], C. Almeida Rodrigues[1], F. Marinho Santos[1] and P. Fonseca Coelho[1]

[1]Psychiatry and Mental Health Department, Unidade Local de Saúde do Médio Tejo, Tomar, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2236

Introduction: Schizophrenia is one of the most disabling mental disorders, affecting around 1% of the population. Although most patients respond to antipsychotic treatment, one third have a limited response to antipsychotic medication, being considered treatment resistant schizophrenia (TRS). Clozapine is the only effective medication for TRS, but 30-40% of TRS patients do not respond to it. Patients with schizophrenia who do not respond to clozapine experience more severe disability, persistent symptoms, a lower quality of life and incur higher economic costs compared to those who respond to treatment.
Objectives: The aim of the present study is to review evidence for therapeutic strategies for patients with treatment-resistant schizophrenia not responding to clozapine.
Methods: Review of the literature regarding treatment-resistant schizophrenia not responding to clozapine. The research was carried out through the PubMed® database, using the terms "treatment resistant schizophrenia", "schizophrenia resistant to clozapine" and "clozapine augmentation".
Results: For patients with treatment-resistant schizophrenia who do not respond to clozapine, several therapeutic strategies have been explored. These include pharmacological approaches, non-pharmacological interventions and brain stimulation procedures [Electroconvulsive Therapy (ECT) and Transcranial Magnetic Stimulation (TMS)]. However, the evidence is weak and the reported benefits were modest.
Conclusions: The current evidence is weak for efficacy of pharmacological augmentation strategies to clozapine. There are contradictory data regarding ECT and clozapine augmentation. More studies are necessary to clarify the potential of these strategies in order to manage these complex patients.

Disclosure of Interest: None Declared

EPV1802

Time to the first relapse after the transcranial magnetic stimulation with H7-coil in patients with predominant negative symptoms of schizophrenia; A randomized, sham controlled trial

K. Matić[1]*, I. Š. Filipčić[2], Ž. Milovac[1], T. Gajšak[1], K. Bosak[1], I. Orgulan[1], V. Požgaj[1], Ž. Bajić[1], V. Grošić[1] and I. Filipčić[3]

[1]Psychiatric Clinic Sveti Ivan; [2]University Hospital Cnetre Zagreb, Zagreb and [3]Faculty of Dental Medicine and Health, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2237

Introduction: Patients with predominant negative symptoms of schizophrenia experience severe functional impairment and limited response to pharmacological treatments. Transcranial magnetic stimulation (TMS) has shown potential for treating negative symptoms, but its impact on long-term outcomes, such as time to relapse, remains underexplored.
Objectives: This study aimed to determine whether TMS with an H7-coil prolongs time to first relapse compared to sham stimulation in patients with low positive symptomatology and predominant negative symptoms.
Methods: This study was a randomized, sham-controlled trial at the Psychiatric Clinic Sveti Ivan, Zagreb, Croatia. The target population were patients with PANSS negative symptoms score > 24 and PANSS positive symptoms score < 20, on stable pharmacotherapy for at least three months The intervention group received high-frequency TMS with an H7-coil, while the control group received sham stimulation, both applied once daily for 20 sessions over four weeks. The outcome was time to first psychiatric relapse, defined as psychiatric rehospitalization. Kaplan-Meier survival curves, log-rank tests, and Cox proportional hazards models were used for statistical comparisons.
Results: A total of 76 outpatients with schizophrenia, aged 18-55 were included; 33% were women. Over the 12-month follow-up, 29% in the H7 group and 24% in the sham group experienced a relapse. The median time to relapse was not reached in either group. The hazard ratio (HR) for relapse in the H7 group relative to sham was 0.82 (95% CI 0.34; 1.97), suggesting no significant effect of TMS on delaying relapse. Adjusted Cox regression model for age, gender, baseline severity of negative and positive symptoms, pharmacotherapy, and number of prior hospitalizations showed similar results (HR = 0.85, 95% CI 0.30; 2.46, p = 0.769). Significant predictors of relapse were baseline severity of negative symptoms (HR = 0.88, 95% CI 0.79; 0.99, p = 0.026) and the number of prior hospitalizations (HR = 1.81, 95% CI 1.16; 2.82, p = 0.009).

Conclusions: No significant effect of H7-coil TMS on delaying relapse was observed in patients with schizophrenia and predominant negative symptoms. Median survival was not reached in either group, suggesting the need for longer follow-up to fully evaluate potential benefits. Baseline severity of negative symptoms and prior hospitalizations should be considered when assessing relapse risk in this patient population.

EPV1803

Association of negative symptom dimensions with sleep efficiency in schizophrenia patients with predominant negative symptoms

Ž. Bajić[1], V. Grošić[1], K. Matić[1]*, I. Š. Filipčić[2], P. F. Grošić[2], K. Bosak[1] and I. Filipčić[3]

[1]Psychiatric Clinic Sveti Ivan; [2]University Hospital Centre Zagreb, Zagreb and [3]Faculty of Dental Medicine and Health, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2238

Introduction: Negative symptoms, such as avolition, blunted affect, or alogia, contribute to functional disability and reduced quality of life in schizophrenia. Patients with predominant negative symptoms and minimal positive symptoms represent a distinct subgroup requiring tailored therapeutic strategies. Sleep disturbances, particularly reduced sleep efficiency, are commonly reported in this population and may exacerbate the severity of negative symptoms. Understanding the differential impact of specific negative symptoms on sleep efficiency could inform individualized approaches for improving otucomes.
Objectives: To explore associations between distinct dimensions of negative symptoms and sleep efficiency in schizophrenia patients with predominant negative symptoms and low positive symptoms.
Methods: This analysis used baseline data from a randomized, sham-controlled trial on the efficacy of transcranial magnetic stimulation in schizophrenia, conducted between 2000 and 2023. The study included patients with PANSS negative subscale score > 24 and PANSS positive subscale score < 20. The outcome variable was the sleep efficiency subscale of the Pittsburgh Sleep Quality Index. Independent variables were the five SANS dimensions: blunted affect, alogia, avolition(/apathy, anhedonia/asociality, and attention impairment. Quantile regression was used to assess associations, and robust standard errors were applied.
Results: We included 76 patients (median age 36 years, 33% women). Alogia was positively associated with sleep efficiency (β = 4.41, p = 0.040), while avolition (β = -3.61, p = 0.014) and attention impairment (β = -4.12, p = 0.041) were negatively associated. Blunted affect and anhedonia/asociality were not significantly associated with sleep efficiency.
Conclusions: Distinct negative symptom dimensions show differential associations with sleep efficiency in schizophrenia patients with predominant negative symptoms. Alogia's association with better sleep efficiency may reflect reduced mental arousal and fewer ruminative thoughts before sleep. Conversely, avolition and impaired attention may worsen sleep through increased inactivity and fragmented sleep patterns. These findings suggest that targeted therapeutic interventions may be necessary to optimize sleep and overall clinical management in this subgroup of patients. Further studies are needed to explore underlying mechanisms and clinical implications of the presented associations.

EPV1804

Validation of the Lithuanian version of the Brief Negative Symptoms Scale

J. Montvidas[1]*, E. Zauka[1] and V. Adomaitienė[1]

[1]Psychiatry, Lithuanian University of Health Sciences, Kaunas, Lithuania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2239

Introduction: Negative symptoms of schizophrenia include abulia, anhedonia, alogia, blunted affect, and social isolation. These symptoms strongly correlate with health-related quality of life and treatment outcomes. (Azaiez et al., 2018; Galderisi et al., 2018; Kirkpatrick et al., 2006). According to current negative symptoms diagnosis and treatment guidelines, the Brief Negative Symptom Scale (BNSS) is the instrument of choice for the psychometric evaluation of negative symptoms (Galderisi et al., 2021). Unfortunately, BNSS was not available in Lithuania.
Objectives: To validate the Lithuanian version of the BNSS in a Lithuanian-speaking sample.
Methods: We performed a double translation from English to Lithuanian and then back to English. The final version of the Lithuanian BNSS (Lit-BNSS) was finalized according to comments from two native Lithuanian-speaking experts, who evaluated the forward translation, and the representatives of the authors of the BNSS, who evaluated the back translation. We performed a validation study in an inpatient setting in a university hospital in Lithuania and asked patients diagnosed with schizophrenia spectrum diagnosis according to ICD-10 to participate in the study. We evaluated the included patients with the Positive and Negative Symptoms Scale (PANSS), Montgomery Asberg Depression Rating Scale (MADRS), Self-Evaluation of Negative Symptoms Scale (SNS), and Calgary Depression Scale for Schizophrenia (CDSS). PANSS Marder factors were calculated for more accurate PANSS scores. We check the convergent validity with the Marder negative symptoms factor, the total score of SNS, and the discriminant validity with the Marder positive symptoms factor, MADRS, and CDSS total scores.
Results: The study included 122 patients. The Lit-BNSS showed great internal consistency for the 13 items (α=0,944) and good consistency for six subscores (α=0,874). Convergent validity was good, with the total score of Lit-BNSS having a strong positive correlation with the Marder negative symptoms factor and a weaker correlation with the SNS total score. Discriminant validity was adequate because there were insignificant correlations with MADRS and CDSS subscores and the Marder positive symptoms factor. Correlation scores can be seen in Table 1.

Table 1. BNSS TS correlation with other scores. MARDER-NEG – PANSS Marder negative symptoms factor; SNS-TS- SNS total score; MARDER-POZ- PANSS Marder positive symptoms factor; MADRS – MADRS total score; CDSS-TS- CDSS total score

Variable	Correlation coefficient	p-value
MARDER-NEG	0,755	<0,001
SNS-TS	0,304	0,001
MARDER-POZ	0,171	0,064
MADRS-TS	0,085	0,361
CDSS-TS	0,472	0,117

Conclusions: The Lit-BNSS is a valid and effective psychometric tool for evaluating negative symptoms in a Lithuanian-speaking sample.

EPV1805

Are negative symptoms evaluated with a self-assessment tool or a semi-structured interview more strongly correlated to mental health-related quality of life?

J. Montvidas[1]*, E. Zauka[1], Ž. Žumbakys[1] and V. Adomaitienė[1]

[1]Psychiatry, Lithuanian University of Health Sciences, Kaunas, Lithuania

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2240

Introduction: Negative symptoms are one of the core symptom groups of schizophrenia. These symptoms are highly prevalent and are proven to have a strong correlation with mental health-related quality of life. Evaluating negative symptoms using the Brief Negative Symptoms Score (BNSS), a semi-structured interview, is recommended. BNSS can be supplemented with the Self-assessment of Negative Symptoms (SNS), a self-assessment scale. It is unclear whether a semi-structured interview or a self-assessment scale is more related to the mental health-related quality of life.

Objectives: To evaluate whether scores BNSS or SNS are more strongly correlated with the mental health-related quality of life.

Methods: We performed a cross-sectional study in an inpatient clinic of a university hospital in Lithuania. Inclusion criteria were a diagnosis of schizophrenia spectrum disorder according to ICD-10, age between 18 and 65. Exclusion criteria were acute and/or severe comorbid psychiatric or somatic disorders. BNSS and SNS were used to evaluate negative symptoms. The 36-item Short Form survey (SF-36) was used to evaluate quality of life. Three independent psychiatrists evaluated the participants of the study. The first psychiatrist evaluated the negative symptoms with BNSS. The second psychiatrist handed out, collected, and scored SNS. The third psychiatrist handed out, collected, and scored SF-36. Afterward, the statistical correlation analysis was performed. Only the energy/fatigue and mental health subscores of SF-36 were included in the study to limit the correlation analysis to only the mental health-related quality of life.

Results: The study included 93 participants. We found that SNS scores significantly correlated with mental health-related quality of life compared. SNS had higher correlation indexes with the energy/fatigue subscore than the mental health subscore of SF-36. The strongest correlation was seen between the total score of SNS and the energy/fatigue subscore of SF-36 (r=-0,508, p<0,001). BNSS had no statistically significant correlations with either the energy/fatigue or the mental health subscore of SF-36. All of the correlation coefficients can be seen in Table 1.

Variable	Correlation coefficient MH	p-value	Correlation coefficient EF	p-value
SNS SI	-0,294	0,04	-0,358	<0,001
SNS A	-0,258	0,13	-0,251	0,015
SNS AV	-0,26	0,012	-0,398	<0.001
SNS AN	-0,354	<0.001	-0,434	<0.001
SNS TS	-0,348	<0,001	-0.508	<0,001

Table 1. Correlation coefficients of SNS and SF-36 scores. MH – SF-36 mental health subscore; EF- SF-36 energy/fatigue subscore; SNS SI – SNS social isolation subscore, SNS A- SNS alogia subscore; SNS AV – SNS avolition subscore; SNS AN – SNS anhedonia subscore; SNS total score.

Conclusions: SNS, a self-evaluation scale, was more strongly correlated to mental health-related quality of life than scores of BNSS.

Ekbom Syndrome: what do we know about it? A case report

C. Munaiz Cossío[1]*, I. M. Peso Navarro[1], N. M. Casado Espada[1], M. Ligero Argudo[1], R. K. Gonzalez Bolaños[1], C. Payo Rodriguez[1], J. I. de la Iglesia Larrad[1] and P. Andres Olivera[1]

[1]Psychiatry, Complejo Asistencial Sanitario de Salamanca, Salamanca, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2241

Introduction: Ekbom Syndrome or delusional parasitosis is a, usually monosymptomatic, somatic type of delusional disorder in which the patients are convinced they are being infested with animal parasites while no objective evidence exists to support this belief (Mumcuoglu KY, Leibovici V, Reuveni I, Bonne O. Isr Med Assoc J. 2018 Jul;20(7):456-460). It has also been described as a hypochondriacal psychosis that causes great suffering for the patient and those around them. (Campbell EH, Elston DM, Hawthorne JD, Beckert DR. J Am Acad Dermatol. 2019 May;80 (5):1428-1434.)

Objectives: To study this syndrome in depth and learn more about these patients.

Methods: The Pubmed database was used to collect the available information about Ekbom syndrome since 2006. Using the search term "delusional parasitosis". We also present the following clinical case:

A 66-year-old woman, with no history of mental health or substance abuse, came to the dermatology department for multiple pruritic wounds all over her body. She reports that when she scratches herself there is a "small ball that crackles, like a living thing", she has tried to bring samples but has not been able to collect them, according to her. She is convinced that she is infested by parasites. In addition, in the last few weeks she has suffered significant hair loss. On physical examination she presents multiple

scabby plaques on the thorax, back, face and scalp. On the scalp she presents frontal alopecia and madarosis.
The patient was referred to Psychiatry.
On psychopathological examination the patient presented moderate ideational and somatic anxiety, reactive to hair loss and feeling of infestation, also admits difficulty in falling asleep. No affective symptoms were observed or described, nor were there any other accompanying psychotic symptoms (self-referentiality, delusions of harm, persecution, etc.).
Results: We started treatment with Olanzapine 5mg before going to bed, plus a rescue tablet if needed due to anxiety.
In the following reviews, the delirious clinic persists, although a notable reduction of the anxiety and improvement of the night rest is observed.
Conclusions: When it comes to treatment, one of the main difficulties we find is that the patient accepts to be evaluated by psychiatry, so it is important to establish a good therapeutic relationship with the patient, since this will determine the patient's therapeutic adherence to the treatment.
Treatment usually consists of antipuriginous and antipsychotic agents. In our case we selected Olanzapine for its sedative effect, with which we observed a significant reduction of symptoms. However, the available literature usually recommends starting treatment with risperidone. Even so, there is little evidence on its efficacy in Eckbom's Syndrome.
Treatment studies are scarce and the evolution varies from one case to another.

Relation between childhood trauma and social vulnerability in adulthood in patients with first episode psychosis

P. Muñoz-Calero[1]*, P. Mola[1], A. Carrasco[1], W. Ahyed[1], M. D. Saiz[1], J. García-Albea[1] and M. Díaz Marsá[1]

[1]Instituto de Psiquiatría y Salud Mental, Hospital Clínico San Carlos, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2242

Introduction: The relationship between childhood adversity and psychosis has been the focus of extensive research in recent years. Studies suggest that individuals who experience significant adversity during childhood,such as abuse,neglect,or trauma, hava an increased risk of developing psychotic disorderser later in life.
Enviromental factor have been shown to play a signitficant role in the development of psychosis,often interacting with genetic predispositions.Nevertheless the relation between childhood trauma and social vulnerability in adulthood in patients with a first episode of psychosis (FEP) patients has not been studied.
Objectives: The aim of this work is to study social factors in patients with childhood trauma and their impact on the development of a FEP.
Methods: The sample was divided into 3 groups, controls,first episode psychosis patients with childhood trauma (FEP with CT) and first episode psychosis patients without childhood trauma (FEP without CT). 135 controls and 190 patients with FEP (58.42% with CT) were assesed through questionnaires on traumatic experiences, life stress events and a socio-demographic interviews. The likelihood of experiencing life stress events in the past year, social vulnerability,affective issues and substance use were examined using logistic regression models.
Results: Four covariates demonstrated a significant association with the clinical group with CT: being without a partner ($p < .01$), unemployment ($p < .01$), a history of psychiatric conditions ($p < .01$), and migration status ($p < .01$). However, stressful events in adulthodd were not found to be significant.
Conclusions: While childhood trauma does not seem to directly trigger re-traumatization in adulthood, it may contribute to place FEP patients in socially vulnerable circumstances that could lead to the development of psychotic symptoms.

Clinical Differences Between Urban and Rural Populations in Adolescents with Clinical High Risk of Psychosis

P. Navalon Rodriguez[1,2]*, Y. Cañada[1,2], A. Jovani[1,2], A. Adriasola[1,2], L. R. Bofill[1,2], E. Pechuan[3] and A. G. Blanco[1,2]

[1]Psychiatry Department, La Fe Hospital; [2]Mental Health Research Group, La Fe Health Research Institute, Valencia and [3]Mental Health Institute, Hospital del Mar, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2243

Introduction: Individuals at Clinical High Risk of Psychosis (CHR-P) show increased risk for developing psychotic disorders. The relationship between the risk of developing psychosis and urbanicity has been previously described; however, there are divergent results regarding the relationship between positive psychotic symptoms and urbanicity.
Objectives: The present study aims to analyze the clinical and sociodemographic differences between an urban and a rural population of youth with CHR-P.
Methods: The characteristics of the CHR-P program at La Fe Hospital (Valencia) are described and compared for the two populations in the study: a rural area comprising 10 towns with populations ranging from 200 to 29,000 inhabitants each, with an average of 12,600 inhabitants, and an urban area corresponding to the northern metropolitan area of Valencia. An analysis and comparison of the sociodemographic and clinical characteristics of the general population in both areas is also conducted.
Results: Preliminary results are provided: The sample consists of 46 patients, 21 from the rural area and 25 from the urban area. The average follow-up for both groups was 8 months, with a transition rate to psychosis during this period of 19% (n=4) for the rural area group compared to 0% for the urban area group (p=0.04). Patients in the rural area group exhibited greater severity of positive psychotic symptoms with a higher positive PANSS score (14.19 ± 4.32) compared to the urban area group (11.12 ± 3.67), and this difference was significant (p=0.032). No statistically significant differences were found between the two groups for the rest of the variables.
Conclusions: The preliminary results of our study show greater symptom severity in individuals from rural areas. Demographic factors, resource provision, or delays in care might be related to this finding.

EPV1809

Influence of duration untreated psychosis in clinical and functional outcomes at 3 months in a cohort of first episode psychosis patients

R. Obeso Menéndez[1]*, R. Pérez Iglesias[1], P. Suárez Pinilla[1], D. Sierra Biddle[1], M. L. Ramírez Bonilla[1], P. Cordero Andrés[1], M. D. C. Flor Gómez[1] and J. Vázquez Bourgon[1]

[1]Psychiatry, Hospital Universitario Marqués de Valdecilla, Santander, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2244

Introduction: A large number of studies have suggested that longer duration of untreated psychosis (DUP) is associated with poor clinical and functioning outcomes.
Objectives: The aim of this study is to explore the association of duration of untreated psychosis and functional and clinical outcomes at short term (3 months) in first episode patients.
Methods: This is a study of all patients admitted to the EI Service of University Hospital Marqués de Valdecilla in Spain, from January 2020 to July 2024, residents in the area (310,000 habitants), aged from 17 to 65, who experiencing a first episode of psychosis. We set the DUP cut-off point at 6 months to compare both groups, short-duration and long-duration psychosis. The response to treatment was assessed at 3 months with standardized scales: the PANSS scale was used to measure clinical response and the GAF scale to asses functional outcomes.
Results: A total of 207 first episode patients were referred to the Early intervention Service (EIS). The mean age was 37 years-old. 54% were woman (n=111). 21% were living alone. 32% were unemployed. Forty percent (n=82) have a psychiatric family history. 63% required hospital admission and forty-nine percent were involuntary.
The mean GAF at the initial assessment was 34.8 (SD: 12.08). The mean duration of untreated psychosis (DUP) was 15 months (SEM ±2.63) and the median was 3 months (SD: 37.87). A total of 67 patients had DUP longer than 6 months.
We did not found significant differences in sex (51.4% women in the short-DUP and 58.2% women in the long-DUP; $\chi 2 = 0.84$; $p = 0.36$) or age (36 years old in the short-DUP vs 37 years old in the long-DUP; $p = 0.52$) between groups.
A greater number of people in the long-DUP group were unemployed ($\chi 2 = 18{,}136$, $p = 0.02$) compared to the short-DUP group. A&E visits were significantly higher in short-DUP group (71.8% vs 28.2%, $\chi 2 = 8.82$; $p = 0.003$). No significant differences were found between groups in terms of hospital admission or duration of stay.
The rate of responders using the PANSS remission criteria proposed by Andreasen was 82.7% at 3 months. Non-responders were 15.9% in the short-DUP vs 20.8% in the long-DUP ($p = 0.43$). Non-significant differences were found.
At 3 months, the rate of patients who scored more than 70 points on the EEAG scale was 71.5%. Non-significant differences were found (70% short-DUP vs 74% long-DUP; $p = 0.49$) between both groups.
Conclusions: We observed that the percentage of non-responders at 3 months is higher in the group with a larger DUP. At 3 months, patients within the early intervention program showed a high level of functioning regardless of the duration of untreated psychosis.

The Reliability of the Volitional Questionnaire in Chinese (VQ-C) for Evaluating Motivation in Individuals with Schizophrenia

W. Peng

Taipei City Hospital, Taipei, Taiwan, Province of China
doi: 10.1192/j.eurpsy.2025.2245

Introduction: Schizophrenia is a common diagnosis among individuals with mental health disorders, characterized by chronic mental illness that affects perception, volition, and emotions. Numerous studies have demonstrated that schizophrenia significantly reduces global functioning and impairs function. Motivation deficit, a core symptom in individuals with schizophrenia, directly or indirectly impacts their functioning and disease outcomes. Currently, there are limited assessment tools available for measuring motivation, especially in Chinese. The fourth edition of the Volitional Questionnaire in Chinese (VQ-C), developed based on the Model of Human Occupation (MOHO), assesses motivation levels in individuals. It is scored through activity observations of clients, providing a simple and clinically feasible evaluation method. The English version of the VQ has proven to be a reliable and valid tool for individuals with mental illnesses. However, the psychometric properties of the VQ-C have not been extensively discussed in the literature.
Objectives: This study aims to test the reliability of the VQ-C in patients with schizophrenia.
Methods: We recruited 45 patients with chronic schizophrenia. The VQ-C assesses clients' motivation by observing their participation in various activities within their environment. The VQ-C consists of fourteen items, each rated on a 4-point scale, with higher scores indicating higher levels of motivation. Two raters independently observed participants' engagement in two different types of activities (static and dynamic) over one week and scored their motivation levels based on their performance. Two testers simultaneously observed participants' performance and provided scores.
In the data analysis, we used descriptive statistics to analyze demographic data of the participants, such as age, gender, and length of illness. Internal consistency was assessed using Cronbach's alpha.
Results: We recruited 45 participants with schizophrenia for the study, with 43 completing the test. The mean age was 43.02 years, and the mean duration of illness was 21.93 years. Each participant was assessed in two different activity contexts, allowing for independent analysis of scores in the sports and art contexts. The analysis of scores in the sports context revealed a Cronbach's alpha of 0.95, indicating high reliability. Similarly, the assessment scores in the art context showed a Cronbach's alpha value of 0.96.
Conclusions: This study investigated the internal reliability of the VQ-C in patients with schizophrenia, demonstrating strong reliability. Based on these results, it is suggested that the VQ-C can be used to assess the motivational state of patients with schizophrenia, facilitating the design and implementation of treatment interventions.

Use of antipsychotics in patients with epilepsy: a case report

P. Perez- Melendez Perez[1]*, H. Vizcaino Herrezuelo[1] and C. Delgado Marmisa[1]

[1]Psychiatry Department, Hospital Universitario Puerta de Hierro, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2246

Introduction: The use of antipsychotic medications in individuals with epilepsy has been studied extensively. Starting neuroleptic therapy in patients with epilepsy is complicated due to the potential for these drugs to lower the seizure threshold. Consequently, both psychiatrists and neurologists must collaborate to develop personalized treatment plans for these patients.
Objectives: To evaluate various therapeutic options for patients experiencing both psychotic symptoms and seizures, aiming to select the most appropriate treatment for each individual.
Methods: This case report describes a 47-year-old male patient who is presented with a diagnosis of symptomatic focal epilepsy in the left temporoparietal malacic area post traumatic brain injury. Following a traffic accident at the age of 14, after which he suffered a temporoparietal hematoma, the patient has presented numerous epileptic seizures. Initially, he abandoned treatment and follow-up with neurology, which he resumed in 2021. Additionally, the patient was referred to psychiatry after verbalizing delusional ideation of persecution with affective repercussions (tendency towards irritability) and behavioral repercussions (tendency towards social isolation and difficulties in the work environment) as well as auditory hallucinations with derogatory content. Neurology initiated treatment with eslicarbazepine 800mg, with cessation of epileptic seizures. After considering different treatment options and taking into account interactions with antiepileptic treatment, risperidone 1mg was initiated.
Results: Following the initiation of risperidone, the patient experienced a reduction in irritability and has not presented further epileptic seizures. Due to potential drug interactions, the risperidone dose was gradually titrated upwards, resulting in a decrease in delusional ideation and improved overall functioning.
Conclusions: Patients with epilepsy and comorbid psychotic symptoms require a multidisciplinary approach, including individualized treatment. Neuroleptic medications can significantly improve quality of life in these patients. Therefore, it is essential to carefully select the appropriate antipsychotic, starting at low doses and gradually titrating upwards, with close monitoring to ensure patient safety and drug efficacy.

EPV1813

Beyond Classification: A Case Report Exploring Paraphrenia in Late-Onset Psychosis

M. O. Pires[1]*, M. Barroso[1], A. S. Pires[1], S. Mouta[1], I. F. Vaz[1] and J. Nunes[1]

[1]Unidade Local de Saúde da Guarda, Guarda, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2247

Introduction: Paraphrenia is a chronic psychotic disorder characterized by persistent delusions, with preservation of cognitive function and personality, which distinguishes it from schizophrenia, where cognitive decline is more pronounced. Although initially defined by Kraepelin, paraphrenia has been excluded from current diagnostic systems, complicating its distinction from schizophrenia and delusional disorders. Over time, experts like Mayer-Gross, Roth, and Munro have debated whether paraphrenia constitutes a distinct diagnostic entity, raising questions about its relevance in contemporary psychiatry.
Objectives: To present a case that resembles paraphrenia and explore the clinical presentation and diagnostic process, particularly in the context of the disorder's exclusion from diagnostic systems.
Methods: This study is based on a case report, supported by a non-systematic review of relevant literature. Clinical data was collected throughout the patient's treatment, and articles on paraphrenia were reviewed to provide historical and diagnostic context.
Results: A 60-year-old woman, single, household cleaner, was brought by her sibling to the emergency department for presenting persecutory delusions, and auditory hallucinations in the prior four months. She believed her downstairs neighbors had installed cameras in her house, controlling her every move. She presented a depressed mood and difficulty falling asleep. Toxicology screening, blood work, and head-CT showed no changes. Due to treatment refractoriness, Clozapine was started. A formal neuropsychological assessment was carried out, which did not show cognitive deterioration. The patient revealed less preoccupation with delusions and hallucinations and was discharged two months after admission.
Conclusions: In this case, the patient exhibited a chronic psychotic disorder marked by persecutory delusions and auditory hallucinations, without encapsulated delusional thinking. These symptoms had persisted for four months, during which the patient maintained personality stability and interpersonal functionality, displaying appropriate emotional responses and no cognitive decline. The onset occurred in middle age, with no psychiatric family history or evidence of premorbid issues. Significant stressors before symptom onset were identified as a likely trigger. This case highlights the persistence of psychotic symptoms with preserved cognitive and emotional stability, aligning with the diagnostic characteristics of paraphrenia. Despite exclusion from modern classification systems, the clinical presentation supports considering paraphrenia as distinct from other psychotic disorders, particularly in terms of its preserved functionality and absence of cognitive decline. This case underscores the need to continue the study on paraphrenia, and possibly rethinking its role in diagnostic frameworks, particularly in cases of late-onset psychosis.

Disclosure of Interest: None Declared

EPV1814

The Importance of Social Environment in Schizophrenia

P. S. Pires[1]*, C. Cunha[1], R. Cabral[1], F. Cunha[1], I. Santos[1] and A. P. Costa[1]

[1]DPSM, ULS Viseu Dão-Lafões, Viseu, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2248

Introduction: Patients with schizophrenia spectrum disorders continue to face societal stigma. This stigma contributes to their loneliness and marginalization, acting as a significant barrier to recovery and clinical stabilization. While medication and clinical follow-up are essential for treatment, social factors are also crucial for individuals to achieve a functional and fulfilling life. It is necessary to explore these factors in this this study.
Objectives: To explore the social factors affecting the recovery and clinical stabilization of patients with schizophrenia spectrum disorders.
- To identify the support needs of these patients to enhance their functional and fulfilling lives.
- To assess the impact of societal stigma on the well-being and integration of individuals with schizophrenia.
- To examine the role of mental health professionals and family involvement in reducing stigma and improving social functioning.
- To highlight the importance of vocational interventions and supportive environments in facilitating the integration of patients into society.

Methods: For the purpose of conducting the non-systematic narrative review on the topic, we performed a search for articles in the PubMed database.
Results: Improvements in the effectiveness of antipsychotics and earlier intervention are enabling more patients to reach a cognitive level that supports a functional life, including maintaining interpersonal and occupational relationships. Thematic analysis has identified four key support needs: skill development, vocational intervention, support and encouragement, and a supportive work environment.
The involvement of mental health professionals with the patient's family is also crucial for addressing and reducing the stigma associated with the illness, thereby enhancing understanding of the individual within the context of their condition.
Social anhedonia, which impairs social functioning, is a significant concern. Additionally, the risk of suicide is notably higher during the initial phase of schizophrenia compared to the general population.
Conclusions: After achieving clinical stabilization with antipsychotics and other psychotropic medications, intervention in the social sphere becomes crucial for the patient's well-being and functionality. Having a professional occupation, when feasible, is a positive indicator of patients' integration and their role in society. To support this integration, psychiatry services and civil society must enhance their efforts. This includes developing occupational services, establishing partnerships with local businesses, and improving public awareness about schizophrenia.

Disclosure of Interest: None Declared

EPV1815

The Role of Adenosine in Schizophrenia: A Literature Review and Perspective

M. Pjevac

University Psychiatric Clinic Ljubljana, Ljubljana, Slovenia
doi: 10.1192/j.eurpsy.2025.2249

Introduction: Schizophrenia is a severe, chronic mental disorder, with about one-third of patients failing to achieve remission. Its multifactorial etiology includes a strong genetic component that remains insufficiently understood. Dysregulation of dopaminergic and glutamatergic neurotransmitter pathways has been implicated in the development of schizophrenia, as revealed through neuromorphological, molecular, pharmacological, and pharmacogenetic studies. Recent research has expanded this focus to include neuroinflammatory mechanisms and metabolic pathways, emphasizing the fine regulation of these neurotransmitter systems. Among these, adenosine has gained attention for its potential role in the pathophysiology of schizophrenia.
Objectives: This literature review aims to explore the role of adenosine in schizophrenia, its connection to dopaminergic and glutamatergic hypotheses, and broader implications for the development of symptoms and complications.
Methods: A comprehensive review of studies investigating adenosine's neuroregulatory, inflammatory, and neuromodulatory functions.
Results: The adenosine hypothesis suggests that reduced adenosine activity plays a critical role in the development of schizophrenia symptoms. Adenosine regulates dopaminergic and glutamatergic neurotransmission via ADORA A1 and ADORA A2 receptors. Studies have shown changes in adenosine receptors, transporters, and enzymes involved in adenosine metabolism in individuals with schizophrenia. Moreover, adenosine's neuroprotective role, particularly in stress and inflammation, connects it to the dopaminergic/glutamatergic systems and the broader neurodevelopmental "two-hit" hypothesis, suggesting that schizophrenia develops through a combination of genetic vulnerability and environmental factors. A study by Ary Gadelha and colleagues proposed a link between hypo-adenosine states and the increased risk of sudden cardiac death in schizophrenia patients, indicating the broader systemic importance of adenosine dysregulation in these individuals.
Conclusions: Adenosine appears to be a potential modulator in the pathophysiology of schizophrenia, connecting various neurotransmitter pathways and influencing genetic vulnerabilities, neuroinflammation, and cardiovascular risks. Further research into adenosine-related mechanisms could offer valuable insights into early interventions, improving treatment outcomes and potentially reducing complications such as treatment resistance and sudden cardiac death in schizophrenia patients.

EPV1816

Cycloid Psychosis: Navigating the Nosological Grey Zone – A Case Report

C. Portela[1]*, R. Dionísio[1], S. M. Sousa[1], D. Areias[1], M. Santos[1] and B. Baptista[1]

[1]ULS Santo António, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2250

Introduction: Cycloid psychosis, first described by Kleist and further developed by Leonhard, is characterized by a cyclic course of acute psychotic episodes, marked by delusions, hallucinations,

affective and motor disturbances. It lies at the intersection of affective and schizophreniform disorders, presenting a diagnostic challenge due to its episodic nature and inter-episodic remission. Currently, no diagnostic category clearly encompasses such clinical pictures, and these patients are usually diagnosed with brief psychotic disorders.
Objectives: This report aims to describe a case of cycloid psychosis, highlighting the nosological and treatment limitations of this entity.
Methods: Consultation and review of the patient's clinical records and articles referenced on the PubMed platform.
Results: This case report presents a 37-year-old male admitted to the emergency department with delusions of persecution and reference, auditory hallucinations, decreased need for sleep, and increased goal-directed activity, alongside a lack of insight into his condition. No significant mood disturbances were observed. Symptoms had progressively worsened over two weeks, and upon examination, the patient exhibited psychomotor agitation, incoherent speech, perplexity, and marked distress. Initial laboratory work and brain imaging were unremarkable. The patient was hospitalized for involuntary treatment, where antipsychotic therapy with risperidone (up to 4mg/day) was initiated but later switched to olanzapine (10mg/day) due to significant extrapyramidal symptoms. He was also started on valproic acid, titrated up to 1000mg/day. During hospitalization, the patient showed progressive behavioral organization, resolution of delusions and auditory hallucinations, improved sleep, and restored insight.
Upon review of his psychiatric history, it was discovered that he had experienced two previous psychotic episodes in 2018 and 2021, diagnosed as *bouffées délirantes* while residing in France. Both episodes were successfully treated with olanzapine, with *restituto ad integrum* within one month, and no signs of personality changes or biographical disruption. Based on these recurrent psychotic episodes and his current presentation, a diagnosis of cycloid psychosis was made, following the criteria proposed by Perris and Brockington.
The patient was discharged after two weeks of inpatient care, and at his one-week follow-up, showed complete remission of psychotic symptoms.
Conclusions: Cycloid psychosis presents significant diagnostic challenges due to its ambiguous nosological status. It does not fit neatly into conventional categories such as schizophrenia or bipolar disorder, as it shares characteristics with both while maintaining a distinct clinical course marked by episodic, self-limiting psychotic phases with full remission. This diagnostic ambiguity also poses difficulties in treatment, as no specific guidelines exist, and current literature is sparce.

EPV1817

Impact of the age of onset and duration of schizophrenia on the quality of treatment adherence

A. Rami

Razi Hospital, Manouba, Tunisia
doi: 10.1192/j.eurpsy.2025.2251

Introduction: Schizophrenia is a chronic, frequent, and disabling psychiatric condition. The prognosis is more severe in the absence of treatment.
Objectives: The aims of our study were to evaluate the quality of treatment adherence and the Impact of the age of onset and duration of schizophrenia on the quality of treatment adherence and to assess the implication of these factors as predictors of poor adherence.
Methods: We conducted a cross-sectional and analytical study. We recruited 150 patients with schizophrenia treated at Razi Hospital of Manouba, divided into 113 patients with good adherence compared to 37 patients with poor adherence. We used the Medical Adherence Report Scale (MARS) to assess the quality of therapeutic adherence.
Results: The average age of onset of the illness was 22.91 ± 4.6 years, with extremes ranging from 13 to 36 years.
The average duration of the illness in the patients in our series was 17 years, with extremes ranging from two to 42 years.
The average duration of untreated psychosis was two years, with a median of 12 months and extremes ranging from one month to 20 years.
A statistically significant association was found between the duration of untreated psychosis and the quality of treatment adherence (p=0.003).
Neither the age of onset of the illness nor its duration had any influence on the quality of patient adherence.
Conclusions: To prevent poor treatment adherence, a systematic screening for predictive factors and adequate management of schizophrenia would be imperative.

HISTORI Experience – a qualitative study of HISTORI patients´ experiences with Semaglutide and placebo

B. S. Rasmussen[1], N. Uhrenholt[2,3], C. Simonÿ[4,5], P. H. Gæde[5,6], B. Lundberg[7], S. T. Rønne[2], P. G. Uhrenholt[1] and S. M. Arnfred[1]*

[1]Psychiatric Research Unit, Region Zealand.; [2]Psychiatry West, Region Zealand, Research Unit for Clinical Psychopharmacology, Slagelse; [3]Child and Adolescent Psychiatry Odense, Mental Health Services in the Region of Southern Denmark, Odense C.; [4]Department of Physiotherapy and Occupational Therapy, Næstved, Slagelse & Ringsted Hospital, Region Zealand, The Research and Implementation Unit PROgrez, Slagelse; [5]The Institute of Regional Health Research University of Southern Denmark, Odense; [6]Department of Cardiology and Endocrinology, Næstved, Slagelse & Ringsted Hospital, Slagelse and [7]Community Mental Health Services, Region Zealand, Vordingborg, Denmark
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2252

Introduction: Qualitative studies of the connection between overweight/ obesity, medicine adherence and symptoms of psychosis are lacking. The project Home-based Intervention with Semaglutide Treatment of Neuroleptica-Related Prediabetes, HISTORI, was a blinded, randomized control trial where people with schizophrenia and prediabetes were randomized to either Semaglutide og placebo injections.
Objectives: The research question in HISTORI Experience focused on the patients´ mindset while participating in HISTORI, their experiences and thoughts regarding weight and exercise, eating behaviors, psychotic symptoms and their interactions with HISTORI staff.
Methods: 19 qualitative, semi structured interviews were conducted. 11 Semaglutide interviews (6 female, 5 male) and 9 placebo interviews (5 female, 3 male). The interviews were analyzed with a reflexive thematic analysis (Braun & Clarke, 2022).
Patient and Public Involvement: One person with lived experience who could not be included in the HISTORI project, joined HISTORI Experience as a co-researcher. She was involved in creating a phenomenological interview guide. She was then introduced to the

coding process and participated in the development of themes. A didactic relationship model was applied as an overall framework for the involvement (Hiim & Hippe, 2007). This model is learning-oriented and takes different factors that might influence the coorporation into account. Factors such as setting, learners´ abilities, learning process, content, goal and evaluation. To ensure a sustainable and active involvement the Involvement Matrix (Smits *et al.* Research Involvement and Engagement; 2020) was used both prospective and retrospective throughout the involvement process.
Results: The results from both HISTORI and HISTORI Experience provides us with new knowledge that can be implementet in treatment with Semaglutide for patients with schizophrenia.
Conclusions: Results and conclusion are expected in April 2025 and will be represented at the EPA conference.

Psychotic disorders and splenium of the corpus callosum tumor: diagnostic and therapeutic approach

S. Ben Aissa[1]*, K. Razki[1], C. Najar[1], A. Larnaout[1] and W. melki[1]
[1]Psychiatry, Razi hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2253

Introduction: Psychosis encompasses a complex spectrum of psychiatric manifestations that can arise from diverse organic etiologies, such as severe head trauma (1), epilepsy, systemic diseases, and tumors. While brain tumors are typically considered neurological conditions primarily affecting cognitive and motor functions, they can also present with psychiatric symptoms that exhibit clinical and evolutionary atypicality. This interplay between organic pathologies and psychiatric symptomatology underscores the intricate nature of mental health disorders originating from physiological disruptions.
Objectives: To describe a case of chronic psychotic disorder with intermittent exacerbations secondary to a neurological tumor and discuss the diagnostic and therapeutic challenges.
Methods: We report the case of a 46-year-old male patient who was admitted to Razi Hospital for aggressive behavior, delusional syndrome, and auditory hallucinations in 2023. The case report is followed by a discussion reviewing relevant literature on the subject.
Results: A 46-year-old Caucasian man with no significant medical history was referred to our psychiatry service due to recent behavioral disturbances marked by hetero-aggressive outbursts. During evaluation, the patient was conscious, well-oriented in time and space, but anxious and attentive. He reported auditory hallucinations with religious content, persecutory delusions, and mystical-religious ideas. According to the patient's history, auditory hallucinations began at age 16, with exacerbations at 25, 34, and 42 years. Psychometric evaluation using the Positive and Negative Syndrome Scale (PANSS) yielded scores of 39 for positive symptoms and 16 for negative symptoms. Neurological examination revealed no abnormalities. Brain MRI showed a tumor in the splenium of the corpus callosum measuring 18 x 14 x 8 mm, with mild hypointensity on T1, hyperintensity on T2 and FLAIR, and minimal contrast enhancement suggesting a glial origin.
The patient was treated with risperidone (4 mg/day) and diazepam (5 mg/day). Over six weeks, PANSS scores decreased (positive: 23 points, negative: 7 points).
After consultation with the neurosurgery team, surgical intervention was not pursued due to the absence of tumor growth and neurological symptoms.
Conclusions: The observed partial remission of psychotic symptoms with pharmacological intervention highlights the potential efficacy of such treatments in ameliorating psychiatric manifestations of organic brain pathologies.

Profiling of patients with treatment-resistant schizophrenia: a retrospective analysis

S. Ben Aissa[1]*, K. Razki[1], C. Najar[1], A. Larnaout[1] and W. melki[1]
[1]Psychiatry, razi hospital, manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2254

Introduction: Treatment-resistant schizophrenia remains a major challenge in psychiatry due to its resistance to conventional therapeutic interventions, leading to persistent symptoms and functional impairment. Efforts to address it focus on exploring alternative approaches, including novel medications, psychosocial interventions, and neurostimulation techniques.
Objectives: To determine the sociodemographic and clinical profile of patients with treatment-resistant schizophrenia.
Methods: We conducted a retrospective descriptive study involving patients diagnosed with treatment-resistant schizophrenia at Psychiatry Service D of Razi Hospital in Tunisia over a five-year period (2019-2023). Data collection was conducted retrospectively by initially referring to medical records and subsequently verifying and supplementing information through patient or family interviews. Sociodemographic variables included age, gender, educational level, socioeconomic status, marital status, and occupation. Clinical data of interest comprised age at onset of mental disorder, duration of untreated psychosis, illness duration, family history of mental illness, previous treatments and their dosages, medical and psychiatric comorbidities, therapeutic adherence, and clinical scores using the Positive and Negative Syndrome Scale (PANSS).
Results: The sample size is 30 patients.
We identified a distinct demographic and clinical profile among patients diagnosed with treatment-resistant schizophrenia. The cohort exhibited a notable male predominance, constituting 60% (n=18) of the study population, with a mean age of 39 ± 14.58 years. The majority of patients were unmarried (70%, n=21) and belonged to a lower socioeconomic status (80%, n=24).
In terms of clinical characteristics, patients experienced an early onset of the disorder at 18 ± 3.58 years, coupled with a prolonged duration of untreated psychosis averaging 8 ± 2.65 years. There was a substantial prevalence of family history of mental illness among the cohort (80%, n=24).
The initial psychiatric assessment, based on PANSS scores obtained from the first hospitalization, revealed elevated symptomatology levels: Positive subscale score averaged 28 ± 5.23, Negative subscale score averaged 20 ± 4.53, and General psychopathology score averaged 65 ± 10.02.

Conclusions: Comprehensive clinical and sociodemographic profiling of individuals with treatment-resistant schizophrenia is essential for enhancing clinical outcomes and tailoring treatment strategies. This approach allows clinicians to better understand the unique challenges these patients face, enabling the development of more targeted and effective interventions to improve their quality of life.

Gender differences in clinical presentation and therapeutic response in schizophrenia

S. Ben Aissa[1]*, K. Razki[1], C. Najar[1], A. Larnaout[1] and W. melki[1]
[1]Psychiatry, Razi hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2255

Introduction: Schizophrenia is a multifaceted psychiatric disorder characterized by disturbances in thinking, emotions, and behavior. It exhibits a diverse spectrum of clinical presentations influenced by various factors, among which gender plays a significant role.
Objectives: To determine the differences in clinical profile and therapeutic response among schizophrenia patients according to gender.
Methods: We conducted a descriptive, cross-sectional, comparative study over a three-month period from January to March 2024, among patients in the post-care service of Psychiatry Department D at Razi Hospital diagnosed with schizophrenia based on DSM-5 criteria. Sociodemographic and clinical data were initially collected from patients' medical records and then verified and supplemented during direct interviews using a pre-established information sheet. The Positive and Negative Syndrome Scale (PANSS) was used to assess symptom severity in participants.
Results: We enrolled 80 participants, of whom 50 were male (62.5%) and 30 were female (37.5%). The mean age of participants was 42.5 years. Men had higher mean scores on the positive symptoms subscale (75.6±12.05) and negative symptoms subscale (64.8±8.69), while women had higher mean scores on the general symptoms subscale (69.3±15.86). Male patients exhibited a higher prevalence of auditory hallucinations (80%) compared to women (55%), with a statistically significant difference ($\chi^2 = 4.32$, $p < 10\text{-}3$). Similarly, a higher prevalence of delusional ideas (72%) was observed in men compared to women (45%), also statistically significant ($\chi^2 = 5.87$, $p = 0.02$). Regarding therapeutic response, men showed a statistically more significant improvement in positive symptoms like hallucinations and delusional ideas, with an average reduction of 15 points on the PANSS scale compared to 10 points in women ($p = 0.02$). Conversely, women demonstrated a more favorable response to negative symptoms such as social withdrawal and apathy, with an average reduction of 12 points on the PANSS negative symptoms subscale compared to 8 points in men ($p = 0.04$).
Conclusions: The observed differences in clinical profiles and therapeutic responses between male and female patients underscore the necessity for tailored treatment approaches aimed at optimizing outcomes and enhancing patient care.

EPV1822

Exploring Suicide Risk Factors in Schizophrenia: A Retrospective Study

S. Ben Aissa[1]*, K. Razki[1], C. Najar[1], A. Larnaout[1] and W. melki[1]
[1]Psychiatry, Razi hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2256

Introduction: Suicide is a significant concern among individuals with schizophrenia, yet it often receives insufficient attention in clinical settings. Understanding the specific risk factors associated with suicide in this population is critical for implementing targeted and effective prevention strategies, enhancing patient care, and ultimately reducing this substantial risk.
Objectives: To identify suicide risk factors within a population of patients with schizophrenia.
Methods: This was a descriptive retrospective study conducted at the Psychiatry Department D of Razi Hospital in Tunisia. Clinical records of patients diagnosed with schizophrenia according to DSM-5 criteria, aged over 18 years, without substance-related disorders or somatic pathology explaining psychiatric symptoms, were reviewed. Patients were followed in the department for ten years (2013-2023) and identified as having at least one suicide attempt during their follow-up. Data collected included sociodemographic information (age, education level, residence, socioeconomic status, marital status, offspring, profession) and clinical details (number and nature of suicide attempts, clinical scores at the time of suicide attempt using PANSS and CDS scales, current antipsychotic treatment, family history of suicide and psychosis, and treatment adherence).
Results: We collected data from 60 patients, with a mean age of 42 ± 12.02 years; 66% (n=40) were male. Regarding education and employment, 60% (n=36) had primary education, and 55% (n=33) were employed. 65% (n=39) were unmarried, and 80% (n=48) had a low socioeconomic status. The average number of suicide attempts per patient was 3.52 ± 1.02, with the most common methods being medication ingestion (60%) and strangulation (20%). Approximately 70% (n=42) of patients had a family history of mental disorders, and 40% (n=24) had a family history of suicide. During suicide attempts, mean scores on PANSS-positive, PANSS-negative, and CDS subscales were 25.4 ± 4.7, 18.6 ± 3.2, and 12.8 ± 2.5, respectively.
We found that male gender (p=0.03; OR=3.33; 95% CI [1.12 - 9.89]), low socioeconomic status (p=0.002; OR=2.25; 95% CI [1.04 - 4.86]), family history of suicide (p=0.04; OR=2.90; 95% CI [1.15 - 7.32]), high PANSS-positive scores (p=0.0019; OR=1.98; 95% CI [1.42 - 3.51]), and high CDS scores (p=0.005; OR=2.50; 95% CI [1.32 - 4.72]) were suicide risk factors in our study participants.
Conclusions: The identified factors, including male gender, low socioeconomic status, family history of suicide, and elevated clinical symptomatology, highlight specific areas that warrant focused attention when evaluating and managing patients with schizophrenia.

Main indications of clozapine in clinical practice: A literature review

P. Rivero Rodriguez[1]*, M. Martinez Grimal[1], J. J. Tascón Cervera[1], A. M. Morales Rivero[1] and F. A. Rodriguez Batista[1]

[1]Psychiatry, Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas de Gran Canaria, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2257

Introduction: Clozapine is an atypical and complex antipsychotic that appears to benefit from actions on multiple neurotransmitter systems. While its mechanisms of action are not fully understood, this broad spectrum of activity accounts for clozapine's superior efficacy in treating refractory schizophrenia and other conditions.
Objectives: The aim of this paper is to review the main indications of clozapine and its applications in clinical practice, as well as to highlight key considerations for its safe and effective management.
Methods: A systematic review of the scientific and clinical literature on clozapine was conducted. The review included databases such as PubMed and Cochrane, covering articles from the past 20 years. The scientific evidence obtained was analyzed and synthesized.
Results: Findings indicate that clozapine remains the treatment of choice for patients with treatment-resistant schizophrenia, showing a superior response rate compared to other antipsychotics. Additionally, its effectiveness in reducing suicidal behaviors in patients with schizophrenia and related disorders has been identified. The indications also extend to psychosis in Parkinson's disease, substance use disorders, and a wide range of psychiatric and neurological disorders.
Conclusions: Clozapine is essential in the treatment of refractory schizophrenia and in reducing suicide risk. Its broad mechanism of action, affecting multiple neurotransmitters, allows its use in secondary psychotic disorders and complex comorbidities, such as Parkinson's disease. However, its use is associated with significant risks, necessitating rigorous monitoring of adverse effects.

Socio-demographic characteristics of a First-Episode Psychosis Programme

C. Rodriguez Valbuena[1]*, M. A. Andreo Vidal[1] and M. Calvo Valcárcel[1]

[1]Psychiatry, Hospital Clínico Universitario de Valladolidd, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2258

Introduction: While it is known that of those people who experience psychotic experiences, approximately 75% of them do so for the first time between the ages of 15 and 30 and that the majority are male, there has recently been increasing interest in the incidence of psychosis in other population groups.
Objectives: The present study aims to analyse the sociodemographic data collected over a period of ten months in a First-Episode Psychosis Programme in a third level hospital, such as the Hospital Clínico Universitario de Valladolid.
Methods: It is a retrospective observational study. Patients have been recruited during ten months and those who presented an episode of the psychosis spectrum for the first time (according to DSM-V diagnostic criteria) were included. Different socio-demographic data regarding their age, sex, marital status and employment status have been collected at the time of their inclusion in the programme.
Results: A sample of 23 patients was recruited, of which 26% were women (n=6) and 74% were men (n=17).
The mean age was 29.95 years.
Regarding marital status, 70% of the patients in the sample were single (n=16), 17% were married (n=4), and 13% were living with a partner (n=3). There were no divorced or widowed patients.
In terms of employment, 36% (n=8) of the patients were in employment at the time of admission to the programme. 26% (n=6) were studying, 21% (n=5) were unemployed, 13% (n=3) were on sick leave and 4% (n=1) were receiving a pension.
Conclusions: Socio-demographic data, in general, are as expected in a programme of these characteristics. However, it should be noted that the mean age of the patients recruited is above that most frequently described in the literature. However, we believe that it would be necessary to increase the sample size to be able to offer more robust results.

Delusional parasitosis disorder or the Ekbom syndrome, in relation to a case

L. Del Canto Martinez[1], C. Rodríguez Valbuena[1]*, G. Lorenzo Chapatte[1], M. Ríos Vaquero[1], L. Rojas Vázquez[1], A. Monllor Lazarraga[1], L. Sobrino Conde[1], M. Fernández Lozano[1], N. Navarro Barriga[1], B. Rodriguez Rodriguez[1], F. J. González Zapatero[1], M. J. Mateos Sexmero[1], A. Aparicio Parras[1], M. P. Pando Fernández[1], P. Martínez Gimeno[1], M. A. Andreo Vidal[1], M. Calvo Valcárcel[1], M. D. L. Á. Guillén Soto[1] and M. E. Espinosa Muth[1]

[1]Hospital Clínico Universitario de Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2259

Introduction: Ekbom syndrome, also known as delusional parasitosis, is a psychiatric disorder in which the affected person is firmly convinced that their body is infested with parasites, insects, or any other microorganism, despite the lack of medical evidence to support it.
A 56-year-old woman presents to the emergency department, referred by her primary care physician, due to a sensation of worms in her vagina and rectum. She reports that larvae are coming out of her nostrils, ears… and she feels them settling in her kidney. She is accompanied by her husband, who mentions that on some occasions, she has shown him the supposed parasite.
Objectives: The objectives of this clinical case are to understand whether Ekbom syndrome can be related to any secondary organic pathology, as well as to identify the conditions with which the differential diagnosis should be made, and to determine the most effective treatments.
Methods: Examination: Sensory-perceptual disturbances in the form of cenesthetic hallucinations. High levels of anxiety with functional impact on her daily life.
Complementary tests: A referral was made to Internal Medicine to rule out the presence of parasites, and to Neurology for an MRI with contrast, which revealed a white matter lesion in the brainstem. Tests for anti-AQP4 and anti-MOG antibodies were also conducted, and both were negative. After these studies, it was concluded that the criteria for secondary Ekbom syndrome due to organic pathology were not met.
Results: The differential diagnosis should be made with other psychiatric disorders such as schizophrenia, major depression, or substance-induced psychosis. Neurological diseases, such as

dementia, multiple sclerosis, or meningoencephalitis, should also be ruled out. Lastly, it is advisable to rule out dermatological conditions, such as scabies.
Treatment was initiated with Risperidone and Alprazolam, with good response and improvement in delusional ideation.
Conclusions: Treatment with atypical antipsychotics is effective for this syndrome, reducing delusional ideas and significantly improving the psychiatric symptoms that accompany the delusion, such as anxiety, depression, and insomnia.
Good collaboration between different medical professionals is essential to rule out associated secondary pathology.

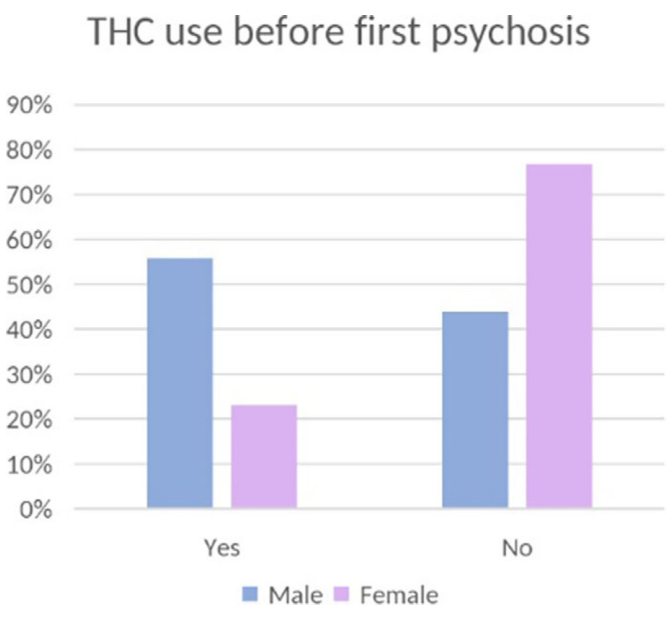
Gender-related differences in cannabis use in schizophrenia patients before and after antipsychotic treatment

A. Rojs[1]*, U. M. Battelino[2], U. Ogrizek[2] and A. Čelofiga[3]
[1]Maribor University Medical Centre; [2]Faculty of Medicine University of Maribor and [3]Department of Psychiatry, Maribor University Medical Centre, Maribor, Slovenia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2260

Introduction: Cannabis is the most widely used psychoactive substance among youth, and its use has been increasingly linked to psychiatric disorders, particularly psychosis. THC, the psychoactive component of cannabis, has the potential to trigger or worsen schizophrenia. Cannabis use is associated with an earlier onset of schizophrenia and is more prevalent among males with first-episode psychosis, which may contribute to an earlier onset of schizophrenia observed in men. With increasing cannabis legalization, understanding gender differences in cannabis use in schizophrenia patients is essential for personalized treatment approaches.
Objectives: To examine the gender-specific impact of cannabis use on schizophrenia or other psychotic disorders, focusing on pre-onset use and discontinuation following antipsychotic (AP) treatment.
Methods: A retrospective study was conducted including personal interviews and medical history reviews of inpatients and outpatients. Inclusion criteria were age between 18 and 65 years, diagnosis of schizophrenia or schizoaffective disorder, and use of AP therapy, both for at least 5 years. Statistical analysis was performed using the Jamovi statistical analysis software.
Results: 136 patients being treated at University Medical Centre Maribor's Department of Psychiatry were included in the study. 38.2% of patients were females and 61.1% were males. The mean age of all participants was 49.2±11.8 years. The mean age at the time of diagnosis was statistically significantly higher in females compared to males (30.4±8.9 versus 26.0±7.9 years; Mann Whitney U test: $p<0.001$). Before the onset of psychosis, 23.1% females and 56.0% males used cannabis, while 76.9% females and 44.0% males did not (Image 1). A chi-squared test showed a significant gender difference in cannabis use ($p<0.001$), indicating higher prevalence among males. After introduction of the AP treatment 58.3% females and 57.4% males discontinued cannabis use (Image 2). A chi-squared test indicated no significant association between sex and cannabis discontinuation ($p=0.956$), with similar rates for both genders.

Image 1:



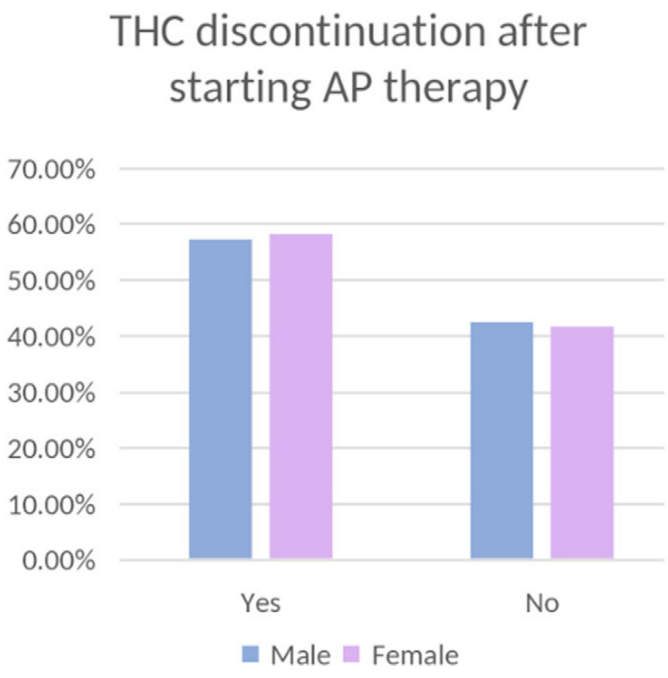


Image 2:

Conclusions: Our study reveals significant gender differences in cannabis use before psychosis onset, with males showing higher prevalence and potentially earlier diagnosis. However, cannabis discontinuation rates after AP treatment were similar across genders, suggesting comparable responses to treatment. As cannabis legalization increases, the need for customized interventions that consider gender-specific factors in managing psychotic disorders is emphasized. Further research is necessary to investigate the long-term effects of cannabis use on treatment outcomes in both males and females.

Exploring Emotional Regulation in Psychosis: A Qualitative Study of Patient Perspectives

E. Rolland-Carlichi[1]*, C. Baeyens[1], C. Dondé[2,3,4,5], B. Gouache[6] and C. Bortolon[1,6,7]

[1]Univ. Grenoble Alpes, Univ. Savoie Mont Blanc, LIP/PC2S; [2]Univ. Grenoble Alpes, GIN; [3]INSERM, U1216, Grenoble; [4]Psychiatry Department, CH Alpes-Isère, Saint-Egrève; [5]Psychiatry Department, CHU Grenoble Alpes; [6]C3R – Centre Référent Réhabilitation Psychosociale et Remédiation Cognitive, CH Alpes-Isère, Grenoble and [7]Institut Universitaire de France (IUF), Paris, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2261

Introduction: The role of emotional regulation (ER) has emerged as a key mechanism associated with psychosis with important implications for its onset and maintenance. However, knowledge about ER in psychosis has been predominantly quantitative, often neglecting patients' own perceptions of the difficulties they experience when dealing with their emotions.
Objectives: To address this gap, we have undertaken a qualitative study to investigate ER in individuals with schizophrenia and schizoaffective disorder using semi-structured interviews. Given the qualitative nature of the study, we have no specific hypotheses. Instead, we aim to explore the stages of emotional regulation and the factors that influence ER in people with schizophrenia and schizoaffective disorder, aligning our investigation with existing theoretical models.
Methods: Patient recruitment and data collection are in progress. Thematic analyses will be carried out.
Results: Results will be presented during the European Congress of Psychiatry.
Conclusions: We expect that this study will provide a deeper understanding of ER from the individuals' perspectives and enrich ER literature and theoretical models related to clinical populations. Ultimately, this research aims to contribute to the development of quantitative studies to test new hypotheses and design individual-tailored psychological interventions aimed at improving ER in patients with schizophrenia and schizoaffective disorder.

EPV1830

Efficacy and safety of dual long-acting injectable antipsychotics in a patient with treatment-resistant schizophrenia: a case report

P. Russo[1], P. Catapano[1], S. Cipolla[1], A. F. Bonamico[1]*, F. Perris[1] and F. Catapano[1]

[1]Department of Psychiatry, University of Campania "Luigi Vanvitelli", Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2262

Introduction: Schizophrenia is often characterized by chronic progression and frequent relapses. However, recent evidence suggests that many patients can achieve symptoms remission and functional recovery through integrated pharmacological and psychosocial interventions. Despite treatment advances, up to 34% of patients are resistant to standard antipsychotic treatments, with clozapine being the gold standard for treatment-resistant schizophrenia (TRS). However, up to 60% of TRS patients may not respond adequately to clozapine due to its adverse effects and lack of compliance. Recently, the use of two long-acting injectable (LAI) antipsychotics has emerged as a potential strategy for managing TRS, particularly in patients with poor adherence to oral therapies.
Objectives: The objective is to provide clinical insights into this novel pharmacological approach consisting in the administration of two LAI antipsychotics in patients with treatment resistant schizophrenia.
Methods: This case report describes the clinical management of a 62-year-old woman with a 20-year history of treatment-resistant paranoid schizophrenia, characterized by multiple hospitalizations, delusions, auditory hallucinations, disorganized behavior, and non-adherence to oral medications.
Results: Due to the patient's poor response to prior treatments, including clozapine, a novel therapeutic strategy was adopted during her hospitalization in March 2023. Two LAI antipsychotics, haloperidol decanoate (100 mg/28 days) and aripiprazole (400 mg/28 days), were administered alternately to optimize symptom control while minimizing adverse effects. Over 8 weeks, the patient demonstrated significant improvements in psychotic symptoms, mood, and functioning. Importantly, adherence to treatment improved.
Conclusions: This case highlights the potential efficacy and safety of combining two LAI antipsychotics in TRS patients, particularly those with poor adherence to oral therapies. The alternating administration of haloperidol and aripiprazole may exploit the synergistic effects of first- and second-generation antipsychotics, offering a promising alternative for managing complex cases of schizophrenia. Further studies are needed to confirm these findings and establish guidelines for dual LAI use in TRS patients.

Cross-modal associations of language brain areas in relation to auditory hallucinations in schizophrenia

P. Salgado-Pineda[1,2], L. Barbosa[1], J. Soler-Vidal[1,2], N. Ramiro[1], P. Fuentes-Claramonte[1,2], P. J. McKenna[1,2], E. Pomarol-Clotet[1,2] and P. del Olmo-Encabo[3]*

[1]FIDMAG- GermanesHospitalàries Research Foundation; [2]CIBERSAM-ISCIII and [3]FIDMAG Germanes Hospitalàries Research Foundation, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2263

Introduction: An influential current theory suggests that auditory verbal hallucinations (AVH) result from abnormal activity in the auditory cortex. Against this, however, Fuentes-Claramonte *et al* (Sci Rep 2021; 11 18890) recently found that AVH did not activate the primary or secondary auditory cortex, although there were activations in other areas including Broca's area. At the level of brain structure, sulcal depth has been increasingly linked to brain function (Natu *et al* Cereb Cortex 2021; 31 48-61; De Vareilles *et al* Dev Cogn Neurosci 2023; 61 101249). Accordingly, exploring brain structural-functional associations for AVH may provide new insights in their biological basis.
Objectives: To assess the relationship between sulcal depth and brain activity during AVH and perception of real speech.
Methods: Functional (fMRI) and structural (sMRI) 3T scans were obtained from 14 patients with schizophrenia who experienced near-continuous AVH. During fMRI, participants pressed a button when they experienced AVH or heard real speech similar in form to

their AVH. Standard fMRI analysis was conducted with FSL, while sMRI images were processed using Freesurfer's recon-all pipeline to measure sulcal depth. Cross-modal registration aligned whole-brain fMRI activation maps to corresponding structural data and correlations between sulcal depth and brain activity were calculated for each vertex; age, sex and estimated premorbid IQ were covaried for. Cluster-based correction was applied for multiple comparisons.
Results: During real speech, a positive correlation was found between brain activations and sulcal depth in the left superior temporal sulcus (STS, BA 22), and negative correlations in the middle temporal (BA 21), frontal (BA 46), and parietal cortex. On the right, positive correlations were seen in the superior and middle temporal cortex (BA 38, 20, 42), while negative correlations were found in the STS (BA 22), pars triangularis (BA45), and precentral (figure a). During AVH, there was a negative correlation in the left pars triangularis (BA 45) only, including Broca's area, with no significant correlations in the right hemisphere (figure b).
Image 1:

Conclusions: The left STS, along with frontal and temporoparietal areas, appear structurally and functionally linked to perception of real speech. In contrast, AVH primarily engages Broca's area and adjacent left inferior frontal regions.

Disclosure of Interest: None Declared

Cognitive function in long term psychosis patients in a tertiary care hospital

S. Shah[1]*, K. Patel[1], A. Bhandari[1], A. Porwal[1], N. Lalwani[1], K. Khetani[2] and M. Parikh[2]
[1]B.J. Medical College and [2]Department of Psychiatry, Civil Hospital, Ahmedabad, India
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2264

Introduction: Psychosis refers to symptoms that are positive, disorganised,or negative and affects 3% of the population yet little information on long-term cognition is available.
Objectives: To determine association between symptom severity,duration of disease and cognitive impairment.
Methods: 50 adult patients suffering from psychosis(DSM-5) for minimum 1 year and currently on at least 1 antipsychotic drug whose cognition and severity of symptoms were assessed by Montreal Cognitive Assessment test(MoCA) and Positive and Negative Syndrome Scale (PANSS) respectively were included in this cross sectional,cohort study.
Results: Mean age of population was 41.5±12.33 years.Disorganised behaviour and speech were the prevalent core symptoms and risperidone was the choice of drug.

Table 1	MALE	FEMALE	P value T-test	Overall mean
Total PANSS Score	68.2 ± 27.5	75.2 ± 34.9	0.430	71.1 ± 30.7
Positive PANSS	15.3 ± 7.67	17.4 ± 7.59	0.357	16.2 ± 7.63
Negative PANSS	17.2 ± 7.06	18.3 ± 8.92	0.646	17.7 ± 7.83
Generalised PANSS	35.6 ± 14.7	39.5 ± 20.6	0.434	37.2 ± 17.3

Table 2	MALE (58%,n=29)	FEMALE (42%,n=21)	OVERALL (n=50)
Mild cognitive impairment(CI)	34%(17)	14%(7)	48%(24)
Moderate CI	24%(12)	20%(10)	44%(22)
Severe CI	0%	8%(4)	8%(4)

Symptom severity was mild and more negative symptoms were prominent (composite score: -1.48±6.47) (Table 1 PANSS Score) and an overall moderate cognitive impairment(16.5 ±4.46, table 2) was seen in population. Females showed a significantly lower MoCA score as compared to males (14.9±4.8 vs 17.65 ± 3.78, p=0.03) implying more cognitive decline (image 3).There is a strong, negative, linear correlation between MoCA and PANSS scores (r= -0.688, p<0.001) wherein all domains(image 1)except memory were negatively correlated to PANSS. Duration of illness showed a moderate, positive,

linear and weak, negative, linear correlation with PANSS(r= 0.417, p =0.003) and MoCA(r = -0.314, p= 0.026) respectively. PANSS items were negatively correlated to MoCA in positive, negative and generalised items except delusions, blunted effect and tension(image 2).

Image 3:

Conclusions: We conclude that cognitive function significantly declines(executive function was the most and memory was not significantly impacted) with respect to increasing disease severity and duration of illness in long term psychosis.Most positive symptoms, excluding delusions,and negative symptoms (apart from blunted affect) and general symptoms (except tension), were significantly linked to cognitive decline.

How Common did the Chronic Schizophrenic Inpatients Suffer from Constipation, and Why? A Cross-sectional Study in A Psychiatric Hospital in Taiwan

Y.-J. Shih[1,2*], N.-Z. Chen[1], Y.-L. Chen[1], H.-W. Chien[2] and Y.-J. Yang[3]

[1]Department of Nursing, Tsao-Tun Psychiatric Centre, Tsao-Tun Township, Nan-Tou County; [2]Department of Healthcare Administration, Asia University, Taichung City and [3]Department of General Psychiatry, Tsao-Tun Psychiatric Centre, Tsao-Tun Township, Nan-Tou County, Taiwan, Province of China
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2265

Introduction: Patients with schizophrenia are at highs risk for constipation and are more likely experienced severe health consequences than the healthy general population. Due to the heterogeneous definition and the health professionals' long-term attitude of taking condition for granted, constipation has been neglected, and the relevant evidence is insufficient.

Objectives: This study aims to investigate the prevalence rate of the chronic schizophrenic inpatients, and to address the relevant factors that may be related with their constipation.

Methods: The study adopted the cross-sectional study design with the approach of purposeful sampling. Hospitalised patients with chronic schizophrenia in a psychiatric hospital in central Taiwan were enrolled through the advertising posters, and a total of 300 persons were finally included after screening with inclusion/exclusion criteria. Both subjective and objective data were collected by questionnaires which were developed and performed by the research

team, and descriptive and inferential statistical analyses were performed with SPSS, version 25. Statistical significance was set at the 5% level.
Results: The definition of constipation was defined as receiving any laxative agent during the study period, and the point prevalence rate of constipation in the chronic schizophrenic inpatients was 74.7%. Three factors were found relevant with constipation with statistical significance. The combined use of first-generation and second-generation antipsychotic medications (OR=3.28 95% CI:1.14-9.46) was regarded as detrimental factors while both increased education years (OR=0.92, 95% CI: 0.87-0.97) and more exercises (more attendance to the twice-a-day self-initiated aerobic exercises) (OR=0.47, 95% CI: 0.23-0.97) were found protective.
Conclusions: The point prevalence rate of constipation was much higher than other similar studies locally or internationally, but, however, such result also faithfully revealed the fact that constipation is literally a ubiquitous health problem among the chronic schizophrenic inpatients. The researchers suggested that performing health education on constipation, enhancing the extent of aerobic exercises and promoting health behaviours for positive cycle, and discussing with the prescribing physicians to simplify the use of antipsychotic agents may mitigate the risk of constipation.

A first case association of Lambert-Eaton Myasthenic Syndrome and First Episode Psychosis: a case report

C. Siopa[1]*, C. Cordeiro[1] and B. M. Moura[2,3]

[1]Department of Neurosciences and Mental Health, ULS Santa Maria, Lisbon, Portugal; [2]Department of Psychiatry and Neuropsychology, School for Mental Health and Neuroscience, Maastricht University Medical Centre, Maastricht, Netherlands and [3]Católica Medical School, Catholic University of Portugal, Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2266

Introduction: Lambert-Eaton Myasthenic Syndrome is an autoimmune neuromuscular junction disorder characterized by proximal weakness, autonomic dysfunction, and areflexia associated with antibodies against voltage-gated calcium channels. Psychotic symptoms can take place in many auto-immune neurological disorders, but their occurrence in myasthenic syndromes has rarely been observed.
Objectives: We report a case of a 21-year-old female with primary autoimmune Lambert-Eaton Myasthenic Syndrome due to anti-voltage-gated calcium channels antibodies subtype P/Q, who developed psychotic symptoms three years after motor symptom onset.
Methods: The patient attended regular psychiatric follow-ups over three years.
Results: With monthly administration, these psychotic symptoms improved after every cycle of intravenous immunoglobulin therapy. The patient displayed partial insight into the mental symptoms. Different causes of reversible psychosis were excluded, such as autoimmune encephalitis and paraneoplastic syndrome, though the patient tested positive for the anti-voltage-gated calcium channels antibodies subtype P/Q. Owing to muscle strength worsening and psychotic episodes, the patient was put on several treatments, including one admission to a Neurology unit. The patient then experienced psychotic exacerbation, leading to treatment with olanzapine at 20 mg/day. Psychotic symptoms persisted but were less severe, with greater intensity at night. After two years, the patient's condition showed significant improvement, with olanzapine increased to 25 mg/day.
Conclusions: This is, to our knowledge, the first described case of psychotic symptoms associated with Lambert-Eaton Myasthenic Syndrome. We speculate that voltage-gated calcium channel antibodies could have a role in developing mental symptoms. However, further hypotheses are discussed. Although the patient had received corticosteroid therapy before symptom onset, the timing and dosage make corticosteroid-induced psychosis unlikely. A primary psychotic disorder, such as schizophrenia, is considered improbable due to the atypical nature of the psychotic symptoms. This case underscores the need for further research on the neurobiological mechanisms linking VGCC antibodies to psychiatric symptoms.

Cognitive Functions in Schizophrenic Patients: A Case-Control Tunisian Study

N. Smaoui[1], D. Jardak[1]*, R. feki[1], S. Omri[1], I. Gassara[1], M. Bou Ali Maalej[1], N. Charfi[1], J. Ben Thabet[1], M. Maalej[1], L. Zouari[1] and L. Triki[2]

[1]psychiarty C, Hedi Chaker University Hospital and [2]Functional Explorations, Habib Bourguiba University Hospital SFAX, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2267

Introduction: Cognitive impairments in schizophrenic patients are present from the first psychotic episode and remain relatively stable over time. These cognitive impairments primarily affect memory, attention, executive functions, and social cognition.
Objectives: The aim of this study was to assess cognitive functions in schizophrenic patients by comparing them to healthy controls.
Methods: Methods: We conducted a cross-sectional, descriptive, and analytical case-control study. It included 15 schizophrenic patients and 15 healthy controls. The study was carried out at the Psychiatry « c » Department outpatient unit at Hedi Chaker University Hospital in Sfax, Tunisia. Both cases and controls underwent interviews to answer predefined questionnaires. We used the Screen For Cognitive Impairment in Psychiatry (SCIP) scale in its literary Arabic version for the assessment of cognitive functions.
Results: The average scores for the total SCIP (ST) and its five subscales (Verbal Learning Test-Immediate (VLT-I), working memory (WMT), verbal fluency (VFT), verbal learning-Test-delayed (VLT-D), and processing speed Test (PST)) were 37.40, 12.87, 14.27, 3.93, 2.47, and 3.93, respectively, for the cases, and 47.27, 15, 18.13, 5.40, 4.33, and 4.40, respectively, for the controls. The cases had significantly lower total SCIP scores than the controls (p=0.05), specifically in the WMT (p=0.02) and VLT-D (p=0.01) subscales. There was no significant difference between the two groups in the VLT-I (p=0.241), VFT (p= 0.202), and PST (p=0.598) subscales.
Conclusions: This study found that cognitive deficits in schizophrenic patients primarily involved impairments in working

memory and verbal learning-delayed recall. Early screening for cognitive impairments in these patients should be systematic to specify the deficits and to hasten the integration in the neurocognitive training programs.

doi: 10.1192/j.eurpsy.2025.2268

Introduction: Cognitive deficits are a fundamental characteristic of schizophrenia, similar to positive and negative symptoms. They lead to significant disability due to their impact on various domains of life.
Objectives: This study aimed to study the relationship between cognitive impairment and sociodemographic, clinical, and therapeutic factors in patients with schizophrenia.
Methods: This study was carried out in the Psychiatry « c » Department at Hedi Chaker University Hospital in Sfax, Tunisia, involving 15 patients with schizophrenia. We used the Screen For Cognitive Impairment in Psychiatry (SCIP) in its literary Arabic version to assess cognitive functions. Data were analyzed using SPSS version 20.0 software.
Results: The mean age of the patients was 40 ± 12.72 years. Among the participants, 80% (n=12) were single. Seven cases (46.7%) had not exceeded primary education. The mean age of illness onset was 27.8 years, and the mean duration of illness was 13.7 years. Five patients (33.3%) had a family history of psychiatric disorders. All patients were receiving antipsychotics (AP), and 13.2% of them were on Haloperidol decanoate (HD). The mean scores for the total SCIP (ST) and its five subscales (verbal learning test-immediate (VLT-I), working memory test (WMT), verbal fluency test (VFT), verbal learning test-delayed (VLT-D), and processing speed test (PST)) were 37.40, 12.87, 14.27, 3.93, 2.47, and 3.93, respectively. A negative correlation was found between age and performance on the ST, WMT, and PST (r values: -0.515, -0.629, -0.615, respectively). Regarding marital status, VLT-I scores were better in single patients ($p=0.007$). Our study revealed that the low level of education was significantly correlated with several cognitive tests measured by the SCIP, including the ST, VLT-I, WMT, VFT, and PST. Mean scores for ST, VLT-I, WMT, VFT and PST were significantly lower in patients with illness onset after age 40 ($p<0.05$). The WMT score was significantly lower in patients with an illness duration exceeding 5 years and in patients with a family history of psychiatric disorders (p values: 0.05; 0.021). The PST score was significantly lower in patients on HD ($p=0.038$).
Conclusions: Sociodemographic, clinical, and therapeutic factors harm the cognitive abilities of patients with schizophrenia. Thus, it is essential to carry out neurocognitive assessments during the follow-up of these patients, taking into account factors likely to predict cognitive impairment.

First episode of psychosis and transition to schizophrenia: the role of polypharmacy

R. Softic[1]* and S. Osmanovic[2]

[1]Psychiatry Clinic, University Clinical Center Tuzla, Tuzla and [2]Psychiatry, Health Center Brcko, Brcko, Bosnia and Herzegovina
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2269

Introduction: The early stages after the onset of a first episode of psychosis (FEP) are crucial for the long-term outcome of the disease. Good outcome can be expected in <50% of patients, but three-quarters of all patients who experience a remission from a first episode of psychosis will have a recurrence of psychotic symptoms within a year of treatment discontinuation. Relapse prevention is key to preventing disease progression and further deterioration. Considerable number of patients experiencing a first episode of psychosis, will eventually transition to a diagnosis of Schizophrenia, so maintenance treatment should be the preferred option even in stable patients after a first episode of psychosis to remain in recovery. There is scarce information about differential effectiveness of antipsycotics in the long term. In such an atmosphere, the idea of polypharmacy with antipsychotics arises and may gain more supporters. Despite its obsolence, and unclear therapeutic benefits, as well as significant health risks, polypharmacy with antipsychotics is relatively common. This practice, due to unwanted effects, can lead to the arbitrary discontinuation of medication, and the consequent relapse of psychosis.
Objectives: To determine the association of transition to schiyophrenia after the first episode of psychosis with a monotherapeutic or polypharmacy approach to the use of antipsychotics.
Methods: A retrospective analysis of all hospitalized patients (87 patients, 65.5% were women), diagnosed with first episode of psychosis during a five-year period was conducted. The rate of relapse, and conversion to schizophrenia was analyzed in relation to the therapeutic approach (monotherapy vs polypharmacy with antipsychotics), within one year after the end of hospitalization due to the first episode of psychosis.
Results: 35.6% (31) of the subjects were treated with monotherapy. 25% (8) of them relapsed within a one-year period. 64.4% (56) of patients were treated with polypharmacy. 55.2% (48) of patients were treated with two antipsychotics, and 9.2% (8) with three. 75% (24) of subjects treated with polypharmacy had a relapse of psychosis within a year after discharge. There is a statistically significant difference between the groups of patients ($p< 0.05$).
Conclusions: A significantly higher rate of relapse, and conversion to schizophrenia within a year after the end of hospitalization due to the first psychotic episode exists in subjects who were treated with two or more antipsychotics compared to subjects treated with monotherapy. The practice of polypharmacy with antipsychotics should remain reserved for individual, specially selected patients.

Management of antipsychotic-induced tardive dyskinesia with calcium channel blockers and botulinum toxin: a case report

A. Souidi[1]*, S. Belbachir[1] and A. Ouanass[1]

[1]Psychiatry B, Ar-razi hospital, Salé, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2270

Introduction: Tardive dyskinesia (TD) is an iatrogenic disorder characterized by a range of movement abnormalities, described as irregular, stereotyped, and choreiform caused by exposure to antipsychotics. This condition can lead to significant or disabling symptoms that affect quality of life. However, the exact mechanism underlying TD remains unclear. Pharmacotherapy of TD includes cholinergic drugs, benzodiazepines, antioxidants, amantadine, propanolol, botulinum toxin, whereas the non-pharmacotherapy approach includes modified electroconvulsive therapy and deep brain stimulation. We successfully treated a chronic schizophrenia patient with comorbid TD using Aripiprazole and botulinum toxin after trying calcium channel blockers in association with Aripiprazole and vitamin E.
Objectives: To determine the effects of calcium channel blocker drugs (Amlodipine) for treatment of neuroleptic-induced tardive dyskinesia in people with schizophrenia, and the efficiency of botulinum toxin in treating induced tardive dyskinesia.
Methods: Through a case report and a literature review, our work aims to study antipsychotics induced tardive dyskinesia and its pharmacotherapy especially the use of calcium channel blocker and botulinum toxin in association with Aripiprazole.
Results: A 22 years male, diagnosed with schizophrenia since the age of 16 years, with one hospitalization. The evolution of his disease was marked by the development of a tardive dyskinesia, cervical and brachial movements disorders with rapid worsening in few months, the patient was treated with olanzapine oral administration. During his follows-up, his tardive dyskinesia disn't resolve despite switching the incriminated antipsychotic to Aripiprazole , lowering the dose since he was on complete remission. we added benzodiazepines and vitamin E to his treatment , before trying the calcium channel blocker for two months, with no improvement , on the contrary a worsening was noted using the Unified Dyskinesia Rating Scale . The aggravation of the movements was a reason for the patient attempted suicide , after this late incident we chose to try the botulinum toxin injections. His tardive dyskinesia was spectacularly improved within the fisrt injections.
Conclusions: Antipsychotic drugs are known to cause a variety of adverse effects, including tardive dyskinesia. Hence the importance of knowing the pharmacotherapy and non-pharmaco- therapy to manage this effect, through this case report where it tardive dyskinesia got treated after using botilinum toxin injections with a spectacular improvement in its Unified Dyskinesia Rating Scale. In our case , we had no response after adding calcium channel blocker .The effects of calcium channel blockers for antipsychotic-induced tardive dyskinesia are unknown, and it use is still limited.

Treatment Strategies in Managing Negative Symptoms in Schizophrenia

S. Y. Teoh

Department of Psychological Medicine, National University of Singapore, Singapore, Singapore
doi: 10.1192/j.eurpsy.2025.2271

Introduction: Negative symptoms pose a significant challenge for the treatment and management of schizophrenia. They refer to the loss or diminishment of normal emotional and behavioural functions, which profoundly impact one's quality of life and socio-occupational outcomes. They are often persistent and difficult to treat.
Objectives: To explore and assess different treatment strategies for addressing negative symptoms of schizophrenia, including pharmacological, psychosocial, and non-invasive neurostimulation interventions. The goal is to provide an overview of current evidence and recommendations for enhancing the quality of life and functional outcomes in individuals with schizophrenia.
Methods: We conducted a review of the extant literature to determine treatment strategies for negative symptoms in schizophrenia. We incorporated findings from randomised controlled studies, meta-analyses and systematic reviews.
Results: We have identified several treatment strategies for negative symptoms in schizophrenia. The literature indicates that second generation antipsychotics such as Cariprazine and Amisulpride are associated with better functional outcomes with lower cognitive impairment. Adding on an anti-depressant, particularly to first-generation antipsychotics, has demonstrated positive effects. Psychosocial interventions including Cognitive Remediation (CR), Social Skills Training (SST) and exercise programs also alleviate negative symptoms. Additionally, non-invasive neurostimulation intervention such as rTMS applied to the left dorsolateral prefrontal cortex (DLPFC) has shown encouraging results in reducing negative symptoms.
Conclusions: The findings highlight the important of comprehensive and holistic treatment approach integrating both pharmacotherapy and non-pharmacotherapy strategies to address the heterogeneity of negative symptoms. There is a need for further research into personalised treatments that address individual symptom profiles.

Disclosure of Interest: None Declared

EPV1843

The influence of self-esteem and therapeutic alliance on psychotic symptom severity

N. Middelkoop[1,2], M. Tetzlaff[1,3*], S. Castelein[1,3,4] and J. Bruins[1,4]

[1]Research, Lenits Psychiatric Institute; [2]Department of mood disorders, PsyQ; [3]Faculty of Behavioral and Social Science, University of Groningen and [4]Rob Giel Research center, University Medical Center Groningen, University Center for Psychiatry, Groningen, Netherlands

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2272

Introduction: The therapeutic alliance (TA) is increasingly acknowledged as a fundamental quality of care indicator. Numerous guidelines advocate TA awareness in practice, but lack specifics on building a strong TA. Yet, previous studies have found independent associations between levels of self-esteem, the quality of TA and severity of clinical symptoms in people with schizophrenia and other psychotic disorders. It suggests that the TA possibly mediates the relationship between self-esteem and psychotic symptoms. The present study therefore examined the relationships between these three factors in people with psychotic disorders.

Objectives: Investigating the mediating effect of TA on the relationship between self-esteem and psychotic symptom severity.

Methods: The short forms of the *Self-Esteem Rating Scale* and the *Working Alliance Inventory*, respectively, were used to assess self-esteem and TA. Psychotic symptoms were evaluated using the *Positive and Negative Syndrome Scale*. Linear regression models were applied, followed by a mediation-model when appropriate.

Results: A higher self-esteem significantly predicted less severe psychotic symptoms (B = -.312; β = -.46, p <.001) and better TA (B = .123, β = .255, p = .009). There was no significant relation between TA and psychotic symptom severity (B = -.161; β = -0.109, p = .289), therefore no mediation-analysis was performed.

Conclusions: We found no association between TA and psychotic symptoms, which may be explained by the mild psychotic symptoms and overall high satisfaction scores on TA in our chronic sample. Another factor might be that current measurements assume a one-on-one relationship between a client and a professional, while nowadays multiple professionals are involved. We recommend re-evaluating the definition and assessment of the TA within chronic psychiatric populations. Our study results also offer practical guidelines for clinicians to improve their quality of care, such as the recommendation to focus on enhancing self-esteem in people with psychosis.

Augmenting clozapine with other antipsychotics: results from two nationwide cohorts

J. Tiihonen[1,2,3*], A. Tanskanen[1,2,4], E. Mittendorfer-Rutz[2] and H. Taipale[1]

[1]Department of Forensic Psychiatry, Niuvanniemi Hospital, University of Eastern Finland, Kuopio, Finland; [2]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden; [3]Neuroscience Center, University of Helsinki and [4]Population Health Unit, Finnish Institute for Health and Welfare, Helsinki, Finland

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2273

Introduction: A large proportion of patients with schizophrenia do not have a sufficient response even to clozapine. Very little is known if any pharmacological augmentation treatment can improve the long-term outcome of these patients.

Objectives: We studied the comparative effectiveness of oral risperidone, olanzapine, quetiapine, and aripiprazole augmentation of clozapine treatment on the risk of hospitalization due to psychotic episode as a marker for severe relapse among patients with schizophrenia.

Methods: In this population-based study, patients with schizophrenia or schizoaffective disorder using clozapine were included from Finnish (years 1996-2017) and Swedish (years 2006-2021) nationwide registers of inpatients care, specialized outpatient care, sickness absence, and disability pension. The risk of hospitalization associated with periods of antipsychotic augmentation vs. clozapine monotherapy (expressed as adjusted hazard ratio, aHR) was assessed by a within-individual design, using each individual as his/her own control, and analyzed with stratified Cox models. The two national cohorts were first analyzed separately, and then results were combined using a random-effect meta-analysis. Secondary outcomes were somatic hospitalization and composite outcome of psychosis/ somatic hospitalization.

Results: In the meta-analysis of 23,206 clozapine users, medium dose (9-16.5 mg/day) aripiprazole augmentation was associated with the lowest risk of relapse among patients with low-dose (< 180 mg/day) (meta-analysis aHR 0.67, 95% CI 0.46-0.97, p=0.03), medium-dose (180-330 mg) (0.79, 0.70-0.91, p= 0.0006), and high-dose (>330 mg) clozapine (0.68, 0.62-0.75, p<0.0001), compared with the same clozapine dose as monotherapy. Augmentation with higher dose of aripiprazole or with other antipsychotics was associated with less favorable outcome. Only aripiprazole augmentations were associated with decreased risk of psychosis/somatic hospitalization, and the lowest risk was observed for medium-dose aripiprazole plus high-dose clozapine (0.70, 0.58-0.84, p=0.0001). Medium-dose aripiprazole plus high-dose clozapine was not associated with the risk of somatic hospitalization (0.66, 0.30-1.44, p=0.29), when compared with clozapine monotherapy in the same dose category.

Conclusions: This meta-analysis of two nation-wide cohorts totaling over 23,000 clozapine using patients indicates that 10-15 mg/day aripiprazole augmentation of clozapine treatment is associated with about 20-30% decreased risk of relapse compared with clozapine monotherapy periods within the same individuals.

doi: 10.1192/j.eurpsy.2025.2274

Introduction: Understanding patient attitudes toward psychoactive substances is essential for improving treatment outcomes in psychotic disorders. Substance use complicates these disorders, worsening symptoms and hindering recovery. Despite known risks, many individuals with psychotic disorders engage in substance use influenced by various factors. The debate over the legalization, decriminalization, and normalization of psychoactive substances, including marijuana and psychedelics, is growing. Legalization removes legal restrictions, decriminalization reduces penalties, and normalization involves societal acceptance of these substances. Alcohol, a culturally embedded substance, is also highly harmful despite its legal status. Recently, there has been increased interest in cannabis for therapeutic use, though its role in psychotic disorders remains contentious. While some evidence suggests the benefits of cannabidiol (CBD), excessive use of high-THC cannabis may elevate the risk of psychosis or exacerbate symptoms.
Objectives: To examine the attitudes and perceptions of patients with psychotic disorders toward alcohol, marijuana, and psychedelics, and to assess the prevalence of psychoactive substance use among individuals with psychotic disorders.
Methods: For this descriptive study, data were collected from September 2023 to September 2024 through a questionnaire distributed to patients during their hospitalization at the University Hospital of Split in the Psychiatry Department. Inclusion criteria included adult patients with ICD diagnoses from F20-F29 who agreed to participate in the study; exclusion criteria included patients with F21 (unless they also have F23) and those who declined to participate.
Results: This study examined the attitudes and behaviors of 62 patients with psychotic disorders regarding alcohol and psychoactive substance use. The sample consisted of 37 men (59.7%) and 25 women (40.3%). Alcohol consumption was reported by 34 respondents (54%) in socially acceptable quantities, while 7 respondents (11.3%) admitted to combining alcohol with medications. Additionally, 8 respondents (12.9%) reported using other psychoactive drugs. Regarding perceptions, 6 respondents (9.7%) believed that marijuana helps their health, and an equal number expressed a similar belief about psychedelics.
Conclusions: Despite therapeutic cooperation, many patients continue to consume alcohol due to its availability and social acceptance. Some patients use marijuana, believing that it improves their mental state, while others use psychedelics; however, fewer patients engage with these substances compared to alcohol. These findings reveal significant variability in substance use and perceptions among patients with psychotic disorders, highlighting the need for further investigation into the factors influencing these behaviors to develop effective treatment strategies and support systems tailored to this population.

Public perception towards marriage involving individuals with schizophrenia and its relationship with affirming attitudes among the general population

Y. Trabelsi[1]*, B. N. Saguem[1] and N. Jaafar[1]

[1]Psychiatry Department, Farhat Hached Hospital, sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2275

Introduction: The perception of marriage involving individuals with schizophrenia remains critical in understanding the broader societal attitudes towards mental illness. Stigma and misconceptions often shape public views. Few studies have been conducted on this subject and the perceptions regarding this topic have not been thoroughly investigated.
Objectives: This study aimed to explore perceptions of the general public regarding marriage in individuals with schizophrenia and to assess the relationships between these perceptions and affirming attitudes.
Methods: A cross sectional study was conducted via an online survey. It included a detailed description of clinical symptoms and outcomes of schizophrenia. Thirteen open-ended questions, adopted from the study of Kumar et al., 2019, and assessing various aspects of marriage in individuals with schizophrenia were asked.
A battery for measurement of affirming attitudes about mental illness was used, comprising the Empowerment scale(ES) to assess people's beliefs about the social worth of people with mental illness, the Recovery scale (RS) to evaluate people's beliefs about potential of recovery from serious mental illness and the self-discrimination scale (SDS) to assess people's expectations about a person with mental illness successfully pursuing his life goals.
Results: A total of 304 participants took part in the study, most of whom were between 20 and 30 years old, 80,9 were women. Additionally, 23.35% mentioned living with someone diagnosed with a psychiatric disorder. Results revealed that the majority of participants held reservations about marriage for individuals with schizophrenia. Over 50% believed that marriage neither cures nor improves symptoms, and more than 60% were reluctant to marry someone with schizophrenia or agreed to a marriage match involving a schizophrenic person. However, 53% agreed that individuals with schizophrenia have the right to make their own decisions about marriage, though concerns remain regarding their ability to manage family responsibilities. Regarding perceptions of schizophrenia, individuals who believed that marriage is not a cure for the illness and those who stated they would never consider marrying someone with schizophrenia exhibited significantly higher RS scores (p=.009 and p<10^-3, respectively). Participants who disagreed with the fact that individuals with schizophrenia have the right to marry showed significantly higher RS (p=.023), ES (p=.03), and SDS (p=.033) scores.
Conclusions: This study highlights the ongoing challenge of stigma towards individuals with schizophrenia, particularly about their perceived suitability for marriage. While there are encouraging signs of changing attitudes, broader efforts are needed to foster a more inclusive and supportive societal perspective on mental health and marriage.

EPV1848

Public Perceptions of Marriage Among Individuals with Bipolar Disorder Versus Schizophrenia: A Comparative Analysis

Y. Trabelsi[1]*, B. N. Saguem[1] and N. Jaafar[1]

[1]Psychiatry Department, Farhat Hached Hospital, sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2276

Introduction: Marriage is widely regarded as an important part of social life, providing emotional support and stability. However, public perceptions of marriages involving individuals with psychiatric conditions like schizophrenia and bipolar disorder are not well understood. Stigma likely plays a crucial role in shaping these perceptions and affects societal attitudes toward such unions.
Objectives: This study aimed to explore and compare public perceptions of marriage in individuals with schizophrenia and in individuals with bipolar disorder, and to examine how these views affect their marital prospects.
Methods: A cross-sectional survey was conducted using an online form to gather data from the general population. It covered socio-demographic and clinical variables, as well as detailed descriptions of schizophrenia and bipolar disorder symptoms and outcomes. The survey also included questions on public attitudes toward marriage involving individuals with schizophrenia and bipolar disorder. Participants answered 13 questions about the right of individuals with these conditions to marry, their capacity to maintain a stable relationship, and whether they would personally consider or recommend marrying someone with these disorders. This study was inspired by the article of Kumar et al., 2019).
Results: The study involved 304 participants, mostly young adults, with 246 being women. Around 35.6% had a family history of psychiatric illness, and 23.35% lived with someone with a psychiatric disorder. The findings revealed significant differences in public perceptions of marriage for individuals with schizophrenia versus bipolar disorder. Participants were more strongly opposed to marriage as a cure, especially for schizophrenia ($p<10^{-3}$), and more had never considered finding a partner for someone with schizophrenia compared to bipolar disorder ($p<10^{-3}$). Reluctance to marry someone with schizophrenia was also significantly higher, even if compatibility was present ($p<10^{-3}$).
Regarding bipolar disorder, concerns about marriage exacerbating symptoms were more prevalent compared to schizophrenia ($p=0.001$). Despite these concerns, the stigma around marriage with individuals affected by bipolar disorder appeared less severe, as indicated by participants' greater openness toward the possibility of such a union in individuals with schizophrenia ($p<10^{-3}$).
Conclusions: Results emphasize the need for targeted awareness and educational initiatives to address misunderstandings and support the marriage goals of individuals with mental health conditions. Future studies should examine the factors shaping these perceptions and develop approaches to promote a more inclusive perspective on marriage and mental health, tackling stigma and challenging widespread stereotypes.

Disclosure of Interest: None Declared

EPV1849

General population's perceptions regarding marriage in patients with schizophrenia

Y. Trabelsi[1]*, B. N. Saguem[1] and N. Jaafar[1]

[1]Psychiatry Department, Farhat Hached Hospital, sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2277

Introduction: Public perceptions of mental illness, particularly in the context of marriage, are shaped by a myriad of factors, including cultural beliefs, media representations, and personal experiences. These perceptions often involve misconceptions and negative stereotypes leading to social stigma and discrimination. For individuals with schizophrenia, stigma can result in significant challenges in forming and maintaining marital relationships.
Objectives: To explore these perceptions we performed a qualitative analysis of public attitudes toward marriage in individuals with schizophrenia. By examining these perceptions, we aimed to identify common themes, misconceptions, and areas where public education might be most effective.
Methods: A cross-sectional study was conducted among general population. A survey was proposed via social networks. It included, additionally to socio-demographic and clinical variables, a detailed description of clinical symptoms and outcomes of schizophrenia along with open-ended questions assessing the perceptions of potential benefits and disbenefits of being an intimate partner of an individual with schizophrenia. Answers were arranged and the commonly reported themes in public opinion were identified.
Results: A total of 304 participants majoritively aged between 20 and 30 years old were included, 80.9% among them were women. The most of them were graduated from university. Family psychiatric history was reported by 35.6% of the participants and 23.35% of them stated that they were living with a person with a psychiatric disorder. About 87% of the participants admitted that they had seen a psychiatrist at least once in their lives. Responses regarding potential disbenefits of being married to a patient with schizophrenia included 8 themes, the most representative ones were 1) the fear of dealing with the exacerbations (16.4%); 2) the risk of being attacked physically (10.9); 3) the impossibility of maintaining a stable relationship (10.9%); 4) the lack of communication (6.6%); and 5) the risk of separation (5.6%). Other themes included concerns about 6) dealing with an irresponsible partner (4.6%); 7) the risk of suicide and 8) the possibility of transmitting the pathology to descendants (2.3%).
About 23% of the participants stated that they were willing to get married with a schizophrenic patient in order to help him survive his illness.
Conclusions: This study has shed light on the complex and multifaceted perceptions held by the general population regarding marriage with a schizophrenic person. However, the study also revealed a glimmer of hope in the form of empathy and a growing recognition of the need for accurate information and support. As public awareness of mental health issues continues to rise, there is potential to challenge and change these negative perceptions.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2278

Introduction: Individuals diagnosed with schizophrenia experience a 2- to 3-fold higher mortality rate compared to the general population, with cardiovascular disease being the primary cause. On average, they lose about 15 years of potential life. Additionally, up to 15% of individuals with schizophrenia develop type 2 diabetes, further exacerbating their health challenges.
Objectives: This study aimed to evaluate the efficacy of Semaglutide, a glucagon-like peptide-1 receptor agonist, as an adjunctive treatment to antipsychotic therapy in patients with schizophrenia spectrum disorders, prediabetes and overweight.
Methods: We conducted an investigator-initiated, randomized, placebo-controlled, double-blind trial across two clinical sites in Denmark. Out of 402 possible eligible participants, 154 were enrolled. Participants were receiving second-generation antipsychotic treatment, were overweight or obese, and had prediabetes (HbA1c 39-47 mmol/mol). Data collection spanned from January 1, 2022, to May 1, 2024. The primary outcome measure was changes in HbA1c, with secondary outcomes including psychotic symptoms, quality of life, BMI, and cardiometabolic parameters. A prespecified statistical analysis plan was registered with ClinicalTrials.gov prior to unblinding the treatment arms.
The trial is spear-headed by Odense University Hospital with recruitment from community psychiatry settings in the Region of Southern Denmark and Region Zealand.
Results: The last patient visit was May 1, 2024 and unblinding occurred primo September 2024. Results will be analyzed in Q4, 2024 and primary and secondary results presented at the conference.
Conclusions: Semaglutide holds potential as a novel therapeutic option for individuals with schizophrenia who experience prediabetes and antipsychotic-induced weight gain.

doi: 10.1192/j.eurpsy.2025.2279

Introduction: Schizophrenia is a severe psychiatric disorder characterized by positive (delusions and hallucinations), negative and disorganization symptoms. According to the influential dopamine hypothesis, positive symptoms of schizophrenia are linked to increased dopamine transmission in subcortical regions, particularly the striatum. Kapur's aberrant salience theory further suggests that hyperdopaminergia leads to increased and disorganized reward prediction error signalling, leading to the misattribution of significance to irrelevant stimuli, which contributes to the development of delusions. Negative symptoms have been argued to reflect reduced reward prediction error signalling.
Objectives: To design an optimized monetary incentive delay (MID) task for use in fMRI studies of schizophrenia patients. For this, a pilot study was conducted in order to test the effects of monetary incentives on task performance in schizophrenia patients and healthy controls.
Methods: Nine healthy controls and seven patients with DSM-5 schizophrenia completed the MID task, including a training and test phase. This task evaluates reward processing by presenting cues that predict either rewarding or non-rewarding outcomes before a target that requires a speeded response. We investigated the effect of these cues on task performance (accuracy and reaction times) through a repeated measures ANOVA that compared rewarding and non-rewarding cues with a between-subjects factor for diagnosis.
Results: The patients with schizophrenia exhibited slower RT and lower accuracy compared to healthy controls (main effect of group, RT $p = 0.008$, accuracy $p = 0.047$). There was also a significant main effect of condition, with better accuracy and shorter RT in the rewarded condition in both the patients and controls (accuracy $p = 0.01$, RT $p = 0.003$). However, there was no significant group*-condition interaction. Both the patients and the controls showed significant improvements in task performance when rewards were offered, compared to when no rewards were provided.
Conclusions: Our MID task shows expected performance effects in patients with schizophrenia, producing effects comparable to those observed in healthy controls. This MID task design is therefore suitable for examining and understanding symptom profiles associated with reward processing, such as delusions and negative symptoms.

Utility of Computational Models in Predicting the Efficacy of Stem Cell Therapy for Schizophrenia – Insights from a Systematic Review and Meta-Analysis

J. Parmar[1], A. A. Pillai[2], R. Walwaikar[2], A. Agrawal[3], A. A. Kumar[4], A. S. Nagendrapandian[5] and F. Sheikh[6]*

[1]Government Medical College, Amritsar; [2]SSPM Medical College and Lifetime Hospital, Sindhudurg, India; [3]Humanitas University, Milan, Italy; [4]GMERS Medical College, Vadnagar, India; [5]West Windsor Plainsboro High School South, New Jersey, United States and [6]Greater manchester mental health trust, Manchester, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2280

Introduction: Schizophrenia is a disorder associated with significant morbidity, largely due to poor treatment outcomes with existing interventions. Emerging evidence demonstrates that stem cell therapy using either patient-derived induced pluripotent stem cells (iPSCs) or mesenchymal stem cells (MSCs), may offer an effective alternative for treating schizophrenia by promoting the restoration of excitatory interneurons. However, given the variability in the therapeutic potential of iPSCs and MSCs, adopting a progressive computational approach to predict the clinical outcomes of these therapies might be an effective strategy.

Objectives: The objective was to evaluate the efficacy of stem cell therapy in schizophrenia and to explore the role of computational models in predicting the outcomes of this therapy.

Methods: We conducted a systematic search of clinical trials and studies published (since 2015) in PubMed, SCOPUS, and EMBASE. The review included all randomized controlled trials involving iPSC or MSCs-based interventions and studies that incorporated computational models to predict outcomes. A total of 22 studies including 1436 individuals were included in the review. Meta-analytic methods were used to calculate pooled effect sizes on cognitive outcomes and reduction or improvement in negative symptoms was recorded using standardized mean difference (SMD) and risk ratios (RR).

Results: This involved 979 patients with schizophrenia from four studies that met quality review criteria, revealing that MSC-based therapies using positive controls significantly improved negative symptoms with a standardized mean difference (SMD) of 0.52 (95% CI, 0.32–0.73; $P < 0.001$). Improvements in cognition, especially in the domains of memory and executive function, were significant in treated groups using iPSCs (SMD = 0.61, 95% CI, 0.40–0.82; $P < 0.0001$). The predictive models that classified interneuron (PV and SST) restoration in terms of sensitivity (83.4%) and specificity (78.2%) enhanced the ability to predict responder treatment effects. Ultimately, computational modeling reduced predictive variance in therapeutic efficacy by 18.7% ($p = 0.006$).

Conclusions: Our meta-analysis revealed that stem cell therapies, particularly MSCs and iPSCs, significantly improved both negative and cognitive symptoms associated with schizophrenia. Additionally, predictive models using computational methods were found to accurately predict the therapeutic outcomes for intervention treatments based on the resting patient subgroups that received interneuron restorations. We conclude that stem-cell-based therapies especially when used alongside computational models have tremendous potential to provide precise and personalized psychiatric care.

Development of a Novel Task to Assess Fast and Slow Thinking in Schizophrenia

B. Yıldırım[1]*, I. Gómez[1], P. Fuentes-Claramonte[1], M. Á. García-León[1], N. Ramiro[1], P. McKenna[1] and E. Pomarol-Clotet[1]

[1]FIDMAG Germanes Hospitalàries Research Foundation, CIBERSAM-ISCIII, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2281

Introduction: Delusions in schizophrenia have been theoretically linked to probabilistic reasoning bias ('jumping to conclusions', JTC), although experimental support has been mixed (Garety *et al* BJP 2013; 203 327-333). Ward and Garety (Schiz Res 2019; 203 80-87) recently proposed a reformulation of the theory in terms of Kahneman's concepts of 'fast' and 'slow' thinking. This proposes that decision-making involves two cognitive processes: a fast, heuristic-based approach which is prone to errors, and a slow, deliberate process that carefully evaluates all the relevant evidence. According to this view, an overreliance on fast thinking and/or reduced engagement of slow thinking underlies the initial development of delusional interpretations of everyday events and also makes them harder to be corrected.

Objectives: Our aim was to develop a novel task to investigate the fast and slow thinking hypothesis of delusions in patients with schizophrenia, for use in behavioural and functional imaging studies. As a preliminary step, we tested this task on healthy participants.

Methods: A battery of 137 experimental questions (where fast thinking leads to incorrect answers) was generated from multiple sources, including examples of the base rate and conjunction fallacies, the cognitive reflection test (CRT), trick questions, and syllogisms. Example questions included: If it takes 5 machines 5 minutes to make 5 widgets, how long would it take 100 machines to make 100 widgets? [Correct answer = 5 minutes; intuitive answer = 100 minutes; category: cognitive reflection] A farmer had 15 sheep and all but 8 died. How many are left? [intuitive answer: 7; correct answer: 8, category: trick question]. 137 control questions (where both fast and slow thinking give the correct answer) were adapted from the experimental questions. The questions were administered online to 176 healthy volunteers using PsychoPy software, with 15 experimental and 15 control questions randomly assigned to each participant.

Results: The sample had a mean age of 40.3 years (range 17-77 years); 55.1% were female and 65.9% had a university education. Correct answers to experimental questions were markedly fewer than answers to control questions in all categories (overall $p < 0.001$). Response latency for the experimental questions was slightly higher than for the control questions, apart from in one category (CRT) (overall $p = 0.004$).

Conclusions: Results from a large sample of healthy participants indicate that a battery of questions can be feasibly developed to reliably detect fast thinking.

Correlates of adherence to antipsychotic Medications in Patients with Schizophrenia and Bipolar Disorders

J. ZAOUALI[1]*, F. ASKRI[1], S. ELLINI[1], M. CHEOUR[1], R. DAMAK[1], S. HALLIT[2] and F. FEKIH-ROMDHANE[1,3]

[1]Psychiatry, Razi Hospital, Tunis, Tunisia; [2]Research, School of Medicine and Medical Sciences, Holy Spirit University of Kaslik, P.O. Box 446, Jounieh, Kaslik, Lebanon and [3]Psychiatry, Tunis El manar university, faculty of Medicine of Tunis, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2282

Introduction: The World Health Organization defines non-adherence to treatment as "a situation where an individual's medication-taking behavior diverges from the agreed recommendations of healthcare professionals". Individuals with psychiatric disorders frequently encounter challenges in adhering to their prescribed treatments, which is due amon other factors to a lack of insight. The non-adherence can lead to increased relapse rates, diminished treatment efficacy over time, and adverse effects on both the individual and the broader community.
Objectives: This study's objectives were towfold : (1) to investigate medication adherence among patients with schizophrenia and bipolar disorders under antipsychotics, and (2) to identify various factors associated with non-adherence to antipsychotic treatments.
Methods: A cross-sectional study was conducted at Razi Hospital, Tunisia, between December 2023 and January 2024. Were included patients who attended the outpatient clinic during the study period, who were in remission for at least one month and who were receiving antipsychotic medication. The Brief Adherence Rating Scale, the Positive and Negative Syndrome Scale and the Glasgow Antipsychotic Side-effects Scale were administered to all patients.
Results: The study included 35 male patients with a mean age of 39 years ± 11 years. Schizophrenia was diagnosed in 86% (N=30) of the participants. Of these, 49% were prescribed first-generation antipsychotics (N=17), while 51% (N=18) were prescribed second-generation antipsychotics. More than half of the patients (63%) demonstrated non-adherence to their treatment regimen. Among these, 65% exhibited moderate to severe lack of insight into their illness, and 66% had not received psychoeducation about their condition. A significant association was found between non-adherence and moderate to severe lack of insight (p=0.000, OR=4, 95% CI [1.4-10]), lack of psychoeducation for the patient (p=0.02, OR=2, 95% CI [1-4.3]), and lack of psychoeducation for the caregiver (p=0.05, OR=1.7, 95% CI [0.9-3.2]). Binary logistic regression analysis indicated that lack of insight (p=0.01, OR=3.6) remained a significant risk factor for non-adherence.
Conclusions: This study underscores significant association between lack of insight and non-adherence to antipsychotic medications. Enhancing insight through early psychoeducational interventions could potentially improve medication adherence and positively influence long-term clinical and functional outcomes for patients.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2283

Introduction: The Epidemiological Study of Cognitive Impairment in Schizophrenia (EPICOG-SCH) is a brief battery to screen for cognitive impact of schizophrenia in outpatient settings. The EPICOG-SCH includes well-known subtests available worldwide that cover key cognitive domains demonstrated to be related to a variety of functional outcomes. Novel composite scores are modelled to predict patient's functionality in daily life at short, mid and long term.
Objectives: We want to progress in the elaboration of specific algorithms first episodes of schizophrenia at different follow up periods by modelling cognitive performance to predict short, mid and long term functionality.
Methods: Data for the present investigation were obtained from an the epidemiological and three-year longitudinal intervention program of first-episode psychosis (PAFIP) conducted at the outpatient clinic and the inpatient unit at the University Hospital Marques de Valdecilla, Spain. The cohort is composed by 167 patients with a diagnose of Schizophrenia and 160 healthy controls recruited between February 2001 to February 2014. For all analyses, a subset of measures was selected corresponding to the EPICOG-SCH domains with the Rey Auditory Verbal Learning Test (RAVLT) task ifor Logical Memory. Functional outcomes were measured by the Disability Assessment Scale (DAS) and the General Assessment for Function (GAF) scales. Functional measurements were conducted regarding premorbid, baseline set at clinical stabilization and 1, 3 year follow-up, and cognitive assessments where conducted at baseline and 1, 3 years of follow up.
Results: A cohort of 122 patients and 114 Controls completed the study with a 3-year follow up were included in the analysis. Changes across evaluations is tested in patients and controls. A regression analysis including the different EPICOG-SCH subtests at baseline as predictors of functionality at the different time points to explore the best predictive algorithms at 1 and 3 years of patient's functionality in daily life following a first-episode.
Conclusions: The EPICOG-SCH brief battery is modelled to be a useful first to screen for the cognitive impact of schizophrenia in daily functionality daily life. This research work will validate the composite scores for a context of use of first-episodes schizophrenia and follow up. To date it has not been described an efficient and straightforward way for clinicians working with schizophrenia to

transfer quantitative information about patient cognitive profile into real life. The EPICOG-SCH global composite score provides valuable information to clinicians which can facilitate disease management, drawing a roadmap for cognitive rehabilitation, and planning of supportive resources from the community and health care system.

Breaking the silence: Understanding the impact of sexual violence on mental health in Tunisia

K. Abdessattar[1]*, B. Amamou[2], H. Ktari[1], H. Mami[1], M. Oumaya[1] and R. Bouzid[1]

[1]Mental health, Med Taher Maamouri Hospital, Nabeul and [2]Mental health, Fatouma Bourguiba hospital, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2284

Introduction: Sexual violence is considered to be one of the most traumatic, pervasive, and common human rights violations. In Tunisia, there is limited research about this issue.
Objectives: The present study aims to explore the relationship between sexual violence and mental health in Tunisia, with a focus on understanding the prevalence and types of mental health problems experienced by victims, as well as different factors related to it.
Methods: This is a descriptive cross-sectional study that took place over six months from September 2022 to March 2023. Data collection was carried out using an online self-administered questionnaire distributed online. It is composed of 24 questions with "restricted" answers in the form of propositions. Each participant was invited to fill out the sociodemographic and clinical data form, the Harvard trauma questionnaire and the Hopkins symptoms questionnaire.
Results: 86.1% of our participants reported that they were subjected to a form of sexual aggression. Including 95.5% female, 4% male, and 0.5% non-binary. The median reported age of the first sexual aggression was 14 years. Our study found no significant correlation between age and trauma outcomes. Participants who reported sexual aggression were more likely to have scores above the cutoff for both the Harvard PTSD score and the Hopkins Symptoms Checklist scores. No statistically significant difference was found in the comparison of scores across genders. Participants with a past medical psychiatric history had a significantly higher average Harvard PTSD score as well as Hopkins symptoms checklist scores compared to those without this history. 35.5% of our participants chose not to disclose their traumatic experience to anyone. Notably, 34% of disclosures were made to friends and 22% to family members. The study found no statistically significant difference in the scores for post-traumatic stress disorder (PTSD), anxiety, or depression between participants who disclosed the assault and those who kept it a secret. The aggressor's identity is mostly unknown (34.7%). Higher scores were reported by those who identified their partner as the aggressor. Our participants reported that they were victims of more than one episode of sexual assault in 67.3% of cases, with a mean age of revictimization of 19 years. A lower age of first sexual aggression was a significant risk factor for subsequent revictimization. 3.8% of our participants took legal action against their aggressor, and they had significantly higher average scores on all measured items and total scores. 30.8% of our participants seek psychiatric help. And the main reason for that would be a lack of awareness and knowledge.
Conclusions: The cultural context of Tunisia, intricately woven into the fabric of our study, emphasizes the need for targeted and culturally sensitive approaches to addressing the aftermath of sexual violence.

Impact of Pornography Consumption on Sexual Self-Esteem in Tunisian Women

D. Achref[1]*, A. Aissa[1], S. Rouached[2] and R. Jomli[1]

[1]Psychiatry department A and [2]Psychiatry department C, Razi Hospital, tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2285

Introduction: The consumption of pornographic products is a phenomenon that continues to increase considerably, especially among young people. It is encouraged by easier access to the Internet. On the other hand the concept of sexual self-esteem is a relatively new and little explored subject in the literature. It has emerged across a range of areas such as weight, sexual trauma and physical satisfaction.
Objectives: The aim of our study is to evaluate the impact of pornography consumption on sexual self-esteem in a population of Tunisian women and to determine the associated factors influencing this relationship.
Methods: This is a cross-sectional, descriptive, and analytical study conducted among 107 Tunisian women.
Data were collected using an anonymous self-questionnaire in French, using Google Forms, distributed across various Facebook platforms. It explored sociodemographic data, medical history and sexual health characteristics, sexual behavior, and pornography consumption along with its impact.
For the evaluation of sexual self-esteem, we used the "Sexual Self-Esteem Inventory for Women - Short Form" (SSEI-W-SF) in French language. (Hannier, S et al. Translation and validation study of the French version of the "SSEI-W-SF". Sexologies. 2022;31.)
Results: The majority of women (76%) are aged between 18 and 30 years, primarily from urban backgrounds (89%), professionally active (81%). In terms of marital status, 43% are single. Most women (60%) have no psychiatric history, 25% are being treated for anxiety disorders, and 20% for mood disorders. More than a quarter (28%) reported experiencing sexual abuse. Regarding sexual education, majority of women (94%) consider its learning essential, although only 11% received structured education at school. Consequently, 80% of women indicated that their main source of sexual education was online. In the studied population, 60% of women reported consuming pornography, primarily in the form of videos (79%). The evaluation of sexual self-esteem using the SSEI-W-SF revealed an average total score of 61.66, ranging from 26 to 82, with a median of 63 and a standard deviation of 10.887. Women with the lowest scores were particularly affected in terms of adaptability and control. We observed a significant correlation between pornography consumption and the absence of sexual

education during childhood (p = 0.009). Women who deemed sexual education essential showed lower consumption of pornography (p = 0.027).
Regarding sexual self-esteem, no statistically significant correlation was found between sexual self-esteem and pornography consumption, either for the global sexual self-esteem score (p = 0.809) or for the five spheres of sexual self-esteem assessed separately.
Conclusions: In conclusion, the influence of pornography on sexual self-esteem warrants careful examination, requiring a balanced perspective that addresses both its positive and negative effects on individuals' well-being.

Sexual Dysfunction in Female Medical Residents: The Influence of Dispositional Mindfulness

R. Masmoudi[1], S. Ajmi[1]*, M. Mnif[1], F. Guermazi[1], I. Feki[1], I. Baati[1] and J. Masmoudi[1]

[1]Psychiatry A department, Hedi Chaker hospital university, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2286

Introduction: Dispositional mindfulness (DM), also known as Trait mindfulness, refers to the inherent ability to focus on and sustain attention on present-moment experiences with an open and nonjudgmental attitude. Recent research has increasingly highlighted the positive impact of DM on mental health.
Objectives: To evaluate the association between DM and sexual dysfunction (SD) among female medical residents.
Methods: A cross-sectional online survey, designed using Google Forms, was distributed on social media platforms. We included married and sexually active medical residents. Female Sexual Function Index (FSFI) was used to evaluate female sexual dysfunction. We used the Mindfulness Attention Awareness Scale (M.A.A.S.) to measure the frequency of open and receptive attention and awareness of ongoing events and experiences and the Spielberger State-Trait Anxiety Inventory (STAI-Y-T) to assess anxiety traits.
Results: Sixty-five medical residents with an average age of 29.43 ± 1.95 years completed the online questionnaire. The average age at first sexual intercourse was 25.15 ± 2.34 years and the average frequency of sexual intercourse was 6.61 ± 4.18 times per month.
The mean scores for the M.A.A.S and STAI-Y-T were 26.25 ±5.61 and 45.85 ±9.36 respectively.
The anxiety assessment using the STAI-Y-T scale showed that 30 residents (46.4%) had moderate anxiety, and 8 (12.3%) had high to very high anxiety levels.
The mean total FSFI score was 26.25 ± 5.61 and SD was noted in 49.2% of the cases.
A positive correlation was found between the level of MAAS and the total FSFI score (p=0.003; r=0.35),"Desire" dimension (p=0.02; r=0.28), "Lubrication" domain (p=0.004; r=0.35), and the "Satisfaction" (p=0.006; r=0.33)
Anxiety levels were negatively correlated with the total FSFI score ($p<10^{-3}$; r=-0.42), the "Desire" dimension (p=0.008; r=-0.32), "Arousal" dimension (p=0.003; r=-0.36), "Lubrication" domain (p=0.002; r=-0.37) and "Satisfaction" domain (p=0.002; r=-0.38).
Conclusions: The results of this study revealed relatively high prevalence rates of SD among medical residents and highlighted several vulnerability factors. Therefore, several measures should be implemented to prevent and determine the factors correlated with SD.

Female Sexual Dysfunction in Medical Residents: Relationships with sociodemographic and clinical Factors

R. Masmoudi[1], S. Ajmi[1]*, M. Mnif[1], M. Bouhamed[1], I. Feki[1], R. sellami[1] and J. Masmoudi[1]

[1]Psychiatry A department, Hedi Chaker hospital university, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2287

Introduction: Female sexual dysfunction (SD)has gained attention in recent years. Multiple factors contribute to women's sexual vulnerability, including neurobiological, sociocultural, psychological, and interpersonal factors.
Objectives: To assess the prevalence of SD and to determine sociodemographic and clinical factors related to this dysfunction.
Methods: We conducted a cross-sectional and descriptive study including married and sexually active female medical residents from different specialties.Data were collected using a self-questionnaire published by GOOGLE FORMS. The questionnaire included sociodemographic characteristics, substance use, marital life information, professional data, and information related to sexual life. Female Sexual Function Index (FSFI) was used to assess female sexual dysfunction.
Results: A total of 65 medical residents completed the online questionnaire. Four residents (6.20%) considered the work environment to be unfavorable, 3.1% were smokers and 55.4% had children. The average frequency of sexual intercourse was 6.61 ± 4.18 times per month. Nine participants (13.8%) reported having sexual intercourse under partner pressure. Sexual dysfunction was observed in 49.2% of the cases. The factors correlated with the total FSFI score were an unfavorable work environment (p=0.02), smoking (p=0.007) and high frequency of sexual activities (p=0.02; r=0.28).The factors correlated with the "Desire" dimension were: sexual intercourse under partner pressure (p=0.002) and high frequency of sexual activities (p=0.001; r=0.41).The factors correlated with the "Arousal" dimension were: an unfavorable work environment (p=0.01) and psychiatric history (p=0.05).The "Lubrication" domain was associated with an unfavorable work environment (p=0.006) and smoking (p=0.02). The "Satisfaction" domain was associated smoking (p=0.004), sexual intercourse under partner pressure (p=0.03) and high frequency of sexual activities (p=0.003; r=0.36). The "Orgasm" domain was inversely correlated with age (p=0.04; r=-2.47), and it was associated with a high frequency of sexual activities (p=0.04; r=0.24). The "Pain" domain was correlated with the presence of children (p=0.02).
Conclusions: The findings underscore the impact of various sociodemographic and clinical factors on sexual health and well-being. Addressing these underlying factors is essential for improving their sexual health and overall quality of life.

Sexual Harassment Among Medical residents and interns in Sfax: Psychological Impact

S. Ajmi[1]*, F. Cherif[1], O. Bouattour[1], D. Mnif[1], I. Feki[1], R. Masmoudi[1] and J. Masmoudi[1]

psychiatry A department, Hedi Chaker hospital university, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2288

Introduction: Sexual harassment (SH) is a pervasive issue, particularly in workplace environments. The medical field, especially in hospitals, is not immune to this issue with medical residents and interns often being disproportionately affected. SH can have profound psychological, emotional, and physical consequences, which can impair professional performance and well-being.
Objectives: To assess the psychological impact of SH among medical residents and interns working in hospitals in Sfax Tunisia.
Methods: We conducted a cross-sectional and descriptive study involving medical residents and interns working in hospitals in Sfax. Data were collected using an anonymous self-questionnaire. This questionnaire was published on social media during January and February 2024. It included sociodemographic characteristics, medical history, psychoactive substance use, professional data, and experiences related SH. The Depression Anxiety Stress Scale (DASS-21) was used to assess the psychological distress of the participants.
Results: We collected 141 responses, of which 19.9% declined to participate in this study.
Finally, a total of 113 participants, with sex ratio (M/F) of 0.54, were recruited. The average age was 27.92 years. In our population, 20.4% were interns. Among the participants, 68.1% were single, 91.2% were from urban backgrounds.
Among the participants, 41.6% reported experiencing sexual harassment during their practice at the hospitals in Sfax. Verbal harassment was the most common form reported as sexual harassment (43,3%). The assessment of the DASS21 questionnaire showed, that 17 participants had a moderate overall score (15%) and seven participants had a severe overall score (6.2%). In our study, the overall DASS scores ($p<0.001$), as well as the Depression ($p<0.001$), Anxiety ($p<0.001$), and Stress ($p=0.002$) sub-scores, were significantly higher among participants who were victims of harassment.
Conclusions: The findings underscore the urgent need for implementing preventive measures in hospital settings, providing support for victims, and raising awareness about SH and its consequences.

Sexual Harassment in the Hospital: Insights from Medical residents and interns in Sfax Tunisia

S. Ajmi[1]*, F. Cherif[1], O. Bouattour[1], D. Mnif[1], I. Feki[1], R. Masmoudi[1] and J. Masmoudi[1]

[1]Psychiatry A department, Hedi Chaker hospital university, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2289

Introduction: Sexual harassment (SH) is defined as any form of pressure aimed at obtaining a sexual act, for the benefit of the perpetrator or a third party. Despite movements aimed at combating sexual harassment, it remains a complex and concerning reality, particularly in the workplace. Unfortunately, the hospital environment is not spared from this issue. Medical residents and interns seem to be the population most affected by the SH.
Objectives: To estimate the prevalence of SH among medical residents and interns.
To describe the profile of SH's victims and examine their perceptions regarding sexual education.
Methods: We conducted a cross-sectional and descriptive study involving medical residents and interns working in hospitals in Sfax. Data were collected using an anonymous self-questionnaire. This questionnaire was published on social media during January and February 2024. It included sociodemographic characteristics, psychiatric and medical history, psychoactive substance use, professional data, information related to sexual life and experiences related SH.
Results: We received 141 responses, of which 19.9% declined to participate in this study. Ultimately, 113 participants, with an average age of 27.92 years, were included in the final analysis. The sex ratio (M/F) was equal to 0.54. In our population, 20.4% were interns. Among the participants, 68.1% were single, 91.2% were from urban origine and 12.4% had psychiatric follow history for anxiety disorders, depression, obsessive-compulsive disorder, and bipolar disorder (n= 8, 2, 2, and 1, respectively).
Among the participants, 41.6% reported experiencing sexual harassment during their practice at the hospitals in Sfax. The most common form reported as harassment was verbal harassment (43,3%). The majority of SH perpetrators were male (87.2%), and 27.6% were senior physicians. According to our study, 8.5% of the SH perpetrators were sanctioned for their actions, and 80.5% of SH victims believed that the perpetrators had continued to exhibit such behavior.
Regarding sexual education, 80.5% of participants thought that it was necessary in school curriculums, with thirty-seven participants believing they had received adequate sexual education.
Conclusions: This study highlighted the high prevalence of sexual harassment among medical trainees in Sfax. These results serve as an urgent call to the development of effective strategies to prevent sexual harassment in hospital environments and highlight the importance of raising awareness among staff about available legal protections.

Sexual Harassment Among Medical residents and interns in Sfax: Impact and correlated factors

S. Ajmi[1]*, F. Cherif[1], O. Bouattour[1], D. Mnif[1], I. Feki[1], R. Masmoudi[1] and J. Masmoudi[1]

[1]Psychiatry A department, Hedi Chaker hospital university, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2290

Introduction: Despite global movements to combat Sexual harassment (SH), it continues to affect individuals in various professions, with medical residents and interns being particularly vulnerable.

Objectives: To explore the prevalence of SH among medical trainees in Sfax, Tunisia.
To evaluate the consequences of SH on this group and factors related to SH.
Methods: We conducted a cross-sectional and descriptive study involving medical residents and interns working in hospitals in Sfax. Data were collected using an anonymous self-questionnaire. This questionnaire was published on social media during January and February 2024. It included sociodemographic characteristics, psychiatric and medical history, psychoactive substance use, professional data, information related to sexual life and experiences related SH.
Results: We collected 141 responses, of which 19.9% declined to participate in this study.
Finally, a total of 113 participants, with an average age of 27.92 years, were recruited. The sex ratio (M/F) was equal to 0.54. In our population, 20.4% were interns. Among the participants, 68.1% were single, 91.2% were from urban backgrounds and 12.4% had psychiatric follow-up. Among the participants, 41.6% reported experiencing sexual harassment during their practice at the hospitals in Sfax. The most common form self-reported as harassment was verbal harassment (43.3%).
In our study, most victims of sexual harassment (SH) tried to ignore (36.2%) and avoid (34%) the harasser. Some participants noted that they were afraid of career repercussions.
Regarding the consequences of SH, sleep disorders and the feeling of burnout were the most frequently reported medical effects, with a prevalence of 10.6% in both cases. Additionally, the onset or increase in tobacco consumption (8%) was the most commonly reported addictive consequence.
On a sexual level, 16 participants (14.2%) reported experiencing negative impacts on their sexuality. Sexual desire disorders (8.8%) were the most frequently reported sexual consequences, followed by a decrease in sexual satisfaction (2.7%).
In our survey, SH was statistically more prevalent among female participants ($p < 0.001$) and among participants with a low or middle socioeconomic status ($p = 0.036$).
Conclusions: These results highlight the urgent need for hospitals to implement preventive measures, support victims, and promote a safer working environment for medical trainees.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2291

Introduction: In the high-stress world of healthcare, the intertwined relationship mental health and the life quality is pivotal. Prioritizing healthcare professionals' mental health and nurturing a positive safety climate are essential to enhancing overall job satisfaction.
Objectives: Evaluate the mental health status of the physiotherapists.
Methods: his is a cross-sectional study among Physiotherapists (PTs) working in the city of Sousse. A self-administrated questionnaire was distributed either manually or via e-mail to collect information about the personal and occupational history of participants. The mentel health was assesed by the the mental component score (MCS-12) of the the Short Form Survey SF-12.
Results: A total of 93 questionnaires were collected. The PTs were 35±8 years old on average. Women made up 65.6% of the PTs. Sixty-six (71.7%) and sixty-two (67.4%) did not provide any medical or surgical history respectively and the majority of the population (54.5%) had a normal BMI. Among all respondents, nineteen (20.4%) PTs were regular smokers and an alcoholic beverage was consumed by 14 (15.7%) PTs. The sport was the common hobby of PTs (53.8%). In this group of PTs, 37 (40.2%) worked in the public sector, and 55 (59.8%) worked in the private sector. The mean seniority was 11.9±7.8 years and the average workweek for the population was 42.42 hours. The mean MCS-12 score was 43.94 (9.05 SD). The findings showed that 35 PTs (37.6%) had MCS-12 scores below the standard value. Male PTs showed slightly higher MCS-12 means than female PTs with a modest difference between PTs working in the public and private sectors. PTs who had more than 15 years of work experience scored the lowest MCS-12 mean 41.40 (SD 9.94) which is a score underneath the reference value indicating in this case low mental health functioning among PTs.
Conclusions: This study showed that Tunisian PTs had low mental health statuts highlighting the need for approaches to improve interventions that effectively enhance well-being, retention, and sustainability of practitioners, and thus the care delivered, in the healthcare system

Prevalence and factors associated with erectile dysfunction in hemodialysis patients: cross-sectional study

A. Ben Haouala[1]*, A. Balti[1], I. Betbout[1], M. Ben Mbarek[1], B. Amamou[1] and A. Mhalla[1]

[1]Psychiatry, University of Monastir, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2292

Introduction: Hemodialysis, although crucial for maintaining the survival of patients suffering from end-stage renal disease, can have severe repercussions on patients' overall quality of life and sexuality.
Objectives: To determine the prevalence and factors associated with sexual dysfunction in hemodialysis patients.
Methods: This is a multicenter, descriptive, cross-sectional study with analytical aims, conducted at 3 hemodialysis units (the Mahmoud El Matri Hospital in Ariana, the El Manzah private hemodialysis center and the El Omrane polyclinic) over a 5-month period (August-December 2023). Patients' sexual dysfunction was assessed using the IIEF5 scale.

Results: Our study population comprised 73 patients. Patient ages ranged from 25 to 86 years, with a median age of 56.87 years. Twenty-eight subjects (38.4%) were between 56 and 70 years of age. Sixty patients (82.2%) were married, with 68 living with relatives. Regarding anamnestic data, organic comorbidity was found in all patients with diabetes in 67.1% and arterial hypertension in 50.7% of cases. The median duration of hemodialysis was 48 months. The frequency of hemodialysis sessions was 3 per week in 69 patients (94.5%).
Erectile dysfunction was diagnosed in 64 patients, corresponding to a prevalence of 87.7%. The dysfunction was mild in 24.7% of cases, moderate in 45.2% and severe in 17.8%.
Erectile dysfunction was significantly correlated with age over 55 with an adjusted OR = 2.43 and the presence of diabetes with an adjusted OR = 1.5.
Conclusions: The prevalence of erectile dysfunction is high in hemodialysis patients. A systematic sexological approach is needed to ensure early and appropriate management.

Study on the Sexuality of Tunisian Women with Systemic Lupus Erythematosus

N. Mseddi[1]*, R. Ben Jmaa[1], F. Frikha[2], I. Châari[1], F. Charfeddine[1], L. Aribi[1] and J. Aloulou[1]

[1]Psychiatry B and [2]Internal Medicine, Hédi Chaker Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2293

Introduction: Systemic Lupus Erythematosus (SLE) is a systemic disease that can significantly impact women's lives. Female sexual function is one of the underestimated areas, and few studies have focused on sexual dysfunctions in women with SLE.
Objectives: To study the sexuality of patients with SLE, the factors associated with it, and the relationship with the disease activity stage.
Methods: A descriptive and analytical cross-sectional study was conducted with 38 patients with SLE followed in the internal medicine department at Hedi Chaker University Hospital, Sfax, over a period of 3 months from September to November 2023. We used:
A socio-demographic and clinical data sheet, and the SLEDAI scale for assessing disease activity criteria.
The Female Sexual Function Index (FSFI) scale to study sexuality over the past 4 weeks.
Results: The average age of the patients was 46.63 ± 10.21 years. Among them, 36 were married, and 44.7% had medical-surgical history.
The average age at SLE diagnosis was 37.11, with an average disease duration of 8.95 years. The mean SLEDAI score was 3.63. Absent to moderate activity was present in 92.1% of cases, and high activity in 7.9%.
Photosensitivity was noted in 36.8%, joint involvement in 63.2%, and anemia in 52.6%. Among the patients, 86.8% were on corticosteroids and 26.3% on immunosuppressants.
The average age of onset for sexual difficulties (SD) was 37.28 years, with an average delay of 3.05 years from disease onset.
According to FSFI: the mean score was 58.38 ± 23.412 [2 - 93]. A decrease in overall sexuality was noted in 44.7%, desire in 63.2%, satisfaction in 57.9%, arousal in 52.6%, and lubrication in 39.5%.
The factors correlated with different FSFI domains were:Desire: associated with medical-surgical history (P=0.001), photosensitivity (P=0.028), and anemia (P=0.003). Sexual satisfaction: associated with medical-surgical history (P=0.011), joint involvement (P=0.034). Arousal: associated with medical-surgical history (P=0.01) and anemia (P=0.004).
There were no statistically significant correlations between the disease activity stage and the different FSFI domains. However, the onset of SD was shortened if use of corticosteroid (P=0.005) or immunosuppressive treatment (P=0.038).
Conclusions: Our results indicate that SLE can impair sexuality in various domains, especially if associated pathologies are present. Therefore, special attention should be given to the sexual function of patients with lupus.

Erectile Dysfunction in Tunisian Veterans: Clinical and Psychological Insights

Y. Ben Othmene[1,1]*, A. Baatout[1], W. Kabtni[1], K. Kefi[1], S. Eddif[1], H. Kefi[1] and A. Oumaya[1]

[1]Psychiatry, Military Hospital, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2294

Introduction: Erectile dysfunction (ED) is a multifactorial condition affecting a significant propotion of men worldwide, impacting their mental well-being, life quality and interpersonal relationships. Often associated with various underlying factors, ED manifests differently in each individual, yet there is a limited understanding of the unique profiles of specific populations, such as military veterans, who may face distinct physical, psychological and social challenges contributing to the condition.
Objectives: This study aimed to explore the clinical profile, demographic factors, and associated comorbidities of Tunisian military veterans affected by ED.
Methods: A cross-sectional descriptive survey was conducted between September and November 2024 on Tunisian veterans seeking consult, using a data file and 2 self-report scales:
The Hospital Anxiety and Depression (HAD) scale, consisting of two subscales: Anxiety (A) and Depression (D), dividing patients into: normal[0-7], borderline case[8-10], an abnormal level of anxiety or depression[11-21].
The IIEF-5 (International Index of Erectile Function 5) to evaluate ED with six categories: [1-4]: uninterpretable, [5-7]: severe, [8-11]: moderate, [12-16]: mild to moderate, [17-21]: mild and [22-25]: no ED.
Results: The study enrolled 28 veterans diagnosed with ED, with an average age of 40 [25-61] years. Most (78.6%) were married while 17.9% were single and 3.6% were divorced.
Smoking was prevalent in 82.1% and 21.4% reported alcohol consumption, with 83.3% drinking occasionally and 16.6% drinking regularly. None reported using cannabis or other illicit drugs.
Regarding medical history, 39.3% had medical health conditions including varicocele, diabetes, combined arterial hypertension and diabetes, myocardial infarction and other health issues.
Psychiatric follow-up was reported by 85.7% of the individuals.
Anxiety symptoms were present in 89.3% of participants with 3.6% classified as borderline cases. Depressive symptoms were reported by 67.9% with 21.4% categorized as borderline symptoms.

Notably, 64.3% of the veterans experienced both anxiety and depressive symptoms and were taking antidepressants, while only one veteran exhibited neither. The remaining had either anxiety or depressive symptoms.
In terms of ED severity, 46.4% had mild to moderate ED, followed by 28.6% with mild ED, 17.9% with severe ED and 7.1% with moderate ED.
Only 14.3% reported using sexual enhancers.
Conclusions: This study provides valuable insights into the unique profile of ED among Tunisian veterans, revealing a high prevalence of psychological comorbidities, particularly anxiety and depression, alongside physical health issues. The interconnection of these factors highlights the importance of a holistic approach adressing both psychological and physical aspects of ED. These results call for further research into the specific challenges faced by veterans for a more personalized and effective interventions.

Transition regret and detransition: what went wrong?

A. Cardoso[1]* and M. Mota[1]

[1]Psychiatry Department, Unidade Local de Saúde de São João, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2295

Introduction: The phenomena of regret and detransition in individuals undergoing *gender-affirming treatments* raise significant medical and bioethical challenges for professionals working in this area.
Objectives: This work aimed to gather the most current evidence regarding the approach to the issues of regret and detransition, characterizing the main factors involved and reflecting on possible prevention strategies.
Methods: A literature review was conducted through research on PubMed, using the keywords "gender dysphoria," "regret," and "detransition". Only articles in English were included. Additional bibliography was selected by consulting the references of the initially included articles.
Results: Regret and detransition are distinct concepts. In fact, there can be regret without detransition and detransition without regret, with the narratives and experiences of these individuals being very diverse. Detransition may be motivated by external or internal factors, depending on whether transgender identity is preserved or lost. Originally thought to be rare, it has been challenging to assess the actual prevalence of these phenomena, whose increase is expected in the future. In an effort to counter this trend, the literature emphasizes the importance of a multidisciplinary and comprehensive approach to individuals with gender dysphoria, based on effective and assertive communication, ensuring responsible and informed decision-making. Regular follow-up combined with psychosocial support throughout the entire transition process is also crucial. Therapeutic approach should be individualized and integrated into a continuing care plan, grounded in an empathetic and non-judgmental attitude.
Conclusions: Regret and detransition are not necessarily synonymous with medical error. Considering the complex spectrum of experiences involving these phenomena, a comprehensive approach that allows for an integrated view of each person and their needs is essential. Further research and development of guidelines regarding the approach and support for this group of individuals are needed.

Irreversible antidepressant-induced sexual dysfunction: what do we know so far?

A. Cardoso[1]* and M. Mota[1]

[1]Psychiatry Department, Unidade Local de Saúde de São João, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2296

Introduction: Serotonergic antidepressants, particularly Selective Serotonin Reuptake Inhibitors (SSRIs), have been known to cause relevant sexual adverse effects, which were originally thought to disappear after treatment course. In later years, an emergent condition concerning the persistence of sexual impairment following SSRI discontinuation has gathered increasing social and scientific interest. Post-SSRI sexual dysfunction (PSSD) is still underrecognized and understudied.
Objectives: Our aim was to gather available evidence regarding the pathophysiological mechanisms and contributing factors to PSSD, as well as current management options.
Methods: A literature review was conducted using PubMed, through research of the following MESH terms: "Selective Serotonin Reuptake Inhibitors", "Antidepressive Agents", "Sexual Dysfunction, Physiological" and "Sexual Dysfunctions, Psychological". Only papers published in English were included.
Results: PSSD has been described as an iatrogenic condition whose symptoms could persist indefinitely. Despite clinical heterogeneity and lack of robust literature surrounding PSSD, there is growing evidence of this concern. In order to diagnose PSSD, sexual dysfunction due to reemergence of depressive illness must be ruled out. Accurate incidence and prevalence rates of this condition are unknown, though it appears to be a rare phenomenon. Several potential etiological explanations for PSSD have been proposed. Some have highlighted a dysregulation in serotonergic activity induced by SSRIs, while others have tested the role of neuroregulatory agents and bioelectric circuits. Another theory involves a possible link between PSSD and other post-discontinuation syndromes. In contrast, some authors have theorized that sexual impairment induced by a long course of SSRIs could induce a negative conditioning effect towards sexual activity in some patients. Despite abovementioned hypotheses, sexual dysfunction is usually complex in nature and thus multifactorial. There is no established treatment to PSSD. Pharmacological and psychotherapeutic approaches have been tested and proposed to ameliorate symptoms of PSSD, but further investigation is warranted.
Conclusions: PSSD is a heterogenous and idiosyncratic syndrome that needs further characterization. It remains unclear why only certain individuals develop PSSD and treatment options are limited. Current evidence is still incipient and insufficient to justify adjusting current SSRI prescription patterns. However, clinicians must be aware of this condition and should monitor and address

these issues with patients. Future research should provide further insights into underlying pathophysiological mechanisms, which in turn could help acknowledge possible preventive and therapeutic interventions.

Erectile Dysfunction in Patients with Mental Disorders: Challenges in Diagnosis and Intervention from a Family Medicine Perspective

C. G. Coronell[1]*, L. E. De Miguel[2], I. J. Contreras[1], O. Pascual[3], L. R. Bello[4], A. Ferrandez[5] and P. Guerrero[6]

[1]Family Practice Department, CAP Vallirana, Vallirana (Barcelona); [2]Psychiatry Department, Hospital Sagrat Cor, Martorell (Barcelona); [3]Nursery Department, CAP Vallirana, Vallirana (Barcelona); [4]Family Practice Department, CUAP La Solana, Sant Andreu de la Barca (Barcelona); [5]Family Practice Department, Centro de Salud Guadarrama, Madrid and [6]Family Practice Department, Centro de Salud de Nájera., La Rioja, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2297

Introduction: In Spain, erectile dysfunction (ED) affects around 19% of men aged 25 to 70, with higher prevalence in older age groups. Family doctors are key for early ED detection, yet it is often underdiagnosed due to limited sexual health training and poor communication. Many patients hesitate to discuss sexual issues, and short consultation times worsen this problem. Early diagnosis is crucial for effective intervention, improving both quality of life and health outcomes.
Objectives: To evaluate the effects of chronic diseases and medications on ED and identify commonly used treatments.
Methods: This retrospective review focused on patients with late-diagnosed ED. We assessed the delay in reporting symptoms and contributing factors such as embarrassment and consultation constraints. The study also explored the impact of chronic conditions like diabetes and hypertension, and the role of psychotropic medications. Data were gathered from the Sexology Patient Database at Vallirana Primary Care Centre (CAP), covering 255 sexual dysfunction cases. The review aimed to understand diagnostic delays and the influence of chronic conditions and medications on ED.
Results: Of 255 sexual dysfunction diagnoses, 193 were ED, making up 75.69%. The average patient age was about 62, with an average delay of 1.95 years before seeking help. ED comorbidities included Cardiovascular and Metabolic Diseases: 33.3%, Musculoskeletal and Articular Diseases: 31.25%, Psychiatric and Sleep Disorders: 29.2%, Digestive Diseases: 20.83%, Respiratory Diseases: 18.75%, Urogenital Disorders: 18.75%, Dermatological Disorders: 12.5%, Neurological Disorders: 10.42%, Endocrine Disorders: 8.33%, and Harmful Habits: 8.33%. Common medications were Antihypertensives: 16.7%, SSRIs: 14.6%, Proton Pump Inhibitors: 12.5%, Benzodiazepines: 10.4%, Antidiabetics: 10.4%, Statins and Fibrates: 10.4%, Bronchodilators and Inhaled Corticosteroids: 10.4%, Antiplatelets: 8.3%, and Other Medications.
Conclusions: The high ED prevalence of 75.69% underscores major issues with timely diagnosis. The average 1.95-year delay highlights barriers to early treatment. Chronic conditions, especially cardiovascular and metabolic disorders, are closely linked to ED. The presence of psychiatric and sleep disorders indicates a complex interaction with sexual dysfunction. The variety of medications used, particularly antihypertensives and SSRIs, necessitates careful management to avoid adverse effects. Family doctors are crucial for diagnosing, managing ED, and referring to specialists. However, time limitations and lack of sexology training often result in underdiagnosis. Enhancing awareness can improve early detection and management, leading to better patient outcomes and timely specialist care.

Gender dysphoria and psychosis - symptom or comorbidity?

B. V. Ferreira[1]*, C. Alves[2], J. F. Fontes[1], M. M. Serra[1], T. Pereira[1], R. R. Henriques[3] and M. Gonçalves[1]

[1]Clínica 5; [2]Clínica 3 and [3]Clínica 2, ULS São José - Hospital Júlio de Matos, Lisboa, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2298

Introduction: Gender dysphoria (GD) refers to the marked incongruity between the experience of one's gender and the sex at birth. Psychiatric illness is one of the major negative prognostic features for the outcome of GD. In particular, much controversy exists regarding whether individuals with psychotic symptoms should receive gender affirmative treatment.
Objectives: The present review aims to provide an overview of the current literature of the occurrence of gender dysphoria symptoms during psychotic episodes and identify challenges in differential diagnosis and treatment and offering recommendations to overcome them.
Methods: Articles published on the last five years were searched on Medline, PubMed, Web of Science and Springer Link using the following keywords: gender identity, psychosis, gender dysphoria.
Results: Delusions about one's physical appearance and the desire to change the body can be observed in patients with schizophrenia or other psychotic disorders. Therefore, the differential diagnosis is critical for therapeutic planning and effort is required to carry out the necessary diagnostics when articulation of gender dysphoric feelings coincides with the onset of psychosis. It is crucial to evaluate the chronology and dynamics of the individual symptoms, their constancy, patient's criticism, and response to antipsychotic treatment.
Conclusions: Some presentations of GD can be created by life experience in individuals who have underlying mental or neurophysiological abnormalities. The experiences of practitioners indicate that coincidence of schizophrenia and gender identity disorder is possible, that is why the differential diagnosis needs time, careful observation, examination and cooperation of psychiatrist and sexologist.
This review addresses the significance of understanding each patient's individual circumstances, focusing specifically on proper physician training and direct patient care.

Pedophilic Disorder and Suicide Risk: Understanding the Intersection

B. V. Ferreira[1]*, C. Alves[2], J. F. Fontes[1], M. M. Serra[1], T. Pereira[1], R. R. Henriques[3] and M. Gonçalves[1]

[1]Clínica 5; [2]Clínica 3 and [3]Clínica 2, ULS São José - Hospital Júlio de Matos, Lisboa, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2299

Introduction: Pedophilic disorder is characterised by a sustained, focused, and intense pattern of sexual arousal involving prepubertal children. In addition, the individual must have acted on these thoughts, fantasies or urges or be markedly distressed by them (ICD - 11).
Beyond its obvious ethical and legal implications, this disorder is often associated with substantial mental health comorbidities, including depression, anxiety, and substance abuse. One particularly alarming yet understudied aspect is the elevated risk of suicidal ideation and behavior among individuals diagnosed with pedophilic disorder. The intersection between pedophilic disorder and suicide risk is critical to understand, as it can inform the development of more effective intervention strategies and support systems.
Objectives: The present review aims to explore the intersection between pedophilic disorder and suicide risk, shedding light on the psychological factors that contribute to suicidal ideation and behavior among individuals with this disorder, including those who have never sexually engaged with children.
Methods: PubMed, Web of Science and Google Scholar were searched using the following keywords "pedophilic disorder", "suicide risk", "suicidal ideation", and "stigma". Articles published within the last decade were included.
Results: The review showed several risk factors, perhaps the most significant being the psychosocial effects of the intense stigma, social isolation, and internalized shame. Other risk factors are prior mental health treatment, weaker attraction to adult women, history of sexual abuse, young age, less education, and additionally, the lack of access to appropriate mental health services.
The relationship between these individuals' emotional distress and their likelihood of sexually engaging with a child is not known, but there is evidence that impulse control is compromised by negative affect. Moreover, literature posits that stigma raises the risk of sexual activity with children via disturbances in emotional, social, cognitive, and health service utilization domains.
Conclusions: It is evident that this population faces unique challenges that require specialized attention and addressing this intersection necessitates a comprehensive approach.
Strategies aimed at reducing stigma, promoting social support, enhancing access to mental health services and fostering supportive environments have the potential to mitigate suicidal risk factors and enhance overall well-being. Furthermore, efforts to destigmatize help-seeking behaviors and improve access to confidential and non-judgmental support services are crucial in reducing the incidence of suicide and promote mental health among this population.

EPV1879

Experiencing sexuality in the perinatal period: what are the challenges?

M. M. Figueiredo[1]*, R. Pereira[2] and V. Vila Nova[1]

[1]Centro Hospitalar Setúbal, ULS Arrábida and [2]USF Santiago de Palmela, Setúbal, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2300

Introduction: The perinatal period, encompassing pregnancy and the first postpartum year, is a transformative phase in a woman's life. It involves profound physical, psychological, social, and emotional changes that can significantly impact sexual experiences.
Objectives: The purpose of this work is to address the challenges of experiencing sexuality during the perinatal period.
Methods: Evidence-based review, through research conducted on PubMed and selection of the most relevant studies, published in the last decade, using the keywords: "Sexuality" and "Perinatal period".
Results: Hormonal fluctuations, physical discomfort, and body image changes during pregnancy can significantly affect sexual desire and satisfaction. By the third trimester, between 83 to 100% of first-time mothers report a decrease in sexual activity. Recent studies indicate that this trend continues into the first postpartum year, with over 60% reporting decreased sexual activity. Postpartum challenges, such as physical recovery, breastfeeding, and fatigue further complicate sexual intimacy. The anticipation of parenthood and shifts in relationship dynamics also play a significant role. Societal pressures and cultural norms regarding sexuality in the perinatal period can influence personal experiences and expectations, and contribute to communication barriers between partners regarding sexual needs and concerns.
Conclusions: The perinatal period presents unique challenges to sexual health and intimacy. A holistic perinatal care, incorporating comprehensive sexual health education and promoting open communication between partners are crucial for addressing these challenges effectively.

EPV1880

The unspoken aspect of dementia care: sexuality

M. M. Figueiredo[1]*, R. Pereira[2] and V. Vila Nova[1]

[1]Centro Hospitalar Setúbal, ULS Arrábida and [2]USF Santiago de Palmela, Setúbal, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2301

Introduction: Sexuality, although an essential component of human health, remains a controversial topic, shrouded in stigma, particularly in the context of dementia, where the expression of sexuality presents unique challenges.
Objectives: The main objective of this work is to address the complexity of the biopsychosocial components of sexuality in patients with dementia, promoting a change in medical perspective and social attitudes.

Methods: Evidence-based review, through research conducted on PubMed and selection of the most relevant studies on this topic, published in the last decade, using the keywords: "Sexuality" and "Dementia".
Results: Cognitive impairment can affect the frequency and satisfaction with sexual activity. Most studies focuses exclusively on the biological (and dysfunctional) component of sexuality, devaluing the challenges and barriers to the expression of this sexuality. The deterioration of cognitive processes, with emphasis on the involvement of the prefrontal cortex, can influence the ability to make decisions, setting boundaries and providing consent. Inappropriate sexual behaviors, such as disinhibition and hypersexuality, have an incidence of 7-25% in patients with dementia, and may require intervention psychopharmacological. These vulnerabilities result in an enormous challenge in terms of establishing a balance between autonomy and safety of these patients, sometimes resulting in neglect of sexual health in treatment environments.
Conclusions: A comprehensive understanding of the sexuality of older adults with dementia is essential to improve the quality of life and clinical care of this population, highlighting the importance of accurate education and inclusive sexual orientation, creating safe spaces for dementia patients to explore and express their sexuality.

Disclosure of Interest: None Declared

EPV1881

Paraphilic disorders: from the past to the current perspective – a review of the state of the art

M. M. Figueiredo[1]*, A. F. Reis[1], T. Cardoso[1] and V. Vila Nova[1]
[1]Centro Hospitalar Setúbal, ULS Arrábida, Setúbal, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2302

Introduction: Sexuality is a central aspect of human life, encompassing its complexities and diversities. In the field of Psychiatry, Paraphilic Disorders remain a subject of ongoing controversy, including debates over the definition of paraphilia itself.
Objectives: The present work aims to present a review of the current state of the art regarding the evolution of Paraphilic Disorders, analyzing the evidence that supports this diagnosis, and promote the importance of evolution, understanding and non-stigmatization of sexualities.
Methods: Evidence-based review, using a PubMed research and selection of the most relevant studies on this topic, published in the last decade.
Results: An evolution was evident in the classification systems, where initially a pathologization of non-normative sexual practices predominated. Homosexuality and masturbation were understood as diseases, and as such susceptible medical and social control.
In DSM III, the concept of paraphilia, sexual arousal outside normal activity patterns, was introduced in an attempt to reduce stigmatization. But only in DSM V was the distinction made between Paraphilia and Paraphilic Disorder, the latter as causing suffering or dysfunction to the individual or others. This distinction marked a change in paradigm.
Conclusions: The definition and categorization of Paraphilic Disorders in the main classification systems has been influenced by changes in sexual and social norms over time, highlighting their influence on the recognition and treatment of paraphilias.
The view of human sexuality continues to be deeply marked by heteronormativity and reproduction as a social and cultural model, causing sexual practices outside this standard to be labeled as pathological. These diagnoses tend to focus on specific behaviors rather than considering the complexity of each person's sexual experiences, and to be based on prejudices and stereotypes rather than robust scientific evidence.

EPV1882

Patient with Undifferentiated Schizophrenia and Gender Incongruence, a Case Report

V. Gaberšek[1]*, N. Rijavec[1] and I. Rahne Otorepec[2]
[1]University Psychiatric Clinic Ljubljana, Ljubljana, Slovenia and [2]Outpatient Clinic for Sexual Health, University Psychiatric Clinic Ljubljana, Ljubljana, Slovenia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2303

Introduction: We represent a case report of a female patient with schizophrenia and gender identity disorder, shedding light on the complexity of her medical condition. The patient gave the informed consent for anonymous presentation of her case.
Objectives: We want to highlight the unique vulnerability of schizophrenia patients with comorbid gender identity issues. The diagnostic and treatment processes of these patients should be insightful, careful and interdisciplinary.
Methods: Descriptive report of a case report based on the regular examination of the patient, review of patients clinical file and a non-systematic literate review.
Results: The 23-year-old female patient, diagnosed with undifferentiated schizophrenia at the age of 18, has been receiving regular one-monthly therapy with aripiprazole long-acting injection since 2019. The psychosis has been in stable remission since 2019. Due to comorbid mixed anxiety and depressive disorder, she was receiving sertraline. In 2021, the patient identified as a transgender male. He was admitted to outpatient clinic for sexual health, where he was diagnosed with gender identity disorder. In February 2023, the patient started receiving testosterone transdermal gel due to the recommendation letter of the Slovenian interdisciplinary team for gender identity confirmation. Three months later, he reported insomnia and strong intrapsychic tension; intense hands tremor was also observed. He was voluntarily admitted to the psychiatric clinic due to suspected psychotic symptoms.
Conclusions: Before prescribing hormone therapy to the patient in our case, the psychotic background of his desire for gender reassignement was excluded by multidisciplinary team. Due to suspected relaps of schizophrenia, which appeared three months after the patient had started receiving testosterone treatment, the Slovenian interdisciplinary team for gender identity confirmation reconsidered the patient's case and decided to temporarly discontinue his testosterone hormone therapy. The patient continues with his psychiatric treatment.
It is important to notice that exacerbation of psychotic symptoms in the course of schizophrenia may prevent implementation of various stages of treatment of gender dysphoria. Hormonal pharmacotherapy can affect the patients emotional state. The use of pharmacological and surgical methods used for gender reassignment should be precluded in the case of current psychotic process. Treatment of

gender dysphoria should be conducted in accordance with current version of the World Professional Association of Transgender Health standards.

Assessment of Women's Sexual Function and Contributing Factors in Tunisia

A. Hadj Salah[1]*, N. Faouel[1], I. Batbout[1], M. ben mbarek[1], A. Haouala[1], F. zaafrane[1], A. mhalla[1] and B. amamou[1]

[1]psychiatry, Fattouma Bourguiba Hospital, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2304

Introduction: Sexual function is essential to women's health, impacting psychological well-being and relationships. In Tunisia, cultural norms may influence how sexual dysfunction is reported and perceived. This study examines the prevalence of sexual dysfunction and its psychological consequences.
Objectives: To evaluate sexual function in Tunisian women and assess its correlation with psychological distress.
Methods: This cross-sectional descriptive study was conducted in March 2023 with 80 Tunisian women, aged 24-50, using a self-administered online questionnaire. Data collection involved the Female Sexual Function Index (FSFI) to assess sexual dysfunction and the Depression Anxiety and Stress Scale (DASS-21) for psychological well-being. Key sociodemographic variables, including marital status, number of children, and socio environmental context were also collected.
Results: We gathered data from 80 women out of 500 distributed questionnaires (16%).
Participants had a mean age of 33.35 years. A majority (63.7%) had children, and 93.8% resided in urban areas. Notably, the majority of women who responded to the questionnaire (74%) were married.
Among the study population, the median FSFI score was 23.65, with 61.3% scoring below the threshold of 26.55, indicating sexual dysfunction. For married women (n=59), the mean FSFI score was 23.7 ± 7.9. The detailed FSFI scores for the entire population and married women are presented in Table I, indicating that the most affected domains of sexual function were excitation and desire. Severe depression, anxiety, and stress were reported by 6.3%, 12.5%, and 6.3% of participants, respectively.
Sexual dysfunction was significantly associated with depression (p=0.02). However, no statistically significant associations were found between anxiety, stress, and sexual dysfunction.
Table I: FSFI Scores among the Study Population

FSFI Domain	Overall Score Mean ± SD	Married Women Score Mean ± SD
Desire	**3.5 ± 1.31**	**3.7 ± 1.10**
Excitation	**3.8 ± 2.10**	**4.1 ± 1.56**
Lubrification	**3.6 ± 2.12**	**4.4 ± 1.48**
Orgasm	**3.38 ± 2.12**	**4.2 ± 1.80**
Satisfaction	**3.38 ± 2.26**	**4.2 ± 1.80**
Pain	**2.5 ± 1.51**	**3.0 ± 1.10**
Total FSFI	**19.79 ± 10.66**	**23.7 ± 7.9**

Conclusions: The study shows a high prevalence of sexual dysfunction among Tunisian women, tied to psychological distress, mainly depression. Enhancing sexual health and mental well-being is key to improving overall quality of life and addressing marital issues. Future research should explore culturally sensitive interventions to enhance sexual health and support women's mental well-being.

Disclosure of Interest: None Declared

EPV1885

Sexual Life in the Postpartum Period of Tunisian Women Following Episiotomy

A. Hadj Salah[1]*, Y. kilani[2], M. ben mbarek[1], A. Haouala[1], I. batbout[1], F. zaafrane[1], A. mhalla[1] and B. amamou[1]

[1]psychiatry, Fattouma Bourguiba Hospital, Monastir and [2]gynecology, Farhat Hached Hospital, sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2305

Introduction: The postpartum period can significantly affect sexual life, particularly for women who have undergone an episiotomy. This study examines the impact of episiotomy on sexual activity during the postpartum period.
Objectives: To evaluate the sexual life of Tunisian women following episiotomy in the postpartum period.
Methods: We conducted a prospective cohort study at the Gynecology and Obstetrics Department of Farhat Hached University Hospital in Sousse. The study included women who delivered vaginally with an episiotomy in 2020. Data were collected from medical records and delivery reports. Nine months postpartum, participants were contacted by phone to complete a questionnaire assessing their experiences with episiotomy and sexual satisfaction.
Results: The final sample comprised 66 women with a mean age of 27 ± 2.8 years (range: 20-34 years).
Regarding sexual function, 84% of women were very or moderately satisfied with their sexual life before pregnancy, and 74% were satisfied during pregnancy. Most women resumed sexual activity between 7 and 8 weeks postpartum (78%), with 22% resuming before 8 weeks. Compared to pre-birth satisfaction, 54% of women reported no change in sexual satisfaction after childbirth, while 29% reported a decrease and 17% an increase.
Sexual satisfaction was statistically related to the mode of delivery, with 55% of women who had forceps delivery being dissatisfied or equally satisfied as dissatisfied (p=0.01).
Factors affecting postpartum sexual activity included fear of pain (32%), fear of another pregnancy (13%), perceived loss of body desirability (37%), body changes (31%), and excessive fatigue (24%).
Conclusions: This study demonstrates that episiotomy can have a notable impact on postpartum sexual life. Several factors, including the type of suture used during delivery and the mode of delivery, influence women's sexual satisfaction. These findings underline the importance of considering both physical and emotional aspects of postpartum recovery to improve the overall sexual health and well-being of women after childbirth.

EPV1886

Exploring Sexual Well-being in Infertile Couples: A Gender Perspective

K. Mahfoudh[1], S. Hamzaoui[1]*, F. Askri[1], A. Ouertani[1], U. Ouali[1], A. Aissa[1] and R. Jomli[1]

[1]Department A, Razi Hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2306

Introduction: Infertility can have a profound impact on couples, causing emotional distress and negatively affecting sexual well-being. In Tunisia, it contributes to over 20% of divorce cases due to relationship strain. Despite its significance, research on the influence of infertility on sexual experiences, particularly gender differences, remains limited.
Objectives: This study aims to evaluate the effects of infertility on sexual health of Tunisian infertile couples and to compare these effects between men and women.
Methods: We conducted a cross-sectional study involving sexually active infertile couples who had been under follow-up for at least one year at a specialized Assisted Reproductive Technology center in Tunis. Each participant completed closed-ended questions regarding their sexual experiences following the infertility diagnosis, including the frequency of sexual intercourse, preferred types of sexual activities, sexual positions believed to enhance conception, and overall sexual rhythm. The Arizona Sexual Experiences Scale (ASEX) was used in Arabic to assess sexual function.
Results: A total of 60 infertile couples participated in the study. The average age of women was 35.07 ± 4 years while the average age of men 41.1 ± 6 years. Regarding sexual intercourse frequency, 35% of women (n=21) and 27% of men (n=16) reported a decrease, with no significant gender difference (p=0.426).
Infertility did not significantly alter preferences for sexual practices, as 78% of women (n=47) and 85% of men (n=51) reported no changes. Vaginal penetration was the predominant activity for both sexes (100%), while mutual masturbation was engaged in by 68% of women and 72% of men. Oral sex was reported by 57% of women and 53% of men, with no significant gender differences (p>0.05).
In terms of sexual positions, 48% of women and 50% of men favored specific positions to enhance conception, with no significant differences (p=0.995). However, 48% of women and 64% of men adhered to a calendar-based rhythm, with women perceiving this regimen as more detrimental to spontaneity (p=0.038 and p=0.041).
Sexual dysfunctions were significantly more common in women, with a prevalence of 28% compared to only 5% in men. Desire disorders were the most commonly reported sexual dysfunction for both genders. Women exhibited significantly higher rates of physical and psychological arousal problems, as well as orgasmic disorders (p<0.05).
Conclusions: Screening for sexual dysfunction in infertile couples is essential not only for improving sexual health but also for providing tailored psychological support that considers gender differences. By identifying and addressing these issues, healthcare providers can enhance the overall well-being of couples dealing with infertility challenges.

Sexual and reproductive dysfunctions induced by chronic manganese exposure: Roles of neuroaffective and olfactory impairments

H. Harifi[1]*, H. Hami[1] and L. Bikjdaouene[1]

Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2307

Introduction: Reproduction in mammals relies on complex interactions involving the genital and olfactory systems, which can be influenced by environmental factors, such as manganese (Mn). Although essential for survival, Mn is potentially toxic over long periods, potentially affecting sexual and reproductive behaviors.
Objectives: This study aims to assess the long-term effects of Mn exposure on sexual and reproductive functions in male Wistar rats, focusing on Mn-induced neuroaffective and olfactory dysfunctions.
Methods: Male Wistar rats received intraperitoneal injections of Mn at doses of 6 mg/kg, 25 mg/kg, and 30 mg/kg for 12 weeks. Each experimental group consisted of one Mn-intoxicated male and four non-intoxicated females. After six days of cohabitation, the females were isolated to evaluate fertility outcomes. The study also monitored weight changes and conducted behavioral assessments for anxiety, depression, and olfactory functions in males.
Results: Higher Mn doses (25 mg/kg and 30 mg/kg) resulted in significant behavioral changes in males, including anxiety, depression, and olfactory dysfunctions, which were associated with decreased reproductive success. Specifically, pregnancy rates were 33% (4 out of 12) at 25 mg/kg and zero at 30 mg/kg. In contrast, males treated with 6 mg/kg Mn exhibited no significant neuroaffective or olfactory impairments, maintaining fertility rates comparable to those of the control groups.
Conclusions: Chronic Mn exposure adversely affects sexual behavior and reproductive success in male Wistar rats, probably due to olfactory and neuroaffective disruptions. Further research is recommended to elucidate the mechanisms underlying these effects.

Psychosocial and relational resilience during the COVID-19 pandemic: Evaluating sexual health and coping strategies in intimate relationships

S. Irnat[1], H. Harifi[1]*, F. Hadrya[2], O. Erefai[3], A. Soulaymani[3], M. Anssoufouddine[4], M. Abdalli Mari[4] and H. Hami[1]

[1]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra; [2]University Hassan First of Settat, Higher Institute of Health Sciences, Health Sciences and Technologies Laboratory, Settat; [3]Higher Institute of Nursing Professions and Health Techniques, Rabat, Morocco and [4]Medical Service, Regional Hospital Center of Anjouan, Mutsamudu, Comoros
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2308

Introduction: The COVID-19 pandemic has significantly altered daily life and affected the sexual dynamics of couples across various contexts. Enforced lockdowns and pervasive social isolation, coupled with heightened anxiety associated with the pandemic, have profoundly affected mental health and intimate relationships, affecting sexual satisfaction among couples. This narrative review examines the psychosocial effects of these changes on couples' sexuality, focusing on the challenges and coping strategies adopted by couples to mitigate the adverse effects and enhance intimate relationship quality.
Objectives: This review systematically analyzes the psychosocial impacts of the pandemic on couples' sexuality, using post-2020 literature to better understand these dynamics and enhance psychosexual support.
Methods: An extensive literature review was conducted across PubMed, Scopus, and Google Scholar, focusing on keywords such as "COVID-19," "sexual health," "intimacy," "divorce," and "coping strategies." Ten high-quality studies published after 2020 were selected based on their methodological rigor and relevance to couples' dynamics. These studies include a mix of quantitative and qualitative research and systematic reviews, providing a broad yet detailed perspective on the topic.
Results: The findings reveal that the pandemic has significantly diminished couples' sexual desire and relationship satisfaction. Notable psychosocial effects include increased anxiety, stress, depression, and relational conflicts. Modifications in sexual frequency and quality were noted, yet many couples have adopted effective coping strategies such as enhanced communication, couples therapy, shared stress management activities, and the utilization of online psychological support resources, which have helped strengthen relationships during the pandemic.
Conclusions: The pandemic has profoundly influenced couples' sexual and relational health, introducing psychosocial stressors. Despite these challenges, the resilience displayed by couples through diverse coping strategies highlights their adaptive capacity. This review emphasizes the need for mental health professionals to integrate targeted interventions to support couples' well-being and prepare them for potential future crises.

Sexual habits and chemsex use in a monographic consultation for sexually transmitted infections (STI)

C. Herranz Serfaty[1], S. Moreno Guillen[2], M. Sánchez[2], A. Muñoz San José[1]*, M. E. Sánchez-Escalonilla Relea[1], M. Viana Perez[1] and Á. Esquembre García[1]

[1]Psychiatry, Hospital Universitario La Paz and [2]Infectious diseases Deparment, Hospital Universitario Ramón y Cajal, MADRID, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2309

Introduction: The use of recreational drugs for sexual intercourse (*chemsex*) is a widespread practice in certain subgroups of the population in recent years. There is documentation of chemsex in men who have sex with men (MSM) but less data on its use in other populations (men who have sex with women, women, transgender women, transgender men) and its effects on mental health.
Objectives: Evaluate the use of chemsex in the population attended in a sexually transmitted infection (STI) consultation.
Methods: To evaluate the use of chemsex in the population attended in a sexually transmitted infection (STI) consultation, a survey was carried out on all patients who attended the STI consultation of the U. Ramón y Cajal Hospital between January and April 2022. The degree of anxiety and depression was assessed using the HADS scale.
Results: A total of 148 surveys were distributed, with 82 being completed. Among those surveyed, 56% had used drugs at some time in their lives, the vast majority of times associated with sexual relations. The most consumed drugs were alcohol, cannabis and poppers. There were no differences between MSM and non-MSM in this consumption (p= 0.073), but there were in the substances consumed: MSM consumed more gamma hydroxy-butyrate acid (GHB/GBL) (p= 0.031), mephedrone (p= 0.031) and poppers (p= 0.019). Using the HADS Scale, 34 patients suffered from anxious (41%) and 11 depressive symptoms (13%), with no significant differences between MSM and non-MSM.
Conclusions: *Chemsex* is a frequent phenomenon among patients attending in an STI consultation, both in the MSM and non-MSM population. It negatively impacts mental health, being associated with anxiety and depression. It is necessary to improve information to reduce drug use in this context.

Navigating sexual health concerns in the medical profession: A Tunisian perspective

A. Karmous[1]*, H. Ghabi[2], N. Karmous[3], E. Khelifa[1], A. Maamri[1] and H. Zalila[1]

[1]emergency and outpatient department; [2]Department G, Razi hospital, Manouba and [3]Gynaecology and obstetrics department B, Charles Nicoles Hospital, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2310

Introduction: Sexual functioning is an essential aspect of human existence. Sexual dysfunctions are prevalent and negatively affect the quality of life in the general population. Little attention has been paid to the sexual function of health workers.
Objectives: The aim of our work was to evaluate sexual dysfunction among Tunisian doctors and to determine associated underlying factors.
Methods: A cross-sectional study was conducted online, from January to March 2024, via a pre-established questionnaire. Tunisian doctors, who had finished their medical studies, working in the public or private sector and who agreed to anonymously respond to the questionnaire were included. Sociodemographic, economic, clinical data and those related to the medical profession were collected. Sexual function was evaluated with the Arizona Sexual Experience Scale (ASEX).
Results: A total of 80 individuals had fully responded to the questionnaire. The mean age of participants was 36.81 ± 7.49 years and 68,7 % (n=55) of them were male. Ninety five percent (n=76) were married and 77.5 % (n=62) had children. The mean working hours per week was 34.32 ± 5.32. A regular physical activity was practiced by 35 % (n=28) of individuals. The mean monthly income

was 3592.5 ± 596 Tunisian Dinars. The results of the ASEX showed that 23,8 % (n=19) of participants, 23,6 % (n=13) of male participants and 24 % of female (n=6) participants had sexual dysfunction. Ten per cent of individuals (n=8) have previously consulted a sexologist. Longer working hours, lower monthly income, less physical exercise were significantly associated with increased risk for sexual dysfunction.

Conclusions: Sexual dysfunctions seem to be common among Tunisian doctors. Knowledge about their sexual functioning is important to promote their physical and mental health and to improve the care delivered.

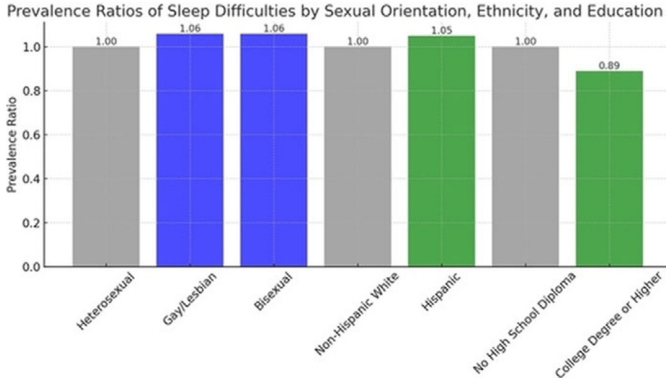
Sleep Health Disparities in Depression: The Role of Sexual Orientation, Education, and Ethnicit

J. Kim[1]*, M. He[2], S. Gunturu[1] and O. El Shahawy[2]

[1]BronxCare Health System, Bronx and [2]New York University Grossman School of Medicine, New York, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2311

Introduction: This study explores sleep health disparities among adults with depressive episodes, focusing specifically on sexual and gender minorities (SGM). Given the high prevalence of sleep disturbances in this population, we aim to understand the influence of sexual orientation, alongside sociodemographic factors, on sleep health.



Objectives:

- To determine the prevalence of sleep difficulties among sexual minorities with depressive episodes.
- To assess how sociodemographic factors, including education and ethnicity, relate to sleep health in this population.

Methods: Using data from the 2020-2021 National Survey on Drug Use and Health (NSDUH), we analyzed a sample of 15,244 individuals who experienced depressive episodes. The study employed weighted estimates to accommodate the survey's multistage sampling design. Descriptive statistics were used to assess the prevalence of various factors, including tobacco and nicotine use, age, gender, ethnicity, income, marital status, and education. To evaluate the relationships between these factors and sleep difficulties, we utilized generalized linear models with Poisson distribution and log-link function to estimate adjusted prevalence ratios for each covariate.

Results: The study identified notable disparities in sleep health among individuals with depressive episodes based on sexual orientation and sociodemographic factors. Gay/lesbian individuals and bisexual individuals were both found to have a higher likelihood of reporting sleep difficulties compared to heterosexuals, with an increased prevalence of 1.06 times ($p = 0.038$ for gay/lesbian and $p = 0.009$ for bisexual). Educational attainment appeared to play a significant protective role; those with a college degree or higher were 0.89 times less likely to report sleep difficulties than individuals without a high school diploma ($p < 0.001$). Additionally, ethnicity influenced sleep health, with Hispanic individuals being 1.05 times more likely to report sleep issues than non-Hispanic Whites ($p = 0.015$).

Image 1:

Conclusions: The findings emphasize the presence of sleep health disparities among sexual and gender minorities experiencing depressive episodes. Gay/lesbian and bisexual individuals face a higher risk of sleep difficulties, highlighting the need for mental health interventions that are sensitive to sexual orientation. The protective effect of higher educational attainment suggests that enhancing access to education and related resources may improve sleep health outcomes. The increased prevalence of sleep difficulties among Hispanic individuals points to the need for culturally tailored approaches in mental health care. Addressing these disparities through individualized and culturally sensitive therapeutic strategies can contribute to better sleep health and overall well-being for these populations, underlining the importance of integrated, comprehensive care in managing depressive disorders.

Antiepileptic drugs and sexual dysfunction in patients with epilepsy

S. Kolsi[1]*, A. Bouaziz[1], A. Haj Ali[2], K. Medhaffar[1], K. Zitoun[1], W. Abbes[1] and E. Ellouz[2]

[1]Psychiatry and [2]Neurology, Hospital University, Gabes, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2312

Introduction: Epilepsy is a common disease that is mostly treated with antiepileptic drugs (AEDs). The sexual dysfunction (SD) side effects related to the use of AEDs have not received sufficient attention.

Objectives: The aims of this study were to assess the prevalence of SD and to study the role played by the AEDs among patients with epilepsy.

Methods: A cross-sectional and analytic study was conducted from September to December 2023, among patients with epilepsy follow up in the neurology outpatients of the University Hospital in Gabes (Tunisia), received AEDs, married for at least six months and sexually active. We collected the therapeutics data including type and number of prescribed AEDs and medication adherence, using pre-established form. SD was measured using the Arizona Sexual Experience Scale (ASEX) questionnaire.

Results: Forty-five patients were enrolled (68.9% male and 31.1% female). The average age was 46.76 years (SD=12.39). The majority of patients had a low socio-economic status (64.4%). Carbamazepine and phenobarbital were the most commonly AEDs prescribed (57.8% and 53.3% respectively), especially as monotherapy (62.3%). Poor medication adherence was observed in 13 patients (28.9%). The frequency of SD among patients, based on ASEX questionnaire, was 44.4%. The factors associated with SD included carbamazepine and phenobarbital prescription (p=0.036 and p=0.045 respectively), double or multiple drug therapies (p=0.006) and poor medication adherence (p=0.033).
Conclusions: SD is very common in patients with epilepsy. This seems to be related to AEDs such as using of carbamazepine and phenobarbital, polytherapy and poor medication adherence.

The sexual behavior of Tunisian adults during Ramadan: an opinion survey

H. Ktari[1]*, B. Amamou[1], K. Abdessatar[2], H. Mami[2], M. Oumaya[2] and R. Bouzid[2]

[1]Psychiatry, Fattouma Bourguiba Hospital, Monastir and [2]Psychiatry, Taher Maamouri Hospital, Nabeul, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2313

Introduction: The month of Ramadan, a sacred period in the Islamic calendar, is a time of fasting, prayer, and reflection for millions of Muslims worldwide. While the effects of fasting on physical and mental health have been extensively studied, there has been little focus on its specific impact on sexual life, particularly in the Tunisian context.
Objectives: The aim of our research was to study the opinions of Tunisians regarding their sexual behavior during the month of Ramadan.
Methods: This was a retrospective, descriptive, and comparative study conducted through an online survey among Tunisian adults. Data collection was carried out via a self-administered online questionnaire during Ramadan 2024, from March 21 to April 4, 2024. Two reminders were sent and the anonymity of the responses was guaranteed.
Results: Our study included 130 Tunisian adults with a mean age of 28.69 years. The majority of our population resided in urban areas (98.5%), 43.8% were single where 29.2% were in a relationship and both genders were equally represented (53.1% female, 46.9% male). The majority of participants identified as heterosexual (89.2%). During Ramadan, 78.5% of participants fasted, and 77.7% believed sexual activity was permissible during this period. Overall, 44.6% of participants felt that fasting had a negative impact on sexual behavior, 30.7% on sexual desire, and 26% on sexual performance. More than 70% reported that fasting influenced their sexual behavior, primarily in a negative way (44.6%). Among those who perceived an impact (n=93), changes were mostly noted in the timing (77.7%) and frequency of sexual activities (75.5%). Furthermore, 72.3% of participants reported that fasting influenced their sexual desire, with 40.9% perceiving this influence positively. Behavioral factors were identified as the most common cause of these changes (52.1%), followed by religious reasons (27.7%) and societal factors (11.7%). Significant gender differences were observed, with women being more affected by religious factors (p=0.02), while men were more influenced by behavioral factors (p=0.03). Women also reported a significantly greater impact on the frequency of sexual activity compared to men (p=0.012) and perceived a more significant negative impact of fasting on sexual performance compared to men (p=0.06).
Conclusions: Our study indicates that Ramadan fasting significantly affects the sexual lives of Tunisians, driven by sociocultural, religious, and physiological factors. This highlights the need for culturally sensitive sexual education and targeted health policies to ensure accessible and inclusive care during Ramadan.

Prevalence and knowledge of gender dysphoria among young medical trainees

N. Regaieg[1]*, F. Guermazi[1], D. Mnif[1], A. Jmal[2], M. Ben Jemaa[3], F. Cherif[1], I. Baati[1] and J. Masmoudi[1]

[1]Psychiatry A department, Hedi Chaker University Hospital; [2]Family medicine department, University of Sfax, Faculty of medicine of Sfax and [3]Community Health and Epidemiology Department, Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2314

Introduction: Gender dysphoria (GD) is a rare entity which involves significant distress experienced by an individual due to a perceived discrepancy between his gender identity and his sex assigned at birth. In the current literature, there is little research on medical students' knowledge and attitudes towards this entity.
Objectives: The objectives of our study were to estimate the prevalence of gender dysphoria within young medical trainees and to explore their knowledge and beliefs about this entity.
Methods: It was a cross-sectional and descriptive study, carried out on GOOGLE FORMS in the period of time from October 1, 2023, to January 31, 2024, and relating to a population of Tunisian young medical trainees. We used a questionnaire including an information sheet and the gender identity/gender dysphoria questionnaire for adolescents and adults (GIDYQ-AA).
Results: Our study involved 111 participants with a sex ratio (M/F) of 0.56. Their median age was 28 years.
The overall prevalence of gender dysphoria was 0.9%. It was 2.5% among participants assigned male at birth (95% CI=[0.06%–13.2%]) and 0% among those assigned female at birth.
Among the participants, 21.6% had received training on GD or sexual identity disorders during their medical education while 3.6% of reported being aware of specialized services for the management and support of GD.
Four-fifths of the participants (80.2%) believed that the development of GD would be due to organic factors, while 70.3% described the contribution of socio-cultural factors and 58.6% attributed it to early family interactions.
More than a third of the participants (40.6%) considered GD as an entity related to sexual development disorders, 28.8% equated it with a symptom of a more general mental pathology, while 30.6% regarded it as a distinct entity.
Regarding the suffering associated with GD, it was attributed to the internal experience of gender incongruence by 42.3% of the participants, social stigma in 29.8% of cases, and to psychiatric

pathology by 27.9% of the participants. GD was mentioned as a risk factor for suicide by 84.7% of the participants.
Conclusions: Our study revealed a low prevalence of GD among young medical trainees, similar to that observed in the general population, which could be explained by reluctance and fear of stigma in our society where sexuality remains a taboo subject. The knowledge of young doctors about this issue, still insufficient, could be improved through sexuality training dedicated to specialists, as well as through the teaching of sexology during the medical education.

« Transsexualism » or « gender dysphoria » : what impact on psychological well-being ?

N. Regaieg[1]*, F. Guermazi[1], F. Cherif[1], D. Mnif[1], A. Jmal[2], M. Ben Jemaa[3], I. Baati[1] and J. Masmoudi[1]

[1]Psychiatry A department, Hedi Chaker University Hospital; [2]Family medicine department, University of Sfax, Faculty of Medicine of Sfax and [3]Community Health and Epidemiology Department, Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2315

Introduction: Gender dysphoria is the feeling of discomfort or distress that might occur in people whose gender identity differs from their sex assigned at birth or sex-related physical characteristics. Individuals with gender dysphoria frequently face social as well as psychoaffective difficulties that can impede their well-being and quality of life.
Objectives: The aim of this study were to assess the impact of gender dysphoria among young medical trainees on their psychological health in terms of stress, anxiety and depression.
Methods: A cross-sectional, descriptive, and analytical study was conducted with a Tunisian population of young medical trainees, during the period of time from October 1, 2023, to January 31, 2024. Data were collected using a questionnaire created with GOOGLE FORMS including an information sheet and two psychometric assessment tools : the Depression, Anxiety, and Stress Scale (DASS-21) and the gender identity/gender dysphoria questionnaire for adolescents and adults (GIDYQ-AA) asssessing subjective, somatic, social, and sociolegal aspects.
Results: A total of 111 participants took part in this study. Their median age was 28 years. They were single in 56.6% of cases, with a male-to-female ratio of 0.56.
The prevalence of depression, anxiety, and stress was 53.2%, 59.5%, and 34.2%, respectively.
Median scores of depresssion, anxiety and stress were 10 (IQR = [2–18]), 8 (IQR =[4–14]) and 10 (IQR =[6–20]), respectively.
The overall median score on the GIDYQ-AA scale was 4.85 (IQR = [4.77–5.0]). The social dimension had the lowest median score at 4.88 (IQR=[4.55–5.0]) while the median score of the subjective dimension was 4.92 (IQR=[4.69-5.0]). Somatic and socio-legal median scores were 5.0 (IQR=[5.0–5.0]).
The score for the subjective dimension of the GIDYQ-AA was negatively correlated with anxiety (p=0.04) and stress (p=0.04) scores.
Conclusions: The psychological vulnerability of young medical trainees may be exacerbated by intrapsychic conflicts which may be related to their gender identity. It is essential to identify and consider the psychological factors associated with gender dysphoria in the care pathway of these individuals, through appropriate psychiatric evaluation and support in order to better guide therapeutic decisions regarding sex reassignment.

EPV1897

Persistent sexual arousal syndrome and schizoaffective disorder: a case report

M. J. Muñoz Algar[1]* and P. Bernal García[1]

[1]PSICHIATRY, HOSPITAL DR. R. LAFORA, MADRID, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2316

Introduction: Persistent sexual arousal syndrome (PSAS) is characterized by unwanted and distressing genital sensations that persist for long time periods without concurrent sexual desire or fantasies. The aetiology of this remains largely enigmatic although it is likely that the condition has a diverse set of neurological, vascular, pharmacological, and psychological precipitants.
Objectives: To analyze the case of a woman with schizoaffective disorder (severe depressive decompensation) and a comorbid PSAS.
Methods: We study the clinical case of a 47-year-old patient who was admitted to the acute care unit due to a major depressive condition with psychotic symptoms in the context of a schizoaffective disorder after partial abandonment and erratic taking of the medication she was previously taking.
Before the admission, the patient was hypomimic, perplexed, with psychomotor inhibition, bradypsychia, thought blockages, sadness, emotional lability, apathy, anhedonia, paranoidism, phenomena of reading and thought control, self-referentiality, delusional ideas of harm and auditory pseudohallucinations in the form of voices that urge her to harm herself. In addition, the patient presented several "sexual" crises that appeared paroxysmal throughout the day, consisting of episodes of sexual hyperarousal in the absence of desire, experienced with intense guilt. Initially, a differential diagnosis was made through an extensive history and organic screening, and she was finally diagnosed with a comorbid PSAS.
Results: Complementary tests (complete blood, urine and imaging tests) were normal.
At the pharmacological level, several strategies were used that were ineffective: paliperidone up to 18mg/day that had to be withdrawn due to intolerable extrapyramidal effects, olanzapine up to 15mg/day with high sleepiness and finally caripracin up to 12mg/day with good tolerance and efficacy. Stabilizing treatment (valproic acid 1000mg/day with optimal blood levels (99.3 microgr/mL)) were added. However, after a month and a half of admission and given the little improvement of the depressive symptoms, even having added an SSRI for 2 weeks at full doses, it was decided together with the patient and her family to start Electroconvulsive Therapy (ECT) sessions. The patient received 12 sessions of bitemporal ECT with onset of response from the 6th session, with a complete remission of the sexual crisis and depressive symptoms.
Conclusions: To our knowledge, Yero et al., reported the first two cases of patients with concomitant PSAS and bipolar disorder treated with ECT. It is important to understand how sexual symptoms differ in PSAS and bipolar disorder. Remission of the mood

episode could have been accompanied by resolution of the sexual symptoms. Although ECT was successful, the mechanism of action in treating PSAS is unknown, and it is premature to suggest that it should be recommended as a first line treatment of PSAS.

Strong Bodies, Stronger Bonds: The Intersection of Strength Training Intensity and Sexual Pleasure

S. Ben Aissa[1]*, C. Najar[1], K. Razki[1], M. Cheour[1] and F. F. Romdhane[1]

[1]Razi Hospital, La Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2317

Introduction: Strength training has long been linked to several physical and mental health advantages, ranging from increased muscle strength and endurance to higher mood and self-esteem. However, the potential link between strength training intensity and sexual satisfaction is a relatively unexplored area of research.
Objectives: This study's objective is to evaluate the potential relationship between the intensity of strength training and an individual's degree of sexual satisfaction among people who exercise at the gym in Tunisia.
Methods: This is a cross-sectional study, conducted from February to March 2024. Participants were recruited online through social media platforms (Tunisian facebook groups and fitness forums) using a posted survey link. We've included respondents who are 18 years of age or older who have been active in strength training with a gym membership for 1 month or more. The respondents were required to answer a questionnaire that included socio-demographic data and to provide strength training intensity related details (sessions frequency, duration, perceived overall intensity using likert scale)
Sexual satisfaction was measured using the Sexual Satisfaction Index (SSI), validated psychometric tool developed by Leth-Nissen et al. in 2021. The sum score of the SSI can range from 0 to 36. A higher sum score indicates a higher level of sexual satisfaction.
Results: The total number of participants was 72, with 86% being male. The majority of responders (n=65, 90.2%) indicated that they performed strength training exercises at least three times per week, with an average session length of 45 minutes. In terms of strength training intensity, 38.8% (n= 28) of participants reported high-intensity sessions, 48.6% (n=35) moderate-intensity sessions, and the remaining participants reported low-intensity sessions.
Analysis of the Sexual Satisfaction Index scores revealed a mean score of 23.6 (SD = 6.2), indicating that individuals had moderate to high sexual satisfaction. A significant association was found between strength training intensity and sexual satisfaction scores ($r = 0.42$, $p < 0.01$), indicating that higher intensity exercises are associated with higher sexual satisfaction.
Conclusions: Our findings aim to shed light on the link between fitness habits and sexual well-being, emphasising the potential value of including exercise interventions in talks about sexual health and satisfaction. The findings could indicate that the benefits of strength training go beyond physical fitness, potentially contributing to improved overall well-being. More research is needed to delve deeper into the underlying mechanisms causing this link and to investigate its broader implications for overall health and quality of life.

The Impact of Metacognitive Beliefs on Sexual Functions and Satisfaction in Vaginismus

S. Önen[1]*, M. Aydın[2] and G. Özdamar Ünal[3]

[1]Department of Psychiatry, University of Health Sciences, Bursa Faculty of Medicine, Bursa; [2]Department of Psychiatry, Selcuk University Faculty of Medicine, Konya and [3]Department of Psychiatry, Süleyman Demirel University Faculty of Medicine, Isparta, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2318

Introduction: Vaginismus is characterized by phobic avoidance, involuntary pelvic muscle contraction, anticipation, fear, and experience of pain during vaginal penetration. In addition to anxiety and fear, vaginismus-specific cognitive and metacognitive beliefs are thought to play a role in the etiology of vaginismus. Impaired sexual functions and decreased sexual satisfaction in women with vaginismus are claimed to be associated with anxiety and depressive symptoms. However, in clinical practice, it is observed that women who do not exhibit anxiety and depressive symptoms also experience sexual dysfunction and reduced sexual satisfaction, but it is noteworthy that the causes of this deterioration have not been sufficiently investigated.
Objectives: The purpose of this study is to assess the impact of metacognitive beliefs on sexual functions and satisfaction in women with vaginismus.
Methods: A total of 64 women with vaginismus and 30 healthy controls were examined through Sociodemographic Data Form (including age, education status, duration of marriage, etc), Beck Depression Inventory (BDI), Beck Anxiety Inventory (BAI), Arizona Sexual Experiences Scale (ASEX), Golombok-Rust Inventory of Sexual Satisfaction (GRISS), and Metacognition Questionnaire-30 (MCQ-30).
Results: The mean ASEX, GRISS, and MCQ-30 scores were significantly higher in the vaginismus group than the healthy controls. No significant difference were found between groups in terms of BDI and BAI scores. Hierarchical Regression Analysis revealed that 13% of ASEX total scores in the vaginismus group were predicted by BDI and BAI scores ($F=4.59$, $p< 0.05$), and the predictability increased significantly to 32% by the addition of MCQ-30 scores to the model ($F=3.79$, $p<0.01$). However, GRISS-Total scores were not statistically significantly predicted by BDI and BAI scores ($F=1.76$, $p>0.05$), but the predictability of variance increased significantly to %26 ($F=2.87$, $p<0.05$) with the addition of MCQ-30 scores to the model. Moreover, the metacognitive dimension of uncontrollability and danger of thoughts, and cognitive self-consciousness were found to be significant factors in predicting both ASEX ($b=0.52$, $p=0.004$ and $b=-0.49$, $p=0.003$, respectively) and GRISS ($b=0.58$, $p=0.002$ and $b=-0.40$, $p=0.017$, respectively) scores in vaginismus.
Conclusions: The current findings of the study indicate that metacognitive beliefs, especially dimensions of uncontrollability and danger of thoughts and cognitive self-consciousness, predict sexual

functioning and sexual satisfaction in women with vaginismus. Understanding the metacognitive characteristics accompanying vaginismus and including metacognitive interventions in sexual therapy for both cognitive self-consciousness and negative beliefs about the uncontrollability of thoughts and danger, may result in increased treatment success, improved sexual functioning, and sexual satisfaction in women with vaginismus.

Divergent Desires: Sexual Expression in ASD and ADHD Individuals

C. Pinheiro Ramos[1]*, A. F. Reis[1], M. J. Freire[1] and S. Mendes[1]

[1]Setúbal Hospital Center, Setúbal, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2319

Introduction: Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD) can both impact psychosexual functioning.
ASD individuals may struggle with appropriate sexual interactions due to challenges in social communication, understanding social norms, and sensory sensitivities. Restricted and repetitive behaviors may also lead to a focus on specific sexualized behaviors.
ADHD-related symptoms may impact psychosexual functioning. Impulsivity can lead to risky sexual behavior, while inattention may increase the risk of sexual dysfunction. Additionally, prescribed ADHD medication has been found to disrupt sexual functioning.
Objectives: Our aim is to better understand the psychosexual profile of neurodivergent individuals.
Methods: A narrative review was carried out using various databases, including PubMed.
Results: Literature suggests a higher prevalence of sexual ambivalence, as well as increased homosexual, bisexual, and asexual tendencies among ASD-individuals. They may also exhibit more inappropriate sexual behavior, which can put them at risk of legal consequences.
Research suggests that ADHD-individuals may have a higher frequency of homosexual experiences and females with ADHD report greater ambivalence about their gender identity. ADHD is associated with risky sexual behaviors, but ADHD-medications may have a protective effect against early pregnancy and STIs.
Conclusions: The literature suggests that individuals with ADHD and/or ASD can lead to different psychosexual functioning compared to neurotypical peers.
Further research is needed to understand the contributing factors.

Make sex great again! - Prevalence and Treatment Options for Postcoital Dysphoria

N. Ramalho[1]*, T. Rocha[1], J. F. Cunha[1], J. C. Moura[1], J. Leal[1], D. Seabra[1], I. Lopes[1], G. Santos[1], M. Rosa[1] and A. Garcia[1]

[1]Psychiatric and Mental Health Department, ULSAR, Barreiro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2320

Introduction: Postcoital dysphoria (PCD) refers to feelings of sadness, anxiety, or irritability following sexual intercourse, even when it is consensual and satisfying. These emotions can last from minutes to hours and affect both genders.
Historically, sex was mainly viewed as a means of reproduction, with pleasure often regarded as secondary. However, during the sexual revolution of the 1960s and 70s, perceptions shifted, recognizing sex as a source of pleasure and emotional connection. Today, despite a focus on mutual satisfaction, some individuals still experience post-sexual distress, highlighting the complexity of human sexuality. As a source of important distress, PCD calls for exploration of therapeutical agents.
Objectives: To examine the prevalence of postcoital dysphoria (PCD) and explore potential therapeutic agents.
Methods: A non-systematic literature review using the keywords "postcoital", "dysphoria" and "tristesse" limited to articles published in English from the PubMed®/MEDLINE® database.
Results: Seven relevant studies were identified regarding postcoital dysphoria (PCD). In a study of 1,208 males, 40% reported experiencing PCT at least once, with 20% experiencing symptoms in the past month, and 3–4% regularly. PCT was linked to psychological distress, childhood sexual abuse, and sexual dysfunctions.
Among women, a UK survey of female twins found that 3.7% reported recent PCT symptoms, while 7.7% had long-term symptoms. Another study indicated that nearly 50% of female university students experienced PCT at least once, with no correlation found between PCT and relationship intimacy.
In the LGBTQIA+ population, a survey of 172 adults revealed PCD prevalence of 42% among men attracted to men and 81% among bisexual/fluid individuals. Significant correlations were observed between sex life satisfaction and PCD in this group. Regarding treatment, one single case report described a patient without psychiatric comorbidities treated successfully with escitalopram (10 mg), with symptomatic relief.
Conclusions: The reviewed studies highlight the prevalence and factors contributing to postcoital dysphoria (PCD) across diverse populations. Among men, up to 40% experience PCD at least once, with contributing psychosocial factors. In women, PCT prevalence varies, with no clear link to relationship intimacy. In the LGBTQIA + community, PCD is notably high, affecting 42% of MSM and 81% of bisexual/fluid individuals, with sexual dissatisfaction and perceived discrimination as key correlates. Treatment options remain unexplored, with only one case report showing positive results using escitalopram. These findings suggest PCD is a complex conditions influenced by psychological, sexual, and societal factors. More research is needed to understand the underlying mechanisms and explore effective treatments, particularly for minority populations and those without psychiatric comorbidities.

Mental and Sexual Health Challenges Among Sexual Minority Individuals

A. Stern[1]*, A. Gewirtz-Meydan[2] and S. Maoz[2]

[1]Occupational Therapy, Ben-Gurion University of the Negev, Beer Sheva and [2]Social Work, University of Haifa, Haifa, Israel
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2321

Introduction: Sexual minority individuals face unique challenges in mental and sexual health, emotion regulation, and well-being. Although understanding the complex dynamics among these variables in the context of diverse sexual orientations and gender identities is crucial to supporting and tailoring comprehensive interventions, limited research has investigated their overlapping relationships and intersections.
Objectives: The current study aims to examine the connections between mental health, sexual health, emotion regulation, and well-being among sexual minority and heterosexual individuals in Israel. The main purpose was to provide a comprehensive understanding of the unique challenges sexual minority individuals face.
Methods: The study included 465 participants, 324 (70%) were identified as heterosexual individuals and 119 (26%) as sexual minority individuals. Various variables were assessed using an online anonymous questionnaire, including mental health (anxiety, depression, suicide ideation, substance use disorder), sexual health (sex-related distress, problematic pornography use, compulsive sexual behavior disorder), emotion-regulation, and well-being. Between-group differences were analyzed using Mann-Whitney U tests. Network analysis was conducted to examine the centrality and edges of relationships between variables within each group.
Results: Significant differences were found between the heterosexual and sexual minority groups across the measured variables. Sexual minority individuals reported higher levels of psychopathology, lower sexual health, as well as lower levels of emotion regulation and well-being compared to heterosexual individuals. Network analysis revealed that the number of diagnosed psychopathologies and depression were central nodes in the sexual minority group, while sexual functioning played a central role in the heterosexual group. The sexual minority group's network showed less stability, suggesting distinct subpopulations within this group.
Conclusions: This study contributes to understanding the unique mental and sexual challenges sexual minority individuals face and the intersections between mental health, sexual health, emotion regulation, and well-being. These findings highlight the importance for mental health professionals to acknowledge and address these connections, emphasizing the need for tailored psychosocial interventions that integrate sexual health.

The Impact of Personality Traits on Mental Stress and Stigmatization in HIV+ Cases

E. ILGIN[1]*, Ö. Yanartaş[1] and S. Göktaş[2]
[1]Psychiatry, Marmara University and [2]Psychology, Yeditepe University, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2322

Introduction: HIV (Human Immunodeficiency Virus) is a virus that damages the immune system, weakening the body's ability to defend against infections and certain types of cancer. If left untreated, HIV can progress to an advanced stage known as AIDS (Acquired Immunodeficiency Syndrome). HIV can be transmitted through blood, sexual contact, from mother to child during childbirth, or through breastfeeding. Today, with antiretroviral treatments, it is possible for individuals living with HIV to lead healthy and long lives. In addition to health issues, HIV-positive individuals face mental stress and societal stigmatization. Their personality traits play a significant role in determining the level of mental stress they experience and their ability to cope with stigma. We have developed a survey for HIV-positive individuals addressing these aspects.
Objectives: This study, aimed to observe how HIV-positive individuals cope with societal stigmatization and the mental stress they experience based on their personality types, as well as the connection between these factors.
Methods: The study's survey was prepared using the open-source platform 'Google Forms' and will be administered in person. The tests used in this study are widely accessible and have been validated for reliability and validity in Turkey. Specifically, we utilized the Enneagram, the HIV Stigma Scale developed by Berger and colleagues, and the Hospital Anxiety and Depression Scale developed by Zigmond and Snaith. The study has no commercial purpose. The analysis was conducted on a total of 63 respondents, consisting of 45 men and 18 women.
Results: In the study, data were collected from 63 individuals, 71.4% of whom were male (n=45) and 28.6% female (n=18). The average age of participants was 39.69 years (range 20-77). It was observed that individuals with primary education were the most stigmatized, while those with middle school education experienced the least stigmatization. The most common personality type among both men and women was Type 2 (the helper). According to the data, participants had an average stigma score of 94.9.
Conclusions: The study did not find a significant relationship between age and stigmatization, nor between gender and stigmatization. Personality types that perceived the highest levels of stigmatization were Type 2 and Type 8, with average scores of 108. Conversely, the personality type that perceived the lowest levels of stigmatization was Type 5, with an average score of 74. These findings highlight that certain personality types may be more susceptible to experiencing or perceiving stigmatization, while others may experience it less. Further research could explore the underlying factors influencing these perceptions and their implications for support and intervention strategies.

Association between Anxiety and Depression with Sleep Quality among Iraqi Polypharmacy Older Adults: A Cross-Sectional Study

G. Alhashem[1], M. Aldawoudi[1]* and M. AlZayadi[1]
[1]Pharmacy, AlSafwa University College, Karbala, Iraq
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2323

Introduction: Many definitions have been proposed for polypharmacy, but the most common is the concurrent use of five or more medications. It is a growing concern among older adults and is associated with numerous adverse effects and drug-drug interactions. Beyond its impact on physical health, research suggests that polypharmacy may also affect mental health, which could potentially be linked to poor sleep quality.

Objectives: The current study objective is to investigate the sleep quality of polypharmacy older adults and its association with depression and anxiety in this population.
Methods: A cross-sectional study was conducted in Iraq from June to August 2024. A total of 245 participants were selected from internal medicine wards in hospitals and private clinics. All participants were aged 50 years or older and had been taking five or more medications for at least 90 days. The study questionnaire comprised three main sections: demographic data, the Patient Health Questionnaire-4 (PHQ-4), and the Pittsburgh Sleep Quality Index (PSQI). A PSQI score greater than 5 was used to identify poor sleepers. The association between poor sleep and other factors was assessed by using chi-squared tests and binary logistic regression.
Results: The sample consisted of 245 polypharmacy patients, with a mean age of 61.5 ± 12.4 years. Of the participants, 150 (61%) were female and 95 (39%) were male. Anxiety was observed in 95 (38.8%) participants, depression in 96 (39.2%), and poor sleep quality in 189 (77.1%). The study found significant associations between both anxiety (OR = 3.4 [95% CI: 1.55-7.57], p = 0.002)and depressive symptoms (OR = 2.43 [95% CI: 1.15-5.15], p = 0.020) with poor sleep quality.
Conclusions: Our study suggests that Iraqi polypharmacy older adults suffer from poor sleep quality, with depression and anxiety potentially exacerbating this issue. The findings suggest that mental health support is necessary for older adults with polypharmacy.

EPV1910

Sleep disorders and stress in children and adolescents with ASD

A. Alvarez[1]*, N. Santamaria[1], V. Bote[1], R. Medina[1], J. A. Monreal[1], B. Sánchez[1] and A. Hervás[1]

[1]Mental Health, University Hospital Mutua Terrassa, Terrassa, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2324

Introduction: Sleep disorders are very common in children with neurodevelopmental disorders such as autism. Poor sleep can have detrimental effects on cognitive processes, attention, memory, language, and regulation of mood and behavior. Many people with autism have difficulty correctly processing sensory information that reaches them from both the environment and their own body. Depending on how the person with autism perceives the sensations, these can impact on sleep, causing nighttime awakenings or poor sleep conciliation. It is vitally important to evaluate nighttime rest and have knowledge of appropriate tools to improve sleep in patients with ASD.
Objectives: In this work we aim to evaluate, in a child-youth population diagnosed with ASD who have been admitted to our ASD Day Hospital during the year 2024, the prevalence of sleep disorders and their characteristics. As well as generating strategies to improve sleep conciliation and factors to take into account or avoid that may be affecting our patients.
Methods: A review is carried out of the clinical history of patients admitted to the TEA Day Hospital during the year 2024. Sleep problems are analyzed, as well as their relationship with stress. Results and measures to improve the quality of night rest in these patients are presented.
Results: From January to September 2024, a total of 26 patients with autism have been treated at the ASD Day Hospital of the University Hospital of Mutua Terrasa, in the following programs: intensive, eating problems and low functionality. Of these, 32% were women, with an average age of 11.64 and an average stay of 40 days.
More than half of the patients had sleep problems, where the majority had more than one. Among the most frequent: difficulties falling asleep (12), maintenance insomnia (8), frequent awakenings (4), night terrors (6), and the need for the presence of parents and/or sensory interventions to be able to fall asleep (12).
The main interventions carried out have consisted of: establishing adequate sleeping habits, avoiding naps, avoiding highly stimulating activities, feeling tired beforehand, adapting environmental conditions to the needs of the child and giving proprioceptive information before sleeping.
Among the most commonly used drugs we found atypical antipsychotics: olanzapine, risperidone. Some antidepressants: mirtazapine and occasionally benzodiazepines. The vast majority of children took melatonin.
Conclusions: Sleep disorders are highly prevalent in patients with ASD, but correct intervention can improve comorbid symptoms such as anxiety, stress and discomfort, which are largely related to poor sleep.
Sensory-perceptive interventions are essential to improve nighttime rest in children with ASD

Daytime Sleepiness Among Healthcare Workers Following SARS-CoV-2 Infection

E. Bechrifa[1]*, D. Brahim[1], N. Mechergui[2], I. Youssef[3], M. Mersni[1], G. Bahri[1], H. Ben Said[4], M. Bani[1] and N. Laadhari[1]

[1]Occupational Medicine Department, Charles Nicolle Hospital; [2]Occupational Medicine Department, Habib Thameur Hospital; [3]Occupational Medicine Department, Mongi Slim Hospital and [4]Occupational Medicine Department, Maternity and Neonatology Center, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2325

Introduction: COVID-19 infections had a variety of symptoms, including a range of sleep disorders such as daytime sleepiness.
Objectives: The objective of the study was to determine the frequency and persistence of daytime Sleepiness among HCWs post-COVID-19 and analysis of related risk factors.
Methods: A prospective descriptive study was conducted over six months (January-July 2022) among HCWs at Charles-Nicolle Hospital in Tunis who contracted COVID-19. Daytime sleepiness was evaluated at three intervals: during the infection (T0), at three months, and at six months post-infection, using the Epworth Sleepiness Scale (ESS) in its French version. Anxiety and depressive symptoms were assessed with the Hospital Anxiety and Depression Scale (HAD) to examine their association with sleep disturbances.
Results: The study included 155 HCWs, with an average age of 40.2 ± 10.3 years and an average work seniority of 14,1 ± 10 years. The assessment of anxiety-depressive disorders in the study population using the HAD scale showed that anxiety symptoms were certain in 27.3% of the personnel, while depressive symptoms were certain in 21.4% of cases. Additionally, 48.1% of participants showed no

signs of anxiety, with 24.7% exhibiting doubtful symptoms. For depression, 59.1% had no symptoms, and 19.4% presented with doubtful symptomatology.
àAt baseline (T0), 47.1% of healthcare workers reported normal levels of sleepiness, 16.8% had moderate sleepiness, and 36.1% experienced abnormal sleepiness. By three months, these levels shifted, with 20.6% reporting normal sleepiness, 21.9% reporting moderate sleepiness, and 11.6% experiencing abnormal sleepiness. At six months, 7.7% reported normal sleepiness, 3.9% had moderate sleepiness, and 6.5% continued to experience abnormal sleepiness. Factors significantly associated with prolonged daytime sleepiness included obesity ($p = 0.005$), thrombophilia ($p = 0.004$), non-medical professional category ($p = 0.019$), hospitalization requiring oxygen therapy ($p < 10^{-3}$), and the death of a close relative due to COVID-19 ($p = 0.016$). Anxiety and/or depression, as assessed by the HAD scale, were also significantly associated with persistent sleepiness ($p = 0.03$).
Conclusions: Persistent daytime sleepiness among HCWs post-COVID-19 infection highlights the need for targeted interventions focused on sleep quality and mental health support, which could enhance well-being and facilitate their occupational reintegration.

Disclosure of Interest: None Declared

EPV1912

Insomnia Among Healthcare Workers Following SARS-CoV-2 Infection

E. Bechrifa[1]*, D. Brahim[1], I. Youssef[2], N. Mechergui[3], H. Ben Said[4], M. Mersni[1], G. Bahri[1], M. Bani[1] and N. Laadhari[1]

[1]Occupational Medicine Department, Charles Nicolle Hospital; [2]Occupational Medicine Department, Mongi Slim Hospital; [3]Occupational Medicine Department, Habib Thameur Hospital and [4]Occupational Medicine Department, Maternity and Neonatology Center, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2326

Introduction: COVID-19 infections had a variety of symptoms, including a range of sleep disorders such as insomnia.
Objectives: The objective of the study was to assess the prevalence of insomnia among healthcare workers (HCWs) following COVID-19 infection and to identify factors associated with its persistence over time.
Methods: This prospective descriptive study was conducted at Charles-Nicolle Hospital in Tunis, monitoring HCWs infected with COVID-19 over a six-month period (January-July 2022). Insomnia severity was evaluated at infection onset (T0), at three months, and at six months post-infection, using the Insomnia Severity Index (ISI) in its French version. The presence of anxiety and depression was assessed via the Hospital Anxiety and Depression Scale (HAD) to determine potential associations.
Results: The study included 155 healthcare workers, with an average age of 40.2 ± 10.3 years and an average work tenure of 14,1 ± 10 years. At baseline (J0), 42.5% of participants reported no insomnia, 21.3% had mild sub-clinical insomnia, 31% had moderate clinical insomnia, and 5.2% experienced severe clinical insomnia. At three months, the rates shifted, with 11.6% reporting no insomnia, 35.5% experiencing mild sub-clinical insomnia, and 7.1% having moderate clinical insomnia. By six months, 7.7% had no insomnia, 6.5% reported mild sub-clinical insomnia, and 3.9% continued to experience moderate clinical insomnia. Factors significantly associated with insomnia included a history of discopathy ($p < 10^{-3}$), hospitalization ($p < 10^{-3}$), and the death of a close relative due to COVID-19 ($p = 0.012$). Additionally, significant associations were found between persistent insomnia and anxiety and/or depression ($p = 0.03$).
Conclusions: Persistent insomnia post-COVID-19 infection in HCWs underscores the importance of integrating mental health and sleep quality interventions into healthcare protocols to improve overall well-being and aid in their professional recovery.

From childhood physical and emotional abuse to self-harm: the mediating effect of sleep disorders among a sample of male prisoners

I. Mlouki[1], A. Ben Haouala[2]*, E. Hariz[1], A. Silini[1], Y. Abess[1], M. Boussaid[3], F. Zaafrane[2] and S. El Mhamdi[1]

[1]Preventive and Community Medicine, University Hospital Tahar Sfar, Mahdia; [2]Research Laboratory "Vulnerability to psychotic disorders", University of Monastir, Monastir and [3]Forensic Medicine, University Hospital Tahar Sfar, Mahdia, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2327

Introduction: According to literature, the link between childhood trauma and mental health disorders is well-established. However, focusing on the mechanisms explaining this pathway remains insufficiently studied mainly among incarcerated population.
Objectives: The current study aimed to assess the mediation effect of sleep disorders in the path from childhood physical neglect and emotional abuse to suicide and self harm behaviors among male prisoners.
Methods: We conducted a cross sectional study among incarcerated males in Mahdia prison on April 2023. The participation was anonymous, voluntary and the measurement tool was self-administrated. Illiterate participants were interviewed by investigator doctors. We assessed physical and emotional abuse using items from the validated Arabic version of the World Health Organization ACE questionnaire. Self-directed violent behaviors were subdivided into suicidal behaviours and self harm. The Hospital Anxiety and Depression Scale and The Pittsburgh sleep quality index were also used.
Results: A total of 540 prisoners were recruited with a response rate of 74.6%. Their mean age was 33.75± 10.89 years. Among participants, 73% reported emotional abuse and 39.2% had experienced physical neglect during their childhood. In the six previous months, 35% of them had suicidal thoughts and 45.9% were engaged in self-harm. Anxiety and depression were screened among 83.2% and 79.6% of them respectively. During incarceration, 88.4% of prisoners reported sleep disorders.
After adjusting for anxiety and depression, we found that physical neglect and emotional abuse predict self harm behaviors through sleep disorders among male prisoners (%mediated= 28.5% and 15% respectively, $p< 0.001$).
Conclusions: Our study emphasize the need for preventing and screening childhood trauma and implementing mental health approaches in jail in order to deal with sleep disorders and to prevent suicidal behaviors among prisoners.

Disclosure of Interest: None Declared

EPV1914

Management of insomnia evaluated by the Psychiatry Interconsultation in a patient with a comorbid medical condition

A. Blanco Barrón[1]*, M. T. González Salvador[1], A. Castiglioni García-Diego[1] and M. Magariños López[1]

[1]Psychiatry, Hospital Puerta de Hierro, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2328

Introduction: Insomnia, affecting about one-third of adults and worsening with age, impacts individual's health, social life, and occupational functioning. Therefore, untreated insomnia can lead to depression. Although it can appear as an independent symptom, it most often presents as a comorbid disorder.
This paper discusses the case of a 71-year-old man with acute necrotizing pancreatitis and history of multiple admissions for recurrent abdominal pain, was assessed by Psychiatry for a possible adaptive disorder. He was diagnosed with persistent insomnia linked to his medical condition and secondary low mood. Sleep hygiene and various medications were recommended but proved ineffective. Eventually, an orexin antagonist, daridorexant, was prescribed.
Objectives: The aim of this work is to orient, within the wide range of psychopharmacology available for the treatment of insomnia, the effectiveness and advantages of the use of daridorexant in patients with comorbid medical pathology.
Methods: To evaluate the efficacy of the drug in improving the quantity and quality of sleep, and the diurnal impact of insomnia, the Athens scale, consisting of 8 items, was used. It has been completed with a sleep diary that provides specific information on sleep. The results obtained were compared with those published by means of a literature search in PubMed.
Permission is requested from the patient to present this case anonymously.
Results: After 30 days of treatment with daridorexant, the Athens Scale score decreased, with a perceived improvement in nocturnal rest (quantity and quality of sleep) and daytime impact of insomnia, with good tolerance and no side effects.
Conclusions: The pharmacological treatment of insomnia has undergone important advances in the last two decades. The treatment of insomnia is multidisciplinary and will depend on its etiology. There seems to be no single, first-choice pharmacological treatment for insomnia, which is why the options are varied and wide-ranging. The management of this disorder seeks two fundamental objectives: to improve the quality of sleep and to improve daytime symptoms. Both are improved in this patient with the help of daridorexant. The review of the available literature supports the observed case, being daridorexant a safe and effective option for the treatment of insomnia. It is worth mentioning that in Spain, daridorexant has been approved in September 2023, so the clinical experience at present is scarce.
In our patient the drug has been well tolerated, with no reported side effects or variations in analytical parameters. With respect to insomnia, anxious and negative expectations regarding sleep, concern about the potential consequences of not sleeping enough or not sleeping well have decreased and, in short, the quality of sleep, functionality during the day, and even mood have improved in general terms.

Disclosure of Interest: None Declared

EPV1915

Treatment of persistent insomnia in patients with benzodiazepine addiction: a case report

A. Castiglioni García-Diego[1]*, A. Blanco Barrón[1], M. T. González Salvador[1], M. Magariños López[1] and I. Álvarez Correa[2]

[1]Psiquiatría and [2]Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2329

Introduction: The diagnosis of persistent insomnia according to DSM-5 and ICD 11 is based on clinical criteria, specially in relation to dissatisfaction with the quantity/quality of sleep and the discomfort or impairment of social and occupational functioning that it generates. On the other hand, in 2023, Spain has positioned itself as the world leader in the consumption of benzodiazepines.
We present the case of a 62-year-old man admitted to neurosurgery for a cerebrospinal fluid fistula and evaluated by the liaison psychiatry for persistent insomnia. The patient was abusing benzodiazepines to improve his night's rest. Different drugs are prescribed to improve sleep and avoid abusive consumption of benzodiazepines such as trazodone, quetiapine, clotiapine, gabapentin with little or no improvement of insomnia. Finally, a dual orexin receptor antagonist, daridorexant, is prescribed and its effectiveness is evaluated.
Objectives: The aim of this work is to evaluate the effectiveness of daridorexant in persistent insomnia, as well as to assess the possibility of its use in benzodiazepine addiction for hypnotic purposes.
Methods: The Oviedo Sleep Questionnaire (COS), which is a structured and hetero-applied instrument, was administered to facilitate the diagnosis and monitoring of sleep pre and post treatment.
A literature search was carried out in PubMed and the conclusions found in the literature were compared with the clinical case presented.
Permission is requested from the patient to present this case anonymously.
Results: After 30 days of treatment with daridorexant, the COS score decreased, and improvement was also observed in the anamnesis, without verbalizing complaints that could be interpreted as side effects.
Regarding lorazepam consumption, this could be gradually reduced until its withdrawal.
Conclusions: Daridorexant is a drug that may be effective in resolving persistent insomnia in patients addicted to benzodiazepines for hypnotic purposes.
The review of the available literature suggests that daridorexant is a safe and effective option for the treatment of persistent insomnia. This has been fulfilled in our patient, given that he has not reported side effects, that the analytical parameters have not changed since its introduction and that it has improved in general terms the quality of sleep and functionality during the day. On the other hand, since the hypnotic purpose of lorazepam was replaced by daridorexant, the former could be withdrawn, which opens the door to the possibility that we are dealing with a drug that reduces the consumption of benzodiazepines.

It should be borne in mind that in Spain daridorexant was recently approved in September 2023, with not much experience in practice.

Relationships Between Fatigue, Aggressiveness, Insomnia, and Sleep Quality Among Nurses

A. M. Cybulska[1]*, K. Rachubińska[1], E. Grochans[1], I. Malicka-Szymoniak[2] and D. Schneider-Matyka[1]

[1]Department of Nursing, Pomeranian Medical University in Szczecin and [2]Independent Public Provincial Hospital in Szczecin, Szczecin, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2330

Introduction: Nurses often face situations where they must deal with aggression from patients or even coworkers. This challenge can have negative consequences for both medical staff and patients.
Objectives: The aim of this study is to examine the relationship between the level of aggression, the severity of fatigue, and the occurrence of sleep disorders among nursing staff.
Methods: The study was conducted in Szczecin and was survey-based, involving 241 nurses working in surgical wards, medical wards, outpatient clinics, and the emergency department. The following tools were used to collect data: a custom survey, the Fatigue Severity Scale (FSS), the Athens Insomnia Scale (AIS), the Buss-Perry Aggression Questionnaire (BPAQ), and the Pittsburgh Sleep Quality Index (PSQI).
Results: It was found that a greater tendency toward overall aggression, verbal aggression, and higher levels of anger and hostility were associated with more severe insomnia problems ($p<0.05$). Data analysis showed statistically significant correlations ($p<0.05$) between overall, physical, and verbal aggression, as well as hostility (based on BPAQ) and sleep quality (based on PSQI). A statistically significant positive correlation ($p<0.05$) was also found between fatigue levels (FSS) and sleep quality (PSQI) — the higher the level of fatigue, the worse the sleep quality.
Table 1. Comparison of results according to BPAQ and AIS, PSQI

Examined Traits	AIS		PSQI	
	r	p	r	p
BPAQ: Total Aggression	0,297	<0,001	0,227	<0,001
BPAQ: Verbal Aggression	0,143	0,026	0,147	0,022
BPAQ: Anger	0,202	0,002	0,118	0,068
BPAQ: Hostility	0,353	0,001	0,317	<0,001

Conclusions: There is a link between aggression levels, fatigue, and sleep disorders. Individuals with stronger tendencies toward aggression were more likely to experience insomnia and sleep problems. Those with higher levels of fatigue also experienced more frequent insomnia and sleep disturbances. Preventive and therapeutic measures are necessary to improve the health of nursing staff.

Defenestration in the Context of Adult Parasomnia: Diagnostic Challenges and Clinical Considerations

O. De Juan Viladegut[1]*, H. Andreu Gracia[1], L. Olivier Mayorga[1], L. Bueno Sanya[1], E. Cesari[1], J. I. Mena[1], I. Ochandiano[1], S. Salmerón[1] and L. Pintor[1]

[1]Servei de Psiquiatria, Institut Clínic de Neurociències, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2331

Introduction: Abnormal motor and behavioral phenomena during sleep are part of a broader category of sleep behaviour disorder, which may manifest during different stages—either during sleep, wakefulness, or the transitions between these states. Such occurrences are particularly prevalent during early childhood, affecting approximately 15-20% of pediatric populations, while about 4% of adults experience similar events. These sleep disturbances are generally categorized into simple behaviors or more complex behaviors.
Objectives: This case report describes a clinical presentation involving defenestration in the context of parasomnia, with initial concerns about a possible suicide attempt. The objective is to highlight the diagnostic challenges in such cases and emphasize the importance of distinguishing between parasomnia-related behavior and intentional self-harm.
Methods: The patient is a 24-year-old male, born in the US, and currently living in Barcelona as part of a study exchange program. He has been consuming 1SCU of cannabis daily since adolescence. He denies any personal or family psychiatric history but reports experiencing episodes of sleepwalking during his childhood and teenage years.
On presentation, the patient sustained multiple traumatic injuries following an accidental fall from a second-floor window. The event was witnessed by neighbors, who alerted emergency services. The patient has no memories of the event and denies suicidal intent. In the hours preceding the incident, the patient consumed approximately 2SDE of alcohol, but he denies the use of any other substances at the time. Additional testing, including CT of the brain and EEG, revealed no significant abnormalities.
Results: This case presents a diagnostic dilemma, as initial suspicions pointed toward a possible suicide attempt. However, the patient's history of sleepwalking, especially during childhood, suggests a parasomnia-related etiology. It is crucial to differentiate between childhood-onset sleepwalking, which is often linked to genetic and developmental factors, and sleepwalking that persists or re-emerges in adulthood, which is more strongly associated with psychopathological factors. The persistence of parasomnias in adults may indicate an underlying psychiatric condition.
Conclusions: This case underscores the complexities in diagnosing parasomnias, particularly when severe and potentially dangerous behaviors are involved. While the patient's history of sleepwalking and lack of psychiatry history suggest a parasomnia-related etiology, the persistence of such behaviors into adulthood warrants careful evaluation for underlying psychopathological factors. Early recognition and accurate diagnosis are paramount to providing effective care and preventing recurrence of such episodes. This case highlights the importance of a multidisciplinary approach, integrating neurology and psychiatry to offer tailored interventions.

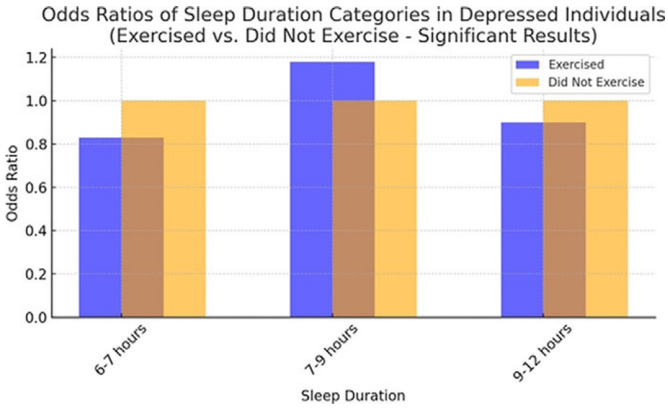
Regular Exercise Influences Sleep Patterns in Depressed Individuals

J. Kim[1,1*], S. Jaka[2], T. Shah[2], S. Gunturu[1] and O. El Shahawy[2]
[1]BronxCare Health System, Bronx and [2]New York University Grossman School of Medicine, New York, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2332

Introduction: Physical activity has been associated with improved sleep health, yet the specific impact on individuals with depressive disorders remains underexplored. This study aims to investigate the relationship between regular physical exercise and sleep duration in individuals diagnosed with a depressive disorder, utilizing data from the Behavioral Risk Factor Surveillance System (BRFSS). Understanding this relationship could inform integrative approaches to managing depressive symptoms and improving overall sleep health in this population.



Objectives:

- To analyze the impact of regular physical exercise on sleep duration among individuals with a depressive disorder.
- To assess the potential role of physical exercise in mitigating inadequate and prolonged sleep patterns within this population.

Methods: Data from the BRFSS for the years 2013, 2014, 2016, 2018, 2020, and 2022 were analyzed to explore the relationship between physical exercise and sleep duration in individuals with depressive disorders. The study included 518,214 participants who reported having a depressive disorder. Of these, 342,276 (weighted 68.5%) reported engaging in physical exercise within the past 30 days. Sleep duration was categorized, and regression analysis was used to assess the association between recent physical exercise and sleep duration.

Results: The analysis indicated that individuals with a depressive disorder who engaged in physical exercise in the past 30 days were less likely to experience inadequate sleep (6-7 hours, Odds Ratio [OR] = 0.83, $p < 0.05$) and more likely to achieve adequate sleep (7-9 hours, OR = 1.18, $p < 0.001$) compared to those who did not exercise. They were slightly less likely to have prolonged sleep (9-12 hours, OR = 0.9, $p < 0.05$). No significant associations were found for very inadequate sleep (<6 hours, OR = 1.34) and very prolonged sleep (>12 hours, OR = 0.6) with physical exercise ($p > 0.05$).

Image 1:

Conclusions: Regular physical exercise appears to be associated with better sleep outcomes in individuals with depressive disorders, particularly in promoting adequate sleep duration (7-9 hours). Exercise was linked to a reduced likelihood of inadequate sleep (6-7 hours) and a slight decrease in prolonged sleep (9-12 hours). However, no significant associations were found for very short (<6 hours) or very prolonged (>12 hours) sleep durations. These findings highlight the potential role of physical exercise in managing sleep health within this population. Incorporating regular physical activity into treatment plans for depression may improve sleep quality and contribute to better overall health outcomes. Further research is needed to understand the mechanisms and long-term effects of exercise on sleep patterns in those with depressive disorders.

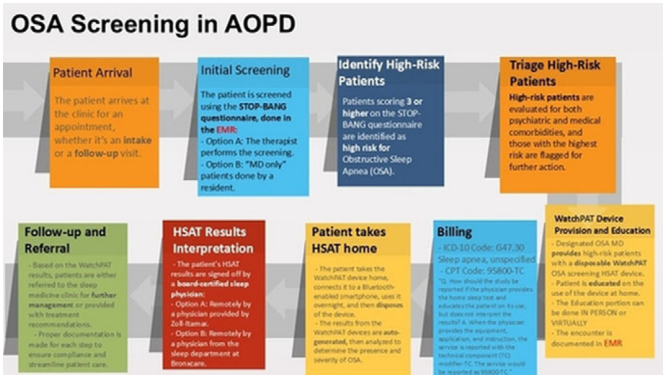
Better Sleep, Better Care: Streamlining Obstructive Sleep Apnea Screening in Psychiatric Outpatients

J. Kim[1*], A. Ramu[1], D. Khorasani[1], T. Kainth[1], A. Javaid[1] and S. Gunturu[1]
[1]BronxCare Health System, Bronx, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2333

Introduction: Obstructive Sleep Apnea (OSA) significantly complicates psychiatric conditions, yet its systematic screening within psychiatric settings is not common. We present a unique collaborative initiative within a tertiary care psychiatric hospital in South Bronx, USA, with approximately 3000 outpatients. We aim to bridge this gap by implementing a comprehensive OSA screening and referral process to improve patient outcomes.



Objectives:

- Implement a standardized Obstructive Sleep Apnea screening in psychiatric outpatient care.
- Enhance collaboration between psychiatry and sleep medicine for integrated care.
- Address compliance barriers by offering at-home sleep diagnostic options.

Methods: Starting in April 2024, patients in the Adult Outpatient Psychiatry Department are being screened for Obstructive Sleep Apnea using the STOP-Bang questionnaire, with this process ending in October 2024. High-risk patients identified through screening will receive WatchPAT Home Sleep Apnea Testing devices, with distribution and testing to be completed by December 2024. Data collected will include the number of patients screened, proportion identified as high-risk, HSAT completion rates, diagnostic outcomes, and subsequent referrals to sleep medicine services.

Results: The STOP-Bang questionnaire has been successfully integrated into routine clinical assessments for psychiatric outpatients, and the screening phase will conclude in October 2024. Preliminary data shows that a substantial number of patients were identified as high risk for Obstructive Sleep Apnea. The distribution of WatchPAT Home Sleep Apnea Testing devices to these high-risk individuals is underway and will be completed by December 2024. Initial results indicate effective triaging of patients and a high rate of compliance with at-home sleep testing. Detailed findings, including the exact number of patients screened, high-risk identification rates, HSAT completion rates, and diagnostic outcomes, will be presented upon project completion.

Image 1:

Conclusions: Early findings from this Quality Improvement project suggest that integrating Obstructive Sleep Apnea screening into psychiatric outpatient care is feasible and beneficial. By identifying at-risk patients and providing accessible, at-home diagnostic tools, we aim to enhance patient care and address the underdiagnosed issue of sleep disturbances in psychiatric populations. The project demonstrates the potential for a streamlined, interdisciplinary approach to improve outcomes and set a scalable model for comprehensive patient management in similar settings. Further analysis will focus on the impact of this intervention on psychiatric care and overall patient health outcomes.

Narcolepsy and the Risk of Pregnancy Complications: Based on a Nationwide Healthcare System Database in South Korea

T. W. Kim[1]* and S.-C. Hong[1]

[1]Psychiatry, St. Vincent's Hospital, The Cathoilc University of Korea, Suwon, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2334

Introduction: Narcolepsy is known as an autoimmune disease which altered metabolic functions. It is believed that narcolepsy makes more pregnancy complications. However clinical evidence in narcolepsy patients, especially in pregnant women, is limited.
Objectives: We aim to find out whether there is relationship between narcolepsy and pregnancy complications.
Methods: We examined data from the South Korean nationwide health insurance claims database from 2010 to 2019. Out study included women narcolepsy patients who gave birth, and age- and sex- matched controls without narcolepsy. We estimated the odds ratio of narcolepsy with pregnancy complications and control group with pregnancy complications using multivariate logistic regression analysis.
Results: Our study included 1,836 women with narcolepsy who gave birth and 28,796 women who gave birth without narcolepsy. We found that women with narcolepsy have a slightly high risk of preterm birth (OR, 1.191; 95% CI, 1.034-1.372). Patients with narcolepsy were at a significantly lower risk of spontaneous abortion, caesarean and gestational diabetes (OR, 0.763; 0.682-0.854, OR, 0.679; 95% CI, 0.560-0.824 and OR, 0.656; 95% CI, 0.556-0.774, respectively).
Conclusions: This study is the first study about pregnancy complications in narcolepsy patients in South Korea. We found that preterm birth happened more in the patient with narcolepsy during pregnancy. But patient had lower risk of spontaneous abortion, caesarean, gestational diabetes compared to heath control group. These findings suggest that narcolepsy is not a definite risk factor for pregnancy complications. Further research is needed to investigate the reasons why narcolepsy patients had lower risk of spontaneous abortion, caesarean, gestational diabetes compared to health control.

Sleep phenotypes and mental disorders: analysis of causality with two-sample Mendelian randomization

M. Marchi[1]*, D. Uberti[1], E. Schiatti[1], K. Rachedi[1], G. M. Galeazzi[1] and S. Ferrari[1]

[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2335

Introduction: Sleep health is s an essential aspect of a healthy lifestyle, and sleep problems are prevalent among individuals with mental disorders. However, this relationship appears complex to explore with classic observational studies, due to bidirectional effects and residual confounding. Additionally, the different measures of sleep quality and the diversity of mental disorders make comprehensive assessment challenging.
Objectives: In the current study, we aimed at investigating the causal relationship between six sleep factors, derived from twelve indicators, and thirteen mental disorders. Specifically, we examined the impact on Alzheimer disease, attention-deficit and hyperactivity disorder (ADHD), anorexia nervosa, anxiety disorder, autism spectrum disorder, alcohol use disorder, bipolar disorder (BD), cannabis use disorder (CUD), major depressive disorder, obsessive-compulsive disorder, post-traumatic stress disorder, suicide attempt, and schizophrenia (SZ).
Methods: Using Genomic Structural Equation Modeling, we estimated genome-wide associations for six sleep factors in the UK Biobank. Next, we examined bidirectional causal relationships with mental disorders in the Psychiatric Genomics Consortium, using Two-sample Mendelian Randomization (MR). Results are presented as inverse-variance weighted betas (B) with 95% confidence intervals (95%CI), representing log-odds for sleep-to-mental disorder causality (forward MR) and linear regression coefficients for mental disorder-to-sleep causality (backward MR).
Results: Our investigation confirmed previous evidence of a six-factor model of sleep, comprising alertness (AF), circadian preference (CPF), efficiency, duration (DF), regularity, and insomnia (IF). MR analyses showed bidirectional causal relationship between IF and ADHD (B:0.747[95%CI:0.392;1.10] and B:0.029[95% CI:0.020;0.040] for forward and backward, respectively). Unidirectional causal effects were found for BD on AF (B:-0.113[95%CI:-0.153;-0.072]), SZ on AF (B:-0.057[95%CI:-0.077;-0.037]), BD on

CPF (B:-0.066[95%CI:-0.104;-0.027]), CPF on ADHD (B:-0.074 [95%CI:-0.113;-0.035]), BD on DF (B:0.038[95%CI:0.026;0.050]), SZ on DF (B:0.022[95%CI:0.016;0.029]), IF on CUD (B:0.764[95% CI:0.130;1.40]), and IF on SZ (B:-0.504[95%CI:-0.802;-0.206]).
Conclusions: This study provide evidence that mental disorders negatively affect sleep quality rather than vice versa. These findings highlight the need to improve detection of sleep problems in mental health care settings and support efforts to identify intervention targets to improve sleep health among individuals with mental disorders.

Sleep quality and academic performance among medical students

I. Baati[1], N. Regaieg[1]*, H. Trigui[1], M. Ben Jemaa[2], R. Masmoudi[1], I. Feki[1], F. Guermazi[1] and J. Masmoudi[1]

[1]Psychaitry A department and [2]Epidemiology department, University of Sfax, Faculty of medicine of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2336

Introduction: Medical studies place significant academic pressure and high stress levels on students resulting in changes in their sleep patterns.and their academic performance, which are two keys of professional success. A hypothesis regarding a potential link between these two entitities could be proposed.
Objectives: The objective of our study was to assess sleep quality and academic performance in a sample of students from the Faculty of Medicine of Sfax, Tunisia, as well as the link between these two entities.
Methods: It was a cross-sectional, descriptive and analytical study, conducted using GOOGLE FORMS during February and March 2024, involving a sample of students from the Faculty of Medicine in Sfax, Tunisia. We used a questionnaire including an information sheet and two psychometric tests : the Pittsburgh Sleep Quality Index (PSQI) aiming to assess sleep quality over the past month and the Study Management and Academic Results Test (SMART) allowing the assessment of students' attitudes towards their studies and academic performance based on four dimensions : "Academic Competence", "Test Competence", "Time Management" and "Strategic Studying".
Results: Our study involved 154 participants with a sex ratio (M/F) of 0.54 and a median age of 22 years (IQR = [20 – 23 years]).
The median PSQI score was 6 (IQR = [3 – 9]). Using a threshold value of 5, we found that 86 students had poor sleep, resulting in a prevalence of 55.8%.
Median scores of the four dimensions were 3.4 (IQR = [3 – 3.8]) for the "Academic Competence", 2.8 (IQR = [2.2 – 3.2]) for the "Test Competence", 2.4 (IQR = [2 – 3]) for the "Time Management" and 3.2 (IQR = [2 .8 – 3.6]) for the "Strategic Studying".
By conducting a bivariate analysis, we found that "Academic Competence" and "Time Management" dimensions were significantly better among students with good sleep quality. In contrast, the dimensions "Test Competence" and "Strategic Studying" were not statistically associated with sleep quality (Table 1).

Table 1: Associations between the sleep quality and the Study Management and Academic Results Test dimensions

	Academic Competence	Test Competence	Time Management	Strategic Studying
Sleep quality				
Good	3.6 (3.2 – 4)	2.8 (2.4 – 3.3)	2.6 (2.2 – 3)	3.2 (2.8 – 3.6)
Poor	3.4 (2.8 – 3.6)	2.8 (2.2 – 3.2)	2.4 (1.8 – 2.8)	3.2 (2.8 – 3.6)
p	**0.01**	0.5	**0.02**	0.7

Conclusions: Our study revealed that more than half of the medical students suffer from poor sleep quality. The analysis of academic performance revealed that the most affected dimensions were the test competence and the time managemement. The lack of sleep among these students had detrimental consequences on their academic performance. Therefore, it is important to encourage good sleep hygiene to enhance both well-being and academic performance in medical students. Additionally, providing balanced study resources, offering therapy and counseling services, and promoting stress management strategies are key to optimizing academic success.

Investigating the Relationship Between Sleep Quality and Sociodemographic, Lifestyle, and Psychological Factors in Bosnian Young Adults

F. Obuća[1]* and O. Aydın[1]

[1]International University of Sarajevo, Sarajevo, Bosnia and Herzegovina
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2337

Introduction: Sleep quality is a critical component of overall well-being, yet it is influenced by a variety of factors, including sociodemographic characteristics, lifestyle habits, and psychological conditions. Despite its importance, research on sleep quality among Bosnian young adults is scarce, making this study particularly valuable in filling that gap.
Objectives: This study aimed to investigate the relationship between sleep quality, as measured by the Pittsburgh Sleep Quality Index (PSQI), and a range of sociodemographic, lifestyle, and psychological factors in a sample of Bosnian young adults.
Methods: A total of 283 Bosnian young adults were enrolled in the study through convenience sampling. The study assessed sociodemographic factors (age, gender, education level, religion, employment, residential area, marital status, income level), lifestyle factors (use of electronic devices before bedtime, daytime napping habits, exercise level, smoking, alcohol consumption, drug abuse, caffeine intake, diet, exposure to natural light, consistent sleep schedule), and psychological factors (mindfulness measured by the Five Facet Mindfulness Questionnaire (FFMQ), and stress,

depression, and anxiety measured by the Depression Anxiety Stress Scales (DASS-21)). Descriptive statistics, correlation analysis, and multiple linear regression were used to analyze the data.
Results: The findings indicate that sleep quality is significantly predicted by several factors. Negative predictors of sleep quality included the Observe facet of mindfulness and maintaining a balanced diet. Conversely, positive predictors that were associated with poorer sleep quality included higher levels of stress, smoking, and the use of electronic devices before bedtime.
Conclusions: The study highlights the complex interplay between sociodemographic, lifestyle, and psychological factors in determining sleep quality among Bosnian young adults. These findings underscore the need for targeted interventions that address these specific factors to improve sleep quality in this population.

Association between night-shift work and sleep quality among nurses

N. Rmadi[1]*, A. Hrairi[1], F. Bouzid[2], F. Dhouib[1], A. Kchaou[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupational medicine department, Hedi chaker university hospital, University of Sfax and [2]Family medicine department, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2338

Introduction: Night-shift work significantly impacts sleep quality among nurses, leading to various adverse health outcomes.
Objectives: This study aimed to assess the link between night-shift work and sleep quality among nurses.
Methods: The study was conducted with a sample of nurses in university hospitals of Sfax. Two groups of staff were defined based on their work schedule: the first group(G1) consisted of those working day shifts, either a regular morning schedule or alternating between morning and afternoon shifts, while the second group (G2) included those working night shifts, either fixed night shifts or alternating between morning, afternoon, and night shifts. Data collection was carried out using an anonymous self-questionnaire developed via an online interface hosted on Google Forms. Sleep disorders were screened using the validated Arabic version of the Pittsburgh Sleep Quality Index (PSQI).
Results: The study population consisted of 114 nurses, with 37 nurses in G1 and 77 in G2. The average age of the workers was 33.8 years ± 7 years with extremes of 23 and 55 years. The average duration of night work was 5.9 years ± 4.64 years, ranging from a minimum of 1 year to a maximum of 25 years. The overall PSQI scale score was on average 6.86 ± 3.2. Based on this scale, 62% were classified as poor sleepers. In bivariate analysis, night-shift work was associated with a bad sleeper profile (p= 0.027, OR=2.44, IC95% [1.09-5;46]). However, day-shift work protected from the bad sleeper profile (p=0.04, OR=0.4, IC95% [0.18-0.91]).
Conclusions: The study highlights the negative association between night-shift work and sleep quality among nurses. it is essential for healthcare organizations to implement strategies that address the unique challenges faced by night-shift nurses, such as promoting better sleep hygiene and providing support resources.

EPV1933

Stress induced by perceived radiological risk among imaging department staff

A. Haddar[1,1], I. Sellami[1,2]*, M. A. Ghrab[1], A. Feki[3], M. Hajjaji[1], M. L. Masmoudi[1] and K. Jmal Hammami[1]

[1]Occupational Medicine, University Hospital Hedi Chaker; [2]LR/18/ES-28, University of Sfax and [3]Rheumatology, University Hospital Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2339

Introduction: Healthcare-workers in medical imaging departments face a variety of professional challenges, including radiological risk, biomechanical constraints, and heavy workload. These cumulative constraints make the staff of these departments particularly vulnerable to stress.
Objectives: The aim of this study was to evaluate perceived stress among radiology technicians and evaluate its associated factors.
Methods: A cross-sectional study was conducted among the staff of a medical imaging department in Sfax in April 2024 during periodic visits. The Perceived-Stress-Scale-10 (PSS-10) questionnaire was used to assess perceived stress. Radiation safety training level (TL), Radiation risk level (RL) and radiation protection level (PL) were auto-evaluated on a scale of 0 to 10.
Results: Our population consisted of 32 paramedical staff, 80% of whom were radiology technicians. The median age was 37 with an interquartile range (IQR) [36; 43]. The sex ratio was 0.28. The median seniority in the job was 5.5 years IQR [4; 8]. The median TL, RL and PL were 3 IQR [2; 5], 6 IQR [5; 7] and 5 IQR [3; 6] respectively. The mean PSS-10 score was 19.3±4.9. In bivariate analysis, the PSS-10 score was inversely correlated with TL (r=-0.622; p=0.001), RL (r=-0.248; p=0.213) and correlated with PL (r=0.458; p=0.016).
Conclusions: Periodic visits in occupational medicine are an opportunity to detect perceived stress in this population and to strengthen their knowledge about radiation protection in order to ensure a healthier and safer working environment.

A designathon to co-create a sleep health communication package in adolescents

H. F. Sit[1]*, A. H. Pang[1,2], W. Y. Chan[3], F. T. W. Cheung[1] and S. X. Li[1,4]

[1]Department of Psychology; [2]School of Public Health, The University of Hong Kong; [3]Department of Psychology, The Education University of Hong Kong and [4]The State Key Laboratory of Brain and Cognitive Sciences, The University of Hong Kong, Hong Kong, Hong Kong
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2340

Introduction: Sleep is essential for one's physical, emotional, and social well-being. Healthy sleep is particularly important for adolescents, individuals who undergo drastic developmental changes, making them susceptible to psychiatric disorders. Education and sleep health promotion to the public are urgently needed to improve population sleep health (Lim *et al.* Lancet Public Health

2023; 8 e820-e826). One novel way to improve sleep health communication is to engage adolescents with lived experiences of sleep disturbances in the development of sleep health innovations.
Objectives: The designathon is a participatory innovation context that brings individuals to co-create communication packages to address a specific challenge within a short period. We aimed to present the process of crowdsourcing designathon to create sleep health communication packages for adolescents and the products produced in the event.
Methods: The designathon was a two-day event held at a university building in Hong Kong. Adolescents were recruited from a summer programme about sleep and psychology and sorted into groups with a balance of educational backgrounds. A judging panel that included experts in sleep and mental health and a youth representative evaluated the communication packages. The products were scored based on content, accuracy, visuals, innovation, and delivery.
Results: A total of 13 participants participated in the designathon. About 61.5% (n=8) of participants reported poor sleep quality. All three groups successfully created a sleep health communication package consisting of a poster, a leaflet, and a slideshow during the 2-day designathon event. One finalist was selected. The finalist package was a comprehensive package comprising psychoeducation and action elements to promote napping in school to address insufficient sleep and psychological health, and was described as structured, interesting, and informative although some information may be too technical to layperson based on judges' comments.
Conclusions: Designathon is a novel and successful strategy to engage the community to co-create sleep health communication package for adolescents. It is promising to utilise crowdsourcing designathon to increase access to sleep educational information and improve knowledge in the public. Future studies are needed to evaluate the feasibility, impact, and implementation of the products.

Implementing group CBT-Insomnia in mental health and addictions services in London: initial results

N. Stanton[1]*, C. Penny[1], L. Sugrue[1], J. Fehler[1], M. Lei-Yee Fok[1] and J. D. King[1]

[1]Central and North West London NHS Foundation Trust, London, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2341

Introduction: Chronic insomnia is prevalent in secondary care mental health populations and is associated with emotional distress, interpersonal impairment and reduced quality of life. In addition, it contributes to the aetiology of major mental health conditions and substance use. CBT for insomnia (CBTi) is a well-established evidence-based treatment approach for chronic insomnia and is recommended as the first-line treatment for adults in the UK by National Institute for Health and Care Excellence (NICE). Despite this, CBTi is not accessible for most secondary care mental health patients and therefore few benefit from this intervention.
Objectives: To examine the feasibility and effectiveness of a 6-week group CBTi programme for people using secondary care mental health and addictions services with chronic insomnia, using a case series design.
Methods: Each participant underwent an initial screening assessment to evaluate their suitability for the programme, the nature and impact of their sleep problem, and exclude other causes of insomnia. Self-reported measures of insomnia, personality functioning and depression were examined pre- and post-intervention using the Pittsburgh Sleep Quality Index (PSQI), Level of Personality Functioning Scale (LPFS) and Patient Health Questionnaire-9 (PHQ-9) respectively. PSQI was also re-assessed at 3-months' follow-up.
Results: Of 42 people referred to the service (26 from mental health and 16 from addictions services), 25 attended baseline assessment, 19 started the group and 12 completed sessions. The most common primary diagnoses were Alcohol Use Disorder (n=8), Treatment Resistant Depression (n=5), Bipolar Affective Disorder (n=3) and Personality Disorder (n=3). There were 9 men and 16 women. The severity of sleep disturbance was high with a cohort average PSQI of 15.4 (s.d. 2.7, range 12-20). Additionally, the level of personality functioning was high (mean 31.0, s.d. 7.6 range 13-45) as well as depressive symptoms (PHQ-9 cohort mean 18.0, s.d. 5.5, range 7-26).
Among the completers, cohort mean PSQI score decreased from 14.1 to 12.0 (p=0.12). Of 10 patients with 3-month follow-up data, there was a relative reduction of 20.3% from baseline, to a cohort mean PSQI score of 11.5 (p=0.16). At 3-months other facets of sleep quality like total sleep time had improved in the cohort by 45 minutes, and onset latency reduced by 35 minutes. Post-group there were also reductions in cohort mean LPFS scores by a relative 10.3% (31.4 at baseline to 28.3 post-group, and in cohort mean PHQ-9 by 14.8% (16.4 to 13.8).
Conclusions: Group CBTi is a potentially scalable and feasible intervention that effectively treats chronic insomnia, depression and personality dysfunction in secondary care mental health and addictions populations. Further research should focus on replicating these findings in larger cohorts, and examine factors associated with uptake and completion of CBTi.

Quantifying Stress and Relaxation: The New Measure of Heart Rate Variability as a Precise Biomarker Beyond Beats

I. Szendi[1,2,3]*, E. Rudics[4], A. Buzas[5], V. Bilicki[6], J. Dombi[7], A. Nagy[6], Z. Szabo[6], A. Palfi[6] and A. Der[5]

[1]Department of Psychiatry, Kiskunhalas Semmelweis University Teaching Hospital, Kiskunhalas; [2]Institute of Psychology; [3]Centre of Excellence for Interdisciplinary Research, Development and Innovation; [4]Doctoral School of Interdisciplinary Medicine, University of Szeged; [5]Institute of Biophysics, HUN-REN Biological Research Centre; [6]Department of Software Engineering and [7]Department of Computer Algorithms and Artificial Intelligence, University of Szeged, Szeged, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2342

Introduction: The basis of this study is established on the unreliability of conventional heart rate variability metrics. The complex physiology of stress and the relaxed state cannot be drawn sufficiently, because the conventional heart rate variability metrics, presented by the established professional medical literatures, are

dependent on the changes in the heart rate and thus cannot provide reliable data.
Objectives: We introduced a novel, heart rate independent variability parameter, which is the normalized variability, and we contrasted it with the consensus-based parameters (RMSSD: root mean square of successive differences between normal heartbeats; SDNN: standard deviation of normal-to-normal interbeat intervals).
Methods: We tested the normalized variability parameter in two studies. During the first study, the work-related stress among professionals in the frontlines of healthcare was reduced during the work-shift via either heart rate variability-biofeedback training or through achieving a relaxed state by allowing the subjects of the test during breaks to relax in their own usual manner. Consequently, the sample of Study 1 was categorized into the heart rate variability biofeedback group (N = 21) and the habitual recreation group (N = 21). Comparatively, Study 2 was concluded on healthy students, where the subject sample consisted of N = 9 participants. In this case, stress response was triggered by one of two laboratory stress induction methods. This meant the application of either the Socially Evaluated Cold Pressor Test (SECPT) or, a novel stress induction procedure, the Socially Evaluated Stroop Test (SEST). Furthermore, we used the Kolmogorov-Smirnov test to compare the distribution of heart rate variability parameters, mean heart rate, logRMSSD, logSDNN, and normalized variability before, during, and after the stress-inducing and the stress-alleviating interventions.
Results: According to our results, on the one hand, logRMSSD and logSDNN did not change significantly throughout the stress alleviation and stress inducing states; on the other hand, the distribution of normalized variability significantly changed during and after both stress decreasing methods ($p \leq 0.01$) and between the period that preceded recreation and during the process of habitual recreation itself ($p = 0.03$). Normalized variability during and after the SECPT ($p = 0.05$) significantly changed as well; however, the heart rate did not change significantly under and during the test.
Conclusions: Normalized variability, a heart rate variability parameter that is independent of the heart rate of the patient, can be considered a sensitive stress indicator and suitable for investigating the complexity of the functions of the vegetative nervous system without the confounding effect of the heart rate.

Different chronotypes are associated with different metabolomics profiles-results from the UK biobank

E. Toffol[1,2*], G. Pauck Bernhardsen[3] and S. M. Lehto[3,4,5]

[1]Department of Public Health, University of Helsinki, Helsinki, Finland; [2]Unit of Epidemiological and Evaluation Psychiatry, IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, Brescia, Italy; [3]Department of Research and Development, Akershus University Hospital; [4]Institute of Clinical Medicine, University of Oslo, Oslo, Norway and [5]Department of Psychiatry, University of Helsinki and Helsinki University Hospital, Helsinki, Finland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2343

Introduction: Individuals with an evening chronotype (i.e., a behavioral phenotype related to a preference for eveningness) commonly display metabolic alterations that predispose to cardiovascular disease and worse cardiometabolic health. While lifestyle habits may partly explain the adverse cardiometabolic findings, underlying independent biological mechanisms may also confer higher risk. However, metabolomics signatures associated with chronotype remain to be determined.
Objectives: This study aimed to use nuclear magnetic resonance (NMR) metabolomics and phenotype data from the UK Biobank to characterize the metabolomics signatures of different chronotypes.
Methods: The population included approximately 245,000 participants with plasma metabolomics and questionnaire data on chronotype, both collected at the first assessment (2006-2010). The levels of 237 metabolites were compared in individuals with morning vs. more morning than evening vs. more evening than morning vs. evening chronotype via univariable and multivariable linear regression models adjusted by fasting time, age, sex, body mass index, economic status, physical activity and smoking status. The False Discovery Rate was applied to account for multiple testing. This research has been conducted using the UK Biobank Resource under application number 99811.
Results: In unadjusted models, compared to morning types, individuals with more evening (163/237 metabolites, median estimate 0.01 SD) and definitely evening (203/237, -0.01 SD) chronotypes had significantly different profiles, suggestive of higher cardiometabolic risk (higher levels of the inflammation marker glycoprotein acetyls, of triglycerides and lipids in Very-Low-Density-Lipoproteins (VLDL), but lower levels of fatty acid unsaturation and of lipids in High-Density-Lipoproteins (HDL)). On the contrary, more morning than evening types had opposite profiles. After adjustments, the risky profiles of evening and intermediate-evening types attenuated partly, especially with respect to fatty acids. However, irrespective of adjustments, evening types had metabolic profiles characterized by less HDL and more VLDL lipoproteins than morning types, while HDL levels appeared less affected in intermediate-evening types. In adjusted models, intermediate-morning types had similar profiles as morning types.
Conclusions: Total or partial preference to eveningness was associated with a metabolic profile suggestive of higher cardiovascular risk. While these associations were partly explained by sociodemographic and lifestyle characteristics, several markers suggestive of higher cardiometabolic risks appeared intrinsic to the chronotype, and more evident in the evening types. Lifestyle habits may induce an even more favorable metabolic profile in intermediate-morning compared to pure morning types.

doi: 10.1192/j.eurpsy.2025.2344

Introduction: Sleep disorders are commonly reported among patients diagnosed with multiple sclerosis (MS), particularly in

the period following the disclosure of the diagnosis. The combination of psychological stress and the chronic nature of the disease contributes to significant sleep disturbances. Understanding the prevalence, causes, and implications of these disorders is crucial for improving patient care.
Objectives: The aim of this study is to evaluate the prevalence and characteristics of sleep disorders in MS patients following the announcement of the diagnosis and to explore the contributing factors, including psychological and physical symptoms.
Methods: A descriptive and analytical cross-sectional study was conducted from March 1, 2023, to January 30, 2024, involving patients diagnosed with multiple sclerosis (MS)who were observed in the neurology department at Habib Bourguiba University Hospital in Sfax. We evaluated sleep disorders using the **insomnia severity index scale** which included 7 items to investigate sleep disturbance.
Results: A total of 100 patients, with a mean age of 38 years ± 10 years, were included, with a strong majority of women (73%). No psychiatric history was noted. The median disease duration was 7.38 years (3-10.75). Among our patients, 64(64%) had attained a university level of education. In addition, 40(40%) were married, and 60 (60%) were single, divorced, or widowed.
The median Insomnia Severity Index was 5 (1-10.75). More than half of our patients (62%) did not suffer from insomnia. However, 9% had a mild subclinical form of insomnia, 10% had moderate clinical insomnia, and 19% suffered from severe clinical insomnia. Primary education level was correlated significantly with mild sleep disorders n=33.3 (33.3%), (p=0.044). On the other hand, those with a higher education level showed a lower prevalence of mild sleep disorders n=22.2(22.2%) (p=0.01). However, a lower prevalence of severe sleep disorders was noted among married individuals (10.5% p=0.004), while a higher frequency was observed in divorced individuals (15.8%, p=0.). Only refusal of the diagnosis upon its initial announcement was significantly associated with severe sleep disorders (63.2%, p=0.012).
Conclusions: Addressing sleep disorders in MS patients requires a holistic approach that incorporates both psychological and symptom management strategies. Early interventions targeting anxiety, depression, and physical discomfort are essential for improving sleep quality and overall well-being in this patient population. Further research is needed to develop tailored therapeutic approaches that address the unique challenges faced by MS patient's post-diagnosis.

Relationship between sleep disorders and impairments in the language development process in cases of ASD

M. Stilpen[1]*, D. Cardilli[1] and D. R. Molini-Avejonas[1]
[1]REHABILITATION SCIENCES, USP, SÃO PAULO, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.569

Introduction: Autism Spectrum Disorder is characterized by persistent deficits in communication and social interaction in multiple contexts, including deficits in social reciprocity, in nonverbal communication behaviors used for social interaction and in skills to develop, maintain and understand relationships,in addition to repetitive patterns of activity. Individuals with Autism Spectrum Disorder (ASD) present a wide variety of cognitive profiles, with levels of symptom severity that differ between those with the same diagnosis. In language development, there are individual differences, both in the acquisition process and in speed and quality. Sleep is an important parameter for child development and its relevance has been associated with healthy physical, cognitive and behavioral development, as well as cognitive functions in children and adolescents. Researchers estimate that between 40% and 80% of children with ASD have sleep disorders.
Objectives: To relate sleep disorders frequently present in cases of ASD to delays in language development in children with ASD.
Methods: The research was approved by the USP ethics committee. To investigate sleep disorders, the Cognitive Speech Therapy Protocol aimed at ASD was used, an accessible and understandable instrument for parents or guardians. To identify language disorders, the ADL2 Language Development Assessment was used. 40 parents and/or guardians of children with ASD, aged between 2 and 12 years, participated in the research. A logistic regression analysis was performed to evaluate the relationship between sleep disturbances and language delay in children with ASD. The sample included 32 children, 28 of whom reported sleep disorders and all of whom had language delays
Results: The results showed that children with sleep disorders are 2.3 times more likely to have delays in receptive and/or expressive language compared to those without sleep disorders. This association is statistically significant, indicating that sleep disorders are a relevant risk factor for language delays in children with ASD.
Conclusions: Sleep disorders can impact the development of expressive language in several ways, such as by reducing the time available for language and interaction practices or by direct effects on cognitive and neurological processes. Therefore, sleep quality should be considered an important factor to be addressed to improve both receptive and expressive language in children with ASD. Therefore, sleep quality should be considered an important factor to be addressed to improve both receptive and expressive language in children with ASD.

doi: 10.1192/j.eurpsy.2025.2345

Introduction: Suicide represents a serious public health problem. Suicidal gestures make up a significant proportion of the psychiatric emergencies treated in Emergency Services.
Objectives: The study aimed to identify which of the total emergency visits were related to suicidal ideation or suicide attempts, and to analyze the epidemiology of these patients in terms of age and gender.

Methods: A retrospective, observational study was conducted by collecting and analyzing data from July 2024 in the Emergency Department of the Clinical Hospital of Salamanca.
Results: Out of a total of 201 patients treated by on-call psychiatry in the Emergency Department, 64 patients (31.8%) presented suicidal ideation or suicide attempts. Of these, 43 were women (67%) and 21 were men (33%). By age group, among the women, 5 were under 18 years old, 11 were between 18 and 35 years old, 16 were between 36 and 55 years old, and 11 were over 55 years old. Among the men, 1 was under 18 years old, 7 were between 18 and 35 years old, 8 were between 36 and 55 years old, and 5 were over 55 years old.
Conclusions: Regarding the profile of patients with suicidal behavior, there is a higher presence of women with suicidal tendencies, as reported in the literature and other studies. No clear relationship was observed between age ranges and suicide attempts. It is important to note that the sample size is not statistically significant to determine representativeness.

Introduction: Hypomentalizing may contribute to heightened social withdrawal and it has been related with an increased risk of and suicide attempt (SA). Although certain studies have identified a relationship between hypomentalizing and suicidal behavior, research on follow-up remains limited.
Objectives: This study aims to examine the relationship between suicide reattempt and the progression of mentalizing within 12-months.
Methods: Our study included a cohort of 1,374 patients who committed a SA. We conducted assessments at the baseline and at a 12-months follow-up. We measured mentalizing using the RFQ-8, and evaluations of suicidal ideation and behavior employing the CSRSS. Demographics, clinical characteristics, and mentalizing were subjected to comparative analysis using the T-student and Chi-square tests.
Results: A total of 310 participants committed a suicide reattempt in the follow-up period. Our results showed that reattempt group were significantly younger, more presence of female gender, suicidal ideation and planning, more previous SA, and higher hypomentalizing means.
Image 1:

Table 1. Mean comparison of socio-demographic, clinical information related to suicidality, and mentalizing in of suicide reattempt for the entire sample (N=1374).

	New Suicide Attempt			
	No N=1064	Yes N=310	p value	Effect size

doi: 10.1192/j.eurpsy.2025.2347

Introduction: Suicide is a significant public health issue, and its study has been approached from various perspectives. This work focuses on analyzing consultations related to suicide attended by the Psychiatry Service at the University Hospital of Salamanca during 2023. Suicide is defined as an intentional act with a fatal outcome, and its prevention is considered a priority in mental health.

Objectives: General Objective: To assess the prevalence of suicide-related consultations within the total psychiatric emergencies attended in 2023.

Specific Objectives:

1. To identify demographic and temporal patterns in suicide-related consultations.
2. To compare the prevalence of suicide-related consultations with other types of psychiatric emergencies attended during the same period.

Methods: The study is observational and retrospective, based on the analysis of psychiatric emergency records from 2023. Demographic variables such as gender and age were analyzed, as well as the cause of the consultations, classified as "suicide-related" or "other psychiatric causes." Statistical tools were used to identify significant patterns and relationships.

Results:

1. **Gender distribution:** 55.2% of the patients were women, and 44.8% were men.
2. **Age distribution:** Most consultations involved adults (74.4%), followed by older adults (16.7%) and minors (8.9%).
3. **Cause of the consultation:** 36.15% of the cases were related to suicidal behavior, while 63.85% were due to other psychiatric emergencies.
4. **Temporal pattern:** There was an increase in consultations during the autumn months, particularly in September and November.

Conclusions: The study reveals that over one-third of psychiatric emergency consultations were related to suicide, underscoring the need to enhance prevention strategies and early intervention. The results also show significant differences by gender and age, as well as seasonal patterns that may be linked to emotional and social factors. The findings emphasize the importance of identifying specific risk factors associated with gender and age, as well as reinforcing the training of emergency personnel to effectively intervene in cases of suicidal behavior. Moreover, attention should be given to months with higher incidence of suicide-related consultations, such as the autumn season.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2348

Introduction: Suicide has become a first-order public health concern, especially following the negative impact of COVID-19 on the mental health of the general population. Few studies analysed the effects of early psychotherapeutic interventions on subjects who have attempted suicide (SA), and even fewer have focused on those hospitalized in non-psychiatric units after a medically serious suicide attempt (MSSA).

Objectives: The main aim of this study is to describe the protocol designed to evaluate the effectiveness of individual psychological treatment for patients hospitalized after an MSSA. The secondary objectives of the study are: 1) to evaluate the impact on quality of life and other psychosocial variables of patients with a recent MSSA who receive early psychological intervention; 2) to analyse the biological, psychological, and clinical impact of early psychotherapeutic treatment on subjects hospitalized after an MSSA.

Methods: An experimental, controlled, and randomized trial will be conducted with patients over 16 years of age admitted to two general hospitals. The case intervention group will enrol for 8-sessions of individual psychotherapy, Suicide Attempts Multicomponent Intervention Treatment (SAMIT), combining Dialectical Behaviour Therapy (DBT), Mentalization-Based Therapy (MBT), and Narrative approach. In contrast, the control group will receive a treatment-as-usual intervention (TAU). Longitudinal assessment will be conducted at baseline (before treatment), post-treatment, and 3, 6, and 12 months after. The main outcome variable will be re-attempting suicide during follow-up.

Results: Results from the interim analysis will be presented at the congress. We are in the recruitment and data-gathering phase.

Conclusions: Some psychotherapeutic interventions, usually implemented in outpatient, have proven to be effective in preventing suicidal behaviours. Early intervention, combining powerful components of main treatments focused on suicidal behaviour can prevent future SA in patients hospitalized after an MSSA. Moreover, assessment of the biological, clinical, and psychometric impact of this new intervention on patients during the first year after the attempt may help understand some of the multi-level factors associated with the effectiveness of psychotherapeutic interventions in MSSAs. The prevalence of high suicide rates requires the design of effective psychological interventions for their prevention, and also in order to design new pharmacological and psychological treatments.

Difficulties of describing suicide statistics in an international environment: The example of Luxembourg

A. Brezina[1]* and J. Lopez-Castroman[2]

[1]Centre Hospitalier de Luxembourg, Luxembourg City, Luxembourg and [2]Department of Psychiatry, University of Santiago de Compostela, A Coruña, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2349

Introduction: Suicide is a major public health issue and different metrics have been put into place in order to compare suicide rates and adapt prevention strategies to local contexts. Two numbers often cited are the number of suicides in a given country in a given year and the rate of suicides per 100.000 people in this country.
As straightforward as those two indicators may seem, they may nevertheless be subject to considerable caveats in specific national contexts. As an example, we will outline the case of Luxembourg.
Luxembourg is a high-income European Union member state and benefits greatly of its multilinguality and close ties to its neighboring countries. Although other European countries also have considerable populations of foreign nationals working in, but not residing in their country, the Luxembourgish context is unique for its proportions: For a population shy of 680.000, there are about 200.000 foreign workers that cross the boarder every day.
Those frontalier-workers, as they are called, might however die by suicide in both their country of residence as well as in Luxembourg. Moreover, the Luxembourgish health care system offers considerable opportunities for patients to be treated in neighboring countries.
Those patients also might die by suicide abroad, thus not being counted into the Luxembourgish statistics.
Objectives: To investigate the influence of a considerable foreign commuters demographic as well as of treatment of Luxembourgish nationals in boardering countries on the number of suicides reported for Luxembourg and its suicide rate.
Methods: Analysis of data by the Ministery of Health (Ministère de la Santé et de la Sécurité sociale), the National Statistics Insitute (Institut national de la statistique et des études économiques du Grand-Duché de Luxembourg) as well as the National Health Fund (Caisse Nationale de Santé)
Results: Different figures are reported for suicide cases, which cannot easily be converted into one another:
One counts the number of suicides taking place in the territory of Luxembourg, an other one describes the causes of death for Luxembourgers who died outside of the country.
Although a considerable demographic, no data exists on the proportion of frontalier-workers among suicide victims in Luxembourg.
Conclusions: The study of suicide rates in Luxembourg highlights how a seemingly simple metric can prompt researchers to reconsider what exactly they aim to measure, enabling them to better design targeted prevention strategies for groups at higher risk.

EPV1946

Relationship between Psychological Pain and Social Cognition with the risk of suicidal behavior in depressed patients in remission: a pilot study

X. Bros[1]*, I. Parra[2,3], M. T. Muñoz[2], B. Soley[1,3], M. Perez[4] and D. Palao[1,2,3]

[1]Psychiatry, Universitat Autònoma de Barcelona, Barcelona; [2]Psychiatry, Taulí Hospital, Sabadell; [3]CIBERSAM, Barcelona and [4]I3PT, Sabadell, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2350

Introduction: Suicide is a major public health problem. Psychological Pain (Psychache) and Social Cognition (SC) may have potential clinical significance. The aim of this study is to determine whether they are clinically relevant in patients with a history of suicide attempts and Major Depression (MD) in remission.
Objectives:
1.- To investigate the severity of Psychache in patients with MD who have attempted suicide.
2.- To identify changes in SC associated with an increased risk of suicidal behavior.
3.- To identify clinical subgroups of patients according to the SC and Psychache typology.
Methods: A controlled cross-sectional observational study is being conducted comparing two groups assessed with a clinical diagnostic interview and a psychological assessment including measures of SC and Psychache: 1) 60 patients with a history of suicide attempts (more than 6 months prior to the study), diagnosed with MD (DSM-5) at the time of their last attempt, and in remission when evaluated (HRDS<15). 2) 60 age/gender matched healthy case controls.
Results: Preliminary results from a group of 23 patients matched with 23 healthy controls:
1.- Psychache: a) Patients vs. Controls: Patients, despite being in remission of depression, have a higher level of Psychache than controls ($p<0.001$). b) Patients: The level of current Psychache is significantly lower than at the time of the suicide attempt ($p<0.001$). c) The level of current Psychache correlates significantly with the depression severity (HDRS) ($r=0.77$). This correlation is significant in the patient group ($p<0.001$) but not in the control group. d) The results obtained on the Total Psychache Scale do not differ from those obtained on the Unbearable Psychache subscale.
2.- Social Cognition: Overall scores on two of the Social Cognition measures (RMET and Hitting Task) were not significantly different between the patient and control groups. In the case of the MASC test, the global scores of the group of patients (with a history of suicide attempts) are significantly lower than those of the control group ($p<0.05$).

Table 1

	CONTROLS	PATIENTS	P-value
Psychache Total	Mean14.7 SD (2.88)	31.3 (14.0)	<0.001
Subtest Unbearable	3.0 (0)	6.3 (3.70)	<0.001
RME (SC)	26.0 (3.02)	23.8 (3.76)	0.062
Hitting (SC)	8.7 (1.14)	8.6 (0.99)	0.424
MASC Total (SC)	31.1 (3.92)	28.3 (4.78)	<0.05

Conclusions: a) Patients with stable depression and a history of suicide risk maintain a significant level of Psychache, which is higher than in the control group. b) The use of the Unbearable Psychache subscale -with only 3 items- discriminate clearly between the patient (suicide attempters) and the control groups: its use in primary care should be considered. c) Differences between patients and controls in SC were not significant in two of the three scales used, but were significant in one (MASC). This should be confirmed and analyzed in the full sample.

Disclosure of Interest: None Declared

EPV1948

Management of serious autolytic attempt in the Emergency Room

Y. D'Hiver Cantalejo[1]*, M. F. Tascón Guerra[1], T. Jamed Muñoz[1] and A. Osca Oliver[1]

[1]Psiquiatria, Hospital Nuestra Señora Del Prado, Talavera de la Reina, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2351

Introduction: Every year, 726,000 people take their own lives and many more attempt it. Suicides can occur at any age and were the third most common cause of death in people aged 15 to 29 worldwide in 2021.
Objectives: Presentation of a clinical case.
Methods: We analyze the case of a 17-year-old patient who came to the ED after ingesting sodium hypochlorite with self-lytic intent. She says that, being accompanied by a friend, she begins to hear "a voice, which is my own voice, telling me to kill myself." With a pretext, he enters the kitchen and overeats. She says that, although she was induced by "the voice," she thinks that "if I continue like this all my life, it would be better to die." She discusses it with her brother and her friend, who inform her mother.
She is the youngest of three brothers. He resides with his mother and her partner, parents divorced at 11 years old. He is in 4th ESO, with poor performance. Pregnancy, childbirth and maturation milestones within normality. Four years ago he began to experience behavioral alterations in the family environment characterized by drug abuse reactive to family arguments. These ingestions are becoming more frequent and for anxiolytic purposes, requiring attention in the ED. Throughout evolution, the attitude has become increasingly regressive, with demands for attention to which the family responds by reinforcing them. He has had several hospital admissions. On current treatment with olanzapine 5 mg/24h, fluoxetine 20 mg/24h and tranxilium 5 mg/8h.
Results: Analysis with blood count, basic biochemistry, arterial blood gases, SO and toxic substances in urine; without significant alterations.
Gastroscopy: Esophagus: Mucosa, distensibility and peristalsis without alterations. Esophago-gastric junction 36 cm from the dental arch with competent cardia at the level. Stomach: isolated antral areas of circumscribed erythema. Centered and permeable pylorus. Duodenum: Bulb and second portion without alterations. Psychopathological examination: COC. Regressive, character traits in the foreground. No alterations in psychomotor skills. Attentive, without memory errors. Discourse with an infantilized tone, spontaneous, fluid and coherent, structured, focused on feelings of vital failure. Referred hypothymia, without apathy or hypohedonia. Referred anxiety, not evidenced. Active autolytic ideation, without criticism, manifesting intentionality of repetition. Low tolerance for frustration with impulsive responses. Preserved appetite. Hypersomnia. Preserved reality judgment. Partial awareness of illness.
Conclusions: Suicidal behavior should never be considered a call for attention but rather for help. In the intervention we must not blame and reconnect the minor with the family. We must talk openly about the circumstances in which it occurred, facilitating emotional expression. We must guarantee the safety of the minor, open dialogue between parent-child and provide support from parents.

Suicidal Attempts in Psychiatric Patients admitted to "Xhavit Gjata" Hospital, Albania: A 2-year Retrospective Descriptive Study

L. Demiraj[1]*, E. Sotiri[1], F. Elezi[1] and E. Petrela[2]

[1]Psychiatry and [2]Public Health (Biostatistic sector), UHC "Mother Teresa", Tirana, Albania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2352

Introduction: Suicide represents one of the most discussed mental health issues in the world today and health challenges for the future. The burden of suicide is calculated in very high numbers (720.000 people per year) ranking it among the most frequent causes of death (World Health Organization. Suicide. WHO Fact Sheet. 2024 https://www.who.int/news-room/fact-sheets/detail/suicide). In the context of patients hospitalized in psychiatric services, the incidence of suicide attempts is particularly high, representing a major challenge for mental health professionals and the health care system.
Objectives: This study aims to analyze the socio-demographic and clinical factors influencing suicide attempts in a sample of psychiatric patients in Albania and looks for statistically significant relationships between them.
Methods: A retrospective study was conducted on 138 psychiatric patients admitted after a suicide attempt and data from August 2022 to July 2024 were obtained. Socio-demographic and clinical data were collected and analyzed. The relationship between these variables were explored. A total of 28 different demographic, clinical and behavioral variables were sampled and pooled with the help of statistical software.
Results: From the data it was found that suicide attempts were more frequent among women with a woman/man ratio of 1.42:1, age 25-44 years and among unemployed persons during the working age. It was more frequent in urban areas, with an uban / rural ratio of 2.85:1. The education level most frequent was primary (8-years of education) in 44.2% of the cases. Our data showed that 86.2% of cases did not live alone, which can be explained by the traditional Albanian family structure. However, only 28.3% of cases had good family support. Suicide attempts were most common in summer. The most frequent discharge diagnosis was a mood disorder in 69.6% of the cases, while a co-diagnosis was present in only 22.5% of cases. 59.1% were hospitalized for a first attempt. The attempt was reported as premeditated in 64.5% of cases, with prior preparation in 21.7% of cases and without asking for help in 62.3% of cases. There is a significant relationship ($p<0.05$) between the

diagnosis and seeking help. A significant relationship was found between compliance and first or repeated attempts and also between diagnosis and first or repeated attempts. The most frequently used type of attempted suicidal method was the use of medications in 41.3% of cases.
Conclusions: The pattern presented in the study group in relation to the characteristics of patients who commit suicide attempts, is close to the patterns presented by similar studies. Differences and non-correlations are atributed to local factors. Identification of suicide behaviors pave the way for treatment and assistance for anyone considering suicide. Further research is needed to examine outpatient and community samples.

EPV1950

Assessing suicidality assessments in physician assisted death applications: Do they filter out traditional suicidality?

K. S. Gaind[1]

[1]University of Toronto, Toronto, Canada
doi: 10.1192/j.eurpsy.2025.2353

Introduction: Physician Assisted Death (PAD) has been legalized or decriminalized in over a dozen jurisdictions around the world, and many other jurisdictions are considering assisted dying laws. Most jurisdictions only allow PAD in terminal conditions while a minority allow PAD outside end-of-life situations, with a small number allowing PAD for sole mental illness conditions. A key element in assessments of PAD requests is whether those assessments can filter out traditional suicidality, for which suicide prevention is provided, from other motivations for assisted death, for which PAD may be provided.
Objectives:
1. To recognize the range of factors that may motivate assisted dying requests.
2. To understand the factors that inform assisted dying assessments, specifically how the assessments attempt to identify suicidality.
3. To appreciate the degree of certainty or uncertainty that assisted dying assessments actually identify suicidality in different patient populations.

Methods: This presentation briefly reviews evidence related to motivations leading to assisted dying requests in different populations, and then focuses on reviewing guidelines PAD assessors use to attempt to identify traditional suicidality, and to distinguish that from other motivations leading to PAD requests. These guidelines are compared to established evidence and factors related to suicide risk and suicide prevention.
Results:
1. Different factors motivate different populations to seek assisted death, with those making PAD requests in terminal situations frequently seeking PAD in efforts to preserve dignity, and those seeking PAD outside terminal conditions or for sole mental illness citing feeling a burden, or an accumulation of multiple life stressors, as fueling their PAD requests.
2. Most of the factors presented in guidance on distinguishing and separating suicidality from PAD requests equally apply to traditionally suicidal individuals and to those requesting PAD.
3. Evidence shows that the few distinguishing factors used to attempt to separate suicidality from PAD requests, specifically impulsivity and acting on one's own, do not actually filter out suicidality.

Conclusions: While a key goal of physician assisted death assessments is to identify and separate traditionally suicidal individuals from those seeking and receiving assisted death, current assessment techniques are unable to filter out suicidal individuals in an unknown number of cases.

ARSUIC Protocol: results in suicide prevention at a Mental Health Community Center

R. Huerta-Ramírez[1]* and Á. Vivero[1]

[1]Mental Health, Tajo University Hospital, Aranjuez (Madrid), Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2354

Introduction: Suicide has a growing importance as a mental health problem, being now the first cause of not-natural death at Spain. Developing suicide prevention strategies is a prioritary goal at mental health care. In our community, ARSUIC protocol was developed as a way to provide specialized preferent care to people with suicide attempts.
Objectives:
- Measure results of ARSUIC protocol at suicide attempts prevention.
- Study level of satisfaction of patients assisted at ARSUIC protocol.

Methods: A qualitative ad-hoc phone interview has been made to patients atended at ARSUIC protocol of our community mental health center, in order to measure their level of satisfaction. Descriptive cuantification of new suicide attempts, visits to Emergency Service and incomings at Psychiatry Hospitalization in the last 6 months has been performed, using clinical history data.
Results: Global level of satisfaction is high at the most of the sample, mainly because of the preferent attendance and the improvement it implies in the therapeutic bond. Indicators of relapse reflect global good evolution at the most of the sample.
Conclusions: Preferent attendance reveals as a proper way to improve clinical care and prevention at people with suicide attempts. Strategies to maintain that kind of frequent attendance along the main risk period of relapse are in develope (group therapy, etc.).

Assessing the completeness of suicidal poisoning surveillance systems in Northwest Morocco: A capture-recapture method

S. Hmimou[1], S. Boukhorb[1], O. Erefai[2], S. Elkafssaoui[3], S. Irnat[1]*, N. Rhalem[4], M. A. Bellimam[5], A. Soulaymani[1], A. Mokhtari[1], R. Soulaymani-Bencheikh[4] and H. Hami[1]

[1]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra; [2]Higher Institute of Nursing Professions and Health Techniques; [3]Royal School of Military Health Service; [4]Moroccan Poison Control Center and [5]Forensic Institute of Royal Gendarmerie, Rabat, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2355

Introduction: Suicidal poisoning represents a significant yet frequently underreported public health concern, particularly in regions where surveillance systems fail to fully capture the scope of the issue.
Objectives: This study aims to bridge this critical gap by estimating the total number of intentional poisoning cases and evaluating the completeness of the national toxicovigilance system in the Tanger-Tétouan-Al Hoceima region of northwest Morocco.
Methods: This study analyzed data from suicidal poisoning cases recorded over a three-year period in the Tanger-Tétouan-Al Hoceima region. We sourced data from the Moroccan Poison Control Center (MPCC) and hospital registers in the region. The two-source capture-recapture method was employed to evaluate the completeness of the poisoning surveillance system.
Results: A total of 824 suicidal poisoning cases were identified after removing duplicates, with 578 cases reported by MPCC and 286 cases from hospital records. Forty duplicates were found between the two sources. The capture-recapture method estimated a total of 4,133 cases (95% CI: 3,548-4,718), revealing that an additional 3,309 cases were not captured by the two data sources. The completeness of the surveillance was estimated at 13.98% for MPCC data and at 6.92% for hospital records.
Conclusions: Despite the presence of a toxicovigilance system in Morocco, significant deficiencies remain in its completeness. There is an urgent need to enhance this system by promoting greater awareness among healthcare professionals regarding the critical importance of spontaneous reporting of intentional poisoning cases.

Exacerbation of suicidal risks among women during the COVID-19 crisis: Insights into epidemiological trends and intervention strategies

S. Hmimou[1], S. Elkafssaoui[2], S. Boukhorb[1], O. Erefai[3], F. Hadrya[4], S. Irnat[1]*, A. Soulaymani[1], A. Mokhtari[1] and H. Hami[1]

[1]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra; [2]Royal School of Military Health Service; [3]Higher Institute of Nursing Professions and Health Techniques, Rabat and [4]University Hassan First of Settat, Higher Institute of Health Sciences, Health Sciences and Technologies Laboratory, Settat, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2356

Introduction: The COVID-19 pandemic has significantly impacted mental health globally, disproportionately affecting women. The widespread repercussions highlight the necessity to delve into the factors exacerbating these impacts and tailor effective mitigation strategies to the unique challenges faced by women.
Objectives: This study aims to identify and delineate specific risk factors that have escalated suicidal behaviors among women during the COVID-19 pandemic and to suggest targeted prevention strategies that address these identified factors.
Methods: Employing a narrative review approach and adhering to the PRISMA guidelines, this study systematically examined literature from **PubMed** and **Scopus** on the impact of the COVID-19 pandemic on women's suicide rates. This review focused on studies published between January 2020 and December 2024 that explored the pandemic's effects on women's mental health.
Results: The findings indicate a profound deterioration in mental health among women during the pandemic, characterized by a spike in depression, anxiety, post-traumatic stress disorder, and suicidal behaviors. The impact was notably severe among women facing unstable living conditions, single mothers, and those experiencing domestic violence. Social isolation emerged as a critical factor exacerbating these conditions, particularly pronounced among young women and those from socioeconomically disadvantaged backgrounds. The literature also underscores a significant increase in suicide attempts, with these groups most profoundly impacted.
Conclusions: This review confirms that the pandemic has exacerbated various risk factors associated with suicidal behaviors in women, particularly due to increased domestic violence, economic instability, and increased caregiving burdens, underscoring the critical need for tailored prevention strategies that specifically address women's unique challenges. These should include measures to protect women from domestic violence, enhance access to mental health services, and increase economic support to buffer the adverse effects of health crises on women's mental health.

Systematic review of Acceptance and Commitment Therapy in suicide prevention in adults. Current perspective

A. Jurado Arevalo[1]*, I. Contreras Pérez[1], P. Vargas Melero[1], M. Valverde Barea[1] and I. Caparrós del Moral[1]

[1]Psychiatry, University Hospital of Jaén, Jaén, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2357

Introduction: Suicidal behavior is a public health problem in which the entire society must commit to implementing all available strategies to prevent it (Tighe et al., 2018), as more than 800,000 people die worldwide each year (Pedrola-Pons et al., 2024).
Objectives: The objective is to determine the efficacy of ACT in reducing suicidal behaviors through a systematic review.
Methods: A systematic review was conducted following the PRISMA 2020 methodology, searching the Cochrane, EMBASE, PubMed, PubPsych, and MEDLINE databases for scientific literature published between 2013 and March 31, 2024, using the keywords: "suicidal behavior" and "acceptance and commitment therapy" in Spanish and English. After applying inclusion and exclusion criteria, 7 studies were finally included in the systematic review.
Results: After conducting the search, 7 studies were included, among which were 1 meta-analysis of randomized controlled trials, a systematic review and meta-analysis, two randomized clinical trials, a systematic review of 5 studies, a program analysis, and an

effectiveness study. The review showed a significant reduction in suicidal behavior in patients who received ACT (Calati et al., 2024). A relationship was observed between increased psychological flexibility and decreased suicidal ideation (Macri et al., 2024). The efficacy of ACT was comparable or superior to other interventions in some of the studies included in the review (Kumpula et al., 2019).
Conclusions: ACT shows promising results in reducing suicidal behaviors. However, more studies with long-term follow-up are needed to confirm its efficacy.
More studies with larger sample sizes and longer participant follow-up are needed to establish the long-term efficacy of ACT in reducing suicidal behavior.

EPV1957

Intent to Die and Suicide Attempts: Exploring Clinical and Circumstantial Correlates

K.-U. Lee[1]*, J. T. Park[2] and K. H. Choi[2]
[1]Psychiatry and [2]Emergency medicine, Uijeongbu St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2358

Introduction: Intent to die is a crucial factor in assessing the risk of suicide attempts, which is difficult to measure.
Objectives: This study examined the characteristics of suicide attempters based on intent to die and aimed to investigate whether clinical and circumstantial evidence can support the assessment of the intent to die.
Methods: A total of 3486 suicide attempters who visited emergency department were divided into two groups: intent to die(n=1085, 31.1%) and no intent to die(n=2401, 68.9%). Demographic variables, clinical characteristics, and factors related to suicide attempt between the two groups were analyzed.
Results: Suicide attempters who reported an intent to die were older (46.7 ± 21.7 vs. 40.5 ± 19.3, t=8.460, $p < 0.001$), had a higher proportion of males (41.1% vs. 33.4%, $\chi2=19.174$, $p < 0.001$), were more likely to be unemployed (60.6% vs. 51.0%, $\chi2=26.954$, $p < 0.001$), had lower socioeconomic status (34.1% vs. 23.4%, $\chi2=44.365$, $p < 0.001$), and experienced more severe depression (76.6% vs. 49.6%, $\chi2=230.442$, $p < 0.001$), intense emotions (92.9% vs. 80.0%, $\chi2=91.138$, $p < 0.001$), agitation (45.5% vs. 40.4%, $\chi2=7.734$, $p < 0.01$), and hopelessness/helplessness (86.1% vs. 60.7%, $\chi2=221.980$, $p < 0.001$) compared to those who did not report an intent to die. Moreover, suicide attempters who reported an intent to die showed more repetitive/intense/continuous suicide ideation (79.8% vs. 42.8%, $\chi2=410.830$, $p < 0.001$), a higher rate of multiple attempts (46.5% vs. 41.1%, $\chi2=8.637$, $p < 0.005$), higher medical risk of death (3.6 ± 1.3 vs. 3.0 ± 1.1, t=15.633, $p < 0.001$), a higher total risk score (9.5 ± 2.2 vs. 8.3 ± 2.0, t=25.596, $p < 0.001$), and a lower total rescue score (12.1 ± 2.0 vs. 12.7 ± 1.9, t=8.649, $p < 0.001$) compared to those who did not report an intent to die. Some circumstantial factors such as planned attempts (19.4% vs. 2.3%, $\chi2=307.079$, $p < 0.001$), presence of suicide notes (21.3% vs. 9.8%, $\chi2=83.625$, $p < 0.001$), absence of regret (75.1% vs. 51.2%, $\chi2=174.849$, $p < 0.001$), and high lethality of suicide methods (18.0% vs. 9.2%, $\chi2=56.161$, $p < 0.001$) showed statistical significant differences, but some proportions of suicide attempters who did not report an intent to die also exhibited these circumstantial factors.
Conclusions: The present study suggests that suicide attempters who reported an intent to die tend to have more severe psychopathologies and serious suicide attempts related to direct factors than suicide attempters who did not report an intent to die.

The unmet needs in suicide prevention among nursing staff

A. Litta[1]*, A. Nannavecchia[2], V. Favia[3], C. Cutrone[4] and F. Bafaro[5]
[1]University of Bari "Aldo Moro"; [2]AReSS Puglia- Regional Strategic Agency for Health and Social; [3]Istituto Tumori Giovanni Paolo II, IRCCS, National Cancer Institute; [4]University of Bari Aldo Moro, Bari and [5]Healthcare Residence Villa Iris, Mesagne, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2359

Introduction: Nurses can play a critical role in suicide prevention, especially in hospital settings. The management of patients at risk of suicide requires specific nursing skills, including early recognition of warning signs and knowledge of preventive and protective strategies. Knowing risk factors and recognizing warning signs for suicide should be part of the professional background of any nurse training programs.
Objectives: In this study we aimed to investigate nurses's comfort, confidence and competence related to preventing suicide with a view to identify correct preventive strategies regarding the nursing management of patients at risk of suicide.
Methods: Our study presents the preliminary descriptive findings from an online survey in nursing staff working in different areas (medical, surgical, critical and emergency) in the Puglia Region. The survey aimed to assess the current knowledge, attitudes, behaviors and training needs of nurses regarding suicide prevention. 84 nurses working in the Puglia Region filled out the questionnaire.
Results: Data highlighted that the majority of participants (81%) recognized the significant role of the nurses in the management of a patient at risk for suicide but only 14.3% believed they had specific training on patients at risk of suicide. 50% of them stated they do not have adequate preparation regarding the possible preventive strategies in suicidal patient. 57.1% of interviewed reported that they had never become aware of protocols or guidelines on the prevention and management of hospitalized patients at risk of suicide. Only 14.3% of those interviewed are satisfied with adequate training on suicidal risk factors in hospitalized patients and even only 7.1% state that they have never received adequate training on possible nursing interventions for the prevention of suicidal risk. Although endorsed suicide prevention guidelines in the health institution where they work, 57.1% responded that they have never viewed them and only 38.9% partially.
Conclusions: Our study highlighted the need to implement specific training programs for nurses on the management of patients at risk of suicide.

"Second victim" as a psychiatrist: a cross-sectional survey about consequences of patient suicide on European early careers psychiatrists and psychiatric trainees

G. Longo[1,2*], F. Santos Martins[2,3], I. P. Peyneshki[2,4], E. K. Durante[2,5], M. Gostiljac[2,6] and D. Cavaleri[2,7]

[1]Department of Neurosciences/Department of Experimental and Clinical Neurosciences (DIMSC), Polytechnic University of Marche, Unit of Clinical Psychiatry, Ancona, Italy; [2]European Federation of Psychiatric Trainees (Research Working Group), Brussels, Belgium; [3]Centro Hospitalar Universitário S. João (CHUSJ), Porto, Portugal; [4]University Psychiatric Services, Old Age Psychiatry, Bern, Switzerland; [5]Center for Research in Epidemiology and StatisticS (CRESS), INSERM UMR 1153, Université Paris Cité, Paris, France; [6]University Clinical Center of Serbia, Clinic for Psychiatry, Belgrade, Serbia and [7]University of Milano-Bicocca, School of Medicine and Surgery, Monza, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2360

Introduction: Suicide involves not only patients but also families and communities, causing long-lasting effects on those who "survive". The term "second victim" is used to define people who experience significant distress after a patient suicide (PS). For mental health professionals, PS could be considered an "occupational hazard".

Objectives: To assess the impact of patient death on psychiatric trainees and early career psychiatrists (ECPs), comparing PS to other causes of death.

Methods: Participants completed a socio-demographic section and a section about the experience of PS. Impact of event scale–revised version (IES-R) based on the last 7 days and the 7 days after the most recent patient death, Suicide Knowledge and Skills Questionnaire (SKSQ), the Impact of a Patient's Suicide on Professional and Personal Lives Scale and the Maslach Burnout Inventory (MBI) were administered.

Results: 110 subjects were recruited from 23 European and 1 Asian countries. The mean age was 31.9 (SD=4.7). Most were trainees (66.4%, n=73), worked in a psychiatric ward (61.8%, n=68), and in general adult psychiatry (83.6%, n=92). Patient death was experienced by 51.8 % (n=57) of the participants. 17.3% (n=19) experienced a PS, 12.7% (n=14) experienced multiple PS, 13.6% (n=15) had patients who died both by suicide and other medical conditions, and 8.2% (n=9) had patients who died from other medical conditions. The most reported feelings were sadness, regret, guilt, helplessness and frustration. Among participants who experienced at least one PS, 89.7% (n=35) developed symptoms. The most common were increased awareness of risk (40.4%; n=19), low mood (34.0%; n=16), anxiety (32.6%; n=15) and lack of concentration (26.1%; n=12). 6.5% (n=3) experienced suicidal thoughts/passive death wishes, and 6.5% (n=3) received individual psychotherapy treatment for their symptomatology. Having experienced a patient loss influenced clinical practice in 33.3% (n=19) of the sample, with 10.5% (n=6) reporting the affliction of the ability to carry out clinical duties. 12.7% (n=14) considered changing careers, 10.5% (n=6) took sick leave, 57.8% (n=33) received helpful support from colleagues. However, 52.3% (n=30) felt they needed additional support. According to the total score of IES-R scored on the 7 days after the most recent patient death, 22.9% (n=11) of the sample who experienced at least one PS had a score indicating a risk of PTSD, compared to 22.2% (n=2) of participants who experienced other type of patient death. No difference in all scales was observed in those experienced PS rather than any other kind of patient death ($p>0.05$).

Conclusions: Our results confirm that PS affects the mental health of ECPs and psychiatric trainees, and impacts their daily lives. A larger sample should be collected to strengthen our results and better characterize the impact of these events.

Beyond Self-Report: Addressing Suicide Risk in Personal Narrative Crisis

I. M. Lopes[1*], D. Seabra[2], G. Santos[1], N. Ramalho[1], T. Coelho Rocha[1], J. Alves Leal[1], J. F. Cunha[3], J. Moura[1], D. Santos[1], A. Garcia[1], M. Rosa[1] and C. Pires[1]

[1]Psychiatry, ULS Arco Ribeirinho; [2]Psychiatry, USL Arco Ribeirinho and [3]Psychiatry, ULS Barreiro, Barreiro, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2361

Introduction: Effective suicide risk assessment remains a significant challenge in psychiatric care, particularly when dealing with patients undergoing acute crises. This case study highlights the limitations of current assessment practices and underscores the need for a more nuanced understanding of suicide risk, particularly through the lens of personal narrative crisis and Suicide Crisis Syndrome (SCS).

Objectives: The objective of this study is to describe a clinical case involving a patient with Suicide Crisis Syndrome (SCS), which emerged from a fundamental alteration in his personal life narrative. Additionally, this study reflects on the existing clinical gap due to the lack of consensual or homogeneous approaches for detecting suicide risk in psychiatric patients experiencing a crisis.

Methods: Methodology: A detailed review of the clinical process and hetero-anamnesis was conducted. The case explores the concept of SCS—an acute mental state that precedes a genuine suicide attempt.

Results: The patient, a 45-year-old single male with no children, had a biographical history marked by traumatic events during military service and the loss of a child in combat at age 30. For years, he exhibited symptoms consistent with Post-Traumatic Stress Disorder (PTSD), which he managed effectively through meditation and martial arts, resulting in total symptom remission for over a decade. However, following complex cardiac surgery two years ago, he experienced a significant loss of functionality and autonomy, leading to the abandonment of his martial arts practice and lifelong profession as a rehabilitation therapist. This change had profound emotional, behavioral, and socio-economic impacts, resulting in depressive symptoms. During psychiatric evaluation, the patient exhibited affective dysregulation, marked hopelessness, a sense of loss of meaning, feelings of non-belonging, social defeat, and difficulty adjusting unrealistic goals to his current situation. Although he denied active suicidal ideation, he reported intrusive thoughts of death.

Conclusions: Conclusion and Implications: The assessment of self-reported suicidal ideation is often unreliable. There is an urgent

need to adopt more comprehensive approaches that focus on the personal narrative crisis and SCS, as current evidence suggests that SCS is a strong predictor of actual suicidal behavior within 1-2 months after discharge.

Suicidal Ideation Among College Students: cross-sectional study

Z. Nesrine[1]*, I. Gassara[2], N. Smaoui[2], R. Feki[2], N. Charfi[2], J. Ben Thabet[2], L. Zouari[2], M. Maalej[2], M. Maalej[2] and S. Omri[2]

[1]pédopsychitrie and [2]psychiatrie C, hopital hedi chaker sfax, sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2362

Introduction: Suicidal ideation, encompassing thoughts, planning, and the desire for death, is a critical facet of the suicidal process, potentially leading to suicide attempts and completion. Understanding its prevalence and severity among college students is vital for preventive interventions.

Objectives: Our study aimed to estimate the prevalence and severity of suicidal ideation among college students.

Methods: We conducted a cross-sectional and analytical study among students from various faculties in Sfax between October 2022 and January 2023. Student recruitment occurred electronically through a Google Forms questionnaire, emphasizing anonymity and the study's scientific purpose. We utilized the Suicidal Ideation Attributes Scale (French Version) (SIDAS-FR) to identify and assess the severity of suicidal ideation.

Results: Our sample comprised 149 students, predominantly female (83,20%), with an average age of 26 years. Among them, 78,5% were single, and 81,9% lived with their families. Nearly half of the students were from the Sfax Faculty of Medicine, and 64,4% were in their 3rd cycle of education. The mean total score on the SIDAS scale was 1,21 +/- 3,84. Suicidal ideation was reported by 11,4% of participants, with 5,36% indicating moderate to high severity. Factors associated with suicidal ideation included psychiatric disorders (p=0,00), alcohol consumption (p=0,033), psychotropic medication use (p=0,001), and unsatisfactory intrafamily communication (p=0,036).

Conclusions: Suicidal ideation, a concerning issue, particularly among young people, demands focused attention in public health efforts. Understanding the associated factors is pivotal for prevention strategies, emphasizing the importance of mental health support and effective communication within families.

EPV1963

Associated factors of suicide attempt among patients with major depressive disorder in Vietnam

S. Nguyen Thi Thu[1,2]* and T. Nguyen Dao Uyen[3]

[1]Psychiatry, University of Medicine and Pharmacy at HCM City; [2]Neuropsyatry, Nguyen Tri Phuong Hospital and [3]Family Medicine, University of Medicine and Pharmacy at HCM City, Ho Chi Minh city, Viet Nam

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2363

Introduction: Suicide attempt is a person's suicidal behavior that does not result in death and may or may not result in injury. Understanding the factors associated with suicide attempts in patients with major depressive disorder is important to predicting future suicide attempts.

Objectives: To identify the associated factors with suicide attempts in patients with MDD at the University Medicine Center in Vietnam.

Methods: This cross-sectional analytical study was conducted in the psychiatry clinic of the University Medical Center of Ho Chi Minh City, Vietnam, from March to October 2023. Individuals aged 18 and more diagnosed with major depressive disorder as per DSM-5 TR were included. Exclusion criteria were current psychosis, severe intellectual disabilities, and acute medical illnesses.

Participants were interviewed using a questionnaire including sociodemographic criteria, clinical information, and the Hamilton Depression Rating Scale (HDRS).

Results: We collected 151 participants. The average age of participants was 41.3±15.5 years, and they were predominantly female (78.8%) and living in urban areas (62.9%). Nearly four fifths (79.5%) of patients are currently in severe depression. The prevalence of suicide attempts in the lifetime and past 3-months were 7.9% and 5.3% respectively.

In univariate logistic regression analysis of sociodemographic factors and clinical features of depression associated with suicidal attempt among individuals with major depressive disorder, we found that young age (OR=0,91; p=0,004), single status (OR=0,09; p=0,002), early onset of illness (OR=0,91; 95% CI 0,85-0,97), and severe depression as measured by the total HDRS score (OR= 1,19; 95% CI 1,06-1,34). In particular, the risk of a suicide attempt was 72 times higher in patients with a history of self-harm (OR=72,22; 95% CI 13,71-380,49). There was no association between gender, area, education level, cohabitation status and employment status with lifetime prevalence of suicide attempts. After adjusting for covariates using a multivariable logistic regression model, only the severity of depressive episode and history of self-harm remained significantly associated with suicide attempts.

Conclusions: Suicide attempts were significantly high among patients of major depressive disorder in Vietnam. The severity of depression and previous self-harm was significantly associated with it. There is a need for more research and a better understanding of the associated factor with suicide attempts in this population which in turn could lead to the development and implementation of effective preventive interventions.

Collaboration Between Nursing, Psycology and Psychiatry in an Intensive Outpatient Program for Suicidal Ideation

T. Bollain Muñoz[1], M. Valtueña Garcia[1], J. Sanchez Adsuara[1], M. L. Barrigón Estevez[1], R. Crespo Rubio[1] and I. Oliveira Amat[1]*

[1]HGUGM, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2364

Introduction: The collaboration between nursing, psychology, and psychiatry is essential for delivering comprehensive and effective mental health care. A multidisciplinary approach ensures that patients receive holistic support where everyone is aligned on the patient's needs, treatment progress, and level of risk, and drawing on the unique skills and expertise of each discipline. Without proper coordination, there is a higher risk of gaps in care, conflicting interventions, or misunderstandings that could negatively impact the patient's safety and well-being.
Objectives: To highlight the importance of collaborative work between nursing, psychology, and psychiatry within the context of an acute, short-term, intensive outpatient program for suicidal ideation, such as PRISURE, is essential. For patients at high risk of suicide, particularly those experiencing acute symptoms, a combined multidisciplinary approach is critical to providing effective and timely care.
Methods: The program distinguishes between two types of interventions: an intensive program and a regular program, both offering a couple months long intervention but differing in the frequency of visits. The entire team meets weekly to assess new cases and discuss patients within the intensive program. An additional meeting is held to coordinate care for patients in the regular program between nursing and psychiatry. Regular multidisciplinary meetings are key to ensuring a coherent and unified approach across both programs. Appointment schedules are carefully coordinated to minimize the time between consultations, ensuring continuous and consistent follow-up for patients. The program also coordinates with regular mental health out-patient clinics within the public health system, to garantee a good transition of care.
Results: During these collaborative meetings, each specialist shared their assessments and observations on the patient's progress, enabling the team to develop a unified therapeutic plan. Any changes in symptoms or new events are promptly communicated among all treating professionals, allowing for a rapid and coordinated multidisciplinary response. The diverse perspectives of each team member contribute to a more nuanced and comprehensive understanding of the patient's needs and treatment.
Conclusions: In summary, the collaboration between nursing, psicology and psychiatry creates a synergistic approach that is essential for delivering high-quality, patient-centered mental health care, particularly for those experiencing suicidal ideation.

doi: 10.1192/j.eurpsy.2025.2365

Introduction: Benzodiazepines are widely prescribed for the management of common mental health disorders. Although a direct relationship between benzodiazepines and suicide risk reduction has not been described, they can be an adequate choice to palliate anxiety and insomnia in patients with suicidal ideation. This is of special interest considering that both anxiety and insomnia are risk factors for suicidal behaviours themselves (May and Klonsky. Clin Psychol: Science and Practice. 2016; 23 5–20)(Park *et al.* J Psychiatr Res. 2020; 131 1-8). Nonetheless, paradoxically, there is a rising concern regarding an increase in suicide risk associated to benzodiazepine use, as some recent evidence seems to suggest (Dodds. Prim Care Companion CNS Disord 2017; 2;19)(McCall *et al.* Am J Psychiatry 2017; 1;174 18-25). Clarifying this potential association can help guide clinical decision-making to promote suicide prevention.
Objectives: To review the currently available evidence regarding the relationship between the use of benzodiazepines for common mental disorders and subsequent suicide, suicidal behaviours and self-injurious behaviours.
Methods: A systematic review of the literature was conducted using a combination of search terms related to "suicide" and "benzodiazepine" to assess publications from inception to February 2024 in 3 different databases (Scopus, PsychInfo, MEDLINE). Eligibility criteria included experimental, observational studies and previous systematic reviews while excluding conference proceedings, case reports/series, editorials, opinion papers and letters. Studies involving individuals with severe psychiatric disorders, dementia or personality disorder were also excluded. Risk of bias was assessed in RCTs with the RoB 2 tool while EPHPP Assessment Tool 2010 was applied for other study types.
Results: A total of 2090 titles and abstracts were screened; 19 papers were reviewed for inclusion and 8 were included in this review for data extraction. Most of the included publications consisted of observational studies. Results tended to indicate a higher risk of suicide, suicidal behaviour and/or self-injurious behaviours in relation to benzodiazepine use although data was contradictory and affected by confounding.
Conclusions: Evidence seems to suggest a positive relationship between benzodiazepines and suicide, suicidal behaviour and/or self-injurious behaviours although, due to the predominant observational study designs and the presence of unadjusted confounding, these results must be extrapolated with care and no causality can be inferred. An interesting approach for future research to palliate such limitations could be Target Trial Emulation (Hernán and Robins. Am J Epidemiol 2016; 15;183(8) 758-64), which has already been adopted to guide decision-making in absence of randomized trials in many fields of medicine.

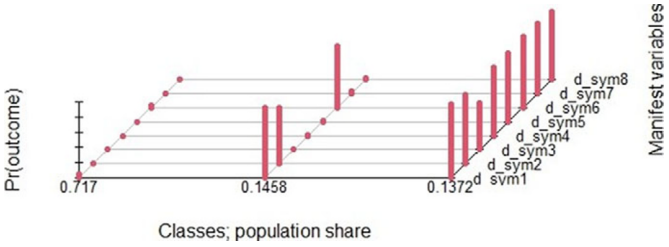
doi: 10.1192/j.eurpsy.2025.2366



Introduction: Depression among older adults is a significant public health issue that often goes underrecognized, despite its profound impact on their quality of life and mental well-being. With advancing age, many individuals encounter challenges such as loneliness, chronic illness, and bereavement, which heighten their vulnerability to depressive symptoms. These symptoms are not only detrimental to overall health but are also strongly associated with an increased risk of suicidal behaviours. Although these suicidal behaviours are preventable, much research should be done to disentangle development pathways in older adults.

Objectives: The aim of this research is to identify the symptomatic profiles of depression in the elderly population and to relate this profile to suicidal outcomes.

Methods: We utilized data from the "*Edad con Salud*" cohort study, a longitudinal household survey conducted on a nationally representative sample in Spain (aged 18+ years). Participants who could not be personally interviewed and those under 50 years old were excluded, resulting in a final sample of 3,533 participants (54.31% female, age = 66.42(10.27)). Suicidal behaviours and depressive symptoms were assessed using the Composite International Diagnostic Interview (CIDI 3.0). A Latent Class Analysis (LCA) was performed at base level to identify participant profiles based on 8 depressive symptoms. We followed this with a survival analysis to assess differences between profiles in the progression of suicidal ideation and attempts in the different waves. Finally, Cox regression was used to examine the impact of sociodemographic and clinical covariates on suicidal behaviours.

Results: The three-cluster model provided the best fit. The first class (72.52%) included most participants without depressive symptoms; the second class (13.67%) included participants with three symptoms (depressive mood, diminished interest or pleasure and fatigue); and the third class (13.81%) included participants with all eight symptoms (see Image 1). Survival analysis revealed significant differences between the groups over time for both suicidal ideation (χ^2=1332, $p < .01$) and suicide attempts (χ^2=215, $p < .01$), with the third group having the highest number of cases. Cox regression indicated that suicidal ideation was associated with the second (*HR* = 5.38) and third classes (*HR* = 59.8), age (*HR* = 0.97), and loneliness (*HR* = 0.91), among other variables. Suicide attempts were associated with the second (*HR* = 6.08) and third classes (*HR* = 25.3), age (*HR* = 0.92), and loneliness (*HR* = 1.02).

Image 1:

Conclusions: Participants with depressive symptoms, even at a subclinical level, have an increased risk of suicidal behaviours, especially when other risk factors such as loneliness are present.

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2367

Introduction: Chronic medical conditions are increasingly recognized as significant contributors to suicide risk, especially in patients without prior psychiatric diagnoses (Østergaard *et al.* JAMA Psychiatry 2024). This case examines the psychiatric impact in a 65-year-old male admitted to general surgery for abdominal pain, who subsequently underwent an ileocolectomy for suspected gastrointestinal malignancy.

Objectives: To explore the psychiatric impact of medical morbidity on suicide risk, emphasizing recent findings suggesting heightened attention for patients without a psychiatric history.

Methods: The patient, with no prior psychiatric history, was observed by liaison psychiatry after verbalizing suicide ideation

without intent or plan. The ideation was associated with worsening mood, particularly over the past week. Emotional distress escalated after perceived medical setbacks and was compounded by familial dynamics, particularly the wife's expressed anxiety. A diagnosis of adjustment disorder with depressive symptoms was considered, with initial treatment involving mirtazapine and psychosocial support.

Results: The case reflects evidence supporting the idea that suicide risk may follow a dose-response pattern based on the disability burden in patients without prior psychiatric history (Østergaard *et al*. JAMA Psychiatry 2024). This suggests clinicians may need to be particularly vigilant in medically ill patients without a psychiatric background, as their suicide risk may increase as disability burdens mount – contrary to the understandable and maybe more intuitive focus on those with established psychiatric diagnoses.

Conclusions: This case highlights the importance of thorough suicide risk evaluation in patients without psychiatric histories, particularly following a major medical diagnosis. While suicide risk remains high in psychiatric patients, clinicians must be equally or even more vigilant with medically ill patients without psychiatric histories. Psychiatric care should be integrated early, with attention to the timing of suicide risk, the disability burden, and psychosocial stressors. This highlights the need for careful monitoring and early intervention, particularly in the acute phase following medical complications, where risk evaluation may be more nuanced.

An online forum for psychiatric patients: Sexual life and self-harm

E. B. Lyubov[1] and N. Semenova[1*]

[1]Moscow Research Institute of Psychiatry – a branch of the V. Serbsky National Medical Research Centre for Psychiatry and Narcology of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2368

Introduction: The significance of intimate life in a person's personal and social experience cannot be overstated. This aspect is intricately woven into the clinical and internal picture of intentional (suicidal or non-suicidal) self-harm (SX), making it a crucial area of study.

Objectives: Study of position on the issue of sexual problems and SX among participants of an open forum.

Methods: We conducted interviews with forty participants (90% women) with a mean age of 27 (range 17-43) years, using an original semi-structured questionnaire. This approach allowed us to delve into the issue of sexual problems and SX among participants of an open forum.

Results: Ten thousand people were interested in the survey during two months of posting on the site, but < 0.5% participated. All questions were answered by 95%. The sample comprised young women, like most of our online polls. For almost 70% of respondents, issues of sexual life are burning and pressing questions, but only ¼ discuss «this» with a psychiatrist and only in terms of drug side effects. During routine visits, the doctors were not interested in the sexual life of about 80% of patients; ¾ of the women were not interviewed about the menstrual cycle or (all men) about erections or galactorrhea. Only ¼ of doctors are interested in the intent of SX. >70% indicate that forced abstinence «worsens» their mental state (makes them irritable), >¾ of singles and ½ family people masturbated 1-3 times a week («to feel alive»). >½ of married women are afraid of pregnancy, but refuse birth control as «harmful». >80% of family problems were associated with apathy and irritability and are considered the main obstacle to regular sex. > ½ report «habitual» weakness, lack of interests (including sexual), and suicidal thoughts for more than three months. <½ respondents link treatment to impotence and frigidity. ½ had SX experience (indistinguishable from suicide attempts) due to the loss of a loved one during their life. Patients considered SX to be a «natural» reaction to shame and mental pain and allowed repetition in a similar situation. Doctors do not regularly assess a patient's risk of suicide.

Conclusions: The findings of this study underscore the need to bring sex and SX topics into the focus of routine psychiatric practice. The passive role of psychiatrists in clarifying patients' problems that influence treatment adherence, well-being, and undertreatment of depression is a significant issue that needs to be addressed. The survey highlights two subtopics of greatest interest to patients: indestructible sex drive and micro social problems as 'reasons' for depression and SX. The 'gray zone' of therapeutic contact and satisfaction with care is an area that warrants further exploration.

Complutense University of Madrid, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2369

Introduction: Suicide is one of the leading causes of preventable death.

The PRISURE program is developed with a series of objectives and actions aligned with the Mental Health Strategy of the

National Health System - (Spain), Strategic Plan for Mental Health and Addictions of the Community of Madrid 2022-2024 and the Prevention Plan suicide in the community of Madrid 2022-2026, based on the experience of the suicide risk prevention program developed between 2014 and 2023 at the Retiro Mental Health Center (CSM) of the Institute of Psychiatry and Mental Health of the General University Hospital Gregorio Marañón.

Objectives: Presentation of a secondary suicide prevention program in the Community of Madrid with 10 years of implementation and reinforcement of the therapeutic team in the last year.

Treatment outcomes, assessment of patients' suicide risk progression during follow-up, referral to patient discharge, and outcome indicators in the past year are measured.

Methods: Description of the functioning of the PRISURE program and descriptive study of sociodemographic and clinical characteristics, suicidal crises, evolution and discharge referrals, of all patients treated in PRISURE. The program's performance indicators, as well as its results, are evaluated over one year from its implementation.

Results: Sociodemographic and clinical characteristics are analyzed, including psychometric evaluation at baseline, 3, 6, 9, and 12 months after referral to PRISURE from August/2023 to August/2024. The suicide risk profile, treatment adherence, program implementation indicators and initial results are evaluated.

Conclusions: PRISURE is a comprehensive care process that includes the prevention, intervention and postvention of suicidal behavior.

It includes interventions indicated for the prevention of suicidal behavior aimed at people in whom relevant signs or symptoms that anticipate the development of a mental disorder, or biological or psychological markers that indicate a high suicidal risk, have been identified.

PRISURE encompasses a set of activities aimed at early detection and indicated prevention, support and care of suicidal behavior, as well as research and promotion of mental health.

Hyperfrequent use and suicidal behavior in hospital psychiatric emergency services

M. Valverde Barea[1]*, P. Vargas Melero[1], G. Ruiz Martinez[1], A. Jurado Arevalo[1] and E. Perdiguero Sempere[1]

[1]H. U. Jaén, Jaén, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2370

Introduction: One of the great challenges for Mental Health Services is dealing with users who repeatedly use the facilities. This phenomenon, beyond representing an increase in the economic cost and in terms of human resources, generates high levels of frustration and dissatisfaction, both in professionals and in the consultants themselves. These users have been called "hyperfrequent users". Users can frequent different services, including the Emergency service. The phenomenon of hyperfrequent use can lead to an inappropriate use of the Emergency services and gives rise to substantial costs for the health system, as well as a decrease in the efficiency of the service.

Objectives: The objective of our work is to describe those factors associated with the hyper-frequent use of Mental Health Hospital Emergency Services by users who engage in suicidal behavior.

Methods: A descriptive, observational study was carried out. The population included all users of the Hospital Emergency Department treated by the Mental Health Service in one year who consulted for suicidal behaviour (self-harming ideas, suicidal attempts or self-harm). Patients who consulted on 4 or more occasions in the hospital psychiatric emergency departments for consultations related to suicidal behaviour were considered as frequent users.

Results: 860 consultations were attended to, corresponding to 546 users who consulted in the psychiatric hospital emergency departments for suicidal behaviour (self-harming ideas, suicidal attempts or self-harm). Of these users, 314 consulted on more than one occasion. Taking as a frequent user >=4 consultations, we have 14 users in one year. Regarding sex, the female sex stands out 86% over the male sex 14%. One user is considered a great frequent user, attending on 17 occasions. The most frequent reasons for suicidal consultation among frequent users are consultations for self-harm ideation (33%) and self-harm attempts (60%) and self-harm (7%). Anxiety and alcohol consumption are the most frequent comorbid diagnoses among frequent users. By sex, self-harm behavior stands out in both women and men and self-harm is more frequent in women. Regarding discharge after assessment, referrals to a community mental health specialist stand out in 45% after consultation and 28% of frequent users required hospital admission after care for suicidal behavior.

Conclusions: In our work, it is observed that the profile of frequent users with suicidal behavior is adult women who consult for self-harm attempts in their majority. These hyper-frequent users continue to demand attention from the health network devices, so knowing their needs would help to improve health care and use resources more efficiently and effectively for these users who engage in suicidal behavior.

EPV1974

Suicide attempt during a dissociative fugue: additional challenges in assessing self-harm risk

M. Velasco Santos[1]*, B. Orgaz Álvarez[1], Á. De Vicente Blanco[1], P. Ibáñez Mendoza[1], I. Diéguez De Juan[1], M. Viaña Pérez[1] and A. Huerta Vena[1]

[1]Psychiatry, Hospital Universitario La Paz, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2371

Introduction: Suicide attempts during dissociative fugue states pose distinct challenges in assessing self-harm risk. Dissociative fugue is characterized by sudden, unplanned travel away from familiar surroundings, coupled with amnesia for personal identity and significant changes in behavior. This case report describes a 31-year-old male who attempted suicide during a dissociative fugue episode.

Objectives: To present a case of a suicide attempt during a dissociative fugue state, highlighting the unique challenges in assessing self-harm risk, and examining the role of substance use and prior psychological trauma in influencing patient behavior.

Methods: This case report describes a single patient. The methodology involves a comprehensive examination of the patient's clinical presentation, including diagnostic work-up, treatment adjustments, and outcomes.
Results: A 31-year-old male was admitted to the emergency department after intentionally ingesting 25 diazepam tablets. Eight months earlier, he had survived a suicide attempt via carbon monoxide poisoning, also during a dissociative fugue state. These fugue episodes were marked by sudden, unplanned disappearances, memory loss, significant behavioral changes, and temporary loss of personal identity. The latest episode followed an emotional conflict with friends, leading to a three-day disappearance, during which the patient traveled to various locations, frequented pubs, and slept in his vehicle. He attempted suicide on the final day by overdose. Medical assessments, including physical and neurological exams, blood tests, and cranial computed tomography (CT) scans, showed no abnormalities. The patient admitted to using alcohol and cocaine, but urine toxicology revealed no other substances. During psychiatric evaluation, he denied any current or past suicidal ideation and exhibited no psychotic or manic symptoms. He reported mild affective decline over recent months and a complex life history, but did not meet the DSM-5 criteria for post-traumatic stress disorder (PTSD).
Conclusions: The key diagnostic challenge in this case is distinguishing between substance intoxication and dissociative fugue. Although the patient was intoxicated with alcohol and cocaine during parts of the episode, intoxication was not consistent throughout the entire period. Moreover, the onset of symptoms was abrupt and triggered by an emotional conflict. Given the patient's history of dissociative fugue and the nature of the current symptoms, dissociative fugue remains the most plausible diagnosis. This case highlights the complexity of managing self-harm risk in patients with dissociative symptoms, where suicide attempts complicate the development of effective safety plans and pose significant challenges to intervention strategies.

The Effectiveness of Dialectical Behavior Therapy (DBT) in Reducing Suicidal Tendencies (ST) in Adolescents with Bipolar Disorder

N. S. G. Abdelrasheed[1,2]

[1]Department of Education and [2]Director of Centre for Student Counseling, Dhofar University, Salalah, Oman
doi: 10.1192/j.eurpsy.2025.773

Introduction: Suicidal tendencies are among the most common problems faced by adolescents who encounter difficulties, issues, or challenges affecting various aspects of their psychological and social lives, often leading to high suicide rates. Bipolar disorder, various depressive disorders, substance abuse disorders, psychosis, and eating disorders are among the most common leading causes of suicide and suicidal tendencies among adolescents. Dialectical Behavior Therapy (DBT) is an integrative therapy employing a combination of techniques. DBT aims to assess the individual's ability to regulate emotions, manage relationships effectively, tolerate distress, reduce maladaptive responses, and decrease impulsive and self-destructive behaviors.
Objectives: The current study aims to investigate the effect of using Dialectical Behavior Therapy (DBT) techniques in reducing suicidal tendencies (ST) among adolescents of both genders who suffer from bipolar disorder. Additionally, to verify the sustained effectiveness of these techniques in reducing suicide risk among adolescents.
Methods: A one-group experimental design was used. The study sample consisted of a (31) adolescents with high or moderate levels of suicidal tendencies who were diagnosed with bipolar disorder. Initially, the Bipolar Disorder Scale was used to identify adolescents exhibiting symptoms of the disorder for more than 6 months. This was followed by administering the Suicidal Tendencies Scale. Individuals with high or moderate suicidal tendencies scores on this scale were selected to participate in the study. They then underwent 23 sessions of psychotherapy based on DBT. After the completion of the therapy program, the Suicidal Tendencies Scale was administered again, and a third administration took place two months after the completion of the program. The research tools included a DBT-based therapy program consisting of 23 sessions, with an average of 3 sessions per week, each lasting 45-60 minutes.
Results: The results indicated a significant improvement among adolescents after the completion of the program. Participants reported benefiting from the program, expressing reduced feelings of despair and increased hope and optimism about life. The adolescents' scores on the Suicidal Tendencies Scale decreased after the program ended compared to their scores before the program. Additionally, their scores remained lower two months after the program ended compared to their pre-program scores. This indicates a positive impact of the counseling program in reducing suicidal tendencies among adolescents, as well as the sustained effectiveness of the program.
Conclusions: Dialectical Behavior Therapy (DBT) is effective in reducing suicidal tendencies and can be applied effectively to a range of other psychological disorders. It is essential to manage suicidal tendencies among adolescents to help decrease suicide rates.

Training in Psychiatry

EPV1976

Impact of Psychiatry Clinical Internship on Medical Students' Specialty Choice

S. Ben Aissa[1]*, R. Khouloud[1], N. Chaima[1], L. Amine[1] and M. Wahid[1]

[1]Psychiatry D, Razi Hospital, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2372

Introduction: Medical students often harbor entrenched and somewhat negative views towards psychiatry, which can impact their interest in pursuing this specialty and pose challenges to recruitment efforts.
Objectives: To assess whether exposure to clinical placements in psychiatry can positively shift medical students' perceptions and influence their career decisions towards this field.
Methods: This study employed a "before/after" longitudinal design over an eight-month period involving 5th-year medical students who were starting their 4-week psychiatric rotation. Evaluations were carried out at the beginning and end of the internship using a comprehensive questionnaire that covered sociodemographic

details, clinical exposure, and students' career inclinations towards psychiatry. The questionnaire also explored various reasons influencing their specialty choice, aiming to identify shifts in perspective directly attributable to their internship experience.
Results: A total of 41 students (n=41) participated in the study. There was a notable positive shift in attitudes towards psychiatry observed at the conclusion of the internship. At the start of the rotation, only 29% of students considered choosing psychiatry as a potential career path. By the end of the internship, this figure had increased to 49%. This substantial increase underscores the transformative potential of direct, immersive experiences in altering career considerations among medical students.
Conclusions: Consistent with the literature, the results of this study demonstrate the positive impact that clinical placements in psychiatry can have on medical students' attitudes towards the specialty and their subsequent choice of it as a career path. This improvement highlights the critical role that such internships play not only in enhancing educational outcomes but also in shaping the future workforce in psychiatry. It is evident that integrating robust psychiatric placements into medical training programs is essential for nurturing an informed, motivated, and committed next generation of psychiatrists. Our findings support the continued advocacy for and expansion of these experiential learning opportunities within medical curricula to foster a deeper understanding and appreciation of psychiatry.

Docimologic analysis of child psychiatry examination

S. Bourgou[1], N. Boujelbene[1], N. Ben Salah[1] and G. Amira[2]*
[1]Faculty of Medicine of Tunis, Tunis and [2]Child psychiatry Department, Mongi Slim Hospital, La Marsa, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2373

Introduction: Docimology is the science that assesses the quality of tests and items, based on different indices and coefficients.
Objectives: The purpose of our study was to perform a docimological analysis, based on docimological indices, of the items and exams of Child psychiatry of psychiatry certificates porposed for the students of the Third Year of the Second Cycle of Medical Studies in the Faculty of Medicine of Tunis.
Methods: We carried out a retrospective and descriptive study. We have included the scores of main sessions' psychiatry certificate exam of six academic years (2016-2017 to 2021- 2022). We did not include the scores of this certificate obtained at the control sessions during the period of our study. We carried out a global docimological analysis of the psychiatry exam, of the child psychiatry exam and its items.
Results: We included a total of 2780 exam scripts spread over 12 main sessions. We found an annual pass rate of 96.7% in the psychiatry certificate and 85.3% in the discipline of child psychiatry. The study of the internal homogeneity of the psychiatric tests showed that the Alpha index of Cronbach varied between 0.64 and 0.82 with an average index of 0.74 which corresponds to an internal homogeneity at least acceptable. We found that the maximum scores obtained in the discipline of child psychiatry varied from 16.5 to 19.75 out of 20. The average rate of students, who passed the psychiatry certificate test without passing the discipline child psychiatry, was 11.9%. The questions were easy in 51.7% (62 questions) ans have at least good discrimination in 31.7%. We found also that 25 questions (65,7%) were "ideal".
Conclusions: Child psychiatry examination in the Faculty of Medicine of Tunis meets globally the docimologic recommendations. This is the first step to build up a bank of items regularly enriched with "ideal" questions with metric qualities known in advance.

Improving External Rotations in Psychiatry Residency Programs: A Mixed-Methods Analysis

J. P. Carrasco[1]*, J. Esteve[2], C. Conde-Pumpido[2], B. Herraiz[2], J.-I. Etxeandia-Pradera[2] and E. Aguilar[2]
[1]Hospital Provincial Castellón, Castellón and [2]Hospital Clínico Universitario de Valencia, Valencia, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2374

Introduction: External rotations allow psychiatry residents to gain exposure to different clinical settings and practices. However, the availability and quality of these rotations vary significantly across training units. This study evaluates residents' experiences with external rotations and identifies areas for improvement.
Objectives: To assess the time allocated for external rotations in different training units and explore residents' suggestions for improving these rotations.
Methods: A cross-sectional survey was distributed to psychiatry residents in Spain. Quantitative data regarding the total time allowed for external rotations was collected, and qualitative responses were analyzed to identify recurring themes for improvement.
Results: A total of 109 responses were analyzed. Quantitatively, 60% of residents reported being allowed 1 to 3 months for external rotations, while 25% stated they had more than 3 months. Only 15% indicated that external rotations were not offered in their unit. Qualitative analysis revealed that the main areas for improvement included more flexibility in choosing rotation locations (40%), better financial support for rotations outside of the home institution (35%), and greater clarity in the application process for external rotations (25%).

Rotation Time Allowed	Percentage (%)
1 to 3 months	60
More than 3 months	25
No external rotations offered	15

Theme	Percentage (%)
Flexibility in location choice	40
Financial support	35
Clarity in application process	25

Conclusions: The majority of psychiatry residents are allocated 1 to 3 months for external rotations, but many see room for improvement in terms of flexibility, financial support, and clarity in the application process. Enhancing these aspects could make external rotations more accessible and beneficial for residents.

EPV1979

Enhancing Autonomy and Supervision During Psychiatry Residency: A Residents' Perspective

J. P. Carrasco[1]*, C. Conde-Pumpido[2], J. Esteve[2], B. Herraiz[2], J.-I. Etxeandia-Pradera[2] and E. Aguilar[2]

[1]Hospital Provincial Castellón, Castellón and [2]Hospital Clínico Universitario de Valencia, Valencia, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2375

Introduction: The progressive acquisition of autonomy, balanced with adequate supervision, is essential during psychiatry residency. However, the adequacy of supervision and the smooth transition to autonomy remains a concern among residents. This study evaluates psychiatry residents' perceptions of the current process of acquiring autonomy from the first to fourth year of training.
Objectives: To assess the perceptions of psychiatry residents in Spain regarding the process of progressively acquiring autonomy and how supervision is managed throughout their residency.
Methods: A qualitative analysis was conducted on responses to the survey question: "What should be improved in the progressive acquisition of autonomy and supervision from R1 to R4?" Data from free-text responses were coded thematically, with common themes identified and quantified.
Results: Responses from 109 residents were analyzed. Thematic analysis revealed that 35% of residents emphasized the need for clearer and more structured feedback from supervisors, while 30% suggested more direct supervision during critical learning periods, particularly in the first two years. Additionally, 20% highlighted the inconsistency of supervision across different units, with some units providing much less oversight than others. Other suggestions included better scheduling of supervisory sessions (10%) and more frequent formal evaluations of their autonomy progression (5%).

Theme	Percentage (%)
Structured feedback	35
Increased direct supervision	30
Consistency across units	20
Better supervisory scheduling	10
Formal evaluations of autonomy	5

Conclusions: Residents identified several key areas for improvement in the process of acquiring autonomy, with a particular focus on the need for more structured feedback and increased supervision during the early years of training. Addressing these concerns may improve the overall quality of psychiatric education and resident preparedness.

EPV1980

Evaluating the Need for Rotation Adjustments in Psychiatry Residency Programs: A Cross-Sectional Study

J. P. Carrasco[1]*, J.-I. Etxeandia-Pradera[2], J. Esteve[2], C. Conde-Pumpido[2], B. Herraiz[2] and E. Aguilar[2]

[1]Hospital Provincial Castellón, Castellón and [2]Hospital Clínico Universitario de Valencia, Valencia, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2376

Introduction: Psychiatry residency programs in Spain offer diverse clinical rotations to ensure comprehensive training. However, certain rotations may require adjustments in length or structure to meet the evolving educational needs of residents. This study assesses the opinions of psychiatry residents regarding which rotations should be extended, shortened, or maintained.
Objectives: To evaluate the perceived need for adjustments in rotation length across various subspecialties of psychiatry, including child and adolescent psychiatry, dual pathology, and psychotherapy, among others.
Methods: Data was collected through a national survey of psychiatry residents in Spain. Respondents were asked to indicate whether specific rotations should be lengthened, shortened, or maintained. Quantitative analysis was performed on responses for seven key rotations: child psychiatry, dual pathology, psychotherapy, research, neuropsychiatry, community psychiatry, and geropsychiatry.
Results: A total of 109 psychiatry residents participated in the survey. The most frequently requested extension was for geropsychiatry, with 57% of respondents advocating for a longer rotation, followed closely by community psychiatry (48%). In contrast, rotations in research (26%) and child psychiatry (24%) were identified as those most needing to be shortened. Most residents supported maintaining the current duration of dual pathology (86%) and neuropsychiatry (83%) rotations.

Rotation	Shorten (%)	Lengthen (%)	Maintain (%)
Child Psychiatry	24	15	64
Dual Pathology	6	11	86
Psychotherapy	10	17	80
Research	26	22	57
Neuropsychiatry	15	10	83
Community Psychiatry	3	48	55
Geropsychiatry	1	57	48

Conclusions: The results suggest a strong desire among psychiatry residents to extend rotations in geropsychiatry and community psychiatry, while shortening research and child psychiatry. These findings highlight the need for training programs to reevaluate the duration of certain rotations to better align with resident learning needs.

EPV1987

Enhancing Medical Resident Confidence in Managing Anxiety and Depression on the Medical Floor Through Evidence-Based Guidelines

J. Li[1]*, M. Khan[1] and H. Raai[1]

[1]Department of Psychiatry and Behavioral Health, SBH Health System, Bronx, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2377

Introduction: Medical and psychiatric conditions often coexist, with complex interrelationships that affect patient outcomes. Medical conditions can induce mental illness through psychological or physiological effects, while mental illness may hinder engagement in medical care due to barriers such as poor motivation and functional impairment. Anxiety and depression are among the most common psychiatric conditions encountered on medical floors, and improved management of these conditions can enhance patient outcomes and increase post-discharge follow-up.
Objectives: The objective of this project was to improve the confidence of medical professionals in treating anxiety and depression on the medical floor by establishing an evidence-based approach for identifying and managing these conditions. The guidelines developed serve as a protocol for rapid, safe interventions, improving outcomes and reducing inefficient healthcare utilization.
Methods: A survey was conducted among 18 medical residents to assess their confidence in evaluating and managing anxiety and depression, and determining when a psychiatric consult is necessary. After completing the initial survey, residents were provided with a stepwise guideline for managing anxiety and depression on the medical floor. A post-guideline survey was then conducted to assess changes in their confidence levels and understanding.
Results: Pre-intervention survey results showed 85.7% of residents were comfortable identifying anxiety, 64.3% with identifying major depressive disorder (MDD), and 71.4% with differentiating MDD from bipolar depression. However, only 64.3% felt comfortable treating anxiety, and 50% initiating treatment for MDD. Post-guideline survey results showed improvements in several areas, including 90% confidence in identifying anxiety and 70.2% in diagnosing MDD. Notably, all residents felt comfortable continuing treatment for depression, and knowledge of medication side effects increased to 100%.
Conclusions: The results suggest that medical residents on the floor showed improved confidence in evaluating and managing anxiety and depression after receiving the guideline. There was increased comfort with knowledge of medications and their side effects, although some discomfort remained in initiating treatment and titrating medications. Implementing universal screening protocols and further educational interventions, such as didactic sessions on specific medications and their side effects, can help address these gaps and enhance psychiatric care on the medical floor.

EPV1988

The Benefits of Active Participation in the European Federation of Psychiatric Trainees (EFPT) for Psychiatric Trainees Across Europe

F. M. Monshizadeh Tehrani[1]*, N. de Ridder[1], V. H. Santos[1] and M. Konings[2]

[1]European Federation of Psychiatric Trainees, Brussels, Belgium and [2]President, European Federation of Psychiatric Trainees, Brussels, Belgium
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2378

Introduction: The European Federation of Psychiatric Trainees (EFPT) unites general adult psychiatry (GAP) and child and adolescent psychiatry (CAP) trainees' associations across Europe, fostering collaboration, education, and professional growth. Trainees across Europe can become EFPT members through their national associations (NTA). Residency can be challenging, with demanding workloads and academic pressures. Having a supportive network like EFPT can ease these difficulties by providing access to valuable resources, support, and collaboration. This abstract highlights the benefits of active participation in EFPT for GAP and CAP trainees across Europe.
Objectives: To explore the diverse benefits provided by EFPT for GAP and CAP trainees across Europe, focusing on professional development, research collaborations, and international exchanges. This abstract highlights strategies for maximizing these opportunities and overcoming the challenges of international psychiatric training.
Methods: A review of EFPT's initiatives, project descriptions, website data, and participant feedback was conducted. This analysis covered webinars, courses, research projects, clinical exchanges, and cultural experiences. Data were gathered from EFPT's resources and European trainees' feedbacks, emphasizing networking, research collaboration, and cultural exchange as key benefits for trainees.
Results: EFPT offers a broad range of benefits for GAP and CAP traineesroughout Europe, including:

- **Networking Opportunities:** Trainees can establish professional connections with peers and experienced psychiatrists from across Europe, fostering collaboration, mentorship, and knowledge sharing.
- **International Participation:** Trainees have access to international congresses, webinars, and specialized courses that enhance clinical and research skills, exposing them to diverse perspectives and practices.
- **Clinical Exchange Programs:** Through EFPT's exchange programs, trainees gain insights into different healthcare systems, broadening their understanding of child and adolescent mental health treatment across Europe and enhancing their cultural competence.
- **Cultural Enrichment:** EFPT's annual forum, including events like Cultural Night, allows trainees to engage in cultural exchange through music, food, and dance, fostering camaraderie and promoting overall well-being among young psychiatrists.

Conclusions: Active participation in EFPT offers European psychiatric trainees unique opportunities beyond traditional training, contributing to both professional growth and personal development. By encouraging involvement in EFPT, trainees can enhance their skills, broaden their networks, and foster international collaboration, ultimately strengthening the psychiatric community across Europe.

EPV1989

Bridging Cultures: A Cambodian Psychiatrist's Perspective on Psychiatry and Addiction Exchange Programs in the Netherlands and South Africa

R. Ngin[1] and S. Bora[1]*

[1]Mental Health, Cambodian's Children Fund, Phnom Penh, Cambodia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2379

Introduction: This knowledge exchange program was designed to enhance the clinical training of a Cambodian psychiatrist in general psychiatry and addiction care. Conducted between July 1, 2024, and August 30, 2024, the program involved immersive clinical experiences in the Netherlands and South Africa. The exchange facilitated engagement with leading mental health institutions, offering valuable insights into advanced psychiatric practices and addiction care models.
Objectives: The primary objectives of the program were to improve clinical competencies in diagnosing and managing psychiatric and addiction disorders, to gain exposure to multidisciplinary and community-based care models, and to develop cultural competence in adapting psychiatric practices to low-resource settings like Cambodia. These goals were pursued through a combination of clinical visits and participatory learning activities.
Methods: The psychiatrist participated in clinical visits and hands-on learning at Radboud University Medical Center and Pro Persona in the Netherlands, as well as Rustenburg Addiction Care in South Africa. These experiences included observing advanced treatments and participating in community-based psychiatric care programs. The program's structure combined hands-on training and multidisciplinary teamwork to provide a comprehensive learning experience.
Results: The program yielded significant improvements in the psychiatrist's ability to manage complex addiction cases and implement community-based care. Additionally, the experience fostered greater cultural competence, enabling the application of psychiatric practices suited to the Cambodian context. The collaboration also promoted potential future psychiatric training initiatives and international partnerships.
Conclusions: The knowledge exchange program was successful in enhancing the psychiatrist's clinical skills and cultural awareness. It underscored the importance of international collaboration in psychiatry and addiction care, providing a model for how mental health professionals from low-income countries can benefit from exposure to global best practices and community-based care strategies.

EPV1990

Clinical Reasoning Skills in Psychiatric Education: Scenario and Question Generation with Chat-GPT

B. Ozel[1]*, E. Emekli[1] and E. Emekli[2]

[1]Department of Psychiatry, Baskent University, Ankara and [2]Department of Radiology, Eskişehir Osmangazi University, Eskişehir, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2380
Introduction: Case-based learning holds a crucial place in psychiatric education. Through methods such as written scenarios, video presentations, patient simulations, or observing real patients, students are expected to gain clinical reasoning skills by observing psychiatric cases.
Objectives: This study aims to generate case scenarios using ChatGPT-4 and create multiple-choice questions based on these cases.
Methods: A prompt was developed based on the literature to generate case scenarios for 12 psychiatric diagnoses, along with five related questions for each case (Figure) (Kıyak. Rev esp educ méd 2023; 4(3)). The scenarios and questions were organized into six forms, each containing two cases and ten questions.
Results: A total of 12 psychiatrists, (5.33 ± 1.31 years of practice) evaluated each form in pairs. The results of the case evaluations are presented in Table 1, and the question evaluations in Table 2.

Table 1	Form 1	Form 2	Form 3	Form 4	Form 5	Form 6	Total
	Schizophrenia/ MDD	Schizophreniform/ AN	Brief PD/ SSD	Panic/ Bipolar I	Dysthymia/ BPD	Conversion/ GAD	
The clinical scenario represents a typical case for the queried disorder.	2/2	2/2	1/2	2/2	2/2	2/2	23/24
The mental status examination findings in the case are appropriate for diagnosis.	2/2	2/2	2/2	2/2	2/2	1/2	23/24
The case scenario is well-written.	2/2	2/1	2/2	2/2	2/2	2/2	23/24
The case is of appropriate difficulty for medical students.	2/2	1/1	2/1	2/2	2/2	1/2	20/24
The case is aimed at measuring clinical reasoning skills.	2/2	2/2	2/1	2/2	1/1	2/2	21/24

Table 2	The question text is clear.	The question is clinically appropriate.	The question has only one correct answer.	The information provided is sufficient to find the correct answer.	The distractors are plausible.	The question was of appropriate difficulty for medical students.	Factual Recall/ Clinical reasoning	Total by question type
Diagnosis	23	23	22	23	23	19	16	149/168
Treatment	24	23	12	20	17	15	17	128/168
Differential diagnosis	22	17	18	16	19	15	20	127/168
Prognosis	23	22	17	21	19	14	14	130/168
Complications	21	19	17	19	13	12	14	115/168
Total by criterion	113/120	104/120	86/120	99/120	91/120	75/120	81/120	

Conclusions: The evaluation confirmed that the case scenarios were typical for the respective disorders and included appropriate mental status examinations for diagnosis (23/24). The cases were deemed suitably challenging for medical students (20/24) and effective in assessing clinical reasoning skills (21/24). However, the questions did not meet certain criteria, such as appropriate

difficulty (75/120), the presence of a single correct answer (86/120), and the plausibility of distractors (91/120). It is suggested that further work on the prompt is needed to improve the quality of the questions. While ChatGPT is suitable for generating case scenarios, the questions should be reviewed before use.

Mental Health Themed Student Selected Components: A Strategy To Increase Recruitment Into Psychiatric Training

T. I. D. Parry[1]*, D. Levy[2] and S. De Souza[3]

[1]Medical Education, Somerset Foundation Trust, Taunton; [2]University of Bristol, Bristol and [3]Somerset Foundation trust, Taunton, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2381

Introduction: The University of Bristol Medical School, United Kingdom, has student-selected components (SSC) making up a substantial proportion of its curriculum. This practice is common among UK medical schools. SSCs can inspire interest in specialities that students may have less exposure to during undergraduate training, such as psychiatry. Psychiatry has a broad range of subspecialities and themes which can be explored in an SSC. The author supervised one such project in which a student researched and produced a series of podcasts about the science of happiness.
Objectives: To explore the use of student-selected components (SSC) in increasing exposure to psychiatry in the undergraduate curriculum
To explore the impact of student-selected components (SSC) in increasing recruitment into psychiatric training
Methods: An initial literature review was performed with the following keywords using Medline on OvidSP.
Results: Fourteen papers addressed the use of psychiatry student-selected components (SSC) in undergraduate medical education and their influence on career specialty choice.
Conclusions: Student-selected components (SSC) are an important strategy for increasing exposure to psychiatry in undergraduate medical education and recruitment into psychiatry.
Keywords: Medical undergraduate education, elective, student-selected components, special study modules, psychiatry, mental health.

Addressing professional burnout among Ukrainian medical workers during wartime: an online intervention study

V. Rusanov[1]*, S. Lahutina[2,3] and T. Abdriakhimova[1]

[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]Center for Affective Neuroscience, Charité - Universitätsmedizin, Berlin and [3]German National Academy of Sciences Leopoldina, Halle, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2382

Introduction: Professional burnout among medical workers is a significant global concern characterized by emotional exhaustion, depersonalization, and a reduced sense of personal accomplishment. In Ukraine, the ongoing war has exacerbated this issue due to additional stressors such as exposure to traumatic events, resource limitations, and constant threats to personal safety. Medical professionals are facing unprecedented challenges, including increased patient loads from wartime casualties and psychological strain from working in high-risk environments.
Objectives: Develop an online psychological training program to address professional burnout among Ukrainian medical workers during wartime, evaluate its feasibility in a conflict setting, and assess its preliminary effectiveness in reducing burnout levels and improving adaptive coping strategies.
Methods: An online training was developed by specialists from Charité University Clinic (Berlin) and Bogomolets Medical University (Kyiv) under the "SOLOMIYA" project (https://solomiya.net.ua/).
Participants: 27 medical workers from Ukraine.
Study design was mixed-methods with quantitative assessments at three time points.
Intervention was delivered online via Zoom in Ukrainian to accommodate regional participants and wartime restrictions. Total duration was 4 hours over two 2-hour sessions, including psychoeducation, practical exercises, and interactive discussions.
Data collection scales: Maslach burnout inventory, Brief COPE, Professional Self-Efficacy, WHO-5 index, participant satisfaction survey.
Results: Preliminary data from the 27 participants indicate a high level of satisfaction with the training program. The mean satisfaction score was 8.7 out of 10 (SD = 1.2), with scores ranging from 6 to 10 and a median of 9. The distribution of satisfaction scores was as follows: excellent (9–10): 59% (16 participants), very good (8): 15% (4), good (7): 19% (5), satisfactory (6): 7% (2).
These results suggest that the majority of participants found the training to be highly valuable and relevant to their needs. Participants reported that the exercises and coping strategies provided were useful for managing stress. Interactive discussions were noted as particularly helpful, demonstrating the importance of social support in reducing burnout. Due to the ongoing nature of data collection, comprehensive statistical analyses of changes in burnout levels, coping strategies, professional self-efficacy, and well-being are not yet available. However, initial observations indicate positive trends in these areas.
Conclusions: Preliminary findings show that online psychological training is feasible and well-received by Ukrainian medical workers during wartime. High satisfaction scores suggest potential benefits. While definitive conclusions on effectiveness are premature, the positive reception aligns with research on tailored interventions in high-stress environments.

EPV1994

Training for Improvement of communication between patient psychiatrists and families

S. Strkalj Ivezic[1]*, D. Bošnjak Kuharić[2], M. Batković[3] and A. Papić[4]
[1]School of Medicine, University Psychiatric Hospital Vrapče; [2]University Psychiatric Hospital Vrapce, Zagreb; [3]Dubrovnik County Hospital, Dubrovnik and [4]Department for psychotic disorders- male, University Psychiatric Hospital Vrapce, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2383

Introduction: Although the collaborative partnership of the psychiatrist, patient and family is vital to recovery from a mental disorder, many patients and their family members are not satisfied with the communication with the psychiatrist. They believe that they are not actively involved in creating a treatment plan and that they do not have enough information about the diagnosis and treatment.
Objectives: Objective of the study is to improve the communication skills of young psychiatrists for collaboration with patients and their families.
Methods: Recognising the pressing need to address dissatisfaction with communication, we implemented the EUFAMI Prospect Common Ground three-way communication program, which we adapted for our study. We measured the increase in communication skills using a self-assessment questionnaire.
Participants: three groups of patients diagnosed with severe mental illness, family members, and young psychiatrists have been working in small groups separately and together in large groups.
Results: Our study's results are promising. The majority of participants expressed satisfaction with the training method. Their feedback highlighted acquiring new communication skills, which they believe will strengthen the collaborative relationship between patients, family members, and psychiatrists.
Conclusions: A training program for improving communication skills for young psychiatrists proves to be useful for improving the creation of a therapeutic relationship of cooperation with patients and their family members.

From Around the World to Johns Hopkins: International Psychiatry Students' Learning Through 'The Perspectives of Psychiatry'

J. Thorman[1]*, M. S. Chisolm[2], K. Elzamzamy[2], A. J. Huang[3], P. Zuñiga[4] and D. Roy[2]
[1]Scania University Hospital, Malmo, Sweden; [2]Johns Hopkins University School of Medicine, Baltimore, United States; [3]The University of Adelaide, Adelaide, Australia and [4]Catholic University of Santiago de Guayaquil, Guayaquil, Ecuador
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2384

Introduction: Whilst the DSM has streamlined research and standardized diagnoses, it faces criticism for falling short in addressing the intricate nature of psychiatric disorders. By relying on checklist-based diagnoses, it overlooks critical dimensions such as personality traits, cognitive functions, the motives driving maladaptive behaviors, and the unique narratives of individuals. In contrast, the Perspectives of Psychiatry (PoP) presents a comprehensive framework that enhances the understanding and treatment of mental health conditions. It integrates diverse origins of psychiatric disorders while emphasizing a thorough evaluation of a patient's life story. The global reach of PoP, with textbooks translated into multiple languages, has led to the creation of an international fellowship program for clinicians and students worldwide.
Objectives: The speakers will explore the PoP framework and share how this system is 1) implemented at Johns Hopkins (Baltimore, MD) in clinical practice and teaching, and 2) taught to international students with the newly established Perspectives of Psychiatry International Learners Program (PoPPIL).
Methods: Faculty from Johns Hopkins will outline how the PoP has been applied at their institution for the past 40 years, while international students from Sweden, Australia, and Ecuador will share their experiences from the PoPPIL.
Results: The PoP provides a structured and integrated framework for clinical practice and teaching. It explicates the rationale behind various treatment methods — medications, psychosocial interventions, motivational strategies, and consolation — whilst enabling patients to contribute more discerningly in their own recovery. Patients undergo a comprehensive and systematic evaluation, before this information is analyzed from each of the 4 perspectives (figure 1). This encourages clinicians to consider the patient holistically, rather than as a collection of symptoms, leading to the creation of management plans that not only addresses their psychiatric symptoms but also their social needs and personal goals. These plans can then be used to work collaboratively and effectively with other providers such as social services, general practitioners and psychologists. The framework is now part of the core curriculum for all psychiatry residents at Johns Hopkins and since 2024, international students can partake in an immersive learning experience which includes clinical observation and teaching. The PoPPIL has also facilitated grassroot global communication among medical students, junior doctors and leading experts.
Image 1:

Conclusions: Moving beyond diagnostic checklists to a framework grounded in intelligible concepts can propel advancements in psychiatry. The program at Johns Hopkins illustrates how these concepts can be effectively applied in clinical settings and shared with students from around the world.

EPV2000

The Rockefeller Foundation and Evidence-based Psychiatry, 1920-1950

J. Wallace[1]

[1]Department of Continuing Education, University of Oxford, Oxford, United Kingdom
doi: 10.1192/j.eurpsy.2025.2385

Introduction: By 1920, the Rockefeller Foundation had set out to systematically improve medical education and clinical practice. This wealthy, formidable agent for change initially focused on surveying the state of medical education world-wide and then targeting individual research institutes and universities with funding aimed at improving their facilities.
Objectives: The aim was to increase understanding of how the Foundation's focus on improving medical education and practice changed over time.
Methods: The Rockefeller Foundation archive documents the philanthropic activities of the Foundation. Employing a social-history methodology, the primary sources utilised involved officer diaries, including that of Alan Gregg who directed support for medical research and education globally throughout the 1930s and 1940s. Also examined were contemporary journals such as *The British Medical Journal,* the *New England Journal of Medicine,* and *The Lancet;* contemporary newspapers such as the *New York Times*, *The Illustrated London News,* and the *Times of India,* among others. The evidence from the diaries was compared with that of journals, newspapers, and other primary sources.
Results: Initially the Foundation employed a disease-control model aimed at eradicating hookworm, malaria, and yellow fever. However, over time the Foundation changed its focus and developed a special interest in building the discipline of psychiatry. Gregg came to firmly believe that the funding of mental health research and teaching should be given the same resources as any other branch of medicine. Gregg supported initiatives to include psychiatry in standard medical school curricula and he also directed Foundation funding toward individual researchers in the field of mental health. He eventually came to serve as an advisor to the National Institute of Mental Health and the psychiatry section of the Department of Veterans Affairs.
Conclusions: The focus of the Rockefeller Foundation changed over time. Using meticulous planning, the Foundation moved from a laboratory-based, disease-eradication model to developing a deep commitment to promoting scientific psychiatry internationally.

Wellness at Work for Psychiatry Trainees in Ireland: A Pilot Quality Improvement Project

P. McLoughlin[1,2*] and C. Dolan[2,3]

[1]Sligo/Leitrim Mental Health services, Health Services Executive, Sligo; [2]The College of Psychiatrists of Ireland, Dublin and [3]Health Services Executive, Sligo, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.917
Introduction: Psychiatry trainees in Ireland are categorised as Non-Consultant Hospital Doctors (NCHD). Research into the wellbeing of NCHD's has consistently highlighted difficult working conditions with the majority reporting they have been told by others they neglect their own health. The learning outcomes of the College of Psychiatrists of Ireland are majority clinical, professional and academic based with only a small focus on outcomes related to trainee wellbeing. Therefore, local and creative initiatives to support psychiatry trainee health and wellbeing are warranted.
Objectives: To conduct a needs analysis amongst psychiatry trainees in the Sligo/Leitrim Mental Health Service to inform the development of a NCHD Wellness at Work Committee and assess its impact over over a six month period from January 2024 – July 2024.
Methods: Following Clinical Director ethical approval, an anonymous online survey was shared with NCHD's through email to assess their workplace wellbeing needs. Results were collected and analysed using Microsoft Excel leading to the creation and implementation of an action plan. At the end of the period, another anonymous online survey was shared through email to assess the usefulness of the project.
Results: 16 out of 23 local NCHD's responded to the needs analysis. 88% identified 'Physical Health' as the top priority for the committee, while 75% endorsed the 'Psychosocial work Environment' and 'Mental Health and Wellbeing'. The 'Physical Work Environment' and 'Healthy Eating' were chosen by 44%.
In terms of a wellness at work development program, the most frequently requested item was 'Activities to support mental health' (69%), followed by 'Corporate Leisure Centre discounts' at 63%, 'Stress Management' and 'Exercise/physical activity classes' both at 56% and 'Access to healthy food' and 'Sports participation' options both at 50%. 'Not enough time' was identified as the greatest barrier to participation by 69% with equal variations across preferred timing of activities.
The action plan included the improvement of the physical work environment along with the arrangement of a financial planning webinar, Human Resources Coaching, Occupational Health and Health Promotion sessions. Information was shared by email on the Cycle to Work scheme and the Living Well stress reduction program along with social events including a breakfast club, provision of time and facilitites pre-trainee teaching for social interaction and a regular social dinner.
An impact assessment survey provided 12 responses from a total requested of 16 with all 12 responding indicating a positive impact. The missing 4 responses were due to trainees moving location.
Conclusions: This is, to our knowledge, the first quality improvement project to date involving the creation of an NCHD Wellness at Work Committee in Ireland.
The results will be used to inform and encourage the development of similar initiatives Deanery wide.

Chirps and Sentiments regarding PMS and PMDD: where does X stand?

C. Noureddine[1], G. Alvim de Paula[1*] and A. Sterchele[1]

[1]Psychiatry, Icahn School of Medicine at Mount Sinai, New York, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2386

Introduction: The emergence of social media platforms like X has created a unique space for mental health discussions. This study aims to analyze the language and themes used in social media discussions to appreciate sentiments about PMS and PMDD by looking at a sample of the most popular tweets on platform X.
Objectives: We hypothesize that this content can provide insight into public perceptions and guide educational campaigns.
Methods: An advanced Twitter/X search for "PMS" and "PMDD" was conducted, filtering for English content. The top 100 tweets for each search term were explored through two different sentiment analysis tools which include Dr. Daniel Soper's Sentiment Analyzer Tool and Text2Data Application Programming Interface (API) Natural Language Processing (NLP) Analysis. Tweets were also analyzed using a word cloud generator to identify the most frequently used terms. Connecting words were eliminated from the final output.
Results: Negative sentiment was more prevalent than positive among the tweets for PMDD, with an overall sentiment analysis of an average of -24.3 per the Daniel Soper Sentiment Analyzer tool, suggesting a negative and serious tone. The most frequently appearing terms in these tweets were "month" (mentioned 17 times), "bad" (16), "love" (15), "feel" (14), "MAFS" (14), "support (14). Per Text2Data's API NLP analysis, the top 150 words had a negative sentiment of -0.59 with a magnitude of 1.69. Negative sentiment was more prevalent than positive among the tweets for PMS, with an overall sentiment analysis of an average of -15.2 per the Daniel Soper Sentiment Analyzer tool, suggesting a somewhat negative and serious tone. The most frequently appearing terms in these tweets were "new" (11), "price" (10), "oxford" (9), "feel" (14), "people" (9), "want" (9). Per Text2Data's API NLP analysis, the top 150 words had neutral sentiment of +0.15 with a magnitude of 1.59.
Conclusions: This study emphasizes a less negative sentiment associated with PMS compared to PMDD. It also highlights how more emotionally charged terms were used among tweets discussing PMDD compared to PMS. This may reflect public perception of the two conditions. Additionally, social media can be a way to gauge public interest and perception of medical topics.

Navigating OCD During Pregnancy: A Case Study and Therapeutic Insights

B. Arribas-Simon[1]*, O. Martin-Santiago[1], C. Alario-Ruiz[1], O. Segurado-Martin[1], M. J. Mateos-Sexmero[1], P. Pando-Fernandez[1], P. Martinez-Gimeno[1], B. Rodriguez-Rodriguez[1], N. Navarro-Barriga[1], P. Andres-Olivera[2], M. Calvo-Valcarcel[1], M. Andreo-Vidal[1] and F.-J. Gonzalez-Zapatero[1]

[1]Psychiatry, Hospital Clinico Universitario, Valladolid and [2]Psychiatry, CAUSA, Salamanca, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2387

Introduction: Obsessive-Compulsive Disorder (OCD) during pregnancy can worsen due to hormonal changes, psychological stress, and concerns about the baby's health. It presents unique challenges for diagnosis and treatment, balancing the mother's mental health with fetal safety. This case focuses on a woman who developed OCD in her third trimester, emphasizing the challenges in managing the condition.
Objectives:
- To describe the impact and progression of OCD during pregnancy.
- To assess the effectiveness of Cognitive Behavioral Therapy (CBT) and evaluate pharmacological options.
- To analyze the risks and benefits of managing OCD therapeutically in pregnant women.

Methods: A clinical case of a 32-year-old woman at 28 weeks of gestation, with newly diagnosed OCD, is presented. Symptoms began in the second trimester with intrusive thoughts about harming her baby and compulsive checking and cleaning behaviors. The patient was treated with CBT, and SSRIs were considered due to symptom severity. Follow-up continued through pregnancy until delivery.
Results: CBT led to a significant reduction in compulsions and improved management of obsessive thoughts. However, moderate symptoms persisted, leading to consideration of SSRIs, which were ultimately avoided due to concerns about side effects. The patient's delivery was uncomplicated, and continued CBT postpartum resulted in significant improvement.
Conclusions: This case illustrates the complexity of treating OCD during pregnancy, where hormonal changes and concerns about fetal health can exacerbate symptoms. Early intervention with CBT can be effective, and treatment decisions must carefully balance maternal and fetal well-being.

Unresolved Grief Resurfacing: managing delayed perinatal grief after subsequent birth

B. Arribas-Simon[1]*, O. Martin-Santiago[1], C. Alario-Ruiz[1], O. Segurado-Martin[1], M. J. Mateos-Sexmero[1], P. Pando-Fernandez[1], P. Martinez-Gimeno[1], B. Rodriguez-Rodriguez[1], N. Navarro-Barriga[1], P. Andres-Olivera[2], M. Calvo-Valcarcel[1] and M. Andreo-Vidal[1]

[1]Psychiatry, Hospital Clinico Universitario, Valladolid and [2]Psychiatry, CAUSA, Salamanca, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2388

Introduction: Delayed perinatal grief occurs when the grieving process for a lost baby is reactivated after the birth of a healthy child. This case presents a 39-year-old mother who, after losing her first baby at 36 weeks due to Patau syndrome, experienced delayed grief following the birth of a full-term baby two years later. Despite receiving one psychological consultation at the time of the loss, the lack of follow-up contributed to the reactivation of her grief postpartum, presenting with sadness and anxiety.
Objectives:
- To describe the process of delayed perinatal grief in a mother who lost a baby due to Patau syndrome.
- To evaluate the psychological impact of the lack of follow-up after the loss on the subsequent development of reactivated grief.
- To propose therapeutic interventions for the management of mothers experiencing delayed perinatal grief.

Methods: We present the case of a 39-year-old mother who lost a baby at 36 weeks of gestation due to Patau syndrome. Following the loss, she received a single psychological consultation with no further follow-up. Two years later, she gave birth to a healthy baby at 40 weeks, and six weeks after delivery, she was referred to psychiatry due to symptoms of profound sadness and anxiety, consistent with delayed perinatal grief. The patient was evaluated by the psychiatry team and began treatment with psychological intervention and pharmacological management when necessary.
Results: The psychiatric intervention led to a gradual improvement in symptoms of sadness and anxiety. The patient responded favorably to psychological treatment, incorporating cognitive-behavioral therapy techniques to manage grief. However, feelings of sadness persisted on dates related to the previous loss. Ongoing emotional support was crucial for the recovery process.
Conclusions: Delayed perinatal grief can reactivate after the birth of a new child, especially in cases where the original loss was not adequately followed up. Proper psychological support is essential to help mothers process their grief and prevent long-term emotional complications.

Attachment style, dyadic adjustment and gender roles attitudes of trans men and their partners in Turkey

M. Az[1]*, N. Direk[2] and B. E. Onur Aysevener[1]

[1]Department of Psychiatry, Private Office, İzmir and [2]Department of Psychiatry, Istanbul Medical Faculty, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2389

Introduction: It is being thought that the presence and quality of relationships to psychosocial adjustment and well-being is important. Little is known about the romantic relationships of individuals diagnosed with gender dysphoria. In the last thirty years, attachment theory has become one of the main references for adult romantic relationship studies. Despite the importance of attributed to the attachment system for overall psychological well-being and the quality of adult relationships, little research has focused on the attachment of individuals with gender dysphoria
Objectives: The present study focuses onresearching the attachment style, dyadic adjustment and gender roles attitudes in trans men and their partners.
Methods: 60 trans men and their 50 partners are included in this study."Experiences in Close Relationships-Revised", "Gender Roles Attitude Scale","Childhood Trauma Questionnaire", "Dyadic Adjustment Scale", "Beck Depression Inventory" and "Beck AnxietyInventory" are conducted to all attendees. Also, we used data form which is included sociodemographic and family features for all participants
Results: Prevalence of insecure attachment style was found high in both groups. Regarding the correlation between attachment style and dyadic adjustment, the dyadic adjustment points in trans men with secure attachment style were found significantly higher than trans men with insecure attachment style (Table 2,p:0,006). The average relationship duration of the participants with secure attachment style was higher than the participants with insecure attachment style. It was found that both groups have egalitarian attitudes in general terms. The egalitarian attitudes subscale points of gender role attitude scale in trans men were found significantly higher than the egalitarian attitudes subscale points of gender role attitude scale in partners (p:0,025)

*Fisher´s Exact test , n: number

Conclusions: The present study constitutes the first study in Turkey, which researching the attachment style, dyadic adjustment and gender roles attitudes in trans men and their partners, was analyzed. There are few studies in the literature investigating the gender roles

of trans men and their partners. In this study, insecure attachment rates were found to be high in both groups. Attachment styles and romantic relationships are fundamental components for psychosocial adjustment and well-being. For this reason, attachment styles should be made a part of the clinical evaluation of transgender people. It should be aimed to increase the sense of security of the person. Thus, clinical studies that should evaluate attachment styles as part of a standardized assessment and increase one's sense of security must be produced primarily. Therefore, individual and group psychotherapeutic work aimed at reshaping internal working models could directly or indirectly facilitate access to support groups, reinforce a more positive self-image.

Perinatal depression and resilience in Polish women during the war-inflation crisis

E. Barszcz[1]*, Z. Blaszczyk[2], A. Wyrzychowski[2], M. Plewka[1] and O. Gawlik-Kotelnicka[3]

[1]Faculty of Medicine, Medical University of Łódź; [2]Department of Clinical Psychology and Psychopathology, University of Łódź and [3]Department of Affective and Psychotic Disorders, Medical University of Łódź, Łódź, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2390

Introduction: The ongoing armed conflict in Ukraine has significantly destabilized Europe's geopolitical and economic situation, leading to a war-inflation crisis that may substantially affect the mental health of women during the perinatal period.
Objectives: Our primary objective was to investigate the prevalence of depressive symptoms and assess the role of resilience as a protective factor against anxiety and depression in Polish perinatal women during the war-inflation crisis. We analyzed the percentage of women experiencing anxiety related to childbirth and the war-economic crisis, as well as their relationship with perinatal depression. The study also aimed to identify risk factors for perinatal depression and various types of anxiety, including those related to childbirth, war, and the global situation.
Methods: 152 women participated in three online surveys – two conducted during pregnancy and one after childbirth. To evaluate mental well-being and the intensity of depressive and anxiety symptoms, we utilized the Edinburgh Postnatal Depression Scale (EPDS), Beck Depression Inventory (BDI-2), Labour Anxiety Questionnaire (LAQ), along with research team-developed questionnaires assessing anxiety related to the war (WAQ) and global situation (GSAQ). Resilience was assessed using the Resilience Measure Questionnaire (KOP-26).
Results: About 32.2% of perinatal women were diagnosed with depression based on the EPDS scale with a cutoff of ≥14. Nearly 70% scored 14 or higher on the LAQ scale, indicating a significant rise in labour-related anxiety. Additionally, 24.3% experienced high levels of anxiety due to the war, while 25% faced severe anxiety related to the global situation. The Kruskal-Wallis analysis, with resilience as the independent variable, revealed statistically significant differences in the distribution of depression ($F=28.302$; $df=2$; $p<0.001$) and global situation anxiety ($F=7.183$; $df=2$; $p<0.028$) variables between the groups. Post hoc analysis showed differences in the severity of depressive symptoms and global situation anxiety between the low and high resilience groups. The correlation heat map between psychometric scores at the start of the study is presented in Table 1.

	EPDS	LAQ	WAQ	GSAQ
EPDS				
LAQ	r=.53 p<.001			
WAQ	r=.10 p=.205	r=.21 p=.008		
GSAQ	r=.33 p<.001	r=.40 p<.001	r=.27 p=.001	

Conclusions: The prevalence of depressive disorders among women in the perinatal period may increase during crises caused by war and inflation, compared to periods of geopolitical and economic stability. This is a strong argument for improving the screening system for perinatal depression in Poland. A lower level of resilience during pregnancy may be a significant predictor of increased severity of depressive symptoms and higher levels of anxiety related to global situation among the perinatal population.

EPV2007

Correlation between postpartum depression and the number of births

P. Batchuluun[1]*, P. Sarantuya[1], B. Ganzorig[1] and T. Urtnasan[1]

[1]Medical department, Etugen University, Ulaanbaatar, Mongolia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2391

Introduction: Postpartum depression is a disorder that usually occurs six weeks after birth and can last for up to a year. If postpartum depression is not diagnosed and treated, there is a risk of suicide. Postpartum depression affects 18% of mothers worldwide.
Objectives: To investigate the relationship between the prevalence of postpartum depression, the number of births, and postpartum depression.
Methods: Women who gave birth will be surveyed using the Edinburgh test specially prepared by WHO for primary health care practitioners.
Results: 41% of the women who gave birth in the study had their first birth, 28% had their second birth, 21% had their third birth, and 10% had four or more births. 2% of women who gave birth had no postpartum depression, 15% had self-managed depression, and 83% had postpartum depression. 4% of women aged 20-24 have no postpartum depression, 20% have self-managed depression, and 76% have postpartum depression. 0% of women aged 25-29 had no postpartum depression, 14.3% had self-managed depression, and 85.7% had postpartum depression. 0% of women aged 30-34 have no postpartum depression, 10% have self-managed depression, and 90% have postpartum depression. 5% of women aged 35-39 have no postpartum depression, 15% have self-managed depression, and 80% have postpartum depression. Among women aged 40-44, 0% had no postpartum depression, 0% had self-managed depression, and 100% had postpartum depression. Among women aged 45-49,

0% had no postpartum depression, 50% had self-managed depression, and 50% had postpartum depression.
Among 41 women with their first child, 2.4% did not have postpartum depression, 17.1% had self-correcting depression, and 80.5% had postpartum depression. Among 28 women with second birth, 0% did not have postpartum depression, 17.9% had self-correcting depression, and 82.1% had postpartum depression. Among 22 women with their third child, 4.5% did not have postpartum depression, 4.5% had self-correcting depression, and 90.9% had postpartum depression. Of the 9 women with four or more births, 0% did not have postpartum depression, 22.2% had self-correcting depression, and 77.8% had postpartum depression.
Conclusions: Postpartum depression is very high among the women who gave birth in the study. According to the results of the study, there is a weak positive correlation between the number of births and the stress of the mother. Stress and insomnia are strongly related. Postpartum depression and insomnia are strongly correlated in Edinburgh. Therefore, there is a need to increase the diagnosis and treatment of postpartum depression.

EPV2008

Determining the level of insomnia in postpartum women, comparing their age and child's age

P. Batchuluun[1]*, P. Sarantuya[1], T. Urtnasan[1] and S. Surlegbaatar[2]
[1]Medical Department and [2]Basic medical department, Etugen University, Ulaanbaatar, Mongolia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2392

Introduction: Studies have shown that postpartum women are more affected by sleep disorders than women who have not given birth. Reasons for sleep disturbances include insufficient sleep time, poor sleep quality, and postpartum depression. Having a sleep disorder has a negative effect on the formation of a close relationship between mother and child.
Objectives: To determine the level of insomnia in postpartum women and study the correlation.
Methods: The study will be conducted by women who agreed to sleep disorder detection questionnaires specially prepared by the World Health Organization for doctors in primary health care institutions. The results of the research parameters were statistically processed using Microsoft Word 2016, Microsoft Excel 2016, and SPSS 26 programs.
Results: Of the 100 women who participated in the study, 25% had no insomnia, 48% had mild sleep disorders, 27% had sleep disturbances, 23% had no stress, 42% had moderate stress, and 35% had high stress. 16% of women aged 20-24 have no insomnia, 72% have mild sleep disorders, and 12% have sleep disorders. 23.8% of women aged 25-29 have no insomnia, 47.6% have mild sleep disorders, and 28.6% have sleep disorders. 25% of women aged 30-34 have no insomnia, 40% have mild sleep disorders, and 35% have sleep disorders. 45% of women aged 35-39 have no insomnia, 20% have mild sleep disorders, and 35% have sleep disorders. 0% of women aged 40-44 have no insomnia, 70% have mild sleep disorders, and 30% have sleep disorders. 50% of women aged 45-49 have no insomnia, 25% have mild sleep disorders, and 25% have sleep disorders. 35% of women with children aged 0-3 months have no insomnia, 35% have mild sleep disorders, and 30% have sleep disorders. 15% of women with children aged 4-6 months have no insomnia, 50% have mild sleep disorders, and 35% have sleep disorders. 35% of women with children aged 7-9 months have no insomnia, 45% have mild sleep disorders, and 20% have sleep disorders. 15% of women with children aged 10 months to 1 year have no insomnia, 50% have mild sleep disorders, and 35% have sleep disorders. 25% of women with 2-year-old children have no insomnia, 60% have mild sleep disorders, and 15% have sleep disturbances.
Conclusions: As mothers age, insomnia rates increase, stress levels decrease, and postpartum depression rates increase. As children age, sleep deprivation rates decrease, stress levels decrease, and postpartum depression rates decrease. As maternal fertility increases, insomnia rates decrease, stress levels decrease, and postpartum depression rates decrease. Insomnia, stress, and postpartum depression are also affected by living conditions.

EPV2009

Perceptions, Attitudes, and Challenges: Are Tunisian Medical Residents Prepared to Address Gender-Based Violence?

K. Mahfoudh[1], A. Hakiri[1], A. Jaoua[1], I. Besbes[1]*, A. Bouallagui[1], G. Amri[1] and R. Ghachem[1]
[1]Department B, Razi Hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2393

Introduction: Violence against women is a worldwide critical public health issue. Despite the introduction of legal frameworks in Tunisia, there remains a need for effective medical intervention and support. Tunisian Medical residents often serve as frontline responders to cases of violence, making their training and awareness crucial in addressing this public health concern.
Objectives: This study aimed to evaluate the knowledge and attitudes of medical residents in Tunisia concerning the management of gender based violence (GBV).
Methods: A cross-sectional survey was conducted using an online questionnaire distributed via social media, completed by 85 medical residents from various specialties. The study included residents from psychiatry, family medicine, medical, and surgical specialties, providing a comprehensive overview of perceptions across disciplines.
Results: We included 85 medical residents. The preliminary results showed that 73% were aged 26 to 29 years, and 75% were women. Specialties included 38.8% in psychiatry or child psychiatry, followed by family medicine (25.9%), medical specialties (24.7%), surgical specialties (3.5%), and medico-surgical (7.1%).
Only 21.2% of residents had received specific training on managing GBV during their studies (Courses, Masterclass, brief training). Regarding prevalence, only 12.9% of participants believed that over 80% of Tunisian women had experienced violence at least once in their lifetime.
In terms of violence types, 35.5% and 17.6% were respectively unaware of economic and political violence.
For 60% of residents, psychological violence was seen as the most prevalent in Tunisia, followed by physical violence (25.9%) and significantly underestimated sexual violence (8.2%). Additionally,

78.8% identified intimate partners as the primary perpetrators of violence. Regarding reporting procedures for suspected gender-based violence cases, 60% of residents believed local authorities should be alerted. However, 48.2% were unaware of Organic Law No. 58 of August 11, 2017, concerning the elimination of violence against women.
Regarding management, only 7.1% of residents felt confident in their ability to handle cases of GBV. The main obstacles identified were a lack of specific training (84.7%), absence of institutional support (67.1%), and lack of time (18.8%). The need for ongoing training in managing GBV was expressed by 64.7% of residents, highlighting the urgent need for improved awareness and skill enhancement in this area.
Conclusions: This study reveals significant gaps in the training and knowledge of medical residents in Tunisia regarding GBV. The lack of awareness of relevant legislation and resources, along with insecurity in case management, underscores the urgent need for targeted training and institutional support to improve medical responses to this critical issue.

Reaching the Unreachable: Effectiveness of Psycho-Education for Improving Mental Health Awareness in Women with Gynecological/Obstetrical Issues in A Low Middle-Income Country

S. Q. Bokhari[1], A. Manzoor[2]*, A. Butt[1], S. Ijaz[2], R. Majeed[2], A. Waheed[1], W. Batul[2] and A. Saleem[2]

[1]Psychiatry, Services Institute of Medical Sciences and [2]Psychology, Services Hospital Lahore, Lahore, Pakistan
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2394

Introduction: This research addresses the significant mental health challenges faced by women in Pakistan, where gynecological/obstetrical issues are prevalent, and mental health awareness is often lacking due to cultural stigmatization and misconceptions. Women with conditions such as infertility, and breast and ovarian cancer are at higher risk of psychiatric disorders, and there is a clear correlation between infertility and psychological comorbidity. Cultural beliefs and regional variations further complicate the perception and understanding of mental health in Pakistan.
Objectives: The primary objective of this research is to dispel myths and misconceptions surrounding mental health by providing group psychoeducation on major psychiatric illnesses. The goal is to raise awareness and promote psychiatric and psychological help-seeking behavior among women with gynecological issues.
Methods: This study employs a quantitative approach with a quasi-experimental design. A sample of 55 married female participants from the Gynecology Department of Services Hospital Lahore, underwent pre- and post- psychoeducation assessments. Only married females seeking treatment for gynecological conditions were included, while those already diagnosed or seeking treatment for mental disorders before the onset of gynecological issues were excluded. To assess the participants' knowledge and beliefs regarding mental illnesses, a self-developed Women Mental Health Checklist was used for pre-and post-assessment. A panel of mental health experts validated the content for the checklist. Psychoeducation material was developed based on established resources, and a panel of experts examined its content validity. A pre-psychoeducation assessment was conducted, followed by psychoeducation sessions that included information about mental disorders associated with gynecological issues. Post-assessment was conducted at a one-month follow-up. SPSS 21 was used to analyze the data.
Results: The repeated measure t-test analysis revealed a statistically significant difference in post-assessment ($t(49) = 14.6$, $p = 0.00$) which indicated a strong impact of psychoeducation on post-assessment.
Conclusions: These findings highlight the importance of psychoeducation in promoting help-seeking behavior. However, it is important to understand the study limitations and that future research should explore psychoeducation's role on a broader level. This research aims to bridge the gap in mental health awareness and help-seeking behavior among women in Pakistan facing gynecological and obstetrical issues, ultimately contributing to improved mental well-being and overall quality of life.

Depression in military wives: the particularities of an understudied population

S. Boughdadi[1]* and M. A. Laffinti[2]

[1]Psychiatry, Mohammed VI university hospital and [2]Psychiatry, Avicenne military hospital, Marrakech, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2395

Introduction: Military spouses often experience separation from their husbands and the risks associated with their deployment in difficult environments. Multiple studies have focused on depression in service members, but little has been done to understand how demographic and military-specific factors affect their wives.
Objectives: The goal of our study is to describe the demographic and military characteristics specific to women with a depressive disorder diagnosis, and are or were married to service men. We also aim to identify possible correlations between the beginning and evolution of the spousal depression and those characteristics.
Methods: This was a retrospective descriptive study. Data was obtained from the medical files of military spouses followed at the psychiatry department of the military hospital in Marrakech between May 2022 and August 2023. Demographic and military-specific information unavailable in the files was collected through phone calls. Inclusion criteria were: a DSM-5 depressive disorder diagnosis, presence at follow-ups, being or having been married to a service man, an available functioning phone number. The statistical analysis was done on the software tool Jamovi® version 2.3.28.
Results: All of the 25 women who were included in our study were diagnosed with major depressive disorder (MDD). Demographic factors related to MDD were noted in most spouses: 64% had a low educational level, 84% were housewives. Concerning the military factors related to service men: we observed that in the 24% of cases where the husband was deployed or lived apart from his family, there was either no or little improvement of depressive symptoms under treatment for the wife. Only 4% of service men had been diagnosed with a psychiatric disorder (MDD) at the time of our study. 44% of our patients reported conflicts with their husbands, out of these men 54% were still active in military forces. 54% of the

patients with marital conflicts reported little to no improvement of their symptoms. 20% of women were victims of domestic violence.
Conclusions: Our findings were able to show a high percentage of demographic risk factors for MDD in the studied population. They also imply a correlation between the husband's deployment and the higher family responsibility reported by the wife in these cases, and a lack of improvement of the depressive symptoms under treatment. Although previous studies reported a correlation between the husband's history of psychiatric disorder and the wife's depression, we didn't reach the same conclusion, this could be limited by the size of our study sample, as well as possibly underdiagnosed disorders in service men. These findings suggest the need for a specific approach for this population, as well as additional support services to help prevent and improve the treatment of depressive disorders in military wives.

EPV2015

The burden of birth control: a narrative review on the mood-related side effects of hormonal contraception

B. P. Brás[1], J. F. Silva[1]*, F. Caldas[1] and H. S. Almeida[1]

[1]Unidade Local de Saúde do Santo António, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2396

Introduction: Hormonal contraception (HC) is widely used by females worldwide. Sex hormones – oestrogen and progesterone – affect the central nervous system's function, structure, and neurotransmission, modulating emotional and behavioural responses. The use of HC, by introducing exogenous hormones and modulating the internal production of sex hormones, may be associated with mood changes and depressive symptoms. These symptoms are commonly reported by females taking HC and are one of the most frequent reasons for its discontinuation.
Objectives: To explore the relationship between HC and depressive symptoms in females of reproductive age, with a focus on clinical implications.
Methods: A narrative literature review was conducted using the *PubMed*® database with the search query: "(Hormonal Contraception) AND ((Mood) OR (depression))". Studies published in the last 20 years were included.
Results: Recent studies have shown an association between HC use and depression. The relationship between HC and mood changes is complex and influenced by various factors, including the type of HC, dosage, patients' psychiatric history, and psychosocial factors. The link between HC and depression seems to be related to the dosage and type of progestogen. Also, the use of progestins with androgenic activity, such as levonorgestrel, may carry a higher risk of deleterious mood changes. Adolescent females, those with a personal or family history of mood disorders, females with premenstrual dysphoric disorder or premenstrual syndrome, and those who have experienced adverse mood effects with previous use of HC are more predisposed to developing depressive symptoms related to HC. HC is also associated with sexual dysfunction and an increased risk of suicide and suicide attempt. On the other hand, continuous use of HC may provide relief from depressive symptoms in females with premenstrual dysphoric disorder by stabilising fluctuations in hormone levels. Limited evidence suggests that HC use among females with depressive or bipolar disorders is not associated with a worse clinical course compared to the use of non-hormonal methods.
Conclusions: The mechanism underlying how HC influences mood remains poorly understood. In clinical practice, the effects of HC on mood seem to be most relevant in selected subsets of females. Most females using HC demonstrate no effect or a beneficial effect on mood, with a low incidence of adverse effects. The risk of adverse mood effects should not preclude the prescription of HC. Mental health risk factors, as well as any newly present or ongoing mental health symptoms, should be considered when initiating and reviewing HC in the management and treatment of female patients.

EPV2016

The self-image of a mother in women with experience of miscarriage

A. M. Bukinich[1]* and A. M. Konovalova[1,2]

[1]Faculty of Psychology, Lomonosov Moscow State University and [2]Department of Pedagogy and Medical Psychology, Sechenov University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2397

Introduction: In the modern world, the problem of infertility is becoming more significant. In particular, the number of women with experience of miscarriage is increasing. Problems with pregnancy, frustration of the desire to become a mother influence the formation of a woman's motherhood and self-image as a mother, which can lead to intrapersonal problems of a woman and to a distortion of care practices and child-parent relations in relation to the future child.
Objectives: To study the features of the self-image as a mother in women with experience of miscarriage.
Methods: A pilot study was conducted. Two methods were used in this study: "Unfinished sentences" (Sachs-Levy, mod. A.G. Dolgikh, 2018), method of semantic differential (spaces proposed by A.G. Dolgikh, 2018).
The study sample consists of 3 groups: 30 women with experience of miscarriage for medical reasons aged 25 to 35 years; 30 women aged 25 to 30 years who have no experience of pregnancy; 30 women raising children under the age of five.
Results: The results of attitudes peculiarities psychodiagnostic study towards motherhood in women using the "Unfinished Sentences" technique demonstrate that generally more expressed positive attitude towards motherhood in general and attitude towards themselves as a future mother for the group of women with experience of miscarriage compared to other groups of women.
The self-image as a mother using the semantic differential method showed that the semantic universals of this image for both the entire sample and for a group of women with miscarriage experience are adjectives "reliability", "caring", "tenderness".
The self-image as a mother semantic profiles comparative analysis revealed significant differences in the indicators of this image among the study groups. Women with the experience of miscarriage characterized themselves as more warm, more soft, more caring and more harmonious ($p<0.05$) compared with women from other groups. They also perceive the image of themselves as a future

mother as lighter, more reliable, more anxious and more affectionate than women without experience of pregnancy and motherhood ($p<0.05$).
Conclusions: Women experienced miscarriage are characterized by more idealized ideas about motherhood probably due to problems with pregnancy and frustration of the desire to become a mother.

Navigating the Hormonal Labyrinth: Understanding the Impact of Menstrual Cycle Dynamics on ADHD Symptoms

M. Cameira[1]*, P. Abreu[1], M. Pereira[1], M. Soares[1], I. Vidó[1], I. Lopes[2] and F. Ramalheira[3]

[1]Hospital Júlio de Matos - ULS São José, Lisboa; [2]Hospital do Barreiro - ULS Arco Ribeirinho, Barreiro and [3]Hospital Júlio de Matos - ULS São José, Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2398

Introduction: Attention-deficit/hyperactivity disorder (ADHD) is a prevalent neurodevelopmental disorder characterized by significant sex differences in symptomatology, prevalence rates, and associated developmental challenges. Research indicates that these disparities are not merely superficial but are rooted in complex biological, psychological, and social factors. Despite the growing recognition of these differences, the underlying etiological mechanisms remain inadequately explored.
Objectives: This study aims to propose a framework addressing hormonal fluctuations in females with ADHD, emphasizing the cyclical nature of ovarian hormones and their impact on executive functioning and behavioral regulation. We hypothesize that hormonal changes exacerbate ADHD symptoms during specific menstrual cycle phases, ultimately enhancing our understanding of sex differences in ADHD and informing future research and treatment strategies.
Methods: We conducted a literature review to synthesize studies on estrogen levels, executive function, and ADHD symptoms. Our focus was on the role of estradiol (E2) in cognitive functions, particularly in the prefrontal cortex, and the effects of cyclical hormonal changes on behavior and cognition in females with ADHD during adolescence and the menstrual cycle.
Results: Evidence suggests that estrogen is crucial for cognitive control, with fluctuations in hormone levels impacting mental performance in women. Notably, ADHD symptoms are more likely to manifest during periods of rapid estrogen decline, particularly within the menstrual cycle. These hormonal decreases correlate with reduced executive function and self-regulation at two critical phases: increased risk-taking behaviors during the mid-cycle (periovulatory phase) and heightened avoidance and negative emotions in the perimenstrual phase. Research indicates that drops in estradiol (E2) can lead to significant increases in inattention and hyperactivity-impulsivity symptoms, especially in young adult women with high impulsivity traits. Additionally, the organizational effects of puberty may interact with hormonal changes, particularly in females with advanced limbic system development, increasing the risk of emotional dysregulation and impulsive behavior. Changes in the limbic system, essential for emotional processing and memory, further underscore the importance of considering individual sensitivity to hormonal variations.
Conclusions: This framework emphasizes the importance of hormonal influences in diagnosing and treating ADHD in females. By recognizing the relationship between hormonal fluctuations and ADHD symptoms, particularly via the Multiple Hormone Sensitivity Theory, we advocate for a tailored treatment approach. Future research should focus on longitudinal studies to deepen understanding and develop targeted interventions, thereby improving ADHD management and quality of life for females.

EPV2019

Prevalence and predictors of generalized anxiety disorder in women during the postpartum period

S. Cipolla[1]*, P. Catapano[1], C. Toni[1], M. Di Vincenzo[1], C. Brandi[1], M. Luciano[1], G. Sampogna[1] and A. Fiorillo[1]

[1]Department of Psychiatry, University of Campania "L. Vanvitelli", Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2399

Introduction: Up to 10% of women experience severe anxiety symptoms during pregnancy and the postpartum period, which are often underdiagnosed and undertreated, leading to negative outcomes for both mother and child.
Objectives: This observational study aims to assess: 1) the prevalence of Generalized Anxiety Disorder (GAD) in the postpartum period, and 2) identify its predictors.
Methods: All women attending the Gynecology and Obstetrics Department at "L. Vanvitelli" University Hospital were invited to participate in the study. Women who provided consent were assessed within three days after delivery using a specifically designed form for sociodemographic and clinical data collection, the Labor and Delivery Questionnaire (LDQ) for obstetric and gynecological information, and the Italian versions of the following assessment tools: Edinburgh Postnatal Depression Scale (EPDS) and the Generalized Anxiety Disorder 7-item scale (GAD-7). A GAD-7 score of ≥10 was used as the cutoff for moderate to severe Generalized Anxiety Disorder.
Results: A sample of 110 women with a mean age of 30.74 (±5.67) years, predominantly Caucasian (91.8%), was recruited. Of these, 18.8% (n = 20) had GAD-7 scores indicating a diagnosis of Generalized Anxiety Disorder. Compared to women without GAD, those with GAD were significantly more likely to be unemployed or face difficulty finding work ($p < 0.05$), have a family history of anxiety disorders ($p < 0.05$), have other children ($p < 0.05$), experience conflicts with their parents ($p < 0.001$), and score higher on the EPDS ($p < 0.001$). Logistic regression analysis showed a higher likelihood of having GAD among younger women (OR: – 0.029; $p < 0.05$), those with a positive family history of anxiety disorders (OR: 0.63; $p < 0.05$), and those with higher EPDS scores (OR: 0.044; $p < 0.001$).
Conclusions: The study highlights that age, employment status, and a family history of anxiety disorders may be significant predictors of GAD in peripartum period. Further studies with larger samples are necessary to confirm these findings; however, collaboration between psychiatrists, gynecologists, and obstetricians is recommended to identify women at risk of developing GAD early

on, facilitating timely and appropriate diagnosis and treatment, and reducing the risks to the mental health of both mother and child.

EPV2020

A Systematic Review of Interventions to Promoting Psychosocial Well-Being and Empowerment of Women victim of gender violence

M. Cruz[1]* and H. Pereira[1]

[1]Psychology, UBI, Covilhã, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2400

Introduction: Gender-based violence (GBV), defined as violence directed at an individual based on their gender, encompasses a range of harmful behaviors, including physical, psychological, and sexual abuse, often perpetrated by intimate partners. In this context psychosocial well-being is often severely compromised (Choden et al., 2022), and is essential interventions that can help women rebuild their sense of self, foster resilience, and improve overall mental health. Empowerment, in the context of GBV, involves not only psychological, emotional and cognitive processes in which the person is able to think positively about themselves and their abilities and master individual and social aspects of their life, but also social and relational processes, since violence occurs in relationships with others (Amirroud et al., 2022), and therefore, empowerment allows women to assert their rights, build confidence, and engage actively in social and economic activities (Malhotra & Schuler, 2005).
Objectives: This systematic literature review (SLR), based on the PRISMA 2020 guidelines, aims to provide an updated overview of interventions designed to promote psychosocial well-being and/or empowerment (PWE) among women who are victims of gender-based violence, with the goal of informing future intervention projects.
Methods: Data collection was conducted through the SCOPUS and Web of Science databases, focusing on studies published between 2018 and January 15, 2024, in English. The inclusion and exclusion criteria were based on the PICO framework: (P) women affected by gender-based violence, (I) interventions to enhance PWE, (C) comparison between initial and final intervention phases, and (O) assessed outcomes related to PWE. thirteen studies were included.
Results: The primary intervention components were counseling, health education, mindfulness and relaxation practices and expressive therapies. Experimental studies reported significant improvements in mood, reductions in depressive symptoms, anxiety, and stress levels. Empowerment components were less frequently addressed, they also showed positive outcomes, including increases in self-esteem and self-efficacy. Overall, EG demonstrated superior results across nearly all assessed variables compared to CG. The most effective interventions were those incorporating mindfulness and relaxation, counseling techniques, and expressive strategies. Key limitations of the included studies involved methodological quality, sample size, and representativeness, as well as the potential for response bias.
Conclusions: This SLR offers an original contribution by advocating for evidence-based practice and providing valuable insights for healthcare professionals, policymakers, and researchers engaged in the integrative health care of women impacted by gender-based violence.

EPV2021

The importance of close follow-up in the postpartum period. Manic episode after childbirth in a patient with bipolar disorder. A case report

P. Del Sol[1]*, A. Izquierdo[1], R. Fernández[2], M. García Moreno[1], B. Tejero[1] and M. Diaz de Neira[1]

[1]Hospital Puerta de Hierro, Madrid and [2]Hospital Infanta Cristina, Parla, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2401

Introduction: Bipolar disorder is a serious mental disorder that requires follow-up and pharmacological treatment for the patient to function properly. It is known that stressful events can generate decompensation in these patients. Pregnancy and postpartum are moments of high vulnerability for women with bipolar disorder, being essential their immediate follow-up and treatment in case of decompensation. In these cases it is essential to ensure an adequate bond with the baby.
Objectives: To present a case of a patient with a diagnosis of bipolar disorder, who in both pregnancies has a manic episode after delivery.
Methods: Case presentation and literature review.
Results: The patient is a 37-year-old woman who comes to the emergency department for manic symptoms. Her psychiatric history includes a diagnosis of bipolar disorder in 2022 after an admission for a manic episode two months after the birth of her first child. She is currently under active follow-up by psychiatry and a perinatal group intervention program. She lives with her husband and two-year-old son. During pregnancy she received lithium without decompensation. When she came to the emergency room, she was on lithium 400 mg every 8 hours and olanzapine 10 mg prescribed 4 weeks ago by her psychiatrist, who had noticed the decompensation, which she stopped a week ago on her own.
In the examination, he shows an accelerated speech with verbose and uninhibited contact. She says that 5 days ago she began to present the idea that she was a threat to her children, with increasing anguish. She began with a decrease in the hours of sleep and suddenly refers that the idea of having to travel to Bali appeared, since "it is her favorite place in the world". Without considering the price and without informing her husband, she left her home and arrived in Bali, where she incurred high expenses. When she arrived there, she reported meeting a friend who helped her to return to her country and informed her family.
Conclusions: Pregnancy and postpartum are moments of high vulnerability and emotional intensity for any woman. It is known that for patients with mental disorders, this vital moment may involve a risk of decompensation of their mental disorder, compromising their health, and may have negative repercussions on the bonding with their baby and the style of attachment they build with it. It is essential to train professionals in pharmacological treatments allowed during pregnancy, postpartum and lactation, as well as to facilitate close follow-up programs for these patients in order to reduce the risk of decompensation as much as possible.

EPV2022

Peripartum administration of esketamine: a way to prevent postpartum depression?

M. Del Valle Martín[1]*, R. De Hita Santillana[2], M. L. Costa Ferreira da Silva[2] and C. Mouriño Sánchez[1]

[1]Psychiatry, Hospital Universitario Severo Ochoa and [2]Psychiatry, Hospital Universitario José Germain, Leganes, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2402

Introduction: Postpartum depression (PPD) is one of the most prevalent mental disorders, with the potential to precipitate complications in childbearing. The estimated prevalence of PPD ranges from 7% to 13% in developed countries and exceeds 20% in underdeveloped countries. Near 20% of women presenting with symptoms of PPD experience suicidal ideation. Prompt detection and management of this patient group is of particular importance. The use of esketamine has shown to reduce the incidence of PPD in previous studies, but its widespread use has been hampered by its side effects and the need for hospitalisation.
Objectives: We aimed to review the available literature on the efficacy and safety of peripartum esketamine use.
Methods: A narrative literature review was carried out in the PubMed, Cochrane and Embase databases, selecting only the articles published in the last 10 years, using the following keywords: pregnancy, esketamine, postpartum depression.
Results: After childbirth 6 week is a high-risk period for PPD, specially the first week. The incidence of PPD is higher in C/S than in normal births. Compared with pregnant women who underwent C/S without the use of esketamine, those who used esketamine in the perioperative period had a 48% reduced risk of developing postpartum depression and a 1.43 point reduction in the Edinburgh Postnatal Depression Scale (EPDS). The optimal dose of esketamine for PPD is unknown; most studies consider high doses above 0.5 mg/kg and low doses inferior. These favourable effects were observed at both short and long-term follow-up and in low and high doses. Compared to intranasal esketamine, intravenous esketamine has a higher bioavailability and is more convenient to dose control. Route of administration and dose of esketamine did not affect the prophylactic effect of esketamine on PPD, but they differ in their adverse effect profiles. The incidence of immediate adverse reactions to intraoperative pumped esketamine is extremely high, particularly during the intraoperative period when more patients receiving esketamine developed neurological or psychiatric symptoms (97.7%). Other common immediate intraoperative maternal adverse events were nausea and vomiting, dizziness and hallucinations, but had no significant effect on postoperative adverse. Adverse reactions to esketamine are usually transient and are more common when single intravenous injection is used (continuous infusion is preferable), with faster and higher doses.
Conclusions: PPD has potentially serious consequences for mothers and their children, and there is an urgent need for safe, effective and accessible treatments. As the use of esketamine has progressed, concerns have arisen about adverse effects, particularly long-term efficacy, addiction and suicide risk. Current evidence suggests that although it may have a good preventive effect, a long research trail is needed to prove and confirm the efficacy and safety of esketamine.

EPV2023

Mothers of infants and toddlers: basic markers of psychological well-being and their correlation with optimism

E. V. Deshchenko[1]*, E. V. Polonetskaya[1] and E. I. Pervichko[1]

[1]Lomonosov Moscow State University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2403

Introduction: Psychological well-being of women during the first years of their maternity is essential for both them and their families. However in the same time mothers of infants and toddlers face a lot of challenges in fulfilling their role so their well-being should be closely monitored.
Objectives: The research aimed to study the basic markers of the psychological well-being of mothers with little children, such as depressive tendencies, anxiety, optimism and aggression.
Methods: To measure depressive tendencies the Beck Depression Inventory (as adapted by N.V. Tarabrina) was used. Anxiety levels were assessed using the State-Trait Anxiety Inventory by C. Spielberger (as adapted by Yu.L. Khanin). Life Orientation Test (as adapted by T.O. Gordeeva *et al*) was used to assess respondents' optimism levels and Bass-Perry Aggression Questionnaire was used to assess the aggression factors (as adapted by S.N. Enikolopov and Tsybul'skii N.P.). Spearman's rank correlation coefficient was used for data analysis. The research was conducted from September 2023 to August 2024. The sample consisted of 253 mothers and 31 fathers (as the control group) with children of three years old and less.
Results: Our sample demonstrated comparably high levels of anxiety and average levels the aggression factors and optimism for women as set out in the table below (mean scores shown) (table 1).
Table 1. Comparative analysis of psychological well-being in women and men.

	State anxiety	*Trait anxiety*	*Anger*	*Hostility*	*Physical aggression*	*Optimism*
Women	48± 24.53%	49± 23.48%	20± 26.97%	21± 31.53%	20± 32.22%	17± 32.70%
Men	41± 30.58%	42± 27.12%	17± 26.97%	19± 31.53%	22± 32.22%	17± 32.70%

Results of 73 women (29%) show expressive depressive tendencies and results of 67 women (27%) show severe depression tendencies (using the cut-off points proposed by Andriushchenko A.V. and his colleagues (Andriushchenko *et al.* Zh Nev rol Psikhiatr Im S S Korsakova 2003; 103(5) 11–18), being 12 points for the expressed depressive tendencies and 20 points for the severe depressive tendencies). Only results of 2 men from the control group (7%) show expressive depressive tendencies and results of 3 men (10%) show severe depression tendencies. Negative correlations of the optimism levels of mothers to the depressive tendencies (r=-0.342, p=0.003) and hostility (r=-0.259, p=0.027) levels were discovered.
Conclusions: Thus, the results of our study indicate that the depression and anxiety levels of mothers of infants and toddlers are comparably high, while the aggression and optimism indicators stay on average levels. The study also shows negative correlations of the optimism level of mothers with the depression tendencies and the hostility level.

EPV2024

Etiology of eating disorders: creation of a new model using standardised nursing language

R. V. Díaz[1]*, M. D. P. Montero López[2], B. Gómez Esteban[3] and S. Montserrat García Font[4]

[1]Community Mental Health Center San Carlos (El Escorial), Hospital El Escorial, San Lorenzo del Escorial; [2]BIOLOGICAL SCIENCES, La Universidad Autónoma de Madrid; [3]CSM EL ESCORIAL and [4]CSM RIVAS-VACIAMADRID, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2404

Introduction: Eating disorders (EDS) have become in recent decades an important focus of interest for basic and clinical research due to the increase in prevalence and incidence observed and, therefore, the evident need to prevent and provide a therapeutic response to situations that affect important sectors of the population. Normal eating behavior and its pathological deviations can only be understood if they are studied under the biopsychosocial approach, since, attending only to the eating aspect, we are ignoring a series of determining factors in the development of this process. Within these factors, important changes have been observed in recent times in relation to the demographic profile, going from being a disease studied predominantly in women, to extending to men and non-binary people or with other sexual and/or gender options.
Objectives: The aim of this study is to propose a new model for the representation of Eating Disorders (EDS) using nursing care languages, which allows us to approach the description of people affected by this pathology and their environment, implementing the perspective of gender, and that facilitates the realization of better diagnoses.
Methods: A systematic bibliographic review on EDS was carried out using databases from the different areas involved. The information was ordered and summarized in tables and concept maps. Next, a comparison was made between the traditional EDS model, described using medical language, and the new model proposed by the nursing discipline, where all the information previously obtained is codified in languages proposed by the North American Nursing Diagnosis Association (NANDA) and the Nursing Development Foundation (FUDEN) in the manual on Standardized Nursing Knowledge (CENES).
Results: The results obtained indicate that, after coding and organizing the existing information through nursing languages, the diagnostic view can be broadened by incorporating a greater number of variables to carry out a more complete approach to EDs. This would make it possible to propose a new conceptual model of these disorders, addressing them not only as a disease, but as a product of the failure of a healthy individualization that leads people who suffer from them to not carry out their self-care adequately, exerting on their person a act of anti-self care.
Conclusions: The energetic representation of care, characteristic of nursing, could be useful in care practice, so that the description of the phenomenology of care for each individual could be established, and it would also provide a series of action algorithms that would favor its implementation for health prevention.

EPV2025

Challenges of alcohol use during pregnancy: maternal and fetal implications

M. M. Figueiredo[1]*, A. Falcão[2], V. Nogueira[3] and J. Teixeira[3]

[1]Centro Hospitalar Setúbal, ULS Arrábida, Setúbal; [2]Centro Hospitalar Psiquiátrico de Lisboa, Lisboa, Lisboa, Portugal and [3]Serviço de Alcoologia e Novas Dependências, Centro Hospitalar Psiquiátrico de Lisboa, Lisboa, Lisboa, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2405

Introduction: In recent years, there has been an increase in alcohol consumption among women. Given that a significant percentage (1 in 3) of pregnancies are unplanned, fetal exposure to alcohol is inevitable in some.
Objectives: The main objective of this work is to present a review of the current state of the art regarding the impact of alcohol use during pregnancy.
Methods: Evidence-based review, using a search on PubMed and selection of the most relevant studies on this topic, published in the last decade.
Results: Although the international consensus recommends total abstinence from alcohol consumption during pregnancy, its global prevalence is 9,8%, with the highest percentage found in Europe (25,2%), which constitutes an important public health problem. Contrary to expectations, a recent study highlights that women who continue to consume alcohol during pregnancy were more likely to be older and have a higher socioeconomic status and educational level. Alcohol consumption during pregnancy is associated with high rates of maternal and child morbidity and mortality, with serious social, personal and family consequences. Prenatal alcohol exposure is the leading preventable cause of birth defects and neurodevelopmental disorders. The psychopharmacological treatment of alcohol use disorder during pregnancy is a challenge, given the limited evidence.
Conclusions: The main guidelines recommend total alcohol abstinence as no safe amount to consume has been identified. Stopping alcohol consumption during pregnancy is the only effective way to eliminate the risk of complications associated with this substance. A focus on early prevention and identification is essential, as well as, when necessary, referral for specialized treatment.

EPV2026

What predicts willingness to engage in consensual non-monogamous relationships? A study among Italian emerging adults

L. Ghidetti[1]*, S. Moscatelli[1], Y. Koc[2] and S. Ciaffoni[1]

[1]Psychology, University of Bologna, Bologna, Italy and [2]Behavioural and Social Sciences, University of Groningen, Groningen, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2406

Introduction: Consensual non-monogamous relationships (CNM) are characterized by a diversity of approaches to intimate

relationships, diverging from the traditional monogamous model and exploring new possibilities. CNM relationships include forms such as polyamory, open relationships, and swinging. There are no official and systematic epidemiological data on CNM relationships in Italy; however, these relationships have recently gained more visibility due to social media, support groups, and open discussions about relationship diversity that are slowly emerging in a country whose culture is traditionally influenced by Catholicism and conservative social norms.
Objectives: Most research focuses on discrimination against individuals involved in CNM, while the factors underlying people's engagement in such relationships are overlooked. This study aims to investigate predictors of willingness to engage and actual engagement in CNM among Italian emerging adults. Specifically, based on the Theory of Planned Behavior (Ajzen, 1991), we examined the role of perceived social norms and perceived behavioral control, as well as other predictors already tested in previous research.
Methods: Participants completed an online questionnaire examining factors such as gender, sexual orientation, willingness to engage in CNM relationships (WECNM; Moors et al., 2015; 6 items), avoidant and anxious attachment style (ECR-S; Wei et al., 2007; 12 items), erotophilia (ATP; Johnson et al., 2015; 5 items), social norms (PSN; custom scale, 4 items), perceived behavioral control in CNM relationships (PBC; custom scale, 2 items). Data were analyzed using SPSS, applying multiple linear regression.
Results: The sample consists of 667 emerging adults (M_{age} = 23.29; age range: 18 – 30) with diverse sexual orientations and gender identities. Of these, 535 participants are involved in monogamous relationships, 65 in polyamorous, and 67 in open relationships. In line with our hypotheses, results show that social norms, perceived behavioral control, non-heterosexual orientation, and cisgender male identity are significant predictors of both the willingness to engage in and the commitment to consensual non-monogamous relationships. Avoidant attachment style, as well as erotophilia, predict the predisposition but not the actual commitment to CNM.
Conclusions: The results contribute to a deeper understanding of CNM relationships in the Italian context by identifying some individual and social factors related to openness and involvement in CNM relationships. This provides preliminary evidence of the utility of the Theory of Planned Behavior in understanding this type of relationship. Moreover, the significant number of individuals involved or interested underscores the importance of considering relationship diversity in future research and social policies, with the aim of promoting greater acceptance and inclusion.

Nutrition and functional compounds of traditional foods in migrant women with schizophrenia: A systematic review

A. González- Rodríguez[1]*, M. Natividad[2], R. Penadés[3], N. Bagué[2], A. Balagué[2], J. P. Paolini San Miguel[2], E. Izquierdo[2], M. Salvador[2], A. Vallet[2], A. Pérez[2] and J. A. Monreal[1]

[1]Mental Health, Mutua Terrassa University Hospital. University of Barcelona. CIBERSAM; [2]Mental Health, Mutua Terrassa University Hospital. University of Barcelona, Terrassa and [3]Psychiatry and Psychology, Barcelona Clinic Schizophrenia Unit (BCSU). Hospital Clinic of Barcelona. IDIBAPS- CIBERSAM., Barcelona, Spain

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2407

Introduction: Several studies have reported that high fruit and vegetable consumption is associated with increased life expectancy. In migrant populations, lifestyle habits are modified in the process of acculturation.
Objectives: Our aim was to review the diversity/functional compounds of food groups in Latin American, African, Asian and European cultures. In a second step, we aimed to review the dietary patterns for migrant women with schizophrenia.
Methods: A two-stage systematic review was conducted using the PubMed and ClinicalTrials.gov databases (2004-2024). The first part included studies reporting information on food and nutrients in adult populations from the nationalities with the highest prevalence of women with schizophrenia attending the Mútua Terrassa Functional Unit for Women with Schizophrenia (Dominican Republic, Venezuela, Ecuador, Morocco, Senegal, Romania and Pakistan). In a second part papers focused on food consumption among migrant women with schizophrenia.
Results: A total of 87 studies were included from a total of 21,306 records screened. First part: (1) Latin America (n=32). Outcomes: food choice trajectories for dietary acculturation, barriers and facilitators for fruit and vegetable consumption (antioxidant effects of polyphenols), fruit/tubers/legumes traditionally consumed. (2) Africa (n=25). Regular consumption of oils, changes in medications during the holy month of Ramadan, anti-inflammatory effects of species. (3) Europe (n=17). Antioxidant properties of phenolics in mushrooms, and polyphenols in berries. (4) Asia (n=13). Women more vegetables, fruit and fish. Second part: Dietary intake of vitamin C, niacin, and folate reduced in schizophrenia. Few studies in women with schizophrenia.
Conclusions: Nutritional intervention programmes for migrant women with schizophrenia should pay attention to biocultural heritage and traditional antioxidant/anti-inflammatory foods.

Unveiling the Mary Wollstonecraft's Self: A Psychoanalytic Reading of "Mary: A Fiction"

I. Hacisalihoglu Aydin[1]* and M. Tomsen[1]

[1]Mood Disorders Research Program, Depression Center Department of Psychiatry and Behavioral Sciences, University of Louisville School of Medicine, Louisville, United States

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2408

Introduction: We can learn a great deal about the power of writing to vanquish the worst forms of psychological trauma by looking closely at Mary Wollstonecraft in the second half of the eighteenth century. Mary Wollstonecraft wrote a Vindication of the Rights of Woman (1792), which is considered by many to be the most important work in feminist thought. Her literary impact went far beyond this foundational work. With the publication of Wollstonecraft's first semi-fictional autobiography, *Mary: A Fiction* (1787), we can see how her personal life did not follow conventional rules either. Her dedication to individual freedom and social progress was not limited to women. Her own personal life history

significantly shaped her influential stance on women's equality. She was a pioneering advocate for women's equal treatment to men.
Objectives: This presentation aims to explore how 'the author,' Mary, coped with her own life traumas by going beyond the era of her time. By examining her real-life reflections of her fictional characteristics through the lens of psychoanalytic formulations, we seek to gain deeper insights into her inner self and coping mechanisms.
Methods: We critically analyzed *Mary: A Fiction* from a psychoanalytical and literary perspective. By connecting each real-life trauma with its fictional retelling, we uncover Mary's liberation.
Results: Self-analysis refers to Freud's exploration and examination of his own psyche, emotions, thoughts, and behaviors in order to gain insight into the unconscious processes that influenced his behavior. In *Mary: A Fiction*, Mary Wollstonecraft wrote her autobiography as a way of her 'self-analysis' in order to erase her family's repression of her ego. In this work, she explores a solitary and challenging self-analytical journey to address the erasure of her identity enforced by her family's adherence to her mother's martyrdom to the role of women. Through this process, she constructs a narrative of anger and righteousness to replace the previously "unspeakable" narrative of submission. In his *Memoirs of Mary Wollstonecraft*, Mary's husband, William Godwin, locates the sadomasochism of her parents', Elizabeth and Edward John's patriarchal marriage, as foundational. In response to this trauma, Mary kills off her brother, mother, and father in the first seven chapters of *Mary: A Fiction*. Once her family is erased, so is their erasure of her. Mary can cast off her guilt and give herself the tools to "work through" the traumas of : her tyrannical, abusive, favored brother; the blows of her alcoholic father, and her family's adherence to her mother's martyrdom. These were the traumatic cornerstones for Mary's pain and repressed rage.
Conclusions: Writing a fictional biography based on one's own life story is a remarkable example of how unresolved conflicts in real life can be reprocessed and lead to eventual healing, similar to the work done in psychoanalysis.

Sexual violence among Tunisian women and marital satisfaction: which association?

R. Jbir[1], L. Aribi[1], A. Hadj ali[1]*, I. Chaari[1], F. Charfeddine[1], N. Messedi[1] and J. Aloulou[1]

[1]Psychiatric department B, Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2409

Introduction: Domestic violence is a scourge that continues to spread, destroying family ties and increasing the prevalence of divorce in our Arab-Muslim societies. In our culture, women often find it hard to disclose domestic violence in general, but what about sexual violence? It's the most under-reported form of violence in Tunisia. However, few studies have focused on sexual violence in the Tunisian context, or on the psychological repercussions of this form of violence.
Objectives: To determine the prevalence and describe the different forms of sexual violence perpetrated by husbands against their wives and to evaluate marital satisfaction and its relation with sexual violence.
Methods: This is a descriptive and analytical cross-sectional study of 122 married women who consulted for medical expertise following domestic violence.
An anonymous survey was asked to these ladies. It included a section for collecting socio-demographic and clinical data on the woman and her partner, and a section for assessing the various forms of sexual violence.
We used the Azrin scale to evaluate marital satisfaction.
Results: One hundred and twenty-two women victims of domestic violence were included in our study. Their average age was 35.66 years, it oscillates between 18 and 64 years. A family history of domestic violence was found in 32.8% of women (N=40). The battered family member was the mother in 41.5% of cases.
A history of childhood sexual abuse was found in 14.8% of women (N=18).
Half of the women (53.3%; n=65) were victims of sexual violence. Different types of sexual violence were reported with decreasing prevalence: forced intercourse (36.1%), unwanted intercourse (15.6%), unusual type of intercourse (31.1%) and pain during intercourse (4.9%).
Seventy-one percent (N=87) had poor marital satisfaction. On multivariate analysis using binary logistic regression, we found that sexual violence: an unusual type of relationship (p=0.04; OR=4.62) and the presence of psychological distress (p=0.04; OR=2.63) were independent factors associated with poor marital satisfaction.
Conclusions: Our study suggests that more attention should be provided to women victims of domestic violence in order to detect any form of sexual violence and provide them with the necessary psychological support.

Navigating Infertility: How Tunisian Men and Women Cope Differently

K. Mahfoudh[1], S. Hamzaoui[1]*, F. Askri[1], A. Ouertani[1], U. Ouali[1], A. Aissa[1] and R. Jomli[1]

[1]Department A, Razi Hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2410

Introduction: Infertility is a significant source of emotional stress for couples worldwide. In Tunisia, it affects approximately 15 to 20% of couples of reproductive age. Studies indicate that women experience higher rates of depression (35% vs. 15%) and anxiety (52% vs. 28%) compared to men, largely due to cultural pressures. For these reasons, understanding these gender differences in coping mechanisms is essential.
Objectives: To analyze the coping styles of infertile couples and identify gender differences in coping mechanisms to inform tailored psychological support.
Methods: We conducted a cross-sectional study involving couples undergoing infertility treatment at a specialized Assisted

Reproductive Technology center inTunis. The participants provided information related to socio-demographic data. Coping strategies were assessed using the Brief Cope scale administred in the Tunisian dialect. These strategies were classified into three categories: problem-focused, emotion-focused, and avoidant coping.
Results: A total of 60 infertile couples participated in the study. The average age of men was 41.1±6 years, while the average age of women was 35.07±4 years. Among them, 68% resided in urban areas, and 73% were from a middle socioeconomic background. Educationally, 47% of women held a university degree, compared to 17% of men. Approximately half of the women were unemployed, while 52% of men were employed.
Problem-focused coping emerged as the most frequently utilized strategy (5.93±1.02), followed by emotion-focused coping (5.32 ±0.82) and avoidant coping (3.95±0.70).
Women significantly employed problem-focused and emotion-focused strategies more than men ($p=0.017$; $p<0.01$). They also scored higher in emotional support, expression of feelings, active coping, planning, and religious coping ($p<0.05$; $p=0.01$). Conversely, men displayed a greater inclination towards acceptance, distraction, and substance use.
Conclusions: In conclusion, addressing gender-specific coping strategies is essential for providing effective psychological support to infertile couples. Healthcare professionals should promote problem-focused coping to help couples actively manage their challenges.

Home treatment in acute postpartum psychosis: a case report

J. Hidalgo-Lopez[1]*, P. Leganes[2] and E. Serna[1]
[1]Hospital Universitario José Germain, Leganés (Madrid) and [2]Hospital Universitario Gregorio Marañón, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2411

Introduction: Postpartum (or puerperal) psychosis is a severe mental health condition about which there is little literature, which recommends measures to prevent separation between mother and baby in the acute crises, such as home treatment. However, there is a lack of published experiences on the subject. Here we present the case of a 36-years-old woman with this diagnosis successfully treated under a home treatment, and with history of one previous hospital admission in a conventional inpatient psychiatric care unit for the same diagnosis.
Objectives: To show the specific advantages of home treatment over conventional hospitalization in acute conditions that are particularly difficult for the family environment, like the postpartum psychosis.
Methods: A case report is presented alongside a qualitative analysis of the perceived experience, based on a brief semi-structured interview with the patient.
Results: The patient's own comparative experience shows less interference in the development of mother-child care and greater satisfaction under the home treatment model.
Conclusions: This case helps to support home treatment as a better way of acute management of postpartum psychosis, compared to conventional hospitalization, and invites to further research on the topic.

Disclosure of Interest: None Declared

EPV2032

Late-Onset Puerperal Psychosis: A Case Report and Challenges in Treatment Decisions

P. Ibáñez Mendoza[1]*, C. Delicado Gascon[1], B. Orgaz Álvarez[1], M. Velasco Santos[1] and Á. de Vicente Blanco[1]
[1]Psychiatry, Hospital Universitario La Paz, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2412

Introduction: The perinatal period is a vulnerable time for women, with specific risk factors for mental health issues. Puerperal psychosis typically presents within the first month postpartum, although the perinatal period extends through the first year after delivery. This condition is understudied, and its nature and pathophysiology remain subjects of debate.
Objectives: To describe a case of late-onset puerperal psychosis, highlighting the challenges in decision-making regarding medical approach.
Methods: A clinical case report and a non-systematic review of the literature.
Results: A 39-year-old woman was brought to the Emergency Unit by her relatives due to paranoid delusions that her partner and in-laws were attempting to poison her. She had previously sought mental health care only once, as an adolescent, for anxiety symptoms following her parents' divorce. She is the mother of a 5-year-old child and a 10-month-old infant, with no reported complications during pregnancy or delivery.
The patient reported experiencing strange occurrences over the preceding 10 days, beginning during a family vacation when she became suspicious of the food and the organization of meals. She believed her in-laws were poisoning her and expressed concern about transmitting poison to her infant through breast milk. Upon returning home, these fears intensified, extending to suspicions that her husband, mother, and sister were involved. She had drastically reduced her food intake the prior days before consulting, her appearance was malnourished and disheveled.
Further psychopathological exploration revealed delusional beliefs centered on being poisoned and potentially poisoning her baby through breastfeeding. These delusions were accompanied by confusion, perplexity, and heightened anxiety. She denied experiencing hallucinations and had no thoughts of harm toward herself or others.
Low-dose olanzapine treatment was initiated and outpatient management was initially chosen to minimize disruption to her role as a mother, in accordance with the patient's preference and the presence of family support. However, hospitalization ultimately became necessary, resulting in complete resolution of psychotic symptoms after 14 days, with olanzapine titrated to a higher dose (20 mg per day).
Conclusions: Puerperal psychosis is a complex condition with potentially severe consequences for both maternal and infant health, including disruptions in mother-child bonding. This case underscores the need for further research and resource allocation in this area. Specifically, the development of more psychiatric mother-

baby units could help prevent unnecessary separations, promote bonding, and provide opportunities for early parenting interventions.

Mental health approach to premenstrual dysphoric syndrome: case series

A. Izquierdo De La Puente[1]*, P. Del Sol Calderon[1] and R. Fernandez Fernandez[2]

[1]Psiquiatria, Hospital Universitario Puerta de Hierro de Majadahonda and [2]Psiquiatria, Hospital Universitario Infanta Cristina, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2413

Introduction: Six clinical cases of patients with premenstrual dysphoric syndrome treated in Mental Health with SSRIs are presented.

Objectives: The aim is to briefly review the pharmacological approach to premenstrual dysphoric syndrome through the presentation of a series of cases.

Methods: Six cases of female patients are presented, with a mean age of 35.4 years, two of whom were nulliparous. All of them had no history of mental health problems. They had regular cycles and had no relevant medical or gynecological history. They reported that for the last three years they had been more irritable, emotionally labile, feeling apathetic and sad, with difficulties in concentration and a feeling of loss of self-control, which made interpersonal relationships difficult, especially at work.

The patients denied that they had previously experienced these symptoms throughout their lives.

Analyses were carried out, with estrogen and progesterone levels, without obtaining significant alterations.

The MADRS and HAMILTON scales were administered to all of them on the 14th day of the cycle, as well as on the 5th day of the cycle. A mean of 9.2 was obtained on the MADRS on the 5th day of the cycle, compared to 15.6 on the 14th day, while the HAMILTON obtained a score of null-mild anxiety on the 5th day and moderate anxiety on the 14th day.

Results: After this comparison, treatment with fluoxetine at a dose of 20mg DMD was started only from the day of ovulation to menstruation, withdrawing this treatment for the rest of the cycle. Again, both scales were compared and the results obtained were more similar on the 5th and 14th day of the cycle.

Conclusions: To avoid hormonal treatment and thus the moderate side effects it presents, premenstrual dysphoric syndrome can be treated by taking SSRIs at low doses, only for 15 days of the cycle.

EPV2036

Subjective anxiety and depression in a sample of pregnant women with panic disorder

I. Kamenova Ilieva[1]* and R. Vladimirova[1]

[1]Psychiatry and Medical Psychology, Medical University Sofia, Sofia, Bulgaria

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2414

Introduction: Panic disorder and depression during pregnancy are significant mental health concerns that can adversely affect both maternal and fetal well-being. Prompt recognition and management of these conditions through early screening are essential, not only for maternal health but also for the neuropsychological development of the child.

Objectives: This study aims to assess anxiety and depression in pregnant women diagnosed with panic disorder, utilizing both objective and subjective measurement tools while integrating patient perspectives.

Methods: The study included pregnant women with a confirmed diagnosis of panic disorder, evaluated in an outpatient setting (N=40). The participants were divided into three groups: (1) those with panic disorder (42.5%), (2) panic disorder with agoraphobia (20.0%), and (3) panic disorder with depression (37.5%). Objective measures such as the Hamilton Depression Rating Scale (HAM-D) and the Hamilton Anxiety Rating Scale (HAM-A) were used, along with self-reported scales, including the Hospital Anxiety and Depression Scale (HADS-A/HADS-D). Statistical methods, including descriptive analyses, the Student's t-test, One-way ANOVA, and multiple linear regression, were employed. Ethical approval was obtained for the study.

Results: Most participants were in their first pregnancy (77.5%) and had no prior psychiatric history (75%). Depression scores, measured by HADS-D ($F(2, 37) = 6.05$, $p = .005$, $\omega = .20$) and HAM-D ($F(2, 37) = 5.71$, $p = .007$, $\omega = .19$), were significantly higher in patients with depression compared to those with panic disorder, with or without agoraphobia. Higher gestational age was also associated with increased self-reported depression ($p = .002$, $R^2 = .324$, $F(6) = 2.632$, $p = .034$). Anxiety, as measured by the HADS-A scale, was significantly higher in the panic disorder group ($F(2, 37) = 71.12$, $p < .01$, $\omega = .78$) than in the agoraphobia and depression groups. No significant differences were found between the groups on the HAM-A scale ($p > .05$).

Conclusions: Proper identification of anxiety and depression during pregnancy is essential, as these conditions can negatively affect maternal functioning and quality of life. Moreover, they may hinder the mother's ability to care for her infant postnatally. Utilizing both objective and subjective tools to assess anxiety and depression can improve diagnostic accuracy. Recognizing depression as a distinct domain in cases of anxiety disorder during pregnancy is also crucial for targeted intervention.

EPV2038

Assessing Personality Traits in Transfemales: A Comparative Analysis with Gender-Affirming Males and Females Using a Binary Logistic Regression Model

N. Konstantinovs[1]

[1]First Medical Faculty, Charles University, Prague, Czech Republic

doi: 10.1192/j.eurpsy.2025.2415

Introduction: Transgender healthcare has increasingly gained importance, particularly in understanding how individuals align with their affirmed gender in various physiological and sociological aspects. Transfemales, individuals assigned male at birth who transition to female, represent a group that is less studied in gender research. There remains uncertainty regarding the degree of similarity transfemales exhibit to cisgender males or females post-transition. This study aims to address this by using a binary logistic regression model to compare transfemales with gender-affirming males and females.
Objectives: The primary objective of this study is to determine whether transfemales are more similar to gender-affirming males or gender-affirming females. Using a binary logistic regression model previously validated on a cohort of transmales, we aim to categorize transfemales based on personality traits.
Methods: A binary logistic regression model, initially developed to distinguish between gender-affirming males and females, was applied to a dataset that included transfemales. The model was trained using characteristics of cisgender males, females and transgender participants. The dataset included 108 gender-affirming males, 260 gender-affirming females, 142 transmales and 20 transfemales, ages 15-25, from Europe. The primary outcome was the classification of transfemales into the male or female categories according to personality trait assessment, using the regression function trained on the gender-affirming cohort.
Results: The binary logistic regression model categorized the vast majority of transfemales as females, with a classification accuracy close to that of gender-affirming females being categorized as female. Specifically, **85%** of transfemales were classified as female, which is slightly lower than the **93%** classification accuracy for gender-affirming females but significantly higher than the **34%** classification accuracy for gender-affirming males being categorized as female. Detailed results are presented in the attached table.

Group	Number of Participants	Classified as Female (%)
Gender-Affirming Males	37	34%
Gender-Affirming Females	242	93%
Transfemales	20	85%

Conclusions: The results suggest that transfemales are more similar to gender-affirming females than to gender-affirming males in their personality traits based on the binary logistic regression model. However, caution must be exercised when interpreting these findings due to the limited sample size of transfemales (n = 20). Furthermore, the predictive accuracy of the model was modest, highlighting the need for further research with larger and more diverse datasets. These findings contribute to the understanding of gender identity and its alignment with personality traits, yet emphasize the complexity of such classifications in transgender populations.

Disclosure of Interest: None Declared

EPV2041

PROMP study: Effects of antidepressants during pregnancy, a retrospective cohort (2006-2018)

A. Kurtz[1,2*], A. M. Kamperman[2], M. Sielk[1] and H. Bijma[3]
[1]Psychiatry, Emergis regional mental health center, Goes; [2]Psychiatry and [3]Obstetrics and Gynaecology, Division of Obstetrics and Fetal Medicine, Erasmus University Medical Center, Rotterdam, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2416

Introduction: Limited research has been done regarding antidepressant use during pregnancy. Current insights show that a higher daily-dose equivalent of maternal SRI during pregnancy is associated with lower birthweight. Additionally, also large-scale registry studies show that prenatal antidepressant exposure is associated with small decreases of pregnancy duration and birthweight, and a higher risk for preterm birth, decreased birthweight, neonatal hospitalization and postnatal neonatal withdrawal symptoms. In these studies, no differences were found regarding PPHN (Persistent Pulmonary Hypertension of the Newborn) and congenital abnormalities. Thus far, research has been done on a general population level. This study is aimed at a specific high risk population group, which makes this study much more relevant for clinical practice.
Objectives: Gain insight into the effects of antidepressants during pregnancy and how they are prescribed. Specifically, the effects on birthweight and pregnancy duration, and whether the antidepressants are prescribed according to the daily-dose equivalent and are prescribed on-label.
Methods: This is a retrospective clinical cohort consisting of women who between 2006 and 2018 gave birth in the Erasmus MC University Hospital, because of a medical or psychiatric referral. All women were treated by the multidisciplinary pregnancy and psychiatry outpatient clinic in the Erasmus MC, were diagnosed with a DMS diagnosis, and for this specific study were selected for antidepressant use. Birth weights were categorized against the Dutch Perined birth registry. We estimated the association of pregnancy duration with the daily-dose equivalent.
Results: Of the 1372 births from mothers with a DSM diagnosis, 323 unique births were selected for antidepressant use during pregnancy. No effects were found regarding birthweight and pregnancy duration. There was a non-significant effect on birthweight: Kruskall-Wallis test statistic (3): 0,962, with a p-value of 0,810. And a non-significant effect on pregnancy duration using linear regression: standardized beta: -0,028, with a p-value of 0,654. The antidepressants, which included SSRIs, SNRIs, and TCAs, were described off-label in 26% of the cases. As a whole, the antidepressants were prescribed lower than the daily-dose equivalent, with a total average of 0.69.
Conclusions: The fact that no effects were found on the use of antidepressants in women with a DSM-diagnosis on birthweight and pregnancy duration, is a reassuring finding. Certainly when taking into account the previous studies, that showed lower birthweights and higher risk for pre-term birth when using antidepressants during pregnancy. This might affect how antidepressants will be prescribed for pregnant women in the future. It is however remarkable, that antidepressants aren't always prescribed on-label, and not always according to the recommended daily-dose.

EPV2042

Variations in the evaluation of the Edinburgh Postnatal Depression Scale in different psychotic states and language versions

N. Igor[1] and B. Larisa[1]*

[1]Department of Mental Health, Medical Psychology, and Psychotherapy, State University of Medicine and Pharmacy Nicolae Testemițanu, Chisinau, Moldova, Republic of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2418

Introduction: Patients with postpartum depression may have an increased risk of developing schizophrenia or bipolar affective psychosis. Conversely, women with schizophrenia may have a higher risk of developing depression during the perinatal period, which could be screened using the EPDS. The presence of cutoff effects complicates the statistical analysis of the Edinburgh Postnatal Depression Scale (EPDS). Sensitivity and specificity, two key parameters, cannot be treated as independent variables in such cases. To improve the precision of EPDS evaluations across different populations, versions with multiple cutoff points are preferable. While linear regression correlations may produce statistically significant results, they can be misleading when nonlinear relationships are present. In these instances, alternative statistical methods are recommended, such as hierarchical (Bayesian) models, bivariate (random effects) models assuming normal distribution, and joint modeling of sensitivity and specificity. Additionally, models with multiple cutoff values for sensitivity and specificity are particularly useful.
Objectives: This study aims to review the literature and assess the validity of the EPDS in its various language versions and across different psychotic states.
Methods: The literature data on the EPDS, across different language versions and psychotic states, was statistically analyzed, focusing on specificity, sensitivity, and the influence of cutoff thresholds.
Results: The analysis of 42 pairs of sensitivity and specificity data using linear regression showed a statistically significant moderate negative correlation (Pearson's $r = -0.4342$, $p = 0.0018$). Visual aids such as the histogram and Q-Q plot indicated the absence of normal distribution, confirmed by formal normality tests. The normality test results were as follows: Kolmogorov-Smirnov: $D(84) = 0.135$, $p<0.001$; Shapiro-Wilk: $W = 0.817$, $p<0.001$.
Conclusions: The Kruskal–Wallis one-way ANOVA test revealed statistically significant differences among the three variables (sensitivity, specificity, and cutoff threshold), with a test statistic of $H(2) = 79.647$, $p<0.001$. The Receiver Operating Characteristic (ROC) curve is widely regarded as the most reliable tool for representing the relationship between sensitivity, specificity, and cutoff thresholds across different language versions of the EPDS. These variations account for cultural and national characteristics, which play a significant role in the scale's overall validity.

Investigating the experience of transgender inmates: a systematic review of qualitative studies

M. Marchi[1]*, E. Vaccari[1], I. Corbellini[1], S. Ferrari[1], L. Ghirotto[2] and G. M. Galeazzi[1]

[1]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena and [2]Qualitative Research Unit, AUSL-IRCCS Reggio Emilia, Reggio Emilia, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2419

Introduction: Research on transgender issues has significantly advanced in recent years, yet transgender individuals in correctional facilities (CF) remain an overlooked and vulnerable population. Transgender inmates (TGI) within CF face intersectional and systemic challenges, particularly concerning housing placement, access to gender-affirming treatments, and mental health support.
Objectives: This systematic review of qualitative studies aims to explore the experience of TGI in CF.
Methods: Medline, Embase, Scopus, PsychInfo, and CINAHL were searched for studies on TGI in CF published until 31 December 2023. Qualitative studies capturing the voices of TGI detained in CF at the time of data collection were eligible for inclusion. Two independent reviewers extracted key constructs (researcher interpretations) and narratives (participant voices), categorizing them into labels and analytical themes. Intensity (I) and frequency (F) were calculated for each theme as the proportion of labels and studies associated with that theme, respectively. Following a socio-constructivist approach, a meta-synthesis was performed to create a new conceptual framework capturing the subjective experiences of TGI in CF. The study was registered with PROSPERO, CRD42023456340.
Results: From 641 studies initially identified, 33 full texts were analyzed, leading to a selection of 13 qualitative studies of TGI in CF. Ten main themes emerged, based on 537 coded labels: (1) feelings and identity (F:92.3%, I:29.1%); (2) mental and physical violence (F:84.6%, I:12.5%); (3) social issues and connections (F:76.9%, I:11.0%); (4) housing (F:76.9%, I:10.2%); (5) mental and physical health (F:61.5%, I:8.8%); (6) discrimination (F:53.8%; I:6.9%); (7) therapy (F:46.1%, I:6.2%); (8) definition and language (F:38.4%, I:11.6%); (9) coming out (F:38.4%, I:2.6%); (10) expectations (F:15.3%, I:1.3%). These findings inform the proposed Safety Model, a new framework for understanding TGI experiences in CF.
Conclusions: CF, as a total institution, with binary and heteronormative characteristics, often fails to ensure the safety of TGI. This review underscores incarceration as a significant social determinant of health for TGI. A comprehensive policy reform and targeted staff training should be promoted to foster inclusive and supportive correctional environments and improve the safety and health of TGI.

EPV2044

Perinatal grief, emergency evaluations: about a case

M. L. Maria Del Carmen[1]

[1]Psychiatric, Hospital General Universitario Gregorio Marañon, Madrir, Spain
doi: 10.1192/j.eurpsy.2025.2420

Introduction: Perinatal grief is the process that occurs after the loss of a baby, either during pregnancy or during the period immediately before or after childbirth (up to a year). In recent years, the increase in specific training and development of programs focused on perinatal mental health has facilitated the creation of specific action protocols. The case of a 38-year-old woman who suffers a gestational loss during the third month of pregnancy is explored. The presence of personal and family antecedents that suppose risk factors for the adequate elaboration of the duel, raise doubts about the handling of the case.
Objectives: This work has several objectives, including reviewing the published literature on perinatal bereavement in an emergency situation and, on the other hand, presenting a case.
Methods: A bibliographic search has been carried out in the main sources of medical information such as pubmed, uptodate as well as in national and international journals. Likewise, the knowledge and clinical experience of the team has been reviewed in order to expose its own experience in this field, defining specific interventions as well as results.
Results: On evaluation, the patient was conscious and oriented to person, time, and space. Approachable and cooperative. Overall calm, although with intermittent crying. Low mood reactive to vital situation, without apathy, apathy, or anhedonia. No previous episodes of hypomania or mania. Not another major affective clinic. Fluid and coherent speech, formally well constructed without glimpse alterations in the course or content of thought. She denied sensory- perceptual alterations, without showing a listening attitude, or suspicion or any other psychotic or dissociative symptoms. She denied ideas of self-harm, death or self-harm, presenting an adequate request for help and coherent and realistic future plans. Altered biological rhythms with insomnia of three days of mixed pattern evolution, preserved appetite. Judgment of reality preserved.
The grief reaction is an experience that must be normalized after the loss of a loved one. However, given the risk factors presented by the patient, preventive management is established in the face of possible complicated perinatal grief. A new appointment is established in less than 10 days to reassess the case with the perinatal mental health team.
Conclusions: Perinatal mental health is an area of knowledge that could provide assistance to mothers, fathers and family systems plunged into a crisis of perinatal grief.
Prevention in situations of possible complicated perinatal mourning is no less important than treatment when the disorder is already established.

EPV2045

"Girls Questionnaire for Autism Spectrum Condition" as a screening protocol - pilot study

M. M. N. Matsumoto[1]*, A. L. G. D. O. Araujo[1] and D. R. Molini-Avejonas[1]

[1]University of Sao Paulo, Sao Paulo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2421

Introduction: Currently, we see an increase in the identification and diagnosis of girls with Autism Spectrum Disorder (ASD) over the years, but where are these girls, now adult women, in the Brazilian population? There are barriers that delay and prevent early diagnosis and intervention in women with ASD, such as active attempts to camouflage or mask the signs of ASD in challenges related to social situations. It is known that people with ASD have high rates of depression, self-harm, and suicidal thoughts, which are exacerbated by difficulties in accessing treatment, professional, and family support. In this sense, obtaining the correct diagnosis and treatment for women with ASD is a challenge, as the measures developed and validated are primarily based on male samples and may not be sensitive to the female autism phenotype. With this in mind, the use of screening protocols is a tool that could minimize these impacts, improve quality of life, and drastically change the referral pathways for adult women with ASD.
Objectives: To present the results of the use of the Girls Questionnaire for Autism Spectrum Condition (GQ-ASC) protocol.
Methods: The screening questionnaire, Girls Questionnaire for Autism Spectrum Condition (GQ-ASC), developed by Brown et al., 2020, was used. In this study, a freely translated version was used, as there is no cross-cultural adaptation to Brazilian Portuguese. The questionnaire was sent via an online form, where participants who accepted the Informed Consent Form had access to the GQ-ASC. The study was approved by the Research Ethics Committee under protocol 65890317.9.0000.0065. The questionnaire consists of 21 items, assessed on a 4-point Likert scale (1=Strongly Disagree, 2=Disagree, 3=Agree, 4=Strongly Agree) that evaluate specific clinical characteristics of ASD presentation in adult females across five dimensions: imagination and play, camouflage, sensory sensitivity, socialization, and interests. At the end, the scores are summed, with a total score above 56 indicating a high level of autistic traits, with 80% sensitivity in the author's studies.
Results: 31 women with self-reported ASD diagnoses responded to the questionnaire. The average age was 24.09 years, 80.64% identified as white, 61.29% reported incomplete higher education, and 22.58% postgraduate education, 25.80% identified as bisexual, and 25.80% as heterosexual. For the GQ-ASC questionnaire, 83.87% of the participants scored above 56, with an average final score of 64.12 and a standard deviation of 7.95.
Conclusions: The results of the pilot study demonstrated that the final score of the GQ-ASC corroborates the self-reported diagnosis of ASD in adult women. The GQ-ASC can be considered a screening tool for this population, requiring cross-cultural adaptation to Brazilian Portuguese and validation so that more research and refinement of this tool can improve the quality of life for these women.

Marriage Reluctance Among Tunisian Women: Myth or Reality?

D. Mezri[1]*, M. T. Ajili[1], A. Gharbia[1], U. Ouali[1], A. Aissa[1] and R. Jomli[1]

[1]Avicenne, Razi hospital, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2422

Introduction: In recent years, Tunisia has observed a notable decrease in marriage rates, with a 36% drop in marriage contracts. This decline has been linked to post-independence reforms, modernization, the influence of tourism, media, foreign languages, rapid communication, and international migration, which have transformed values and behaviors related to marriage and family. However, it remains to be determined if the reluctance of women toward marriage is the primary cause of the decrease in marriage rates, or if other factors, such as socioeconomic conditions and male migration, are also contributing to this decline.
Objectives: To determine if women are reluctant to marry.
Methods: A cross-sectional study was conducted with Tunisian women using a questionnaire distributed via Google Forms and social media.
Results: The study included 138 women with 121 women being not married at the time of the study. Only not married women were part of the study. The age range of the participants was from 20 to 40 years with a majority in the age range between 20 and 25 years. The majority of the participants had a university-level education (88%), came from an urban background, were active (99%); 64% were employed, 28% were university students and 7% were high school students. Interest in a serious relationship and openness to marriage was expressed by 65% of the women. 30% of women who are open to marry, reported that they are unable to find a suitable partner. Among the cases, 1.3% women were homosexual, and the lack of same-sex marriage legislation in our country was the reason they had not yet married. Additionally, 1.3% of the women admitted to having a disability or deformity, which they perceived as a challenge for a potential partner. In 16% of cases, the women expressed that economic difficulties are the reason, as they and their partners are unable to cover the costs of the wedding ceremony. However, 31% of these women reported that they are not affected by social pressure regarding marriage.
Conclusions: The study indicates that reluctance to marry among Tunisian women is influenced by multiple factors rather than being a single cause. While 65% of participants expressed interest in serious relationships or marriage, challenges such as difficulty finding a suitable partner, economic constraints, lack of same-sex marriage legislation and personal disabilities or deformities contribute to the observed decrease in marriage rates. However, some women remain unaffected by social pressure. This suggests that the decline in marriage rates is a multifaceted issue, involving a combination of personal, economic, and legislative factors rather than a singular reluctance to marry.

Mental disorders in the peripartum period: A review

A. M. Morales Rivero[1]*, F. A. Rodríguez Batista[1], E. E. Morales Castellano[1], P. Rivero Rodríguez[1] and M. Martínez Grimal[1]

[1]Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2423

Introduction: Perinatal mental illness refers to all psychiatric disorders that occur during pregnancy and up to one year after childbirth. For a long time, pregnancy was believed to be a protective factor for women, representing a period of emotional well-being. However, research has shown that pregnancy does not shield women from the onset or persistence of psychiatric disorders. Instead, it poses a risk factor. The mother's mental state directly influences the cognitive, emotional, behavioral, and physical development of the child. Mothers experiencing mental health issues during this critical period may struggle with bonding with the baby, and these difficulties might persist even after the resolution of the triggering mental disorder. Hence, early diagnosis and treatment are crucial.
Objectives: The objective of this study is to review the available evidence on mental disorders in the peripartum period, focusing on the most common ones (postpartum blues, postpartum depression, and postpartum psychosis). Additionally, we will discuss data regarding the most severe consequences, such as maternal suicide and filicide.
Methods: A systematic literature review was conducted, analyzing documents published in various scientific journals with online publications.
Results: The prevalence is high; depending on the studies, between 15-20% of women experience some form of treatable pathology during pregnancy and postpartum. We will discuss postpartum blues, postpartum depression, and postpartum psychosis. Postpartum blues are characterized by transient mood disturbances (spontaneous relief within 2-3 weeks) occurring between the first day and the third week postpartum. Symptoms include emotional lability, episodes of crying, sadness, anxiety, irritability, fatigue, and mild depressive mood. Postpartum depression is a clinical syndrome characterized by moderate to severe depressive symptoms lasting longer than postpartum blues and significantly impacting family life. It begins within the first 4 weeks after childbirth, although some studies date it between 6-7 weeks postpartum. Prevalence ranges from 5-15%. The term postpartum psychosis refers to an acute psychotic episode starting between 4-6 weeks after childbirth. Its prevalence in the general population is 0.1-0.2%, rising to 20-25% in individuals with personal or family history of affective disorders.
Conclusions: Perinatal mental disorders are a public health problem with high prevalence, associated with complications in maternal health, pregnancy, neonatal outcomes, mother-infant bonding, and neonatal neurodevelopment. The perinatal period increases the risk of relapses in women with severe mental disorders and the onset of mental disorders.

Adaptation Study of the Genital Appearance Satisfaction Scale into Turkish

D. Ocaklik Altunkiliç[1]* and H. Bilgin[2]

[1]Mental Health and Psychiatric Nursing, Bakırköy Mazhar Osman Mental Health and Neurological Diseases Education and Research Hospital and [2]Mental Health and Psychiatric Nursing, Istanbul University-Cerrahpasa, Istanbul, Turks and Caicos Islands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2424

Introduction: As a result of dissatisfaction with genital appearance, even the most intimate genital organs have become open to change, leading to the emergence of female genital cosmetic surgery (FGCS). Although there is known to be a significant increase in the number of women seeking these procedures, the psychosocial aspects and motivations of women undergoing these procedures are not fully understood. It is believed that satisfaction with genital appearance is related to body satisfaction, self-esteem and the importance placed on appearance. Many women are known to have negative perceptions regarding their genital organs.
Objectives: Given the lack of research on the subject in our country and the need to better understand women's perceptions of their own genital appearance, the primary aim of this study is to examine the validity and reliability of the Genital Appearance Satisfaction Scale in Turkish women. In this context, it is planned to conduct the Turkish adaptation of the "Genital Appearance Satisfaction Scale" in order to identify the factors contributing to the development of genital appearance dissatisfaction in women and to determine the current state of the issue.
Methods: The research is a descriptive, methodological and cross-sectional study. The population consists of women aged 18-65 and data were collected through a web-based survey. First, the scale was translated from English to Turkish and after evaluation by experts, it was back-translated. The translations were compared and presented for expert opinion. The scale was created by applying content validity. To test the clarity of the items, a pilot study was conducted and the final version of the scale was formed. The data obtained from the research were analyzed using SPSS 24 with descriptive statistics, analyses required for psychometric standardization (item correlations, factor analysis, internal consistency coefficient, etc.), comparison and correlation statistics. The construct validity of the scale was tested using confirmatory factor analysis with the AMOS program. The test-retest measurements of the scale were tested with a paired t-test and correlation analysis.
Results: A reliability analysis was applied to the scale, and the Cronbach's Alpha coefficient was found to be 0.83. The Cronbach's Alpha values for the subscales were calculated as follows: 0.88 for the "Genital Appearance" subscale, 0.85 for the "Impact of Genital Satisfaction on Daily Life" subscale, and 0.85 for the "Impact of Genital Satisfaction on Sexual Life" subscale.
Conclusions: The fit indices calculated via confirmatory factor analysis showed that the scale is acceptably compatible with the previously identified factor structure. When the standardized coefficients were examined, it was found that the factor loadings were high, standard error values were low and t-values were significant. These results confirmed the construct validity of the previously identified factor structure.

The Relationship Between Internalized Homophobia, Social Anxiety, and Psychological Resilience in Lesbian, Gay and Bisexual Individuals

H. Öztürk[1]* and M. Hacıoğlu Yıldırım[2]

[1]Psychiatry, Republic of Türkiye Ministry of Health Adana City Training and Research Hospital, Adana and [2]Psychiatry, Trauma and Disaster Study Unit of the Türkiye Psychiatric Association, CETAD trainer and coordinator of the CETAD Trauma Scientific Study Unit, İstanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2425

Introduction: Lesbian, gay, and bisexual (LGB) individuals with high psychological resilience are less likely to experience minority stress and mental health issues. This study will investigate the role of psychological resilience in the relationship between internalized homophobia and social anxiety among LGB individuals.
Objectives: LGB individuals experience higher levels of social anxiety compared to heterosexual individuals. This is due to internalized homophobia, a result of minority stress. Psychological resilience is a significant factor that determines LGB individuals' ability to cope with these challenges. This study aims to determine the levels of internalized homophobia, social anxiety, and psychological resilience in LGB individuals and to examine the relationships between these concepts. Additionally, the study will investigate the mediating role of psychological resilience in the impact of sociodemographic and clinical characteristics of LGB individuals on internalized homophobia and social anxiety.
Methods: The study used a cross-sectional design to survey 131 LGB individuals. Participants were recruited through snowball and purposive sampling. Data was collected using sociodemographic and clinical questionnaires, the Internalized Homophobia Scale, Liebowitz Social Anxiety Scale, and Adult Resilience Scale.
Results: Gay individuals exhibited significantly higher levels of psychological resilience and lower levels of social anxiety compared to lesbian and bisexual individuals. Factors such as younger age, lower socioeconomic status, unemployment, female gender, suicide attempts, seeking psychological support and partial disclosure of sexual orientation were associated with higher levels of social anxiety. A negative correlation was found between levels of social anxiety and psychological resilience. Additionally, a negative correlation was observed between the social resources subscale of psychological resilience and levels of internalized homophobia. Structural style, social resources, and social competence subscales of social anxiety and psychological resilience were found to be significant predictors of internalized homophobia.
Conclusions: This study provides a deeper understanding of the psychological challenges faced by LGB individuals and the underlying factors contributing to these challenges. It particularly focuses on the complex relationships between internalized homophobia, social anxiety, and psychological resilience. Attending to internalized homophobia and social anxiety in the assessment of LGB individuals is crucial for preventing mental health issues and enhancing psychological resilience. These findings may contribute to the development of more effective psychological support programs for LGB individuals.

Traumatic Childbirth Experience and Postnatal Post-traumatic Stress Disorder

B. Peixoto[1]*, M. Cruz[2] and V. Ustares[1]

[1]Psychiatry, Hospital do Divino Espirito Santo and [2]Psychiatry, Hospital do Divino Espírito Santo, Ponta Delgada, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2426

Introduction: Although childbirth represents a positive experience for most mothers and fathers, it can also be potentially traumatic when it endangers the life of the mother or the baby. In more severe cases, it can even develop into Post-Traumatic Stress Disorder (PTSD) postpartum. Studies indicate birth-related PTSD impacts around 17% of postpartum parents. This condition includes intrusive symptoms, hyperactivation, avoidance behaviors, and negative changes in mood and cognition, significantly impacting the mother-baby bond and the family's well-being.
Objectives: The authors pretend to raise awareness of postpartum PTSD.
Methods: The authors did a non-systematic review of the current literature.
Results: The etiology of postpartum PTSD is multifactorial and results from the combination of pre-birth risk factors (depression during pregnancy, fear of childbirth, medical complications during pregnancy, history of trauma or sexual abuse, history of mental disorders), factors during childbirth (subjectively experienced negative childbirth, obstetric complications, and severe maternal morbidity), and postpartum factors (postpartum depression, maternal complications after childbirth, or maladaptive coping mechanisms). The risk factors related to childbirth appear to be independent of neonatal complications, with the latter constituting an additional stressor factor. Psychological trauma during childbirth and postpartum PTSD, despite having a significant impact on families, are often not recognized in maternity services, hindering timely intervention. Currently, there are no recommended treatments to prevent or mitigate postpartum PTSD. However, there is some evidence of the benefits of prenatal and postnatal interventions, such as early identification of risk factors for postpartum PTSD and postnatal counseling.
Conclusions: The studies suggests that women should be assessed for negative traumatic birth experiences and PTSD, to allow targeted observation for psychopathologies and therapeutic interventions. Further research is needed with larger sample sizes, validated and reliable clinical interviews to assess PTSD.

The Effects of War and Trauma on Attitudes Toward Restorative Justice for Sexual Offenses

I. Peleg Koriat[1]* and D. Weimann Saks[2]

[1]Criminology and [2]Communication, Max Stern Yezreel Valley College, Yezreel Valley, Israel
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2427

Introduction: On October 7, 2023, a Hamas terror attack targeted both Jewish and Arab Israelis. The unprecedented scale of the event resulted in over 1,400 deaths and numerous kidnappings, leading to the ongoing Hamas-Israel war. The attacks also exposed a wide range of sexual violence, which was broadcasted or witnessed by family members (Association of Rape Crisis Centers in Israel, 2024; UN SRSG-SVC, 2024). This event has exacerbated collective trauma and anxiety, influencing various societal issues, including public attitudes toward justice, particularly sexual offenses (Feingold et al., 2024).
Objectives: This study aims to explore how exposure to a war characterized by violent crimes affects public support for restorative justice (RJ) processes, particularly in sexual offenses, and whether the collective trauma has led to a decline in the belief that sexual offenders can be rehabilitated.
Methods: The research surveyed 339 Israeli participants at two points: before the war and during its early weeks. The study employed quantitative analyses to measure attitudes toward offender rehabilitation and support for RJ. A paired t-test was conducted to assess changes over time, and correlation analyses examined the relationship between the perceived malleability of offenders and support for RJ.
Results: The findings revealed a significant decline during the war in the belief that sexual offenders can be rehabilitated ($t(51) = 2.67$, $p < .01$). This belief was correlated to reduced support for RJ (rp = .45, $p < .001$). The exposure to sexual violence during the war, combined with widespread testimonies highlighting its brutality, likely contributed to a shift in public attitudes. The attacks served to instill terror and dehumanize the victims, reinforcing the public's resistance to perceived "lenient" justice alternatives such as RJ.
Conclusions: In addition to the well-known effects of trauma, the study highlights the profound influence of collective trauma on public attitudes toward justice, particularly in sexual offenses. Exposure to extreme violence, during a war characterized by violent crimes creates significant barriers to the acceptance of RJ. While RJ can potentially provide healing avenues for survivors of sexual offenses (Klar-Chalamish & Peleg-Koriat, 2021) the widespread trauma and public anxiety pose significant barriers to its acceptance.

EPV2054

Evaluating breastfeeding among active Tunisian mothers

A. Hrairi[1], N. Rmadi[1]*, O. Ben Ayed[2], A. Kchaou[1], F. Dhouib[1], E. Belkhir[3], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupational medicine department, Hedi chaker university hospital, University of Sfax; [2]Family medicine department, university of Sfax, Sfax and [3]Lactabelle Society, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2428

Introduction: Breastfeeding is an important determinant of both mother and child healths regarding its physical and psychological benefits. Working mothers usually consider the work as a barrier to breastfeeding, thus this population needs a particular attention to enhance their breastfeeeding rate.
Objectives: Determining the prevalence of breastfeeding among active women in Tunisia and evaluating their perceptions and their practices towards this process.
Methods: We have conducted a descriptive and cross sectional study. Data were collected during one week through an online questionnaire designed by Google Forms and distributed via Social

media. It had included active women who had a child aged between 6 months and 5 years. Exclusive breastfeeding (EBF) is feeding the baby only breast milk (not any other foods or liquids).
Results: A total of 51 active mothers had participated with a mea age of 32.4±3.8 years. A proportion of 47.1% worked in healthcare facilities. Nineteen participants were doctors. All the participants had experienced breastfeeding with a mean duration of 12.7 ±7.5 months [ranging from 2 to 25 months]. The mean duration of EBF was 3.1±2.0 months [ranging from 0 to 6 months]. A percentage of 64.7% had experienced mixed feeding. Regarding breastfeeding perceptions, 92.2% of women always believe that breastmilk was the right option to feed their babies. Tweenty two (43.1%) always believe that they could successfuly breastfeed their child and sixteen (31.4%) consider that they was usually sure that they were able to balance between work and breastfeeding. Participants mothers had returned to their job within a mean of 12.7 ±7.5 months [ranging from 2 to 25 months]. After returning to work, 56.9% of participants consider that breastfeeding represented a big challenge. EBF was negatively associated to the number of working hours /week (p=0.026).
Conclusions: The participation of women in the labor force makes the continuation of breastfeeding a challenging option. Thus, promoting and supporting breastfeeding in the workplace are essential and have the potential to ameliorate babies and mothers lives, and to positively affect the employees productivity and well-being.

Women, Gender, and Mental Health: Analysis of a Case of Multiple Psychiatric Diagnoses and Gender Conditioning

A. Romero Teruel[1]*, M. L. del Pozo[1] and C. P. Usaola[2]

[1]Psiquiatría, Hospital Dr. Rodríguez Lafora and [2]Psiquiatría, Centro de Salud Mental de Hortaleza (HRYC), Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2429

Introduction: Gender significantly impacts the diagnosis and treatment of mental disorders. This case shows how being a woman, alongside trauma and violence exposure, shaped a patient's diagnoses over time, affecting recovery, and culminating in a late-stage lung cancer diagnosis.
Objectives: Analyze how experiences of violence, trauma, and social stigmatization shaped the diagnostic path of a female patient with schizophrenia, multiple hospitalizations, and a fatal outcome, with delayed lung cancer diagnosis despite recurrent emergency visits for respiratory issues.
Methods: We reviewed the clinical course of a 55-year-old woman with schizophrenia. She was admitted to a psychiatric care unit from November 2000 until 2017. In her final years, she was treated for respiratory issues that eventually led to a diagnosis of lung cancer with vertebral metastasis. The late diagnosis underscores the impact of her psychiatric history on care quality.
Results:
Violence and Trauma:
- The patient experienced early-life violence: parental abandonment, her mother's suicide, and her own suicide attempts.
- In later years, she faced recurrent respiratory issues overlooked due to her psychiatric background.

Gender Conditioning:
- Perceived as "emotional" and "exaggerating," physical symptoms were minimized, delaying the advanced lung cancer diagnosis.
- Respiratory difficulties were dismissed as secondary to mental health, resulting in a delayed cancer diagnosis.

Social Context:
- Lack of social support and healthcare barriers led to the progressive decline in her physical and mental health.
- Lung cancer with vertebral metastasis was diagnosed after multiple admissions, highlighting how her psychiatric condition delayed the oncological diagnosis.

Diagnostic Evolution:
- After 17 years in a psychiatric facility for schizophrenia, she developed respiratory symptoms that were inadequately explored, leading to a delayed lung cancer diagnosis, followed by her passing after palliative care.

Conclusions: This case highlights the need to consider gender-based biases in diagnosing women with mental health conditions. Her psychiatric history and gender contributed to the downplaying of her symptoms, delaying the crucial lung cancer diagnosis. Gender and mental health stigma can cause serious healthcare delays. A gender-sensitive approach is essential to ensure timely, thorough medical evaluations for women. Integrated mental and physical health care can prevent delays in diagnosis and improve outcomes for women with psychiatric disorders.

Gender differences regarding problematic smartphone use, mediating by mental well-being, emotional regulation, and social anxiety in young adult sample

C. Sándor[1]*, N. Pirwani[2], M. Csibi[3] and A. Szabo[2]

[1]Faculty of Psychology, Department of Sciences and Letters, George Emil Palade University of Medicine, Pharmacy, Science, and Technology, Targu Mures, Romania; [2]Institute of Health Promotion and Sport Sciences, Faculty of Education and Psychology, ELTE Eötvös Loránd University, Budapest and [3]Institute of Special Education, Faculty of Pedagogy, Eszterházy Károly Catholic University, Eger, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2430

Introduction: Research underlay various results concerning the differences focusing on gender in smartphone use and mental issues. Some find no difference, but assessing mental factors reveals the influence of social interactivity, low emotional understanding, and perceived social support variations according to problematic smartphone use.
Objectives: Our research aims to investigate problematic smartphone use, mental well-being, emotional regulation, and social anxiety as a function of gender to explore specific ways of functioning in the addiction process.
Methods: The study participants were 400 young adults, of whom 104 were men (26%), 293 were women (73.2%), and three individuals (0.8%) were of another gender. The mean age of the participants was 25.9 years (SD 10.9). Registered answers refer to demographic data (gender, age, smartphone usage habits) as well

as psychological measures: a Smartphone Application-Based Addiction Scale (SABAS), a Mental Health Continuum Scale (MHC), an Assessing Emotions Scale (AES), and Fear of Negative Perception Questionnaire (FNPQ).
Results: The results showed that gender showed significant differences in the mediating factors that affect problematic smartphone use. In the mediation model, gender relates significantly related to time spent with smartphones (p=.001) and fear of negative perception (p=.001). The statistical mediation model highlighted the gender-depending significant role of the mediating factors (time of use per day, MHC, AES, FNPQ) in problematic smartphone use.
Conclusions: Our research highlights gender differences in excessive smartphone use, such as higher social anxiety, which is a higher predisposing factor in women than in men. Gender is a significant indirect determinant of problematic smartphone use.

EPV2057

A 5-year Retrospective Study of Women with Postpartum Psychiatric Disorders Hospitalized in the Clinical Hospital of Psychiatry, Chisinau, Republic of Moldova

L. Sanduleac[1]*, I. Deliv[1], V. Tapes[1] and I. Cosciug[1]

[1]Mental Health, Clinical Psychology and Psychotherapy Department, University of Medicine and Pharmacy "Nicolae Testemițanu", Chisinau, Moldova, Republic of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2431

Introduction: The postpartum period is critical for the onset of mood disorders. Three primary postpartum affective disorders are recognized: baby blues, postpartum depression, and postpartum psychosis, each differing in prevalence, presentation, and treatment. Obstetric factors like primiparity, complications during pregnancy and birth, Cesarean sections, and preterm births are associated with increased neuropsychiatric risks during the puerperium.
Objectives: This study analyzes the demographic, clinical, and obstetric factors linked to postpartum psychiatric disorders and case management in women hospitalized at the Hospital of Psychiatry in Chisinau, Moldova, over a five-year period.
Methods: A longitudinal, retrospective study was conducted, reviewing medical records of 35 women hospitalized between 2019 and 2024. A literature review was also performed to identify relevant obstetric and clinical risk factors.
Results: Patients ranged from 20 to 41 years old, with an average age of 29.8 years ±1,5 years. Out of reviewed cases, 42.9% were from urban areas, 25.7% had a family history of psychiatric illness, and 54.3% developed postpartum psychosis after their first birth, suggesting primiparity as a key risk factor. Psychosis onset ranged from three days to two months postpartum in 45.7% of cases, with 37.1% showing symptoms within the first two weeks. Comorbidities included cardiovascular diseases (20.0%), digestive disorders (14.3%), renal issues (8.6%), and autoimmune conditions (2.9%). Severe mental and behavioral disorders (F53.1) were diagnosed in 74.3% of cases, while 25.7% had milder forms (F53.0). First-time hospitalizations accounted for 88.6%, but 48.6% had prior hospitalizations, with later diagnoses evolving into paranoid schizophrenia, schizotypal disorder, and recurrent depression. Psychological consultation was provided in 48.6% of cases, using tools like PHQ-9, TAG, MMPI, BDI. Treatment varied significantly, with antipsychotics, antidepressants, and benzodiazepines prescribed, yet no standardized protocol was followed.
Conclusions: Primiparity is a significant risk factor for postpartum psychiatric disorders, with early onset often occurring within the first two weeks. This underscores the critical need for prompt recognition and intervention. Comorbid disorders add complexity to patient management. The variability in pharmacological and nonpharmacological treatment highlights a gap in evaluation and case management, potentially delaying timely diagnosis and treatment and it emphasizes the need for consistent and standardized guidelines. The evolving nature of diagnoses, reinforces the importance of ongoing monitoring, psychoeducation, and psychological support throughout the postpartum period.

Disclosure of Interest: None Declared

EPV2058

Assessment of psychological well-being among female medical residents in Tunisia

H. Daoud[1], I. Sellami[1,2]*, A. Feki[3], K. Jmal Hammami[1], M. Hajjaji[1] and M. L. Masmoudi[1]

[1]Department of Occupational Medicine, Hedi Chaker Hospital; [2]LR/18/ES-28, Sfax university and [3]Department of rheumatology, Hedi Chaker Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2432

Introduction: Medical residents encounter high work demands, significant responsibilities, and a strong commitment to their roles. Female residents, in particular, face unique challenges that can affect their emotional and mental well-being. Emotional intelligence (EI), resilience, and mental health disorders are critical factors influencing their performance and job satisfaction.
Objectives: This study aims to assess and evaluate these factors among female medical residents in Tunisian hospitals.
Methods: We conducted a cross-sectional study involving female medical residents undergoing training in Tunisian hospitals. Data were collected anonymously through a questionnaire-based survey using Google Forms between October 2023 and January 2024. Participants completed a sociodemographic questionnaire, followed by four scales : the Trait Emotional Intelligence Questionnaire-Short Form (TEIQue-SF), which assesses global trait EI, the Brief Resilience Scale (BRS), the Perceived Stress Scale-4 (PSS-4) to measure stress levels, and the Patient Health Questionnaire-4 (PHQ-4) to assess levels of depression and anxiety. An additional question was included to evaluate job satisfaction on a scale ranging from 0 to 10.

Results: ur study included 95 female participants. The mean age was 27.14 ±1.29 years, with the majority (95.8%) being under 30. Most participants were single (78.9%), and only 6.3% were smokers. The mean resilience score was 3±0.75, while the total EI score averaged 4.52±0.67. The mean scores for the PSS-4 and the PHQ-4 were 7.54±2.47 and 4.19±2.89, respectively. The mean work satisfaction level was 6.19±1.75.
Univariate analysis showed that higher resilience and EI levels were more common among non-smokers ($p = 0.045$ and $p = 0.02$). Furthermore, greater work satisfaction was significantly associated with lower stress ($p = 0.000$, $r = -0.482$), anxiety and depression ($p = 0.000$, $r = -0.42$), and higher resilience ($p = 0.000$, $r = 0.359$) and EI ($p = 0.000$, $r = 0.444$).
Conclusions: Our study highlights the importance of addressing emotional intelligence, resilience, and mental health disordes among female medical residents to enhance their overall well-being and job satisfaction. Targeted interventions are essential to support their mental health and optimize their performance in demanding roles.

Psychological problems and mental disorders in female victims of domestic violence

N. Semenova[1]*, M. Kachaeva[2], K. Tukhtaeva[2], N. Skibina[2] and L. Nazarova[3]

[1]Moscow Research Institute of Psychiatry; [2]V. Serbsky National Medical Research Centre for Psychiatry and Narcology and [3]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2433

Introduction: Domestic violence against women has increasingly been recognized nationally and internationally as a serious problem. Violence against women is a troubling phenomenon in Russia. Meanwhile, domestic abuse against women often results in severe psychological and mental health problems, including but not limited to depression, anxiety, and post-traumatic stress disorder.
Objectives: The main aim of the study was to find out the psychological and psychiatric consequences of intrafamily violence against women.
Methods: A cohort of 18 females turned to psychologists and psychiatrists and was examined. Details of background, as well as psychological and mental problems, were extracted. Each item was assessed with the help of descriptive statistics.
Results: Research has been carried out on the basis of psychological and psychiatric assessment of women who had a long history of violence by their husbands or partners, including sexual violence and maltreatment. Clinical assessment has revealed depression, anxiety, and adaptation disorders, accompanied by acute and chronic somatic diseases, low self-esteem, post-traumatic stress disorder, and drug abuse.
Conclusions: The research shows the high social and clinical significance of the consequences of abuse against women and also the necessity of domestic violence prevention by legal provisions and multidisciplinary research with the participation of psychiatrists, psychologists, and specialists in the fields of primary healthcare, education, and social protection.

Moroccan women and tattoos: characteristics, perception and stigmatization

A. Souidi[1,2]*, S. Stati[1], S. Belbachir[2] and A. Ouanass[2]

[1]Ar-razi hospital, Sale and [2]psychiatry B, Ar-razi hospital, Salé, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2434

Introduction: Tattooing is a mode of bodily expression that belongs to both tradition and modernity. This form of expression is rich in variant and variable meanings for women in general, and women with psychiatric disorders in particular. Their popularity and prevalence are increasing rapidly, particularly among young people. However, despite this expansion, the social perception of tattoos, particularly among women, remains a complex and often stigmatized subject. Hence the interest in knowing the characteristics of tattoos among women in Morocco, the different perceptions of the latter as well as the correlation of tattooing with psychiatric disorders.
Objectives: To study the characteristics, meaning and perception of tattoos among Moroccan women, past and present. In an attempt to better understand the potential health implications of this mode of expression and its correlation with mental health.
Methods: A descriptive cross-sectional study was carried out among women of different profiles. Data were collected using a form sent online and distributed in paper form. The form collected socio-demographic data, descriptive characteristics of the tattoos and the women's mental health status. Statistical analysis was performed using Jamovi 2.3.
Results: Our results focused on the socio-demographic characteristics of our population, it was carried out on 52 women, 57.7% of whom were aged between 25 and 40, 62% of our sample were single and the majority(92%) had a level of education higher than the baccalaureate. Also, almost 30% were unemployed. ours study results focused essentially on the tattoo characteristics, summarized in Image 1 . Image 2 shows the results concerning the psychiatric history of our population.

Image 1:

Prevalence	N=52(100%)
Number of tattoos	
1	22(42%)
2-5	24(47%)
>5	6(11%)
Age of first tattoo	
<18 years	8(16%)
18-22	16(30%)
22-25	18(35%)
>25 years	10(19%)
Size of tattoos	
Small<5cm	32(61,5%)
5-15cm	16(30,8%)
Big >15cm	4(7,7%)
Motivation(s) for tattooing	
Individuality	38,5%
Coping mechanism	16(30,8%)
Sexuality	0(0%)
After a life event	46,2%
Couple life	4(7,7%)
Other	6(11,5%)
Feelings towards tattoos	
Regret	6 (11,5%)
Neutral	26(50%)
Proud	18(34,6%)
Other	2(3,9%)
Desire to remove	
Yes	5(15,4%)
No	47(84,6%)

Image 2:

Prevalence	N=52(100%)
History of psychiatric consultation	
Yes	22(42,3%)
No	30(57,7%)
Psychiatric diagnosis	
Yes	8(15,4%)
Bipolar disorder	2(3,8%)
Depression	2(3,8%)
Anxiety disorder	1(1,9%)
Substance use disorder	1(1,9%)
Borderline personality	2(3,8%)
Psychiatric medication	5(9,6%)

Conclusions: Tattooing is a means of expression and a form of body modification, rich in cultural and personal significance, with a dual affiliation to tradition and modernity. It is highly prevalent among women, and has implications for both mental and physical health.

Factors affecting psychological distress or quality of life, and association between psychological distress and quality of life in Korean infertile women

H. Suh[1]* and S. Kim[2]

[1]Psychiatry, CHA University, School of Medicine and [2]Obstetrics and Gynecology, Fertility Center of CHA Gangnam Medical Center, CHA University School of Medicine, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2435

Introduction: Infertile patients are more likely to experience psychiatric illnesses than fertile patients, therefore it is important to have early intervention for psychiatric illnesses in infertile patients.
Objectives: This study aimed to determine the clinical factors affecting psychological distress and quality of life (QoL), and investigate the association between psychological distress and QoL in infertile women.
Methods: This was a prospective cohort study of 100 infertile women who voluntarily agreed to participate at their first visit from November 2018 to May 2019. Psychological distress and QoL were evaluated using the 2 questionnaires (SCREENIVF and FertiQoL) specifically designed for infertility.
Results: The prevalence screening positive for anxiety and depression risk were 42% and 29%, respectively. The number of miscarriage and *in vitro* fertilization (IVF) treatments were significantly associated with helplessness risk factor. Furthermore, women with 2 or more IVF treatments had lower emotional, and mind/body QoL domain scores than women with less than 2 IVF treatments. Regarding the association between the levels of psychological distress and QoL in infertile women, the largest association was observed between helplessness risk factor and mind/body QoL domain (r=-0.795, $p < 0.001$). Patients with more risk factors for psychological distress had the worse emotional, and mind/body QoL domain scores.
Conclusions: The levels of psychological distress were significantly associated with QoL in infertile women. These psychologically vulnerable infertile women may receive psychological evaluations and interventions from various angles with conventional treatments for infertility.

Attentional skills following traumatic brain injuries in elite female athletes

N. Syrmos[1]

[1]Aristotle University, Thessaloniki, Greece
doi: 10.1192/j.eurpsy.2025.2436

Introduction: Traumatic brain injuries are serious traumatic situations
Objectives: Aim of this study was to evaluate the attentional skills in cases with traumatic brain injuries, in elite female athlete
Methods: 3 female elite athletes (1 basket ball player, 1 runner and 1 ping pong player) were participated in this study, 60 days more or little less after cervical spine injuries. Range of age 25-35 years and mean age 29.
We used specific performance tests, letter cancellation exam, naming trials and iq tests.
Results: All of them(3,100%) reported deficits in all areas of attention function and also cognitive and emotional status.2 of them (66%) reported also difficulty in complex task activities, especially when time limits were imposed.
Conclusions: All these exams are good and efficient tools in order to evaluate this kind of patients.

Women, Gender and Mental Health: What factors help mentally ill birth mothers navigate Child Welfare Services during the perinatal period?

H. L. A. C. R. Wanigasekera[1]* and A. Buist[2]

[1]Psychiatry, Austin Health and [2]Psychiatry, University of Melbourne, Melbourne, Australia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2437

Introduction: Women, Gender and Mental Health: What factors help mentally ill birth mothers navigate Child Welfare Services during the perinatal period?
Chamali Wanigasekera[1] MBBS, AMC, MPsych, FRANZCP
Anne Buist[1,2] MBBS, MMed, MD, FRANZCP
1. Austin Health, Heidelberg, Victoria, Australia
2. University of Melbourne, Victoria, Australia

Email: Chamali.WANIGASEKERA@austin.org.au; a.buist@unimelb.edu.au
Background: Mental Illness is common in the perinatal period. Given the dependency of infants, additional factors such as lack of support, family violence and comorbid drug use may place the infant at significant physical and psychological harm. Anecdotal information suggests that many of these women do not receive adequate support during the perinatal period. However, the factors that predict and protect families, enabling them to stay together and function in a "good enough "manner, remain unclear.
Objectives: Aims: To review the current literature examining protective service involvement in the women who present with mental illness in the perinatal period.
Methods: A systematized review of the literature was conducted through a comprehensive search of databases for psychosocial and medical research (MEDLINE, PsycINFO, Embase, Emcare, Cochrane Library) and a targeted search of the grey literature to select the relevant studies that meet the inclusion criteria. Original papers were included if they were written in English and published before September 1, 2022. Sixteen studies were selected for inclusion.
Results: Protective and predictive factors that help mentally ill mothers to continue as primary caregivers will be presented. The factors that determine risks for child protective involvement and child removal in mothers with mental illness are also discussed.
Conclusions: The results of this research will provide recommendations on how to deliver sensitive perinatal mental health care for mothers already involved with the Child Welfare Services, aiming to minimize child removal.

Anxiety and depression in women cycling naturally and taking oral contraceptives – a daily diary study

M. Kowalczyk[1]*, M. Kornacka[2] and I. Krejtz[1]

[1]Psychology, SWPS University, Warsaw and [2]Psychology, SWPS University, Katowice, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.633

Introduction: While the literature is inconsistent about the link between anxiety and oral contraceptives (OC) (Beltz FIN 2022; 67) the link between depression and OC is recognized in women who started taking OC during adolescence (Skovlund *et al.* JAMA Psychiatry 2016; 73). The review by Beltz gives many indications on how to conduct studies on these topics in a more reliable manner as there are a lot of variables to consider, such as assessing the exact phases of the menstrual cycle, comparing the active and inactive phases of OC or considering the types of OC. Other limitations described in the review are a lack of longitudinal studies and small sample sizes. The present study tried to take into account as many of these variables as possible.
Objectives: Our study aimed to understand the differences between women taking OC and naturally cycling (NC) women regarding their daily levels of anxiety, depression, protective factors (self-esteem and daily satisfaction with life), perseverative cognition (worry and perseverative thinking) and stress.
Methods: 89 women (48 – OC; 41 – NC) participated in a daily diary study in which they completed an online diary for 15 days divided into 3 phases of the menstrual cycle: menstruation, follicular and luteal. The women using OC were further classified according to the androgenicity of their OC: androgenic progestins are derived from testosterone while anti-androgenic progestins block androgen receptors (Raudrant & Rabe Drugs 2003; 63).
Results: There were no differences between groups in daily levels of anxiety, perseverative cognition, and stress. However, anti-androgenic OC users had higher levels of daily depression than NC women in all the phases of the menstrual cycle while androgenic OC users had higher levels of depression than NC women in the menses and follicular phases. Both groups of women taking OC had lower levels of daily self-esteem than NC women in all phases of the menstrual cycle. Androgenic OC users had higher daily satisfaction with life than anti-androgenic OC users in two phases.
Conclusions: Our study found differences between groups in daily levels of depression and protective factors linked with it, namely self-esteem and satisfaction with life. Overall, OC users had higher levels of depression and lower levels of self-esteem than NC women. However androgenic OC users had higher daily satisfaction with life than anti-androgenic OC users. We believe that our study has contributed to the literature by conducting a longitudinal assessment of anxiety and depression on a daily level by comparing NC

women and OC users during multiple phases of the menstrual cycle and taking into account the differences between androgenic and anti-androgenic OC. Future studies could explore the link between depression and its protective factors in women taking OC.

Obsessive-Compulsive Disorder: Neurocognitive Links with Impulsivity and Inhibitory Control

D. V. Cotovio[1]*, R. S. Nogueira[1], R. Lousada[1], M. B. Resende[1], F. Agostinho[1], M. M. Melo[1] and M. J. Heitor[1]

[1]Departamento de Psiquiatria e Saúde Mental, Hospital Beatriz Ângelo, Loures, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2438

Introduction: Obsessive-compulsive disorder (OCD) and attention-deficit/hyperactivity disorder (ADHD) share overlapping neurobiological and neurocognitive profiles, particularly in domains such as impulsivity, compulsivity and inhibitory control. Recent research has explored these commonalities, as well as the differences in brain structure, neural circuits, and cognitive impairments.
Objectives: The aim of this review is to synthesize findings about the neurocognitive and neurobiological profiles of OCD and ADHD.
Methods: A literature search was conducted on PubMed in September 2024 using the following terms: "OCD" AND "ADHD," "OCD" AND "attention-deficit/hyperactivity disorder," "obsessive-compulsive disorder" AND "ADHD," and "obsessive-compulsive disorder" AND "attention-deficit/hyperactivity disorder." Only systematic reviews and meta-analyses were included, with no year or language restrictions. Seven articles met the scope of this review.
Results: On one hand, the selected studies indicate that both OCD and ADHD exhibit significant deficits in inhibitory control, as measured in the Stop Signal Task and antisaccade task. These findings are corroborated by neuroimaging abnormalities in brain regions implicated in inhibition, that includes the frontostriatal circuits. Studies also suggest that compulsivity may stem from dysfunctional glutamatergic transmission in frontostriatal circuits. On the other hand, though structural analyses reveal a shared pattern of brain alterations in OCD, major depressive disorder, bipolar disorder, and schizophrenia, ADHD appears to have different morphometric properties. Furthermore, electrophysiological studies also demonstrate contrasting patterns of error detection between the disorders: increased error-related negativity (ERN) in OCD and reduced ERN in ADHD.
Conclusions: OCD and ADHD share common neurobiological and neurocognitive traits, yet distinct differences in brain structure and neurocognitive processing also emerge. This review highlights the importance of transdiagnostic approaches, which may facilitate the development of more targeted treatments for patients with overlapping neuropsychiatric conditions. Further research is necessary to understand the full extent of these shared and unique characteristics, in order to inform more refined diagnostic criteria and therapies.

Old Age Psychiatry

EPV2068

Evaluation of a Psychiatry of Later Life Consult Liaison Integration Initiative

S. Crowley[1]*, M. Russell[2] and N. McCarthy[2]

[1]South Lee Mental Health Services, Cork University Hospital, Cork and [2]Clare Pscyhiatry Of Later Life, Gort Glas, Lifford Road, Ennis, Co. Clare, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2439

Introduction: Older people's complex healthcare needs require the development of integrated mental and physical health services. The College of Psychiatrists of Ireland's Faculty of Psychiatry of Old Age (POA) is in the process of drafting a position statement on the integration of POA with other services for older people such as the Integrated Care Program for Older People (ICPOP). ICPOP provides geriatric multi-disciplinary treatment in the community. In January 2024, the Clare Psychiatry of Later Life (POLL) team set up a novel consult liaison (CL) service with our local colleagues ICPOP colleagues.
Objectives: The authors aim to describe a novel model of care for our newly developed ICPOP CL service. It may be of interest to other POLL teams who wish to expand their CL service to include their local ICPOP services or other community services. We also evaluated: referral patterns to the Clare POLL CL service, the number of referrals from the ICPOP CL service in its first six months, and key patient characteristics of ICPOP CL referrals compared to inpatient CL referrals.
Methods: The model of care for our novel ICPOP CL clinic is described in detail. Patients were discussed at integrated multidisciplinary meetings. Cases brought by ICPOP for discussion with POLL could result in advice, a consult in a designated ICPOP CL clinic, or a referral for joint care. Joint teaching sessions were also arranged.
Results: 71.25 % (n=57, n=80) of referrals from Ennis General were for POLL CL. Conversely, CL referrals made up 21.43 % (n=81, n=378) of referrals to the Clare POLL service overall. ICPOP CL referrals made up 31.58% (n=18, n=57) of the POLL CL referrals over six months and made up 10% (n=18, n=180) of overall referrals to the Clare POLL service for the same period. Of these 18 ICPOP CL referrals, only four (22.22%) required joint care. Seven patients were referred by POLL to ICPOP for joint care over the same period. Patient characteristics were summarized by table 1.

Image 1:

Table 1. Clare POLL Consult Liaison Referrals

	Referrals	Inpatient CL	ICPOP CL	Overall
		n =63 (78%)	*n=18 (22%)*	*n=81 (100%)*
Gender	Female	35 (56)	16 (89)	51 (63)
Age	65-70	4 (6)	0 (0)	4 (5)
	70-80	18 (29)	6 (33)	24 (30)
	80-90	33 (52)	11 (61)	44 (54)
	90+	8 (13)	1 (6)	9 (11)
Psychiatric History	Nil Reported	26 (41)	11 (61)	37 (46)
	Treated by GP only	16 (26)	3 (17)	19 (23)
	Previously known to CMHT	21 (33)	4 (22)	25 (31)
Reason for referral	Agitation/confusion	26 (41)	0 (0)	26 (32)
	Low mood/anxiety	24 (38)	10 (56)	34 (42)
	Psychotic symptoms	6 (10)	0 (0)	6 (7)
	Dementia/MCI diagnosis	4 (6)	5 (28)	9 (11)
	BPSD	1 (2)	3 (16)	4 (5)
	Other	2 (3)		2 (3)
Diagnosis on review	Delirium	34 (54)	0 (0)	34 (42)
	Dementia	7 (11)	3 (17)	10 (12)
	BPSD	1 (2)	4 (22)	5 (6)
	Depression	1 (2)	4 (22)	5 (6)
	Anxiety Disorder	2 (3)	2 (11)	4 (5)
	Adjustment	7 (11)	3 (17)	10 (12)
	Psychosis	0 (0)	0 (0)	0 (0)
	Other	3 (5)	2 (11)	5 (6)
	Not assessed	8 (13)	0 (0)	8 (10)
POLL follow-up required		23 (37)	4 (22)	27 (33)

Table 1: CL=consult Liaison, POLL=Psychiatry of Later Life, ICPOP=Integrated Care for Older People Service, BPSD= Behavioural and Psychological Symptoms of Dementia.

Conclusions: The authors present a service integration initiative between a local POLL and ICPOP service, which they believe was mutually beneficial to both services and the patients they serve. The characteristics of patients referred to POLL from the new integration with ICPOP resemble other community referrals, as opposed to inpatient CL referrals.

EPV2069

The relation between perception of vulnerability, stress, depression and anxiety in public health threats

C. de Sousa[1,2,3], J. Ferreira[4]* and S. Tukaiev[5]

[1]Higher School of Health Atlântica, Barcarena; [2]Center for Research in Education and Psychology (CIEP-UÉ), Evora; [3]Atlântica - University Institute, Barcarena; [4]Faculty of Medicine, University of Coimbra, coimbra, Portugal and [5]National University of Ukraine on Physical Education and Sport, Kyiv, Ukraine

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2445

Introduction: Several authors have demonstrated that COVID-19 pandemic was characterized by feelings of fear, anxiety and insecurity (Wang *et al.*, Int JERPH 2020; 17, 1729) Emotions and affective states as nervous, apprehension, despair, preoccupation was also studied (de Sousa *et al.*, *PSYCH* 2024; *6*(1), 163-176). Therefore, affective but also cognitive factors were important to the perception of the pandemic threat and its impact. In accordance, it seems important to understand if the perception of each one vulnerability to COVID-19 is related with the development of high levels of stress, depression and anxiety symptoms.
Objectives: The main goal of this study was to evaluate the relation between the perception of vulnerability, stress, depression and anxiety in public health threats, as COVID 19.
Methods: This study followed a cross-sectional design and its sample consisted of 600 participants, distributed between two countries (N_{Brasil}=300; $N_{Portugal}$=300). The instrument used to assess the three dimensions: stress, anxiety, and depression, with seven items each were the Depression Anxiety Stress Scale 21-item version (DASS-21) (Lovibond & Lovibond; BHV, 1995; 33, 335-43) presented in a four-point response scale (0-Not applied to me; 3- Applied to me most of the time). To assess the perception of vulnerability to COVID-19 a 5 item Likert Scale were used (1-Not vulnerable; 5-Extremely vulnerable). The protocol was developed online, presenting the objectives of the study, and ensuring the anonymity and confidentiality of data. A non-probabilistic sampling technique of convenience and snowball were used. The data was collected in 2023 and referred to COVID-19.
Results: The results suggest that perception of vulnerability to COVID-19 are very similar in both countries (M_{Brazil}= 3.20, DP_{Brazil}= .98 ; $M_{Portugal}$= 3.13, $DP_{Portugal}$=.91). The values in Brazil of stress (M=7.40), depression (M=5.73) and anxiety (M=4.01) are higher compared to Portugal, with the following values of stress (M=4.07), depression (M=2.62) and anxiety (M=1.6). The perception of vulnerability is related with the three dimensions studied (stress, anxiety and depression) in both countries, with the following values in Brasil: Stress (r=.341; p< .01); depression (r=.270; p<.01) and anxiety (r=.316; p<.01). In Portugal the values of correlation were: Stress (r=.284; p< .01); depression (r=.252; p<.01) and anxiety (r=.350; p<.01). These results emphasized that relation between the perception of vulnerability and anxiety presented higher levels in both countries.
Conclusions: In conclusion, our study have shown significative relations between the perception of vulnerability to COVID-19 with levels of stress, depression and anxiety in the countries studied. Therefore, our data emphasized the relevance to study the perception of vulnerability in public health events to better manage and prevent psychopathological symptoms.
