Objectives: To present the clinical case of a 14-year-old male with an unspecified eating disorder and high-risk mental state for psychosish To highlight the importance of early identification and intervention in eating disorders with psychotic features.
Methods: A Pubmed database was used to collect information about psycothic symptoms in EDs, using the terms 'eating disorder', 'pyscosis' and 'high risk mental state'.
We present the following clinical case:
A 14-year-old spanish male of Bolivian descent. The patient exhibited a two-year history of food restriction, vigorous exercise, social isolation, and absenteeism from school. Detailed clinical evaluations were performed, documenting his physical, psychological, and behavioral symptoms. The patient's diagnosis was reevaluated based on emerging psychotic symptoms during hospitalization.
Results: The patient reported intense distress about perceived fat accumulation in his face and trunk, which he believed diminished immediately after exercise. He engaged in excessive physical activity, including jumping rope for at least two hours multiple times a day, and swimming against currents. He also experienced episodes of binge eating followed by purging and compensatory exercise. Social withdrawal, emotional blunting, disorganized biological rhythms, and soliloquies were observed during his admission. Based on these findings, his diagnosis was revised to an unspecified ED with a high-risk mental state for psychosis.
Conclusions: Psychotic symptoms, particularly in restrictive anorexia, can arise during the course of an ED, with malnutrition acting as both a cause and sustaining factor by exacerbating serotonin-dopamine dysregulation (Sarró, S (2018). Those courageous boys: 73 years after the Minnesota starvation experiment. A psychiatrist's view. Neurosciences and History, 6(1) , 28-37). While these symptoms may result from malnutrition, they could also signal the onset of a primary psychotic disorder, with males at higher risk (3.6%). Early detection of attenuated or prodromal psychotic symptoms is essential, and regular reevaluation is recommended, especially during the first months of follow-up, to prevent short-, medium-, and long-term complications.

Beyond the Plate: Evidence-Based Psychotherapies for Eating Disorders - A Transdiagnostic Comparison

R. M. Lopes[1]*, A. F. Silva[1], A. C. Rodrigues[1], A. C. Matias-Martins[1], F. M. A. Santos[1], P. M. F. Coelho[1], T. A. A. Vieira[1] and V. S. Melo[1]

[1]Psychiatry and Mental Health Department, Unidade Local de Saúde do Médio Tejo, Tomar, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1401

Introduction: Eating disorders (EDs), including binge-eating disorder (BED), bulimia nervosa (BN), and anorexia nervosa (AN), represent serious mental health conditions characterized by disturbances in eating behavior and body image concerns. These disorders significantly impair health, psychosocial functioning, and quality of life. Evidence-based psychotherapies have shown effectiveness in treating EDs.
Objectives: This study aims to evaluate and compare the effectiveness of various psychotherapies for treating BED, BN, and AN, with a focus on both short-term and long-term outcomes. A secondary objective is to assess the applicability of transdiagnostic psychotherapy approaches across different EDs.
Methods: A literature review was conducted using articles from PubMed, focusing on the terms "eating disorders", "evidence-based psychotherapy", "cognitive-behavioral therapy", and "interpersonal psychotherapy". The selection prioritized the most relevant clinical trials and meta-analyses.
Results: Cognitive-behavioral therapy (CBT) consistently demonstrated significant short-term effects in reducing binge-eating episodes and EDs psychopathology, particularly in BED and BN. It outperformed both inactive controls (e.g., wait-lists) and other psychotherapies. Long-term, CBT continued to show sustained improvements in symptom reduction, particularly for BED, though it was less effective for BN and AN.
For the treatment of AN, most guidelines recommended psychological interventions, particularly family-based therapy (FBT) for younger patients. CBT and structured therapies like Maudsley Anorexia Nervosa Treatment for Adults (MANTRA) were also recommended. Interpersonal psychotherapy (IPT) received limited support due to insufficient evidence.

In BN, CBT was widely endorsed as the first-line treatment. IPT was recommended as an alternative, noted for its slower symptom \reduction but equivalent long-term efficacy. FBT was recommended for younger patients.
For BED, CBT was consistently recommended as the first-line treatment, with growing evidence supporting guided CBT self-help. IPT was recommended by several guidelines as an alternative.
Conclusions: CBT was the most consistently recommended treatment for all EDs, particularly for BN and BED, offering faster symptom reduction, higher remission rates, and better long-term outcomes. While IPT is a viable alternative, particularly for BED, it generally takes longer to achieve comparable results. The findings emphasize the need for more personalized treatment approaches and the exploration of adjunctive therapies to improve outcomes, especially for AN. Further research is required to refine therapy selection and address the distinct challenges posed by different ED subtypes, particularly in achieving long-term treatment success.

Critical Insights: Hospital Admissions for Eating Disorders in Spanish Youth – A National Study

A. Muñoz San Jose[1,2,3,4]*, P. Vázquez-Giraldo[1] and T. López-Cuadrado[5,6]

[1]Department of Psychiatry, Clinical Psychology, and Mental Health, La Paz University Hospital; [2]Department of Psychiatry, Autonomous University of Madrid (UAM); [3]Psychiatry and Mental Health Group, Neurosciences Research Area, Hospital La Paz Institute for Health Research (IdiPAZ), Madrid; [4]Centre of Biomedical Research in Mental Health (CIBERSAM: CB/07/09/0013), Institute of Health Carlos III, Spain; [5]Department of Chronic Diseases Epidemiology, National Centre for Epidemiology, Institute of Health Carlos III and [6]Department of Preventive Medicine and Public Health, Autonomous University of Madrid (UAM), Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1402

Introduction: Eating disorders (EDs) are complex conditions with significant impacts on physical and mental health. This study investigates hospital admissions and resource utilization for EDs among pediatric patients in Spain over a seven-year period, emphasizing the effects of the COVID-19 pandemic.
Objectives: To analyze the epidemiological trends, prevalence, and hospital resource use for pediatric ED admissions in Spain from 2016 to 2022.
Methods: A retrospective analysis was conducted using data from Spain's Minimum Basic Data Set of acute hospitals (CMBD-H) for patients aged 10–19 years with an ED diagnosis (ICD-10-CM code F50) between January 1, 2016, and December 31, 2022. Trends in hospitalization rates, types of EDs, comorbidities, and resource utilization were assessed.
Results: The study identified 8,275 pediatric ED admissions, comprising 17% of all mental disorder admissions. **Table 1** summarizes the characteristics of hospital admissions by age group (10-14 years and 15-19 years). Hospitalization rates increased from 19.4 per 100,000 in 2016 to 32.7 in 2022, with a notable rise in the 10–14-year age group post-pandemic. Anorexia Nervosa (AN) was the predominant diagnosis (71.6%). Psychiatric comorbidities were present in 35.6% of cases. The average length of stay was 24 days, with annual direct medical costs totaling €3 million and a median cost per admission of €11,580. AN patients had longer hospital stays (median 28 days) compared to other disorders, while Bulimia Nervosa (BN) patients had shorter stays (median 14 days) but higher average costs (€12,300). **Table 2** details the average hospital length of stay and average cost of hospital admissions for EDs among adolescents in Spain.

Image 1:

Table 1. General characteristics of hospital admissions for EDs in children and youth divided by age group.

	Total	10-14y	15-19y	P-value†
Number of admissions	8,275	3,450	4,825	
Sex, female	7,669 (92.7)	3,162 (91.6)	4,507 (93.4)	.002
Hospital admission				<.001
Anorexia Nervosa	5,923 (71.6)	2,518 (73.0)	3,405 (70.6)	
Bulimia Nervosa	361 (4.6)	55 (1.6)	306 (6.4)	
Other Eating Disorders	422 (5.1)	229 (6.6)	193 (4.0)

Main psychiatric comorbidities				<.001
Yes	2,945 (35.6)	1,013 (29.4)	1,932 (40.0)	
Median stay (IQR) in days‡	24 (10, 40)	26 (11, 40)	23 (9, 40)	.0032

†Chi-2 Test; ‡ U-Mann Whitney Test, IQR: Interquartile range

Image 2:

Table 2. Use of hospital resources

	Median stay (IQR) in days			Average costs in euros		
	All-age	10-14y	15-19y	All-age	10-14y	15-19y
Eating disorders	24 (10, 40)	26 (11, 40)	23 (9, 40)	11580	11497	11639
Anorexia nervosa	28 (14, 43)	29 (15, 42)	28 (13, 44)	13216	13183	13241
Bulimia nervosa	14 (8, 23)	15 (12, 24)	14 (7, 23)	12292	12631	12230
Other eating	12 (5, 28)	13 (5, 28)	12 (5, 27)	6028	5964	6105
Eating disorder, unspecified	15 (6, 29)	17 (7, 30)	14 (5, 28)	6731	6808	6678

Conclusions: There was a 70% increase in pediatric ED admissions in Spain from 2016 to 2022, with a significant post-pandemic rise in younger patients. This underscores the need for improved early detection and intervention strategies, as well as enhanced screening for comorbid mental health conditions to manage the growing hospital demand effectively.

The Digital Diet Dilemma: Social Media's Role in the Rise of Interest in Orthorexia

J. Parkerson[1]* and C. Noureddine[1]

[1]Psychiatry, Icahn School of Medicine at Mount Sinai, New York, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1403

Introduction: Since its inception in 1997, the term orthorexia nervosa (ON), derived from the Greek words for "right" and "appetite" (Donini et al, 2022), has been utilized to describe an obsession with "correct" or "healthy" eating. Despite numerous

authors suggesting diagnostic criteria and the publication of several theoretical papers, consensus regarding a definition or even the existence of ON remains elusive (Dunn and Bratman, 2016). Conversely, anorexia nervosa (AN) has been recognized since the first iteration of the DSM (Bhattacharya et al, 2022; Dell'Osso et al 2016). Layperson awareness of these conditions has been increasing, with a notable increase in interest in "orthorexia" over the past several years, potentially influenced by popular culture and increased social media use (Sharma et al, 2023)

Objectives: The purpose is to understand shifts in public interest as well as the ever-present influence of the online world on patients, especially those with disorder eating patterns.

Methods: This study compared United States Google search trends for the terms "orthorexia" and "anorexia" . Using Google Trends data, we reviewed the average monthly search volume from January 2004 to March 2024. We analyzed the data to determine if there was a significant difference in search volume over time.

Results: Google search data revealed a monthly search volume of ˜7000 queries for "orthorexia" in January 2004, and analysis of the volume revealed that there has been a significant and sustained increase in the searches for "orthorexia". Additionally, searches for the term "anorexia" reached a height of 2.1 million in 2007, but have been steadily declining in the past several years.

While anorexia remains the more prominent search term, over time the queries for anorexia have decreased from their peak in the early 2000's. The rise in the term orthorexia may be partly due to the proliferation of highly visual social media platforms, particularly YouTube and TikTok, where content creators often focus on healthy eating and lifestyle trends (Sharma et al, 2023).

Additionally, there is a possibility that orthorexia is being used on these platforms to describe a subset of AN. Some individuals with anorexia may present with behaviors resembling orthorexia, such as a fixation on healthy eating or a rigid adherence to specific dietary guidelines.

Conclusions: The findings indicate a shift in the public's interest in orthorexia and anorexia during the past several years, possibly influenced by increased social media use. Further research is needed to understand the implications of this trend on individuals' attitudes towards healthy eating and body image.

Personality traits and risk of eating disorders among Polish women: the moderating role of self-esteem

K. Rachubińska[1]*, D. Schneider-Matyka[1], A. M. Cybulska[1], M. Nowak[1] and E. Grochans[1]

[1]Department of Nursing, Pomeranian Medical University, Szczecin, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1404

Introduction: Personality dimensions should be taken into account when diagnosing individuals with disordered eating behaviours in the hope of better understanding their etiology and symptom progression and when planning treatment.

Objectives: The objective of this study was to attempt to determine the moderating role of self-esteem in the relationships between personality traits included in the Big Five model among Polish women and the occurrence of eating disorders.

Methods: The study was conducted among 556 Polish women from Zachodniopomorskie Voivodeship. A diagnostic survey was used as the research method, and the empirical data were collected using the following research tools: The NEO Five-Factor Inventory (NEO-FFI), Rosenberg Self-Esteem Scale (SES), ORTO – 15 *Questionnaire*, The Three-Factor Eating Questionnaire (TFEQ-13), and the authors' original questionnaire.

Results: Only the personality trait of neuroticism exhibits a statistically significant effect on the "Cognitive Restraint of Eating", "Uncontrolled Eating", and "Emotional Eating" scores ($p<0.001$). The moderation effect was demonstrated between self-esteem and the personality trait of conscientiousness on the "Cognitive Restraint of Eating" scale score. There is a moderation effect between self-esteem and the personality trait of extraversion on the "Uncontrolled Eating" subscale score. There is a moderation effect between self-esteem and the personality trait of conscientiousness on the "Uncontrolled Eating" scale score.

Table 1. Analysis and the moderation effect between self-esteem and the personality trait of conscientiousness in the effect on the "Cognitive Restraint of Eating" subscale score.

		95% Confidence Interval			
	b	Lower	Upper	Z	p
C stens	-0.150	-0.220	-0.080	-4.214	< 0.001
Rsbrg	-0.001	-0.022	0.020	-0.097	0.923
C stens * Rsbrg	0.010	0.000	0.019	2.040	0.041
Low (-1SD)	-0.221	-0.320	-0.122	-4.380	< 0.001
Average	-0.150	-0.220	-0.080	-4.200	< 0.001
High (+1SD)	-0.079	-0.176	0.018	-1.590	0.111

b – unstandardised regression coefficient, CI – confidence interval; * moderation effect. *Note.* shows the effect of the predictor (conscientiousness) on the dependent variable (Cognitive Restraint of Eating) at different levels of the moderator (Rsbrg)

Conclusions: Self-esteem was not a predictor of the occurrence of eating disorders while playing a moderating role in the relationship between certain personality traits and the occurrence of eating disorders. A higher level of neuroticism was identified as an important predictor of higher results for orthorexia, Cognitive Restraint of Eating, Uncontrolled Eating, and Emotional Eating. It was also demonstrated that the orthorexia risk index decreased with increased extraversion and openness to experience.

EPV0718

The relationship between depressiveness and eating behaviors among women

K. Rachubińska[1]*, D. Schneider-Matyka[1], E. Grochans[1], I. Cerzniewska[1] and A. M. Cybulska[1]

[1]Department of Nursing, Pomeranian Medical University, Szczecin, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1405

Introduction: Research has demonstrated the effect of eating disorders on the occurrence of depressiveness as well as the effect of depressiveness on the occurrence of eating disorders.

Objectives: The objective of the study was to determine the relationship between depressiveness and the occurrence of eating disorders, i.e., emotional eating, uncontrolled eating, cognitive restraint of eating, and the risk of orthorexia.
Methods: The study was conducted among 556 women from the West Pomeranian Voivodeship (Poland). The study employed the diagnostic survey method using a questionnaire technique: The Beck Depression Inventory, the ORTO—15 Questionnaire, the Three-Factor Eating Questionnaire, and a sociodemographic questionnaire.
Results: Higher depressiveness severity is associated with a higher score on the "Cognitive Restraint of Eating" scale. The authors' original study demonstrated a statistically significant relationship only between depressiveness and the "Uncontrolled Eating" subscale ($p = 0.001$).
Table 1. A multivariate model without moderation—analysis of the effect of sociodemographic variables and the severity of depressiveness according to the BDI on cognitive restraint of eating according to TFEQ-13

	Level	ß	−95% CI	+95% CI	t	p
Marital status	Single (ref.)					
	In a relationship	0.091	0.005	0.176	2.084	0.038
Professional activity	Inactive (ref.)					
	Active	−0.046	−0.135	0.043	−1.008	0.314
Age		−0.166	−0.260	−0.073	−3.511	<0.001
BDI (scoring)		0.228	0.147	0.309	5.527	<0.001

ref.—reference level, ß—standardized regression coefficient, CI—confidence interval, and BDI—Beck Depression Inventory
Table 2. A multivariate model with moderation—analysis of the effect of sociodemographic variables and the severity of depressiveness according to the BDI on cognitive restraint of eating according to TFEQ-13

	ß	−95% CI	+95% CI	t	p
Absolute term				1.914	0.056
Marital status*BDI	0.015	−0.147	0.176	0.178	0.859
Age*BDI	−1.344	−6.233	3.545	−0.540	0.589
Professional activity*BDI	−0.037	−0.236	0.162	−0.362	0.717
Educational background*BDI	0.013	−0.145	0.171	0.165	0.869
Residence *BDI	0.153	0.002	0.305	1.994	0.047

ref.—reference level, ß—standardized regression coefficient, CI—confidence interval, BDI—Beck Depression Inventory, and * moderation effect
Conclusions: The results of this study suggest that depressiveness is an important factor that contributes to a better understanding of eating behaviors. In addition, the results of this study suggest that eating behaviors and psychological factors should be taken into account in psychological interventions in the treatment of eating disorders. The clinical goal can be considered to be an improvement in non-normative eating behaviors, such as a reduction in overeating episodes or eating less frequently in the absence of a feeling of hunger.

Disclosure of Interest: None Declared

EPV0719

Deontological guilt feelings in eating disorders: data from an Italian experience

F. Raffone[1]*, D. Atripaldi[2], F. Mancini[3], A. M. Saliani[3] and A. M. Monteleone[4]
[1]Department of Mental Health, Asl Napoli 1 Centro,Università degli Studi della Campania "L. Vanvitelli"; [2]Department of Advanced Medical and Surgical Sciences, Università degli Studi della Campania "L. Vanvitelli", Naples; [3]Scuole di Psicoterapia Cognitiva APC-AIPC-SPC-SICC, Rome and [4]Department of Mental Health, Università degli Studi della Campania "L. Vanvitelli", Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1406

Introduction: Guilt and shame are common emotional experiences that may influence the prognosis and treatment of many psychiatric disorders.
Objectives: The aim of this study was to examine the role of guilt and shame in individuals with eating disorders (ED).
Methods: Forty-three adults diagnosed with anorexia nervosa, bulimia nervosa, and binge eating disorder were included in the study. They completed the following questionnaires: the Moral Orientation Guilt Scale (MOGS), which measures different components of guilt, and the Eating Disorder Inventory 2 (EDI-2), which measures ED psychopathology. To assess the relationships between MOGS and EDI-2 subscales, Spearman's correlations and a stepwise multiple regression have been conducted including all patients in a unique ED group.
Results: Positive correlations were found between the EDI-2 bulimia subscale and the MNV (moral normal violation) subscale of the MOGS (0.26, p.=0.05), between the EDI-2 interpersonal distrust subscale and the MNV subscale of the MOGS (Rho=0.28, p=0.03), and between the EDI-2 interpersonal distrust subscale and both altruistic guilt components of the MOGS (Rho=0.33, p=0.01 for harm; Rho=0.29, p=0.03 for empathy). The multiple linear regression model was significant (R^2=0.29, F=8.38, p.<0.01) and showed age (t=-2.9, p<0.01) and the HARM subscale (t=3.4, p<0.01) as predictors of interpersonal distrust.
Conclusions: The results provide preliminary evidence for a possible role of guilt in the aetiopathogenesis of ED. Sensitivity to altruistic guilt, and especially to the harm caused, seems to influence the ability to trust others. Avoidance, distancing, or closure may be strategies to overcome high sensitivity to guilt. Further studies with larger samples, including both ED patients and healthy individuals, are needed to determine the role of guilt in EDs.

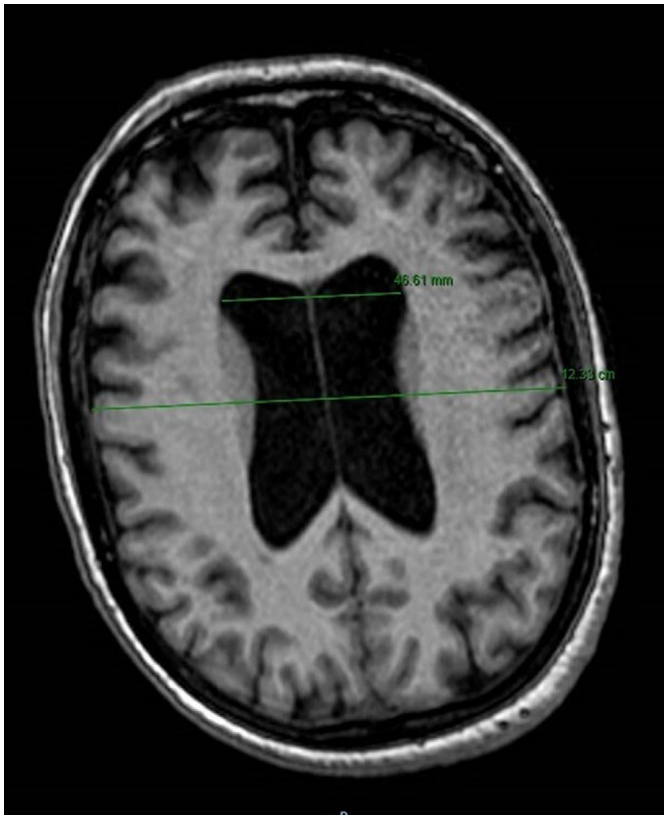
Pica, a complex differential diagnosis. A case report

I. Ramos Suárez[1]* and M. Guerrero Jiménez[1,2]

[1]Psychiatry, San Cecilio University Hospital and [2]Psychiatry, Granada University of Medicine, Granada, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1407

Introduction: The Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) defines pica as the ingestion of non-nutritive and non-food substances. For a diagnosis to be made, the behavior must persist for at least one month, not be consistent with the child's developmental stage, and not be a socially normative or culturally accepted practice.The etiology of pica is not well understood. Additionally, knowledge about its overall prevalence is limited.

Objectives: We present the case of a 61-year-old female patient diagnosed with histrionic personality disorder and generalized anxiety disorder, who began to frequently visit the hospital emergency department due to the ingestion of various objects, such as screws, paper clips… (Image 1). It was decided to admit her to the psychiatric ward with two main objectives:To halt the progression of disruptive behaviors and to determine the underlying cause of the pica behaviors.



Methods: During hospitalization, no clear affective disturbances toward any polarity were observed. Additionally, the patient was unable to coherently justify her behaviors, merely describing them as "spontaneous and irresistible impulses." However, significant cognitive impairment was evident during the admission. Furthermore, the presence of balance disturbances with lower limb incoordination and urinary incontinence was confirmed. The described triad—gait disturbances, urinary incontinence, and cognitive deterioration—is characteristic of adult chronic hydrocephalus (ACH). Given this suspicion, a cranial computed tomography (CT) scan, was requested.

Results: The Evans' index (EI) was calculated. An EI greater than 0.30 is indicative of ventricular dilation, and the patient's EI was 0.39 (Image 2). The high clinical suspicion, insidious onset, and the ventricular dilation observed made the diagnosis of ACH highly probable. Consequently, the patient was referred to the neurosurgery department to evaluate the potential placement of a cerebrospinal fluid shunt.

Image 1:

Image 2:

Conclusions: Although pica behaviors can be associated with various psychiatric disorders, there is often an underlying organic substrate. In this patient, the initial diagnosis of personality disorders and generalized anxiety, coupled with the repetitive pica behaviors, might have initially pointed exclusively toward a psychiatric approach. The identification of a broader symptomatic pattern, led to the suspicion of adult chronic hydrocephalus (ACH). The triad of symptoms in ACH, though classic, may not always be evident, and neuropsychiatric manifestations such as pica could be indirect signs of brain involvement.
This case underscores the need to consider organic differential diagnoses in patients presenting with atypical or unexplained behaviors from a purely psychiatric standpoint.

Case study of GBMT post-bariatric surgery with psychiatric co-morbidities

S. Ramos-Perdigués[1,2*], Ï. Robert-Montaner[3], M. Martín-Fernández[4], M. Pérez[1], J. Ramos[5], O. Sarroca[4] and C. Mur de Viu[1]

[1]Psychiatry, Hospital Nostra Senyora de Meritxell, Escaldes-Engordany, Andorra; [2]Psychiatry, Gestió de Serveis Sanitaris, La Seu d'Urgell, Spain; [3]Sherwood Forest Hospitals NHS Foundation Trust, Sutton in Ashfield, United Kingdom; [4]Internal Medicine and [5]Psychology, Hospital Nostra Senyora de Meritxell, Escaldes-Engordany, Andorra
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1408

Introduction: Gelatinous bone marrow transformation (GBMT) is a degenerative change in hematopoietic bone marrow, initially linked to anorexia nervosa (AN) and recently to bariatric surgery (BS) (Böhm *et al.* Am J Surg Pathol 2000; 24(1) 56-65). BS is associated to malabsorption, nutrient deficits, diets, and medical complications resembling eating disorders (ED) (Conceição *et al.* Int J Eat Disord 2023; 56(4) 831-834), complicating diagnosis and management. Treating the underlying cause is key for GBMT recovery.
Objectives: Review BS complications: malnutrition, GBMT and AN with normal Body Mass Index (BMI).
Methods: This case study highlight the emergence of GBMT and atypical AN following BS.
Results: A 55-year-old woman first sought treatment from the Community Mental Health Team (CMHT) over 30 years ago for marital issues and was given medication. In 2006, she underwent bariatric surgery (BS) due to morbid obesity (BMI 52.6 kg/m^2). Since 2007, she had 3 hospitalizations for cosmetic surgeries and 5 for medical complications, including oedema, hypoproteinaemia, pancytopenia, zinc deficiency, and sepsis requiring ICU admission. She also showed symptoms of depressive disorder (DD), AN, and purgative symptoms. In 2017, she was re-referred to CMHT and diagnosed with DD, anorexia was considered a symptom of DD.
In 04/2024 she was readmitted under Internal Medicine care with subacute multifactorial diarrhoea, severe malnutrition, pancytopenia, coagulopathy, vitamins A, E, D and Zn deficiency and lower limb oedema (likely contributing to a normal BMI).
Diarrhoea was managed by switching sertraline to citalopram and budesonide added to treat lymphocytic colitis. Moreover, ciprofloxacin and metronidazole were used for small intestinal bacterial overgrowth.
Psychiatric involvement confirmed DD, anxiety disorder (AD), and atypical AN. Topiramate, mirtazapine and olanzapine were stopped to possible myelotoxic effects. A bone marrow aspirate confirmed GBMT. Benzodiazepines and gabapentin were used to manage AD. Her malnutrition was managed with Total Parenteral Nutrition and she was transferred to a psychiatric ward where she received specific treatment for ED. Pancreatic enzymes were added to reduce malabsorptive impact of BS. The option of reversing the bypass was considered.
Once the vital risk decreased and she was consuming normalized intakes, she was discharged with a BMI=20.9.
One month later, she was euthymic, reduced anxiety and coagulopathy and nutritional parameters normalized with haematological improvement.
Conclusions: Given the high prevalence of malnutrition and ED post-BS, ED should be systematically assessed even in patients with normal BMI. Early diagnosis prevents worsening of symptoms, which only improve after nutritional recovery (Steinhausen *et al.* Am J Psychiatry 2002; 159(8) 1284-93). Multidisciplinary management is crucial to achieve optimal nutritional outcomes.

EPV0722

Refeeding Syndrome and Its Interventions: A Literature Review

M. A. Rodrigues[1]

[1]Universidade Anhembi Morumbi, São Paulo, Brazil
doi: 10.1192/j.eurpsy.2025.1409

Introduction: Refeeding syndrome is a severe metabolic condition seen in psychiatric patients, particularly those with anorexia nervosa or other eating disorders, after rapid nutrient reintroduction. It involves disturbances such as hypophosphatemia, hypokalemia, and hypomagnesemia, creating challenges in psychiatric and medical settings. Early identification and management are critical to prevent complications like cardiac and respiratory failure (1,2,3).
Objectives: This study analyzes the pathophysiological mechanisms of refeeding syndrome, focusing on key metabolic, psychiatric and electrolyte disturbances during the refeeding process in malnourished patients. It also discusses prevention strategies and clinical management, emphasizing the role of multidisciplinary teams in early diagnosis and treatment (1,2,3).
Methods: A literature review was conducted using Scielo, PubMed, Cochrane, and BMJ, focusing on studies about the pathophysiology, risks, and interventions related to refeeding syndrome. From 40 articles analyzed, 12 published between 2000 and 2023 were selected, focusing on clinical management and treatment guidelines for malnourished patients.
Results: The review highlights that refeeding syndrome (RS) is a serious metabolic condition in malnourished patients, especially those with psychiatric disorders like anorexia nervosa. Rapid nutrient intake can cause metabolic issues, such as hypophosphatemia and hypokalemia, alongside significant psychiatric stress. Anxiety and treatment resistance may increase, especially in patients fearing weight gain, raising the risk of relapse.
Physical discomfort from refeeding, such as fluid retention, can worsen anxiety and complicate treatment. This may lead to extended hospitalization and poor treatment adherence. In psychiatric settings, inadequate management of RS can lead to agitation or

self-harm. Preventive measures like controlled carbohydrate intake, thiamine supplementation, and electrolyte monitoring are crucial. Multidisciplinary teams, including psychiatrists, psychologists, and nutritionists, are key to managing RS. Guidelines like those from NICE recommend gradual refeeding to reduce both metabolic and psychiatric stress.
Conclusions: Refeeding syndrome is a preventable yet potentially fatal condition. Early identification of at-risk patients and careful nutritional strategies are essential to reduce morbidity and mortality. Multidisciplinary teams play a crucial role in managing and educating patients, while further research is needed to inform clinical practices (6-7).

Orthorexia Nervosa, Eating Disorders and Obsessive-Compulsive Disorder: A Selective Review of the Last Seven Years

M. A. Rodrigues[1]*, F. M. Amorim[1], M. H. R. Delgado[1] and L. A. Lemes[1]

[1]Universidade Anhembi Morumbi, São Paulo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1410

Introduction: Orthorexia Nervosa (ON) is an eating disorder, characterized by rigid and irrational rules about nutrition and food preparation. Although it is not officially recognized by the DSM-5 as a mental disorder, individuals with ON exhibit compulsive and obsessive behaviors related to their diets, with an interest that starts moderate but gradually becomes excessive and potentially pathological.
Objectives: To assess individuals facing eating disorders, with an emphasis on Orthorexia Nervosa (ON) and Obsessive-Compulsive Disorder (OCD).
Methods: This is an integrative literature review, with analyses conducted on the National Library of Medicine (PUBMED) using the descriptors and boolean operators: (Orthorexia Nervosa) AND (Eating Disorders) AND (Obsessive-Compulsive Disorder) AND (obsessive compulsive). Filters applied included: articles published in the last 10 years and available in full text. All articles were analyzed a priori based on the information in the title, followed by reading the abstract, and subsequently, reading the full article.
Results: Seventeen studies were found. According to the data, the age range between 23 and 26 years is at the highest risk for ON, while the risk is lower in individuals between 16 and 19 years. Orthorexic tendencies are more prevalent among Hispanics/Latinos and individuals with overweight or obesity. ON is frequently associated with patients who have body distortions, dissatisfaction with body image, excessive desire for thinness, and eating disorders such as anorexia and bulimia nervosa. Additionally, ON is linked to compulsive behaviors, obesity, strict diets, perfectionism. In individuals on diets, behaviors and problems similar to those seen in eating disorders are often observed, including orthorexic tendencies and obsession with adhering to strict dietary rules. Perfectionism is a common trait among these patients, who often begin with the desire to improve their diet and adopt a healthier lifestyle. However, this pursuit can become excessive, leading to behaviors such as social isolation, high spending on food, and nutritional deficiencies. Various tests conducted in the analyzed studies showed effects in identifying patients with ON, indicating the need for further research to better understand risk factors in different populations and to develop effective strategies for diagnosis, prevention, and treatment.
Conclusions: While a careful diet is not pathological in itself, severe dietary restrictions and social problems should raise the possibility of ON. Improving the identification of risk factors and behaviors may contribute to a better understanding, prevention, and management of ON.

Screening eating disorders among workers from an electricity company

I. Sellami[1]*, A. Abbes[1], A. Hrairi[1], M. A. Ghrab[1], A. Feki[2], A. Meska[1], M. Tah[1], M. Hajjaji[1], M. L. Masmoudi[1] and K. Jmal Hammami[1]

[1]Occupationnal medecine and [2]Rheumatology, CHU Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1411

Introduction: Eating disorders (EDs) can significantly worsen one's physical and psychological well-being. In the professional environment, EDs may have serious consequences on the psychological and physical health of workers.
Objectives: Our study aims to screen EDs and psychological health among workers.
Methods: We conducted a descriptive, analytical, cross-sectional survey among workers from an electricity company. We collected sociodemographic and professional characteristics. We screened EDs using the SCOFF questionnaire (Sick, Control, One stone, Fat, Food). Psychological health of our participants was assessed using the Hospital anxiety and depression scale (HADS).
Results: Our study included 497 workers with an average age of 42.2 ± 11.1 years. Among them, 381 were male (76.7%) and 72.2% were married. Two hundred twenty-two participants engaged in physical activity, and 44.1% were smokers. The average job tenure was 15.2 ± 10.8 years. According to the SCOFF questionnaire, 35.6% of participants showed signs of possible eating disorders (EDs). Additionally, 12.5% of participants were found to be anxious, and 13.9% were depressed. The likelihood of EDs was higher among those with depression. Factors associated with an increased probability of EDs included feeling slowed down, experiencing anxiety symptoms like 'butterflies' in the stomach, and losing interest in personal appearance.
Conclusions: Eating disorders are common among workers, with notable rates of anxiety and depression also observed. It is essential to raise awareness about the importance of a healthy, balanced diet to support mental well-being and, in turn, improve workplace productivity.

Not on the List: A Case Report on Diabulimia and the limitations of existing classification systems

F. M. Silva[1]* and C. Murta[1]

[1]Department of Psychiatry and Mental Health, ULS Algarve, Faro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1412

Introduction: Eating disorders have some of the highest mortality rates among mental health conditions, particularly when co-occurring with diabetes. In such cases, the risk of complications like recurrent diabetic ketoacidosis and premature mortality significantly increases. Diabulimia, characterized by intentional insulin restriction in individuals with type 1 diabetes to lose weight, remains unrecognized as a distinct diagnosis in psychiatric classification systems, limiting effective treatment options.
Objectives: To examine the unique clinical challenges of managing diabulimia and address the diagnostic limitations in current psychiatric frameworks
Methods: A comprehensive case report was conducted, which included a review of the patient's clinical history, treatment responses, and psychosocial interventions. Additionally, a literature review was performed using multiple databases, including PubMed, PsycINFO, and Scopus, to evaluate current research on the co-occurrence of eating disorders and diabetes, with particular emphasis on diabulimia. This review helped contextualize the case findings within the broader clinical understanding of diabulimia and its management.
Results: The patient, a 22-year-old woman, has a long history of type 1 diabetes and struggles with diabulimia. She is aware of the severe risks associated with insulin omission, but her desire for weight control leads her to intentionally restrict insulin, particularly during periods of emotional distress. She has a concurrent psychiatric history of depression and anxiety, which exacerbate her difficulties with diabetes management. The patient's adherence to insulin therapy has been inconsistent, with cycles of brief compliance followed by relapse, particularly during times of heightened stress and body image dissatisfaction. Despite treatment with fluoxetine and ongoing cognitive-behavioral therapy (CBT), she continues to face significant challenges in managing both her diabetes and eating disorder. Recent interventions, including a structured fitness program and targeted psychotherapy, have yielded partial improvements, helping her develop healthier coping mechanisms and improve self-management. However, sustaining these gains remains difficult, and she continues to experience frequent hospitalizations due to metabolic decompensation.
Conclusions: Diabulimia presents unique diagnostic and therapeutic challenges, primarily due to its lack of recognition as a distinct disorder within current psychiatric classification systems. This case highlights the complex interplay between eating disorders, mental health, and diabetes management, highlighting the need for an integrated, multidisciplinary approach to treatment. There is a critical need for increased awareness, the development of specific diagnostic criteria, and tailored therapeutic interventions to improve outcomes for individuals affected by this often-overlooked condition.

EPV0726

Sociocultural factors in eating disorder. A comprehensive review

G. Strada[1]*, B. Serván[1], L. Reyes[1], I. López[1] and M. Díaz[1]

[1]Hospital Universitario Clínico San Carlos, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1413

Introduction: Eating disorders, such as anorexa nervosa, bulimia nervosa and binge eating disorder, are complex conditions that affect both a person's physical and mental health. Although biological and psychological factors have been extensively studied, sociocultural factors play a fundamental role in the developmental and maintenance of these disorders.
Objectives: This poster explores how peer pressure, beauty standards, the influence of the media and social media, along with aspects such as gender, social class and culture, contribute to the emergence of eating disorders, especially among teenagers and young women.
Methods: Literature review
Results: Patterns are identified that show a significant correlation between the idealization of thinness and increased body dissatisfaction. The impact of patriarchy, diet culture and social media consumption are discussed, and how these influences are amplified in different sociocultural contexts. Additionally, differences in the prevalence of eating disorders by gender and ethnicity are discussed, as well as implications for treatment prevention.
Conclusions: Intervention strategies that address sociocultural factors and promote a more inclusive and healthy view of the body are needed, with the aim of reducing the impact of these factors on the appearance of eating disorders. The research highlights the need for public policies that regulate media content and promote educational programs on physical and mental health.

Preoperative psychological assessment for bariatric surgery in the Brazilian public health system

A. A. Lemos[1], C. M. Trentini[1]*, E. R. Marcon[2] and J. U. Castan[3]

[1]Psychology, UFRGS; [2]Physical Education and [3]Psychology, HCPA, Porto Alegre, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1414

Introduction: The Preoperative Psychological Assessment of Bariatric Surgery and Metabolic (PP-BSM) aims to detect psychopathologies before the procedure, facilitating interventions and lifestyle changes.
Objectives: Describing and analyzing the psychological aspects and tools used for pre-bariatric surgery psychological evaluation in the Brazilian Public Health System.
Methods: Descriptive cross-sectional study. The convenience sample was composed by psychologists of the bariatric surgery and metabolic teams in the public health system in a region in the South of Brazil. Data were collected through an electronic questionnaire administered via telephone survey, focusing on PP-BSM.

Results: There was consensus regarding the areas to be assessed: cognition, emotion, social support, and psychiatric comorbidities. Variation was found in the protocols and instruments used for PP-BSM, with each hospital using its own protocol. Semi-structured clinical interviews, along with self-reported scales and questionnaires, were used by most psychologists.
Conclusions: Although the psychological aspects assessed are aligned with current Brazilian guidelines, there is a lack of either standardized protocols among services or specific instruments for bariatric surgery candidates. Providing adequate tools and training professionals in their use may contribute to increasing safety and long-term positive surgical outcomes.

EPV0728

Pharmacological treatments for eating disorders – How far are we from new solutions?

V. A. Voicu[1,2,3*] and O. Vasiliu[1,4]

[1]Carol Davila University of Medicine and Pharmacy; [2]Romanian Academy of Medical Sciences; [3]Romanian Academy and [4]Psychiatry Dept., Dr. Carol Davila University Emergency Central Military Hospital, Bucharest, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1415

Introduction: Eating disorders (EDs) are an important and highly prevalent class of disorders worldwide, with the global lifetime prevalence reaching more than 8% in females and 2% in males. Also, EDs associate high rates of mortality, comorbidity, organic and psychiatric complications, and years lived with disability (YLD), low quality of life and increased healthcare costs. Yet, the pharmacological armamentarium available to treat EDs is quite reduced, a phenomenon that creates difficult challenges for the case management of these patients.
Objectives: To review the existing literature in order to find new targets explored for the treatment of EDs.
Methods: A literature review was conducted in four electronic databases (PubMed, EMBASE, Cochrane, and Clarivate/Web of Science) and the US National Library of Medicine database for clinical trials (www.clinicaltrials.gov) to find clinical studies published between January 2000 and September 2024. The keywords used were “eating disorders”, “feeding disorders”, “anorexia nervosa”, “bulimia nervosa”, “binge eating disorder”, “drugs in pipeline”, and “pharmacological treatment”. Only adult participants were included, and only sources published in English were selected.
Results: The following data are based on 33 sources found during the literature search. Lisdexampheatmine and vortioxetine are explored for in BED, with the first agent receiving FDA approval for moderate and severe binge eating disorder (BED) in adults. Olanzapine is explored in patients with anorexia nervosa (AN), chromium picolinate for BED, methylphenidate + CBT also for BED, and antibiotics for bulimia nervosa (BN). Psychedelics, e.g., psilocybin and MDMA, are explored for AN and BED, but there is a limited number of trials dedicated to these agents that reach only phase 2a. Therapeutic guidelines dedicated to EDs have very few level A recommendations, i.e., fluoxetine and topiramate for BED, lisdexamphetamine for BED, and olanzapine for AN, with several cautionary notes regarding adverse events and restricted availability for some of these drugs.
Conclusions: There is a dearth of good-quality data regarding the efficacy and tolerability of newer pharmacological agents for treating EDs. Therapeutic guidelines dedicated to this type of disorders have only scarce recommendations regarding pharmacotherapy, and there is an urgent need to find more agents that could improve the prognosis of patients with ED.

Longitudinal observational study of resting-state brain functional connectivity changes in anorexia nervosa post-treatment

S. Yennampelli[1*] and P. Holštajn Zemánková[2]

[1]Department of Psychiatry, Masaryk University and [2]Department of Psychiatry, Masaryk University and University Hospital Brno, Brno, Czech Republic
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1416

Introduction: Altered brain functional connectivity (FC) of patients with anorexia nervosa (AN) has been observed in the acute phase of the disorder, but it remains unclear to what extent these alterations recover during weight normalization.
Objectives: In this study, we used resting-state functional imaging data collected during hospitalization and six months post-treatment to investigate longitudinal changes in FC patterns in patients with AN during weight normalization. Since a core feature of AN is the disconnect between body signals and the brain, we aimed to elucidate whether treatment led to changes in the FC of the anterior cingulate cortex (ACC), a part of the brain’s limbic system that plays a crucial role in integrating visceral, attentional, and emotional information.
Methods: Seventeen women with restricting type AN underwent MRI scans and assessments to measure BMI and eating disorder symptomatology (Eating Disorder Inventory- EDI) upon hospital admission and six months after discharge. Functional imaging data were processed using seed-based connectivity analysis with ACC as a seed.
Results: Longitudinal analyses showed a significant ($p<0.05$ FDR corrected) increased FC post-treatment between the ACC and the precuneus, specifically Brodmann area 7. Participants demonstrated significant BMI increases, although no significant changes were observed in clinical symptomatology assessed by EDI.
Conclusions: The findings indicate greater FC between the ACC and the precuneus as patients with AN complete treatment and undergo weight normalization. The precuneus is integral to one’s sense of self, perceived information integration, and reaction to cues. Therefore, increased FC between the ACC and precuneus might improve proprioception, body awareness, and frequency of body image disturbances—all abnormalities central to AN.

EPV0730

Digital Cognitive Behavioral Therapy (CBT) Apps for ADHD: A Systematic Review of Recent Evidence

A. Alalsultan Alghory[1]
[1]Istanbul Medipol University, Istanbul, Türkiye
doi: 10.1192/j.eurpsy.2025.1417

Introduction: Attention-deficit/hyperactivity disorder (ADHD) is a neurodevelopmental condition characterized by persistent patterns of inattention, hyperactivity, and impulsivity. Cognitive Behavioral Therapy (CBT) is a well-established intervention for ADHD, helping individuals manage symptoms by targeting dysfunctional thought patterns and behaviors. In recent years, the accessibility of digital CBT apps has expanded, providing a potential alternative to traditional therapy. This systematic review aims to assess the efficacy of digital CBT apps for symptom management in individuals with ADHD.
Objectives: This review seeks to (1) evaluate the effectiveness of digital CBT apps in reducing ADHD-related symptoms such as inattention and impulsivity, (2) assess the adherence and usability of these apps, and (3) identify gaps in the literature to guide future research on digital interventions for ADHD.
Methods: A systematic search was conducted using PubMed and Google Scholar to identify peer-reviewed studies published within the last 5 years (2019–2024). The search terms used included "ADHD," "digital CBT," "mobile apps," and "cognitive behavioral therapy." Inclusion criteria were studies that focused on the use of digital CBT interventions specifically for ADHD symptom management in both children and adults. Studies that assessed the effectiveness of these interventions using standardized symptom rating scales were prioritized. Articles that involved non-CBT digital interventions, case reports, or review articles were excluded.
Results: Six studies met the inclusion criteria. The results showed promising outcomes for ADHD symptom reduction, particularly in reducing inattention and impulsivity. Lenhard et al. (2018) demonstrated significant improvement in ADHD symptoms in children using digital CBT programs. Nigg et al. (2020) found similar improvements in adults. Sibley et al. (2021) observed enhanced executive functioning with high adherence to app-based interventions. In Torous et al. (2020), digital CBT apps improved patient engagement and accessibility to care. Hirvikoski et al. (2017) reported moderate effectiveness in symptom control but emphasized the need for continued monitoring of user adherence. Russell et al. (2021) highlighted the potential for personalization in digital therapies, although further research is needed to optimize these interventions.
Conclusions: The review suggests that digital CBT apps offer a promising approach for ADHD symptom management, particularly in increasing accessibility and adherence to therapy. While these interventions show moderate to significant effectiveness in reducing core symptoms like inattention and impulsivity, further research is needed to address personalization and long-term efficacy. This highlights the growing potential for digital mental health interventions to complement traditional ADHD treatments.

A promising future for tele-mental health in Oman: A qualitative exploration of clients and therapists' experiences

T. Al-Mahrouqi[1]*, K. Al-Alawi[1], M. Al-Alawi[2], N. Al Balushi[2], A. Al Ghailani[1], H. Al Sabti[1] and H. Al Sinawi[2]
[1]Oman Medical Speciality Board and [2]Sultan Qaboos University Hospital, Muscat, Oman
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1418

Introduction: Objectives: Tele-mental health services can play an important role in overcoming barriers in mental health services in the Eastern Mediterranean Region. However, despite its potential, tele-mental health has not been widely adopted in Oman.
Objectives: This study is an exploratory investigation into the experiences of therapists and their clients in utilizing video-based tele-mental health care during the COVID-19 pandemic.
Methods: A total of 19 semistructured qualitative interviews were individually conducted, it included 13 adult clients with mental health conditions who received video-based tele-mental health care and six clinical psychologists who provided video-based tele-mental health care during the COVID-19 pandemic.
Results: The clients reported favorable experiences using tele-mental health, with the primary benefits being convenience, easy accessibility to subspecialized care, reduced absenteeism from work with commuting costs, and alleviated mental health stigma. The therapists also expressed experiencing benefits from tele-mental health, such as reduced risk of intrahospital infection, reduced healthcare costs, and the achievement of work-life balance. Primary concerns were related to the lack of public tele-mental health services, lack of specified tele-mental health guidelines, shortage of trained therapists, limited access to high-speed Internet, electronic devices, privacy, and concerns toward the security of tele-health systems in general.
Conclusions: Clients and therapists report that tele-mental health offers new opportunities to improve the quality of mental health-care services in Oman, and that the challenges could be resolved by establishing governmental tele-mental health services along with developing tele-mental health guidelines and implementing local postgraduate clinical psychology programs in universities in Oman.

EPV0732

Suicide Prevention based on IA detection for Inpatients (SPIIN)

S. Berrouiguet[1], C. Apprederisse[1]*, L. Carvalho-Fontes[2] and M. Irles[2]
[1]Adult Psychiatry, CHU Brest and [2]Human Science department, ISEN, Brest, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1419

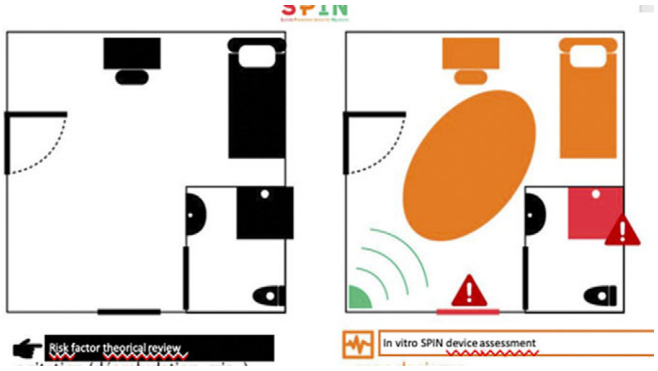
Introduction: Hospital suicide rates vary according to study from 100 to 550 per 100,000 admissions. This is 10 to 30 times the rate of suicide rate in the general population. In prison, there is an average of one death every two or three days, Most of them by suicide.

Sensors and Artificial Intelligence to avoid and/or interrupt suicide in the inpatients population. Preliminary explorations will determine weather this kind of device might be acceptable for care providers and patients.
Objectives: Determine weather careproviders (doctors, nurses) consider the SPIN system as usable in a routine hospilat care setting Determine weather careproviders (doctors, nurses) consider the SPIN system as acceptable
Establish the technical feasability of the SPIN sytem includin hadware (sensors) and softwar (algorithm) in an invitro setting.
Methods: A full presentation of the spin device was presented to the careproviders in a in vitro setting and via a video tutorial of the data capture procédure.
Participants were interviewed during a personal meeting.
Evaluation criteria were :Score to the SUS usablity scale, score the net promoter score and Analysis of the qualitative contents of the interviews.
Results: Qualitative analysis of the interviews contents showed a good
The Spin system will enable earlier intervention in cases where risk factors associated with increased suicidal risk are identified, as well as adjustment of therapies associated with the management of suicidal risk. It can also be used to adjust hospitalization conditions for patients at risk of suicide. transfer knowledge to the prison environment, for example, or to the home of a patient identified as being at high risk (repeat patient).
According to participants, the SPIN device will:

- alleviate the mental workload of caregivers whose job it is to supervise high-risk patients (risk of falling, risk of agitation, risk of suicide, etc.).
- admit patients under better conditions (less frequent searches on admission, less frequent room visits, more human-centred care).

This type of system will free us from the logistical constraints associated with the proximity of surveillance rooms and treatment rooms, or even their availability. In this way, patients in intensive care units (monitoring rooms with a view of the nurses' station) can benefit from more flexible hospital conditions (accommodation), thanks to a remote monitoring system.

Image:



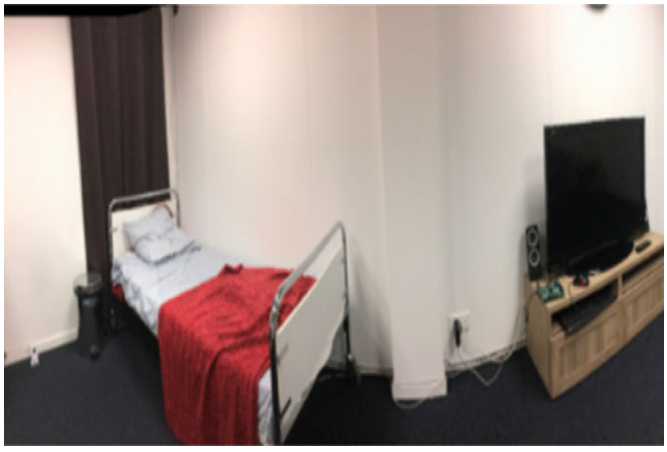


Image 2:

Conclusions: Overall, our study showed a good acceptance of the in vitro setting of the SPIN device in the careproviders population. The newt step of our study will decribe the acceptance in a patient populations and the efficiency on suicidal outcomes in routine population.

Disclosure of Interest: None Declared

Efficacy of Step-by-Step (SbS) in Improving Depressive Symptoms and Functional Impairment: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

V. Astori[1]*, F. Pesente[2], G. de Oliveira e Souza[3], T. Y. Kimura[3], G. Coachman Hollenstein[1], L. Pontes de Oliveira[1] and D. Fernandes Holanda[4]

[1]Escola Superior de Ciências da Santa Casa de Misericórdia de Vitória; [2]Universidade Federal do Espírito Santo, Vitória; [3]Universidade Federal de Minas Gerais, Belo Horizonte and [4]Universidade Federal do Amazonas, Manaus, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1420

Introduction: The growing need for effective solutions to bridge the mental health treatment gap is particularly critical in countries where economic and political crises have exacerbated existing mental health challenges. In this context, the urgency for scalable and accessible interventions is evident. Step-by-Step (SbS), a guided digital self-help program developed by the World Health Organization (WHO), has been implemented as a promising approach to alleviate depressive symptoms and improve functionality in vulnerable populations.
Objectives: This meta-analysis aims to evaluate the findings of studies that examined the efficacy of SbS, compared with enhanced care as usual (ECAU), in reducing depressive symptoms and functional impairment.
Methods: We systematically searched PubMed, Cochrane, and Scopus for randomized controlled trials (RCTs) comparing SbS with ECAU. The pooled outcomes were the overall improvement in

depressive symptoms, measured by the Patient Health Questionnaire (PHQ-9), as well as functional impairment measured by the WHO Disability Assessment Schedule-12 (WHODAS). We calculated the mean difference (MD) for the outcomes, with 95% confidence intervals (CIs). Statistical analysis was performed using Review Manager (RevMan) 8.1.1 with a fixed-effect model. Heterogeneity was assessed using the I^2 statistic.
Results: Three RCTs were included, encompassing 604 patients, of whom 263 (43.5%) participated in SbS. The population consisted of 35.1% males and 64.9% females. The mean age was 28.8 years, with a standard deviation of 8.7. SbS reduced PHQ-9 scores (MD = -3.48; 95% CI [-4.44, -2.52]; $P < 0.00001$; $I^2 = 3\%$; Figure 1) and WHODAS scores (MD = -3.37; 95% CI [-4.84, -1.90]; $P < 0.00001$; $I^2 = 0\%$; Figure 2) compared with ECAU.

Image 1:

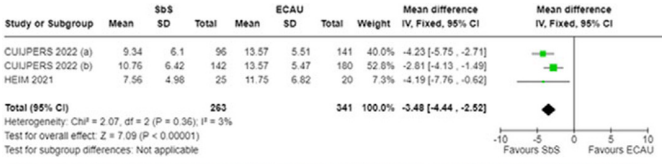

Figure 1 - Forest plot showing a significant reduction in depressive symptoms (PHQ-9 Scores) with SbS compared to ECAU (P < 0.00001)

Image 2:

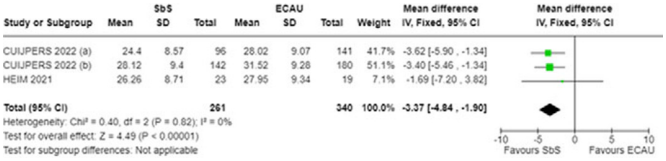

Figure 2 - Forest plot indicating a significant improvement in functional impairment (WHODAS Scores) with SbS compared to ECAU (P < 0.00001)

Conclusions: This meta-analysis of RCTs suggests that SbS has a positive effect in reducing depressive symptoms and functional impairment compared with ECAU.

My Virtual Parent, Adult, and Child: Simulating Ego-States in Transactional Analysis with LLM

A. M. Bukinich[1]*, A. M. Gerashenko[1], G. D. Vzorin[1] and A. M. Konovalova[1,2]

[1]Faculty of Psychology, Lomonosov Moscow State University and [2]Department of Pedagogy and Medical Psychology, Sechenov University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1421

Introduction: Recent advancements in large language models (LLMs) demonstrate their ability to perform verbal generalization and simulate agency, opening new possibilities for innovative applications in psychotherapy. One promising avenue is the integration of LLMs into Eric Berne's Transactional Analysis, a psychotherapeutic approach that conceptualizes human personality through three distinct ego-states: Parent, Adult, and Child.
Objectives: To investigate the potential of LLMs in Transactional Analysis.
Methods: LLM capabilities described in the literature were compared with demands derived from the theory.
Results: By examining the interactions among ego-states in Transactional Analysis, individuals can become aware of their behavior patterns and modify ineffective ones, fostering healthier relationships and improving social adaptation. Incorporating LLMs into Transactional Analysis offers a novel tool for psychotherapeutic interventions. Therapists could utilize AI to help clients recognize emotional experiences and identify maladaptive interaction patterns. By simulating the Parent, Adult, and Child ego-states, an LLM could engage in dialogues that reflect these internal states, allowing the client to explore and better understand their emotional reactions and needs. This interaction would enable clients to actively engage with different parts of their personality, promoting self-awareness and providing valuable insights into the causes of relational difficulties. While the potential benefits are clear, further research is needed to assess the practical effectiveness of integrating LLMs into Transactional Analysis. Empirical studies should investigate the degree to which LLMs can accurately simulate ego-states and contribute to positive therapeutic outcomes. Additionally, ethical considerations must be addressed to ensure that the application of AI in psychotherapy is both responsible and beneficial for clients.
Conclusions: The proposed approach fosters a deeper understanding of internal conflicts and provides a structured, controlled environment where clients can work through problematic situations.

Developing an early support mHealth intervention for women and partners after perinatal loss: A secondary study of the e-Perinatal Project

P. de-Juan-Iglesias[1,2]*, S. Carretero[3], C. García-Terol[4], R. Company-Córdoba[1,2], F. J. Nieto-Casado[1,2], C. Barquero-Jiménez[1,2], L. Goossens[5], J. J. Gil-Cosano[5] and E. Motrico[1,2]

[1]Perinatal-IBIS Lab, Institute of Biomedicine of Seville (IBiS), Seville; [2]Department of Developmental Psychology and Education, Universidad de Sevilla; [3]Psychology, Loyola University, Sevile; [4]Hospital maternoinfantil Sant Joan de Déu, Barcelona and [5]Department of Health and Biomedical Sciences, Loyola University, Sevile, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1422

Introduction: Perinatal loss is a prevalent health concern worldwide, with one in four pregnancies ending in loss. Spontaneous perinatal loss (i.e., miscarriage, stillbirth, and neonatal death) is an excruciating experience that becomes part of parental identity and represents a unique form of grief. Online interventions offer a cost-effective and feasible option for reducing symptoms of depression, anxiety, and grief in cases of perinatal loss. Involving stakeholders during the early stages of content design and development results in interventions that are more relevant and effective.

Objectives: This study aims to co-design evidence-based online content for offering psychological support in the early stages after perinatal loss and to integrate this content into the e-Perinatal app (mHealth application for the prevention of Perinatal Mental Health Disorders). It involves collaboration with local stakeholders, including bereaved women, non-birthing partners, and health professionals, to ensure that the intervention meets the population's needs and aligns with the local sociocultural context. This is a secondary study of the ERC Starting Grant ePerinatal project (101042139), funded by Banco Sabadell Foundation.
Methods: This study employed a qualitative design to conduct a multi-stage co-design and development process (pre-design, generative and evaluative phases). Two online focus groups were conducted: 1) bereaved women and non-birthing partners (n = 9), and 2) healthcare professionals with experience in perinatal loss care (n = 12). Following the presentation of the app prototype, participants were asked to provide feedback on both the evidence-based content (micro-intervention contents and information provided) and the app design features. The qualitative data were analysed using thematic analysis with NVivo software, while sociodemographic data were analysed through descriptive analysis. All data were coded by two researchers.
Results: The analysis process is ongoing, and the emerging themes and subthemes are being categorized into: 1) user-related (e.g., health status, previous experience with the public health system, social support), 2) program-related (e.g., intervention content, formal and informal social connectedness), 3) user experience (e.g., information architecture [length], content strategy [wording]), and 4) professional-related (e.g., factors influencing healthcare professionals' recommendations of the app).
Conclusions: The content developed for perinatal loss will be designed to align with local stakeholders' expectations and be integrated into the e-Perinatal app. By offering accessible support for women and their partners, the app will aim to help manage the psychological reactions often experienced during this vulnerable period, including grief, stigma, and an increased risk to mental health, as it is implemented in routine maternal care.

Internet Addiction among Nursing Students and its impact on their academic performance: Case study at the Higher Institute of Nursing Professions and Health Techniques of Oujda

S. Essadki[1], M. Fourtassi[2], O. Gouaz[1], N.-E. H. SEHB[1] and R. BOUGHOUFA[2]*
[1]Higher Institute of Nursing professions and Health Techniques, Oujda and [2]Laboratory of Life and Health Sciences, Faculty of Medicine of Tangier, Tangier, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1423

Introduction: Nowadays, the use of the Internet has become a very popular practice. However, excessive use can lead to serious problems such as cyberaddiction. This phenomenon has repercussions on several levels, including academic performance.
Objectives: This study aimed to explore the prevalence of cyberaddiction and its associated factors among nursing students at the Higher Institute of Nursing Professions and Health Techniques of Oujda in Morocco.
Methods: A cross-sectional study was carried out among undergraduate nursing students in the city of Oujda, Morocco. The data were collected through a self-administered questionnaire that was directly distributed to all of the targeted students, exploring their demographic and academic profiles. Young scale was used to identify the levels of cyberaddiction among participants.
Results: The average student's daily connection time was 5.3+/-3.2 hours. 26.3% of the participants were identified as cyber-dependent, and 1.4% were suffering serious issues linked to cyber-addiction. Internet addiction was significantly associated with academic failure.
Conclusions: These results should lead to preventive measures in order to protect nursing students from the potential harmful effects of internet excessive use.

Reconnected project in Kosovo: first steps in co-creation process

N. Fanaj[1,2]*, S. Mustafa[2,3], E. Krasniqi[2,4] and A. Cerga Pashoja[5]
[1]Alma Mater Europae Campus College Rezonanca, Prishtina; [2]PMSH, Prizren; [3]AAB College; [4]UBT College, Prishtina, Kosovo and [5]Faculty of Sport, Technology and Health Sciences, St Mary's University, London, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1424

Introduction: Current global societal challenges pose significant threats to the mental well-being of European citizens. The 'RECONNECTED' project, supported by the EU/Horizon Europe program, aims to tackle mental health issues experienced by vulnerable populations in Europe, including those in Kosovo, particularly individuals with low socioeconomic status.
Objectives: The objective is to present key pillars of project and outline some key findings that will inform the consortium toward finalizing the conceptual framework of RECONNECTED which draws inspiration from the Urban Mental Health (UMH) framework, with a focus on particular aspects related to Kosovo.
Methods: It's a mixed-methods study design. We have reviewed the literature related to three key pillars of project: social prescribing, mental health literacy and personalized micro-interventions in Kosovo, and analysed preliminary some recent cross-sectional samples focusing on sociodemographic and psychosocial variables. Data processing was done with SPSS 27.0 and Microsoft Excel 2019.
Results: The literature review in internet does not find information about the implementation of social prescription and personalized micro-interventions in Kosovo so far. However, we can see that similar fragmented activities of social prescription have been implemented in Kosovo in various unstructured and informal designs. There is also information about the individual use of various applications by young people. Furthermore, no study is found regarding mental health literacy in Kosovo, and we have found that there are no mental health promotion programs. Recent cross-sectional samples analysis highlights the association between gender, dysfunctional coping style, social support and low socio-economic status with mental health indicators like anxiety, depression and suicidal ideation among young individuals.

Conclusions: These findings highlight how key mental health challenges could impact the implementation and use of a digital support system like RECONNECTED within a community care model. Addressing these factors during the co-creation process between researchers, stakeholders and end-users is crucial for ensuring the success of this innovative scientific approach in Kosovo, a low-middle-income country.

Disclosure of Interest: N. Fanaj Grant / Research support from: Principal Researcher for Kosovo in Project RECONNECTED, S. Mustafa Grant / Research support from: Researcher Officer for Kosovo in Project RECONNECTED, E. Krasniqi Grant / Research support from: Researcher Officer for Kosovo in Project RECONNECTED, A. Cerga Pashoja Grant / Research support from: Principal Researcher for UK in Project RECONNECTED

EPV0740

Efficacy of Teletherapy vs. Conventional Therapy in Improving Depressive Symptoms: A Meta-Analysis of PHQ-9 Scores Outcomes

S. Queiroz[1], D. Fernandes de Holanda[2]* and I. SalhaMD[3]

[1]Medicina, UEPG, Ponta Grossa; [2]Medicina, UFAM, Manaus, Brazil and [3]Medicine, Internation Organization of Migration (IOM), Palestinian, Palestinian, State of

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1425

Introduction: Tele-rehabilitation (Tele-TR) has emerged as a promising alternative to traditional, in-person cardiac rehabilitation (Conventional-CR), offering accessible and convenient rehabilitation options for patients who may face logistical or health-related barriers to attending conventional programs. Advances in digital health technologies, coupled with the increasing demand for remote healthcare solutions, have led to the widespread adoption of Tele-TR, particularly for patients recovering from cardiac events or undergoing surgery. However, there is a need for a comprehensive evaluation of the comparative effectiveness of Tele-TR versus Conventional-CR, especially in terms of clinical outcomes. Given the rise in mental health concerns among patients undergoing cardiac rehabilitation, the impact of these rehabilitation modalities on psychological well-being, particularly depressive symptoms, has become an important area of focus.

Objectives: This meta-analysis aims to evaluate the efficacy of Tele-TR in comparison to Conventional-CR, specifically assessing their effects on depressive symptoms. The primary objective is to determine the mean differences in health assessment scores, such as the PHQ-9, across studies that compare Tele-TR and Conventional-CR. By synthesizing the findings from multiple randomized controlled trials (RCTs), this analysis will provide insights into the relative effectiveness of these two rehabilitation approaches, with a particular emphasis on mental health outcomes and their implications for patient recovery and quality of life.

Methods: Three studies were included, comparing Tele-TR with Conventional-CR. Outcomes were assessed based on mean differences (MDs) and 95% confidence intervals (CIs) for continuous data. Heterogeneity among studies was quantified using Tau^2 and I^2 statistics, and a random-effects model was employed to account for variability across studies.

Results: The analysis of post-treatment improvement in PHQ-9 scores across included studies demonstrated an overall mean difference of -1.94 (95% CI [-4.02; 0.15]), suggesting a trend favoring Tele-TR over Conventional-CR. However, this improvement did not reach statistical significance (Z = -1.82, P = 0.07). High heterogeneity was noted (Tau^2 = 3.36, I^2 = 100%, P < 0.01), indicating substantial variability in treatment effects among studies.

Image:

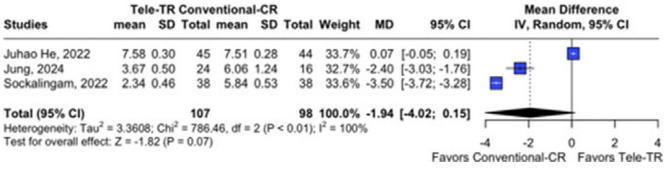

Image 2:

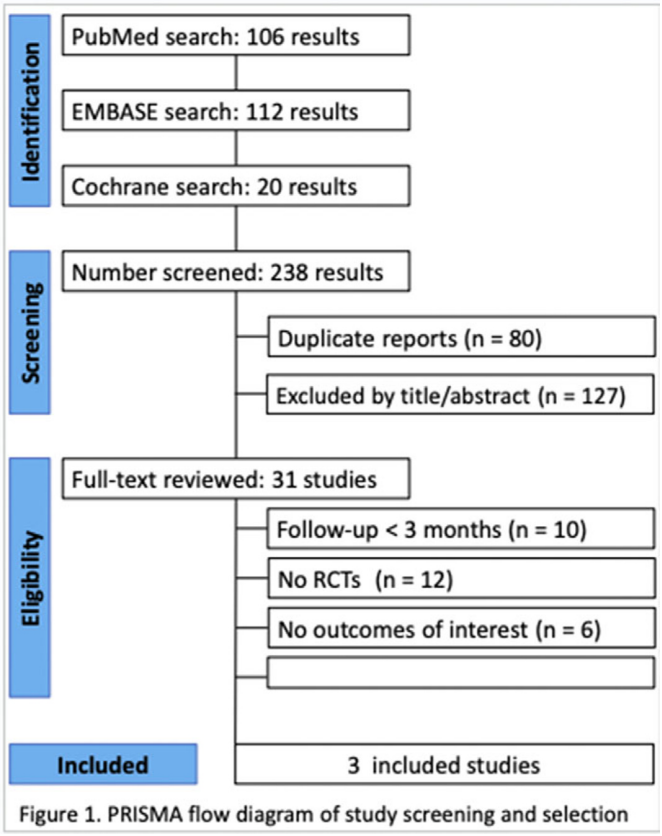

Figure 1. PRISMA flow diagram of study screening and selection

Conclusions: While Tele-TR showed a trend toward improvement over Conventional-CR, the findings did not achieve statistical significance. High heterogeneity suggests differences in study design and patient populations, warranting further research to clarify the potential benefits of Tele-TR and identify the contexts where it may offer the most significant advantages.

Strengths and limitations of the use of Artificial Intelligence in Mental Health

A. Alberca-González[1] and E. Fernández-Jiménez[1,2,3]*

[1]Faculty of Social Sciences and Communication, Universidad Europea de Madrid, Villaviciosa de Odón; [2]Department of Psychiatry, Clinical Psychology and Mental Health, La Paz University Hospital and [3]Hospital La Paz Institute for Health Research (IdiPAZ), Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1426

Introduction: Artificial intelligence (AI) is emerging as a disruptive tool in medicine and healthcare, especially in Mental Health. Its ability to process large volumes of data and detect complex patterns has opened up new possibilities for the diagnosis, treatment, and monitoring of mental disorders, providing opportunities to improve the clinical accuracy and personalisation of therapeutic intervention. However, the use of AI in Mental Health poses critical challenges involving ethical, privacy, and inherent issues regarding the quality and validity of the models employed.
Objectives: The aim of this review is to critically analyse the strengths and limitations of the use of AI in Mental Health, offering a balanced perspective on the potential benefits and associated risks.
Methods: A narrative review of the current scientific literature was conducted on the main applications of AI in the diagnosis, treatment, and monitoring of mental disorders as well as the barriers to its effective implementation.
Results: The main strengths identified were the ability of AI to provide more accurate and personalised diagnoses, continuous monitoring of patients' well-being, increased efficiency in the delivery of Mental Health services, and the possibility of analysing large volumes of data in reduced times, thus improving the ability to detect and track symptoms. However, regarding limitations, the scientific literature highlights the lack of transparency in many of the studies conducted, problems of methodological quality, risks regarding the perpetuation of pre-existing biases, concerns about the privacy of sensitive data, and the potential risk of dehumanisation of care by prioritising automated systems over human contact. In addition, the need for rigorous validation and a clear regulatory framework are key issues in ensuring the ethical and safe use of these technologies.
Conclusions: In conclusion, AI represents a resource with immense potential for transforming clinical practice in Mental Health care, providing more accurate diagnoses, personalised interventions, and real-time monitoring. However, its implementation must be accompanied by rigorous scientific and regulatory scrutiny to mitigate ethical risks and ensure the protection of patients' privacy and dignity. It is necessary to ensure that technological advances go hand in hand with a humanised approach, where technology complements, but does not replace, the essential therapeutic connection in Mental Health care.

Disclosure of Interest: None Declared

EPV0742

Perceptions and Attitudes Towards Artificial Intelligence Among Education and Mental Health Professionals: A Comparative Pilot Study

A. Alberca-González[2] and E. Fernández-Jiménez[1,2,3]*

[1]Department of Psychiatry, Clinical Psychology and Mental Health, La Paz University Hospital, Madrid; [2]Faculty of Social Sciences and Communication, Universidad Europea de Madrid, Villaviciosa de Odón and [3]Hospital La Paz Institute for Health Research (IdiPAZ), Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1427

Introduction: The integration of Artificial Intelligence (AI) in education and mental health fields represents an innovative path to optimize diagnostic, intervention, and monitoring processes, although it poses ethical and technical challenges that must be carefully assessed. Understanding how professionals in these areas perceive this technology is essential to support its informed and effective adoption.
Objectives: This study aimed to explore and compare perceptions and attitudes towards AI among professionals in education and mental health by examining key dimensions such as efficiency, personalization, diagnosis, monitoring, privacy, and validation.
Methods: A cross-sectional pilot study was conducted with a sample of 17 professionals divided into two groups: five from the educational sector and 12 from the clinical-mental health sector. An online structured questionnaire, designed ad hoc, was used, comprising ten dimensions addressing diagnosis, monitoring, efficiency, data analysis, quality, ethics, dependency, validation, ease of use, and AI acceptance. All participants provided written informed consent to participate in this study.
Results: The findings are as follows:

- High agreement in perceived efficiency across both sectors (>80%).
- Greater optimism in personalization within the educational sector (80% vs. 58.3% in mental health).
- General concern about the validation of AI systems (94.1% consider it insufficiently rigorous).
- Significant resistance to AI implementation (82.4%).
- Key perceived barriers: Data privacy (85%) and risk of dehumanization (76%).

Conclusions: While AI's potential to enhance efficiency is acknowledged in both areas, reservations persist concerning the validity and safety of these systems, particularly regarding data privacy and the integrity of professional-patient or student relationships. These findings suggest the need to develop comprehensive validation programs and specific protocols that facilitate the ethical and technically sound implementation of AI in these fields.

Process evaluation of eHealth interventions for healthcare workers with psychological distress

B. García-Vázquez[1,2,3]*, C. Bayón Pérez[1,2,3,4,5], M. F. Bravo Ortiz[1,2,3,4,5], R. Mediavilla Torres[3,4,5,6,7], J. M. Haro[5,8,9], M. Felez-Nobrega[5,8,9] and J. L. Ayuso Mateos[3,4,5,7,10]

[1]Psychiatry, Clinical Psychology and Mental Health, Hospital Universitario La Paz (HULP); [2]Psychiatry, Instituto de Investigación Sanitaria La Paz (IdiPAZ); [3]Psychiatry, Universidad Autónoma de Madrid (UAM); [4]Centro de Investigación Biomédica en Red de Salud Mental (CIBERSAM); [5]Instituto de Investigación Carlos III; [6]Hospital Universitario La Princesa; [7]Instituto de Investigación Sanitaria del Hospital Universitario La Princesa, Madrid; [8]Parc Sanitari Sant Joan de Deu (IRSJD); [9]Centro de Investigación Biomédica en Red de Salud Mental (CIBERSAM), Barcelona and [10]Psychiatry, Hospital Universitario La Princesa, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1428

Introduction: Over the past two decades, public health research has increasingly informed decision-making, but more evidence is needed on implementing interventions in real-life conditions. The COVID-19 pandemic highlighted these challenges, particularly in mental health. A study in Spain (RESPOND-HCWs) adapted and implemented psychological interventions for healthcare workers during the pandemic, showing significant reductions in anxiety and depression symptoms. This process evaluation aims to guide the practical implementation of these interventions in crisis settings.
Objectives: This study provides a process evaluation of a successful stepped-care program involving eHealth interventions (Doing What Matters in Times of Stress [DWM] and Problem Management Plus [PM+]) designed for healthcare workers experiencing psychological distress (REsponding to Psychological distress among HCWs [RESPOND-HCWs] trial) conducted in Spain. The aim is to analyze program delivery context, assess implementation outcomes, and explore mechanisms of action.
Methods: We utilized mixed methods, gathering quantitative data through routine RCT monitoring and structured observation, complemented by qualitative insights from semi-structured interviews with trial participants (n = 12) and decision-makers (n = 7), and a focus group discussion involving intervention providers (n = 7). Quantitative data were analyzed descriptively using R Software. Qualitative data underwent thematic analysis with NVivo.
Results: Context analysis identified implementation barriers, such as DWM visual design, confidentiality, time to practice, stigma, unrealistic expectations about stepped-care programme, DWM phone calls, trust in the health system, internet literacy and intervention provider profile; and enabling factors, such as flexibility in schedules, remote delivery and mental health awareness initiatives. The implementation of the interventions was feasible, appropriate, and had minimal protocol deviations, with good participant acceptance. Mechanisms of action included confidence in intervention effects, a strong therapeutic relationship, and specific intervention components.
Conclusions: The results serve as a complement to outcome evaluation and can guide wider implementation in similar settings. Recommendations include raising awareness about mental health and reducing stigma, providing brief orientation sessions, offering flexible schedules, and encouraging peer support.

Econsult system: direct coordination between mental health and primary care

A. Izquierdo De La Puente[1]*, P. Del Sol Calderon[1], R. Fernandez Fernandez[2], T. Gonzalez Salvador[1] and M. García Moreno[1]

[1]Psiquiatria, Hospital Universitario Puerta de Hierro de Majadahonda and [2]Psiquiatria, Hospital Universitario Infanta Cristina, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1429

Introduction: The econsulta is the telematic coordination system between hospital care and primary care. In this way, it allows an agile and fluid coordination, improving the coordination and the care process of the patient.
Objectives: With the data collected and analyzed, a descriptive study of the functioning of the econsulta as a coordination tool between Mental Health and Primary Care is carried out.
Methods: The data collected corresponds to health area 6 of the Community of Madrid, which consists of 18 primary health centers for a Mental Health Center. The econsultations carried out between January 2022 and August 2024 are analyzed.
The data collected are broken down into patient diagnoses, coded according to the ICD-10 classification system, and the attitude to be taken in each of them.
Results: A total of 1489 econsults performed in the period between January 2022 and August 2024 were obtained. The majority diagnoses are:

- Organic mental disorders, including symptomatic.
- Mental and behavioral disorders due to the use of multiple drugs or other psychotropic substances.
- Schizophrenia, schizotypal disorder and delusional disorders.
- Mood (affective) disorders.
- Mood disorders
- Neurotic disorders, secondary to stressful situations and somatoform disorders.
- Eating behavior disorders.
- Personality and behavioral disorders in adults.
- Mental retardation.
- ADHD

Thanks to the econsult, 692 patients have been resolved, without requiring referral to Mental Health, through direct indications and recommendations on treatments prescribed in Primary Care. Likewise, 61 of them avoided referral only to obtain a visa for the usual treatment. On the other hand, 378 patients required direct referral to Mental Health and 54 to the CAID. In addition, 229 of the patients who were already under follow-up were consulted about their treatment.
After analyzing the data, Primary Care made adequate use of the system, given that only 40 of the consultations were not appropriate.
Conclusions: After analyzing the data, the econsultation is a fast and effective coordination system that increases the efficiency of the patient care system.

TELMA-PSYK - A Digital Homebased Research and Treatment Application in the Mental Health Service

N. M. B. Johansen[1]*, S. F. Austin[1], A. A. Shaker[1] and S. M. Arnfred[1]
[1]Psychiatric Research Unit, Region Zealand Psychiatry, Slagelse, Denmark
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1430

Introduction: The gap between staff resources and population needs for psychiatric treatment and support, as well as the geographical gap between services delivered in rural areas and in cities is a major challenge for the Danish society as well as globally.
The current project will investigate video consultations (VC) in the context of developing a full-scale home-based mental health service for users with severe mental illness (SMI) necessitating multidisciplinary and municipal support. Digital patient reported outcome (PRO) monitoring can strengthen shared decision making in consultations, and is frequently applied for users with SMI, but it is not regularly combined with VC.
TELMA (Telemedical Monitoring Application) is a national IT system that makes it possible to monitor a patients' health status in their own home. TELMA includes several questionnaires and the option to connect telemedicine devices that can send vital data such as sleep quality or heart rate measurements directly to the app using Bluetooth. A number of affiliated, cross-sectoral teams who monitors the patient's health status can view the patient's responses and data. By mapping the needs and preferences of patients and staff along with an initial trial of the application of TELMA-PSYK for home-based treatment in psychiatry, this study will pave the way for the development of fully digital, person-centered, sector integrating home-based treatment.
Objectives: This study aims to explore barriers and opportunities to home-based treatment for users with severe mental illness as seen by stakeholders, staff, management and users in mental health services and municipalities.
Methods: TELMA-PSYK will be examined in a small-scale feasibility study.
Twenty users with SMI and their regional and municipal staff will be invited to participate in the study. A qualitative study based on phenomenological enquiry will capture the respondents' experiences of VC and their concerns for and opportunities of full-scale home-based mental health service with PRO recording.
Qualitative data will be interviews examining the users' experience of three months' home-based service provision, and the corresponding staffs' experience of the user's treatment course and the intervention. Qualitative data will be analyzed with reflexive thematic analysis.
Results: It is expected results from the feasibility study will be ready by March 2025.
Conclusions: It is expected conclusions from the feasibility study will be ready by March 2025.

Resources, support and integration as influencing factors in the implementation of blended therapy in psychiatric inpatient care

W. Kawohl[1,2,3]* and N. Gupta[4]
[1]Clienia Schlössli AG, Oetwil am See, Zurich; [2]Psychiatry, Psychotherapy and Psychosomatics, University of Zurich, Zurich, Switzerland; [3]UNIC Medical School, University of Nicosia, Nicosia, Cyprus and [4]Clienia Schlössli AG, Oetwil am See, Switzerland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1431

Introduction: Blended therapy (BT) is defined as the use of digital tools combined with traditional face-to-face therapy. Despite growing evidence concerning BT in outpatient settings, there is not much data on BT in inpatient care. To our knowledge, this is one of the first studies to investigate the implementation of BT in the routine care of psychiatric inpatients.
Objectives: Our objective was to identify factors potential barriers and facilitating factors influencing the implementation of BT in psychiatric inpatient settings.
Methods: We used a retrospective, exploratory qualitative research design and developed a semi-structured interview to collect our data. This enabled us to gain insights into the experiences of healthcare staff and patients. Participants were asked to reflect on the following themes we had pre-defined: resources, support, integration and sequential BT.
Results: Therapists cited work overload with inadequate time adjustments and lack of ongoing training to sustain the use of BT in the long term as common barriers. A key finding of this study from the therapists' perspective was also the importance of a clearly defined concept and setting for successful implementation. Patients valued the availability of satisfactory instructions for use, integration by therapists and a flexible setting. There were mixed opinions on sequential BT, with therapists mentioning in particular a lack of resources for patient care after discharge.
Conclusions: In summary, the results show that therapists reported more barriers in contrast to patients' perceptions. This highlights that while understanding the patient's perspective is important, healthcare professionals play the central role in implementing and maintaining BT.

EPV0747

The Impact of Online Dating on External Validation and Self-Perception

M. K. Khamassi[1,2]*, Y. Trabelsi[1,2], A. Mtiraoui[1,2] and J. Nakhli[1,2]
[1]Research Laboratory LR12ES04, University of Sousse, Faculty of Medecine of Sousse and [2]Department of Psychiatry, Farhat Hached Hospital, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1432

Introduction: In the digital era, online dating platforms have emerged as a prominent means for establishing social relationships. While these platforms facilitate connections, they also introduce a distinct form of external validation through likes, matches, and compliments. Despite their popularity, researchs on the psychological effects of this validation on users are limited.
Objectives: This study aimed to reveal the profile of dating platforms users and assess whether these platforms foster a dependence on external validation and affect operator's self-esteem
Methods: A cross-sectional study was shared via social media and online forums. In addition to socio demographic and work related

variables, it comprised an evaluation of dependency on external validation through a series of targeted questions, and explored its relationship with the use of dating platform. The Rosenberg Self-Esteem Scale was used to assess participants' self-esteem, with a score below 31 indicating low self-esteem.
Results: The study included 55 participants aged between 19 and 40 years, with a mean age of 26.27. The gender distribution was nearly equal, with 49.1% male (n=27) and 50.9% female(n=28). Most participants (54.54%) were single, and 40% reported using dating apps primarily for casual dating and entertainment.
Among applications users, 46.7% engaged with the platforms several times a week, while 20% used them daily. Furthermore, 53.7% of users plan to continue using them.
Regarding external validation, 64.4% reported that receiving validation motivated them to use the applications more frequently, while 56.2% indicated they would adjust their behavior based on feedbacks. Additionally, 47.1% felt influenced by compliments, and 58.9% reported that criticism and rejection affected them negatively.
According to the Rosenberg Self-Esteem Scale, 33.3% of users exhibited low self-esteem and 28.5% of users reported that dating applications had a negative impact on their self-esteem. Notably, no significant correlation was found between dating applications' usage and self-esteem ($p = 0.53 > 0.05$).
Conclusions: This study highlights a reliance on external validation among online dating users, suggesting that these platforms may encourage behaviors driven by the need for approval. This underscores the importance of further research into the psychological effects of such dependence.

Stigma in development and evaluation of web-based weight loss programs? Characteristics of study samples - a systematic review

N. Khorikian-Ghazari[1]*, A. Hasan[1,2], J. Grimmer[1] and I. Papazova[1]

[1]Department of Psychiatry, Psychotherapy and Psychosomatics, University of Augsburg, Medical Faculty and [2]DZPG (German Center for Mental Health), partner site München/Augsburg, Augsburg, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1433

Introduction: People with a severe mental illness (SMI) have a higher prevalence of obesity than the general population. Weight gain is one of the main adverse side effects of antipsychotic treatment, leading to health complications, higher mortality and low treatment adherence in people with SMI. E-Health programs are increasingly used for weight loss.
Objectives: This systematic review aims to analyze target groups and the inclusion and exclusion criteria in evaluation studies of such programs, with a focus on the exclusion of individuals with SMI and the resulting gap in healthcare.
Methods: The systematic search consisted of studies in English using the databases PUBMED, PsychInfo and Cochrane Database, published between January 1, 2003 - February 29, 2024. Exclusion criteria were studies with a focus on programs other than weight loss or combined interventions. Further, we used the search terms: web-based, app* OR artificial intelligence* OR software OR online OR machine learning* OR digital* OR Internet AND weight loss OR body mass index OR weight reduction* OR body weight OR waist circumference OR obesity* OR BMI OR weight. The database search identified 4560 records, of those 633 duplicates were removed. The remaining 3927 records were further screened and 3584 were excluded, 343 full-text articles were assessed for eligibility. 117 full text articles were excluded with reasons and finally 226 studies were included in qualitative synthesis.
Results: Preliminary results showed that app recommendations were reported in only 44 out of 226 studies. Additionally, analysis of target groups for recommended apps indicated that most were designed for individuals with diabetes, closely followed by apps targeting maternity, hypertension or cardiovascular diseases and corporate health management. Notably, none of the apps were specifically designed for people with a mental illness. Moreover, a comparison of the frequency of exclusion criteria for mental vs. somatic vs. chronic illnesses in general resulted in: 77:54:105. The terminology used for exclusion specifically for people with a mental illness was often general (e.g. "mental impairments", "any psychological problem", "unstable emotional condition").
Conclusions: The results point to deficits in the area of app recommendation and in sample selection. Specifically, people with a mental illness were most frequently excluded using vague terminology. Furthermore, there is an enormous lack of such programs for people with SMI. Knowledge about such gaps is crucial in order to avoid inadequate care for vulnerable groups. Excluding people with SMI from the development and subsequent evaluation of such programs may not adequately address their challenges and may lead to additional frustration experienced by this group due to inadequate app recommendations. The results suggest a potential stigmatization.

Generative Pre-trained Transformer-4 (GPT-4) generated psychological reports in psychodynamic perspective: a pilot study on quality of report, risk of hallucination, and client satisfaction

T.-S. Kim[1]*, N. Kim[2] and J. Lee[3]

[1]Department of Psychiatry, Seoul St. Mary's Hospital, The Catholic University of Korea, College of Medicine; [2]Department of Clinical Medical Sciences, Seoul National University, Seoul and [3]Department of Psychiatry, Uijeongbu Eulji Medical Center, Eulji University School of Medicine, Uijeongbu, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1434

Introduction: Recently, there has been growing interest in leveraging large language models (LLMs) in psychiatry and counseling. Specifically, there is a need to develop LLM-based programs that generate psychodynamic assessments, helping individuals gain self-insight and evaluate the quality of such services. However, research in this area remains limited.
Objectives: This pilot study aims to evaluate quality, risk of hallucination, and client satisfaction with psychodynamic psychological reports generated by GPT-4.

Methods: The reports consisted of five components: psychodynamic formulation, psychopathology, parental influence, defense mechanisms, and client strengths. Participants experiencing distress from recurring interpersonal issues were recruited for the study, which followed three stages: 1) GPT-4 generated tailored questions for participants to infer psychodynamic formulations, then used the responses to create psychological reports. 2) Seven psychiatry professors from various university hospitals assessed the reports for quality and hallucination risk, comparing GPT-4-generated reports with expert-inferred reports. 3) Participants evaluated their satisfaction with the psychological reports. All assessments were conducted using self-report questionnaires based on a Likert scale developed for this study.
Results: Ten participants were recruited for the study, with an average age of 32 years. The median response indicated that the quality across all five components of the psychological report aligned closely with expert evaluations. The risk of hallucination was assessed to be minimal, ranging from unlikely to minor. In the satisfaction evaluation, over 90% of participants agreed or strongly agreed that the report was clear, insightful, credible, useful, satisfying, and recommendable.
Conclusions: These findings suggest that artificial intelligence may have the potential to provide expert-level psychodynamic interpretations with minimum face-to-face interaction.

Artificial intelligence in healthcare – Attitudes towards AI among Hungarian healthcare professionals

Á. K. Magyary[1,2,3]*, N. Z. Mészáros[3,4], M. B. Szondy[3,5], Z. Demetrovics[2,6,7] and Á. Zsila[2,3]

[1]Doctoral School of Psychology; [2]Institute of Psychology, ELTE Eötvös Loránd University; [3]Institute of Psychology, Catholic University of Pázmány Péter, Budapest; [4]Institute of Psychology, Universsity of Pécs, Pécs; [5]MAZSIHISZ Charity Hospital, Budapest, Hungary; [6]Centre of Excellence in Responsible Gaming, University of Gibraltar, Gibraltar, Gibraltar and [7]College of Education, Psychology and Social Work, Flinders University, Adelaide, Australia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1435

Introduction: Artificial intelligence (AI) can potentially enhance healthcare professionals' understanding of certain disorders, facilitating improved diagnosis, treatment, and prevention. Exploring potential psychological factors that can possibly influence healthcare professionals' attitudes towards AI in their work is crucial to assist successful adoption and utilization of these technologies.
Objectives: The possible role of burnout, perceived distress, and factors related to work circumstances on willingness to use AI were explored in this investigation.
Methods: Attitudes towards artificial intelligence, perceived distress and factors related to work were assessed by using an online questionnaire. Participants (86 % women, *Mage* = 46.9 years, SD = 11.3) were healthcare professionals recruited from Hungarian hospitals and healthcare institutions.
Results: Linear regression analysis indicated that most participants (58%) were open to using AI in their work. Significant predictors of use were job satisfaction, work performance, and administrative workload. Higher burnout levels and perceived distress were not associated with attitudes towards AI.
Conclusions: The present findings suggested that work-related environmental factors may have a greater predictive power in explaining the propensity to use AI in healthcare than individual psychological factors. However, the explanatory power of these factors in AI use was modest (7.5%), suggesting that future research should investigate further possible predictors of attitudes towards AI such as social factors.

EPV0753

Development of Virtual Reality Systems for Social Skills Training in Individuals with Autism Spectrum Disorder: A Systematic Literature Review

H. Masullo[1]* and M. Galloro[1]

[1]Unisa, São Paulo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1436

Introduction: Autism Spectrum Disorder is a neurodevelopmental condition characterized by deficits in social communication, restricted and repetitive patterns of behavior. In recent years, there has been a growing interest in using virtual reality technologies for social skills training in individuals with ASD. Virtual reality offers the opportunity to create immersive and interactive virtual environments where participants can practice and enhance their social skills in a safe and controlled setting.
Objectives: To analyze the quality of using virtual reality as a treatment method for patients with autism spectrum disorder to improve their social skills.
Methods: Through a descriptive systematic review, studies in Spanish and English from the years 2021 to 2024 were analyzed, selected from the databases PubMed, Scielo, and Lilacs, using the keywords: "Virtual reality"; "Autism spectrum disorder"; "Social skills". Articles that did not address virtual reality as the main training method, were off-topic, or did not present results from this method were excluded.
Results: Children and Social Skills
Programs like FaceMe use gamified environments to teach facial expressions, while tools like GameBook use interactive scenarios and augmented reality to reinforce these skills. VR's ability to track and analyze eye movement patterns offers insights into social behavior. Programs like "Virtual Farm" and VR games such as Zentastic have demonstrated positive effects, with children engaging in various virtual social scenarios. Programs like VRESS use immersive scenarios to teach social skills that provide real-time feedback on behavior can help individuals develop self-awareness and adjust their interactions.
Adults and Social Skills
Adults with autism face challenges in non-verbal communication, understanding social cues, and forming relationships, which can lead to social isolation. VR offers simulations for practicing social interactions, enhancing communication, empathy, and conflict resolution. Programs like VRESS use immersive scenarios to teach social skills, and tools that provide real-time feedback on behavior can help individuals develop self-awareness and adjust their interactions.

Conclusions: The development of virtual reality systems for social skills training in individuals with autism spectrum disorders represents an innovative and promising approach to assisting in the development of these skills in both children and adults with autism. Virtual reality offers a more engaging and effective training experience, allowing users to practice social skills in a controlled environment tailored to their individual needs. Despite the promising results, there are still challenges to be faced, such as methodological issues and the need for awareness and training of health and education professionals.

Nomophobia and mental health: are cell phones taking our sleep away?

A. C. Matias-Martins[1]*, T. Vieira[1], A. Ferreira Silva[1], R. Machado Lopes[1], C. Almeida Rodrigues[1], F. Marinho Santos[1] and P. Fonseca Coelho[1]

[1]Psychiatry and Mental Health Department, Unidade Local de Saúde do Médio Tejo, Tomar, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1437

Introduction: The widespread use of mobile devices, particularly among young people, extends beyond entertainment to education and professional purposes. However, excessive smartphone use has led to health issues such as headaches, poor concentration, sleep problems, and anxiety. A condition called nomophobia, or the fear of being without a mobile phone, has emerged, though it's not officially recognized as a psychiatric disorder. In adults, 20% experience mild nomophobia, 50% moderate, and 20% severe symptoms, which can be measured using the Nomophobia Questionnaire (NMP-Q). Smartphone overuse is also linked to psychopathological issues like insomnia and anxiety.
Objectives: The aim of this study is to evaluate the impact of nomophobia in insomnia and anxiety.
Methods: Non-systematic review of the literature regarding nomophobia and anxiety and insomnia. The research was carried out through the PubMed® database, using the terms "nomophobia", "nomophobia and anxiety" and "nomophobia and insomnia".
Results: The included studies highlight that nomophobia is associated with higher anxiety levels in most individuals as well as a substantial correlation between nomophobia symptoms and insomnia.
Conclusions: Nomophobia is increasing due to technological advancements and widespread access. Overuse of mobile phones is linked to psychopathologic symptoms, like anxiety and insomnia. Raising awareness and helping young adults manage their phone use is essential for promoting health and well-being as digital technologies become an integral part of daily life.

Contextual analysis for the implementation of a digital psychosocial intervention to enhance mental health outcomes in North Macedonia

M. Milutinovic[1]*, L. Novotni[1], A. Novotni[1], S. Bajraktarov[1] and S. Arsova[1]

[1]University Clinic of Psychiatry, Skopje, North Macedonia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1438

Introduction: This study represents the first effort in North Macedonia to examine the contextual attributes that may influence the effectiveness and acceptability of a novel digital intervention, DIALOG+, within the mental health care system. The intervention aims to enhance mental health outcomes through a structured approach, but its success depends on understanding the specific characteristics of the local health context.
Objectives: The primary objective of this research is to identify the key contextual attributes within the mental health care system of North Macedonia that are relevant to the successful implementation of DIALOG+. This includes examining factors that could impact both the effectiveness of the intervention and its acceptance by various stakeholders, including patients, clinicians, carers, and policymakers.
Methods: Data for this study were drawn from a variety of sources, including the National Mental Health Strategy 2018-2025, relevant documents from the World Health Organization, and other action plans. In addition, interviews were conducted with key stakeholders —patients, carers, clinicians, and policymakers—to gather perspectives on the anticipated introduction of DIALOG+ and assess the readiness of the mental health centers for its implementation. The data were subsequently mapped to a framework developed by the Ottawa Implementation Group, which outlines 14 key contextual attributes influencing health interventions.
Results: The findings were categorized into two subgroups, identifying both facilitators and barriers to the implementation of DIALOG+ in North Macedonia's mental health system. The intervention's characteristics as a broadly applicable psychosocial tool align well with modern approaches to psychosocial rehabilitation, particularly for individuals diagnosed with psychosis.
Conclusions: DIALOG+ presents a valuable tool for mental health professionals in North Macedonia, offering structured support for monitoring patient progress and achieving institutional objectives. The intervention has the potential to facilitate patients' reintegration into society, enhance their independence, and enable them to reach their full potential in the pursuit of a healthy and functional life.

Evaluating the Clinical Reasoning Capabilities of AI Language Models in Diagnosing and Treating Depression

V. W. L. Mok[1], S. N. Sasidharan[1], N. Q. Y. Chua[1]* and C. S. Lim[1]

[1]Psychological Medicine, Changi General Hospital, Singapore, Singapore
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1439

Introduction: Artificial intelligence (AI) language models are increasingly accessible tools that offer potential support in mental health care. Despite their promise in revolutionizing mental health care through symptom assessment and treatment suggestions, concerns about their validity, accuracy, ethical considerations, and risk management persist. This study evaluates the clinical reasoning capabilities of two leading AI language models in assessing a clinical case vignette of Major Depressive Disorder (MDD).

Objectives: To evaluate the diagnostic accuracy, risk assessment proficiency, and quality of treatment recommendations provided by ChatGPT and Claude when applied to a standardised clinical vignette of a case of MDD.
Methods: A clinical vignette describing a 50-year-old male patient exhibiting symptoms consistent with MDD was presented to both ChatGPT 4o and Claude 3.5 Sonnet. The patient had significant cardiac disease, leading to unemployment, social withdrawal, and passive suicidal ideation. Both AI models were asked five identical questions regarding: (1) diagnosis, (2) severity assessment, (3) first-line treatment recommendations, (4) optimal antidepressant selection, and (5) suicide risk evaluation. Two psychiatrists independently reviewed the responses for accuracy, comprehensiveness, and alignment with established guidelines and evidence-based treatment for depression with comorbid cardiac disease.
Results: Both AI models correctly diagnosed MDD and accurately recognized the severity of the case due to the presence of suicidal ideation and significant functional impairment. Both offered comprehensive treatment recommendations, including pharmacotherapy and psychotherapy, and specifically suggested Sertraline as the antidepressant of choice due to its favourable cardiac safety profile. Both models assessed the patient as having a moderate to high suicide risk and provided a reasonably thorough analysis of risk and protective factors. However, limitations were noted in their ability to incorporate individualized patient nuances and psychosocial factors fully.
Conclusions: ChatGPT 4o and Claude 3.5 Sonnet demonstrated significant capabilities in clinical reasoning, providing diagnoses and treatment recommendations that align with best clinical practices. Their responses were largely accurate and comprehensive, indicating potential utility as supportive tools for healthcare professionals. AI models may assist non-specialists in preliminary assessment and management but are not substitutes for professional psychiatric evaluation. Caution is advised in relying on AI for clinical decision making, and further refinement is necessary to enhance their ability to integrate patients-centered care and adherence to ethical guidelines, to mitigate risks associated with self-diagnosis and inappropriate treatment.

EPV0757

The wait time study: (Cost-) Effectiveness of a personalized e-health intervention for patients with psychiatric disorders on waiting lists for treatment– a randomized controlled trial

A. N. Nelissen[1]* and E. J. Giltay[1]
[1]LUMC, Leiden, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1440

Introduction: Access to timely mental health care in the Netherlands has become increasingly challenging, with waiting times steadily increasing in recent years. Extended waiting times for treatment in mental health care can be harmful due to increased severity of symptoms, poorer treatment outcomes and a reduced quality of life. There is growing interest in the potential of unguided e-health interventions to provide support during these waiting periods without overburdening healthcare professionals
Objectives: The main objective of this study is to test the clinical effectiveness and cost-effectiveness of a personalized unguided e-health intervention during the waiting list period.
Methods: A Randomized Controlled Trial (RCT) with two trial arms will be conducted: the intervention condition and the treatment as usual waiting list condition. Adult outpatients awaiting an intake at a several specialized mental health care institutions will be included in the study. Both trial arms will include repeated measures during the waiting period. The intervention arm will receive online access to a selection of existing e-health modules. Personalization will be achieved by employing both innovative and traditional methods to identify symptoms that are most influential for each individual participant. A Dynamic Time Warping analysis based on a three-week ecological momentary assessment (EMA) will be used to determine which specific symptoms are most responsible for maintaining the patient's overall complaints (4). This analysis will be used to provide tailored recommendations of e-health modules. The study's outcomes will focus on symptom severity, cost-effectiveness, quality of life, digital phenotyping and patient satisfaction during the waiting period.
Results: At this stage, no results are available yet as the study is still being conducted.
Conclusions: No conclusions can be drawn as the study is still being conducted.

Disclosure of Interest: None Declared

A Preliminary Exploratory Clinical Trial of the Efficacy of Digital Therapeutics for ADHD children in Korea

M.-S. Shin[1], G.-E. Nam[1], C. Park[1], S.-H. Park[1], B.-N. Kim[1], S. Lee[2], S. Oh[2]*, M. J. Kang[2], H. W. Lee[2] and C. Jo[2]
[1]Psychiatry, Seoul National University Hospital and [2]DH team, Dragonfly GF Co., Ltd., Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1441

Introduction: Recently, CBT-based digital therapy has been developed and used for the treatment of various psychiatric disorders, including insomnia, depression, anxiety and panic disorders, and alcohol/drug addiction. In the United States, the first game-based digital therapy for ADHD has also received FDA approval and is being used for the treatment of children and adolescents with ADHD.
Objectives: We conducted a randomized controlled study to examine the effectiveness of a digital therapeutic (model named 'ADAM-101') for children with ADHD in Korea, which was developed by Dragonfly GF Co., Ltd."
Methods: Participants are 18 children with ADHD, aged 7 to 13 years, who are visiting the Department of Child and Adolescent Psychiatry at Seoul National University Children's Hospital in Seoul, Korea. ADHD children with an IQ of 70 or above, who are currently taking stimulants and do not have other pediatric psychiatric disorders such as depression, anxiety disorders, tic disorders, ASD, were included in the study. They were randomly assigned to either the combined treatment group (medication + digital therapy, n = 9) or the medication-only group (n = 9). The digital therapy program was conducted using a tablet PC for 25 minutes a day, 5 days a week, for 4 weeks. Before starting the study, permission was obtained from the Institutional Review Board of Seoul National University Hospital. As

a primary outcome measure, the Korean version of the Continuous Performance Test (KAT) was administered individually to the ADHD children by child clinical psychologists to assess inattention, impulsivity, and processing speed, after obtaining written agreement to participate in the study. Additionally, the Korean version f the ADHD Rating Scale-5 (K-ARS-5) was administered to the parents of the ADHD children.
Results: We have not yet completed the study. Currently, out of the 18 ADHD children, 8 have completed the training and both pre- and post-assessments. All training and evaluations are expected to be completed by early October, and an analysis to verify the effectiveness of the digital therapeutic will be conducted in mid-October. Since this was not a double-blind study, we observed that, based on some children's CPT and K-ARS-5 results, children in the combined treatment group tended to show a reduction in omission and commission errors on the CPT compared to those in the medication-only group. Additionally, there was a trend towards a reduction in inattention and hyperactivity-impulsivity scores on the K-ARS-5 in the combined treatment group.
Conclusions: Despite being conducted with a small sample, these results suggest the potential efficacy of the digital therapeutic (model named 'ADAM-101') for Korean ADHD children, indicating its potential clinical usefulness as an adjunctive treatment tool for ADHD children

Effectiveness of a guided e-health sleep and biological clock intervention in university students (i-Sleep & BioClock) – results of a randomized controlled trial

L. M. Pape[1]*, A. van Straten[2], S. Struijs[2], P. Spinhoven[1] and N. Antypa[1]

[1]Department of Clinical Psychology, Leiden University, Leiden and [2]Department of Clinical, Neuro- & Developmental Psychology, Vrije Universiteit Amsterdam, Amsterdam, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1442

Introduction: Sleep problems are very prevalent among university students, affecting their mood, energy levels, daily functioning, and quality of life. Irregular sleep-wake patterns contribute to the disruption of their circadian rhythms. Cognitive behavioural therapy for insomnia (CBT-I) has been proven effective in adults, but research in university students is still limited.
Objectives: The aim of this study is to investigate the effectiveness of a guided digital self-help intervention targeting sleep and the biological clock in university students to improve sleep and mental health outcomes.
Methods: We conducted a two-arm randomized controlled trial in nine Dutch Universities. We included 196 university students (Bachelor, Master, and PhD) with self-reported insomnia symptoms (Insomnia Severity Index ≥ 10) and randomly assigned them (1:1) to receive the 5-week 'i-Sleep & BioClock' intervention or online psychoeducation. The intervention is based on CBT-I with specific emphasis on the biological clock. It consists of 5 weekly online modules and is guided by online coaches. The primary outcome is insomnia severity. Secondary outcomes are depression, anxiety, daily functioning, academic performance, quality of life, and sleep & light exposure diary outcomes. Outcomes were measured at baseline, mid-treatment (3 weeks), post-treatment (6 weeks after baseline), and at 18 weeks follow-up. Data will be analyzed with intention-to-treat analysis using linear mixed models. The study is registered at ClinicalTrials.gov (NCT06023693).
Results: Recruitment started on Nov 1st, 2023 and ended on Sept 5th, 2024. Data collection is currently ongoing and will be finalized in January 2025. We hypothesize that the guided digital self-help intervention will reduce insomnia severity and improve mental health outcomes in students (results will be presented).
Conclusions: Findings from this randomized controlled trial will contribute to the growing body of knowledge on digital sleep interventions and their potential impact on mental health. If the intervention proves effective, we aim to disseminate the intervention widely in higher education to benefit a broader student population.

Studying the Impact of Online Mental Health Therapy: Platform Usage Patterns and Effectiveness of Chat-Based Therapy for Anxiety

C. Gil Lopez[1], A. Rez[1]* and G. Hoter Ishay[2]

[1]Research, Ifeelonline, Madrid, Spain and [2]Research, Ono Academic College, Kiryat Ono, Israel
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1443

Introduction: The treatment landscape for mental health has transformed significantly with the emergence of digital platforms, which offer a promising public health solution by expanding access to mental health services. Despite their potential, further research is needed to evaluate both the usability and clinical effectiveness of these online interventions.
Objectives: To investigate the usage patterns of an online mental health app and the effectiveness of chat-based emotional support (ES) in reducing psychological distress and achieving therapeutic goals.
Methods: The analysis included data from 3,751 users of *ifeel* app onboarded in 2023, 58% of whom were female and 42% male. Two main modalities were studied: chat-based therapy,(N= 3,170) and video therapy,(N=1,942), with some overlap as users could engage in both modalities. Key metrics for analysis included session frequency, session timing, session duration, and user demographics. The study also explored chat-based ES therapy by evaluating 113 individuals at two points in time: after one week of therapy, and after three weeks. Psychological distress levels were measured using the Kessler Psychological Distress Scale (K6), and goal attainment was measured through self-reports over the two time points.
Results: Usage data showed a strong preference for chat-based therapy, with 85% of users engaging in chat therapy compared to 52% who used video therapy. Younger users, particularly those aged 25-34, were the most active in engaging with chat-based therapy. On average, chat therapy users send between 14 to 17 messages per month, whereas video therapy users take 2 sessions per month. These results underscore the higher frequency of engagement in chat therapy, particularly among younger demographics. In terms of clinical effectiveness, psychological distress was reduced significantly at both one week and three weeks of therapy. After one week of treatment, participants showed a significant reduction in distress symptoms *($F(1) = 5.10$, $p = .03$*)* this was evident also after three

weeks *(F(1) = 24.25, p = .000***).* Goal attainment showed substantial progress over time, with significant improvements in both groups *(F(1) = 5.03, p = .03*; F(1) = 31.61, p = .000*),* indicating that users were making meaningful strides toward their therapeutic goals.

Conclusions: This study underscores the usage pattern and clear preference for chat-based therapy, particularly among younger users. Chat-based emotional support therapy was found effective in reducing psychological distress, suggesting that online platforms, especially those offering chat-based therapy, are both accessible and clinically effective. Further research should focus on refining these services to maximize clinical outcomes, adapt to diverse user demographics, and ensure long-term engagement.

Development of app-based neuropsychological tasks for screening people at mental health high risk

M.-S. Shin[1]*, S. Um[2], M. Jeon[2] and Y. Ahn[2]

[1]Psychology, Korea University and [2]Psychiatry, Seoul National University Hospital, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1444

Introduction: Depressive and anxiety disorders have a high prevalence and pose a significant socioeconomic burden. To reduce this, the importance of early intervention through the screening of high-risk groups has been highlighted by many researchers and clinicians. However, due to the heterogeneity of symptoms and comorbidity with other mental disorders, it is challenging to identify high-risk groups of depression and anxiety disorders early on. To address this issue, we developed App-based neuropsychological tasks for screening high-risk groups and classifying subtypes of depression and anxiety disorders through services in the metaverse.

Objectives: As a preliminary step, we have developed four app-based neuropsychological tasks for the early screening and subtype classification of individuals at high risk for depression and anxiety disorders, and examined the reliability and validity of the tasks.

Methods: Subjects were 30 adults with mean age of 32.93(male=8, female=22). After obtaining written agreement to participate the study, smartphones with the app-based neuropsychological tasks were provided to them, and then smartphone app tasks as well as digitized self-report scales related to depression and anxiety were performed. To analyze the reliability of the tasks, Cronbach's alpha was calculated. And correlation analyses were conducted between the scores of each task (ex; number of correct response, reaction time, number of skipping the task level) and the scores of the self-questionnaires to verify validity of the tasks. The overview of the tasks developed in this study is as follows: The catching raccoon task investigates the tendency to abandon performance in complex working memory task situations. The soccer task measures vitality and planning abilities. The risk-taking decision-making task examines the tendency to take risks. In the verbal memory task with mood induction, we investigate whether attention bias towards negative emotions, such as depression, affect the memory functions after inducing negative emotions through audiovisual stimuli.

Results: The range of Cronbach's alpha values for the task was between .71 and .92, showing that the tasks are reliable. Additionally, three out of the four tasks showed statistically significant correlations with the scores of depression or anxiety measured by self-report rating scales, confirming the validity of the tasks.

Conclusions: Despite being conducted with a normal population, these results verified the reliability and validity of the tasks, suggesting the potential usefulness of the tasks for early intervention through the screening of high-risk groups with depression and anxiety disorders.

A 12-week app-based multidomain intervention ameliorates cognitive performance in patients with mild cognitive impairment: preliminary results of the MEMODIO_APP@CARE RCT

G. Nelles[1], T. Steinmann[2], D. Stein[2], V. Weil[2]*, A. Bicu[3] and C. Polidori[4]

[1]Neuromed-Campus, Cologne; [2]memodio GmbH, Potsdam; [3]Radiation Oncology, University Medical Center Mannheim, Medical Faculty Mannheim, University of Heidelberg, Mannheim and [4]Department II of Internal Medicine and Center for Molecular Medicine Cologne, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1445

Introduction: The *Lancet Commission on dementia prevention, intervention and care* and the *WHO Guidelines on risk reduction of cognitive decline and dementia* provide evidence-based recommendations on lifestyle behaviours and interventions to delay or prevent cognitive decline and dementia. Due to demographic change and because new developments in pharmacotherapy are not suitable for all patients, there is a great need for non-pharmacological interventions. The MEMODIO app was developed to provide a multidomain therapy for users with Mild Cognitive Impairment (MCI) and dementia. A screenshot of the app is shown in Image 1.

Objectives: The aim of this study was the exploratory evaluation of whether an app-based therapy can improve cognitive function in patients with MCI and mild dementia. For the interim analysis as of October 2024, the results of the MCI study arm are reported (n=42).

Methods: One hundred forty patients with confirmed diagnosis of MCI [Montreal Cognitive Assessment (MoCA) score 21-25] or Mild Dementia (MoCA score 14-20) were randomized to an intervention (IG) or standard of care (SoC) group. IG patients received SoC plus the MEMODIO app, providing cognitive and physical exercises, as well as psychoeducation on a brain-healthy diet and risk factors for cognitive decline, for 12 weeks. MoCA, Amsterdam Instrumental Activity of Daily Living Questionnaire - Short version (A-IADL-Q-SV) Dementia-Related Quality of Life (DEMQOL) as well as Physical Activity Questionnaire (PAQ 50+) were collected at baseline and study end.

Results: In the MCI group, the mean age was 71 years, 20 out of 42 patients were female. Preliminary outcomes are shown in Images 2 and 3.

The preliminary analysis on MCI patients (mean age: 71 y ±9,49 SD, 48% were female) showed statistically significant improvements in MoCA in the IG (-0.84±3.5 SoC vs. 1.96±2.7 IG, p=0.006). Quality of life, physical activity and activities of daily living at the time point of the interim evaluation were not significantly different from baseline, but the activity level measured by PAQ showed a non-significant improvement in the SoC group.

Image:

Image 2:

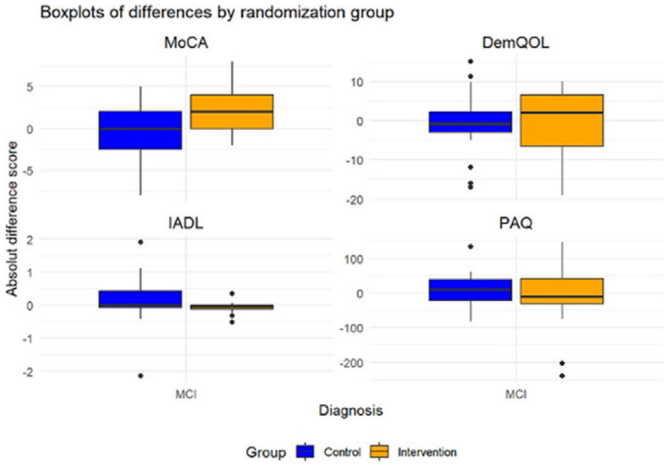

Image 3:

Outcome MCI (n=42)	Mean of differences t0 to t1 control group (SD)	Mean of differences t0 to t1 intervention group (SD)	p-Value
Cognitive function (MoCA)	-0.836 (3.46)	1.957 (2.74)	0.006
QoL (DEMQOL)	-0.609 (7.72)	-0.565 (8.67)	0.986
Daily abilities (A-IADL-Q-SV)	0.092 (0.74)	-0.071 (0.18)	0.339
Activity level (PAQ 50+)	9.368 (48.7)	-8.757 (92.3)	0.453

Conclusions: In this RCT, a significant improvement in cognition was shown in MCI-patients using the MEMODIO app compared to those receiving SoC alone. Further analyses are ongoing.

Cognitive Adaptation Training for healthcare professionals & relatives: The development of a web-application through User Centered Design

T. van Brouwershaven[1]*, B. J. Hoekman[2], M. de Koning[3,4], S. Gangadin[5], N. Boonstra[6,7] and L. van der Meer[1,8]

[1]Department of Rehabilitation, Lentis Psychiatric Institute, Zuidlaren; [2]Lectorship digital transformation, Hanzehogeschool Groningen, Groningen; [3]Department of Research, Arkin Institute for Mental Health; [4]Department of Research, Amsterdam UMC, Amsterdam; [5]Department of Psychiatry, UMC Groningen, Groningen; [6]Department of Neuroscience, UMC Utrecht, Utrecht; [7]Department of Research and Innovation, KieN VIP Mental Health Care Services, Leeuwarden and [8]Department of Clinical and Developmental Neuropsychology, University of Groningen, Groningen, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1446

Introduction: Cognitive impairments often hinder daily functioning in people with severe mental illness (SMI). Cognitive Adaptation Training (CAT) is an effective psychosocial intervention that reduces this impact. However, barriers such as the two-day training and lack of neuropsychological expertise in some professionals hinder CAT implementation.
Objectives: To make CAT more accessible to healthcare professionals and relatives of people with SMI by developing a web application (House-CAT) that guides users through the intervention.
Methods: For the development, User Centered Design (UCD) is used: a design process where close cooperation with future users (healthcare professionals, relatives, service users) is important to make sure that their needs are met. Although UCD is circular and iterative, three phases can be distinguished: analysis, design, and evaluation. In the analysis phase, users' needs are identified and translated into design criteria. A testable prototype of House-CAT is created (design phase), followed by implementation and evaluation on efficiency, acceptability, and user-friendliness (evaluation phase).
Results: Three focus groups were conducted in the analysis phase: CAT-experienced professionals (n=5); professionals unfamiliar with CAT (n=4); and relatives (n=5). Further, individual meetings with family members (n=8), and professionals (n=6) were conducted. Design criteria included the app's ability to (1) support with setting up individual goals; (2) find personalized strategies or tools; (3) improve communication between professionals; (4) encourage cooperation between professionals, relatives, and service users; (5) be available in hybrid form; (6) use simple language. The design- and evaluation phase are currently in process: the web app and results from the evaluation phase will be presented at the conference.
Conclusions: House-CAT should support users in creating individual goals and personalized strategies, stimulate contact between professionals, relatives and service users, and be simple to use.

Implementation of a Remote Primary Care and Psychiatry Model for Early Detection and Treatment of Depressive Symptoms in Adolescents

S. B. Vázquez[1] and L. Diaz-Castro[2]*

[1]Direction of epidemiological and psychosocial research and [2]Nacional Institute of Psichyatry Ramon de la Fuente, Mexico City, Mexico
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1447

Introduction: Psychopathology in adolescents is influenced by genetic factors, hormonal changes, individual vulnerabilities, and coping skills. Telepsychiatry has proven effective in improving access to mental health services.
Objectives: To implement a Remote Primary Care and Psychiatry Model (MAP/PSI) to facilitate early diagnosis and timely treatment of depressive symptoms in youths from the Municipality of Ciudad Fernández, San Luis Potosí, Mexico, using an implementation science approach
Methods: A prospective study was conducted with 38 patients evaluated in child psychiatry, using the PHQ-9 (Patient Health Questionnaire) and GAD-7 (Generalized Anxiety Disorder) scales. Non-parametric statistical tests were applied
Results: The sample included patients aged 15 to 25. Diagnoses included 8 (20%) with generalized anxiety, 8 (20%) with mild depression, 15 (35%) with moderate depression, and 9 (25%) with severe depression, who were referred to the general hospital due to suicidal ideation. 60% of patients were female and 40% male. The mean age was 20 years ±3, with mean scores on the PHQ-9 of 16 ±7 and on the GAD-7 of 13 ±6, reduced in the final consultation to 8 ±6 and 7 ±6, respectively. Increased symptom frequency was observed in females ($p < 0.044$) and older age correlated with higher initial PHQ-9 scores ($p < 0.034$), with no correlation to generalized anxiety ($p < 0.021$). No relationship was found between the duration of symptoms and improvement
Conclusions: The MAP-PSI model facilitated early detection and treatment of depressive and anxiety symptoms in youths, preventing progression to severe depression and its complications.

Ecological Momentary Assessments: A Real-World Solution for Understanding Functional Challenges

S. Volovic Shushan[1,2]*, A. Stern[3] and N. Josman[1]

[1]The Faculty of Social Welfare and Health Sciences,Department of Occupational Therapy, University of Haifa, Haifa; [2]"Clalit" health services, "Shalvata" Mental Health Hospital, Hod-Ha'Sharon and [3]Faculty of Health Sciences, Occupational Therapy Department, Ben-Gurion University of the Negev, Beer Sheva, Israel
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1448

Introduction: Major Depressive Disorder (MDD) is the leading cause of disability worldwide, affecting individuals' functioning in various life areas. Prolonged residual functional impairment is one of the risk factors for recurrence. Moreover, symptoms severity and accompanying functional disabilities negatively impact quality of life (QoL) and personal well-being, affecting the recovery process of

people with MDD and their reintegration into daily life. Therefore, restoring functional abilities is no less important than reducing symptoms.

Objectives: Recent changes in mental health policy have led to an expansion of client-oriented community-based services, focusing on preventing health problems and promoting QoL and well-being. A significant change can also be seen in depression evaluation and treatment, moving from traditional face-to-face therapy to hybrid care settings that incorporate remote or home-based treatments and assessments of everyday life.

While traditional assessments of symptoms and behavior often rely on questionnaires and interviews, they frequently miss the dynamic changes in daily functioning experienced by people with MDD. Clinicians primarily rely on patients' retrospective reports regarding mood, affective state, thoughts, and behavior. However, understanding and gaining insight into day-to-day experiences requires addressing dynamic processes and changes that occur over time, rather than in a single time point. Hence, **ecological momentary assessment** (EMA) is a powerful and effective technique for assessing moment-to-moment function patterns in daily life.

Methods: Advancements in technology have enabled the use of computer-assisted methodology and real-time monitoring EMAs. The methodological advantages, including the circumvention of retrospective bias and increased longitudinal and ecological validity, have facilitated the widespread use of EMA in mood disorder clinical practice. Nevertheless, addressing everyday functioning using EMA remains limited in clinical research and practice.

Results: Utilizing EMA can enhance our understanding of human experience, leading to human-centered research, design practice, and mental health care. It has the potential to reveal real everyday functioning and reflect the activities and contexts chosen and experienced by people with MDD. Addressing each patient's unique functional profile can facilitate personalized interventions, supporting the recovery process and improving QoL.

Conclusions: This presentation will review the benefits of EMA in the field of mood traits, and especially EMA monitoring for daily function. Additionally, it will present recent studies using EMA and discuss advancements and clinical applications.

doi: 10.1192/j.eurpsy.2025.1449

Introduction: Since the risk of relapse is particularly high after completion of acute treatment of depression until remission, the guidelines recommend maintenance therapy or continuation over several months and subsequent relapse prevention. In contrast, average waiting time for further outpatient treatment after a part-time inpatient stay is 19.9 weeks in Germany. Digital health technologies can help to support patients at the vulnerable interface when changing health care sectors from part-time inpatient treatment to further outpatient treatment and contribute to a successful change of health care sectors.

Objectives: Flowzone is a digital communication platform in which therapists and patients can stay in contact after completion of part-time inpatient treatment. Individualized therapy content can be shared with patients in weekly plans and communication can be maintained via the chat function. The aim of the current study is to investigate whether Flowzone enables continuity despite long waiting times when health care sectors changes from part-time inpatient to outpatient care.

Methods: In a longitudinal intervention study depressive symptoms (BDI-II) and quality of life (WHOqoL-Bref) will be assed at the end of part-time inpatient treatment (t1) and 8 weeks after end of treatment (t2). Participants diagnosed with depression will be recruited in a day clinic with treatment focus of men of a psychiatric psychotherapeutic specialist hospital in Lower Saxony (Germany). Participants of control group (CG, $n = 11$) will take part in the local 8 week aftercare groups of the psychiatric hospital. Participants of intervention group (IG, $n = 21$) will take part in the digital aftercare with Flowzone. Furthermore subjective benefit, of IG will be measured. In addition, the subjective benefit and user experiences of IG will be measured.

Results: Mean BDI scores of IG are t1 = 14 vs. t2 = 15 and of CG t1 = 9. Mean values of IG for WHOqoL-Bref domains are general quality of life t1= 77/ t2 = 73; physical health t1= 71/ t2 = 68; psychological health t1 = 59/ t2 = 55; social relationships t1 = 65/ t2 = 57; environment t1 = 77/ t2= 71. Further inferential statistical analysis and group comparisons will be reported when date are available.

Conclusions: Results might suggest that depressive symptoms and quality of life could be stabilized with the use of Flowzone 8 weeks after part-time inpatient treatment. Further data collection will allow statistical comparisons to CG. Inclusion of the CG with standard follow-up in an outpatient setting is needed. Flowzone could help to bridge the gap in treatment when patients switch health care sectors and experience a gap between part-time inpatient care and further outpatient care.

Do patients with Autism Spectrum Disorder receive more sedatives in the Emergency Department? A case matched cohort study

S. Das[1,2]*, N. Thomas[1] and R. Arasu[3]

[1]Psychiatry, Western Health; [2]Psychiatry, University of Melbourne and [3]Emergency Medicine, Western Health, Melbourne, Australia

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1450

Introduction: Adult patients with Autism Spectrum Disorder (ASD) exhibit a range of behaviours that can be disruptive to the medical care of themselves and other patients and as a result, are at higher risk of being sedated.Symptom severity is heterogenous. Some patients are completely non-verbal, some require assistance with basic activities of daily living, and others function independently with only mild difficulties . Roughly two thirds of patients with ASD have a comorbid psychiatric diagnosis, with the most frequent comorbidities

being ADHD, anxiety and depressive disorders or intellectual disability. These comorbidities complicate the management of these patients, and may further increase their agitation and distress.
Objectives: The present study aims to determine whether adult patients with ASD who present with acute psychiatric illnesses receive more sedatives in the emergency department.
Methods: 43 adult patients with a previous diagnosis of ASD who were referred to the mental health team at a single, large emergency department in metropolitan Victoria over the year of 2021 were identified and matched with an equal number of controls within the same cohort. Sedative medications were converted to diazepam and chlorpromazine equivalent doses.
Results: There were 41.9% female participants among cases and controls. The mean age of patients with ASD was 26.7 (SD = 7.9), which was similar to the mean age of controls of 27.4 (SD = 7.6). The mean hospital length of stay was 13.4 hours (SD 8.6) among cases and 14.0 (SD 7.0) among controls.A higher proportion of patients with ASD received benzodiazepines at 60.5% compared to 46.5% among controls, with a difference that was not statistically significant. A lower proportion of 30.2% of patients with ASD received antipsychotics compared to 44.1% among controls, with a difference that was not statistically significant.
Conclusions: This study shows evidence that patients with ASD are more heavily sedated in the emergency department compared to patients who present similarly but do not have a prior diagnosis of ASD. While the observed increased dose of benzodiazepines was modest, it does represent a potentially increased degree of harm to patients with ASD. We strongly recommends that every attempt should always be made to reduce the use of sedative medications in favour of other techniques for behavioural management. These include verbal de-escalation, reducing sensory stimuli, one-to-one nursing, prompt security presence and the involvement of family or friends. Since patients with ASD are at a higher risk of receiving sedatives, efforts should be made to recognise their patterns of behaviour and difficulty, to understand them and formulate constructive and safe ways to manage their behaviour.

Patterns in Psychiatric Emergency Care: a Three-Month Statistical Approach

A. DE LA CRUZ DAVILA[1]*, M. Navarro[1], K. Muñoz[1] and A. Gómez[1]

[1]Psychiatry Service, Hospital Álvaro Cunqueiro, Vigo, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1451

Introduction: Psychiatric emergencies represent a significant challenge for healthcare systems due to their impact on patients, families and also healthcare professionals. These emergencies often arise in crisis situations, requiring immediate and appropriate intervention. Effective management not only involves stabilizing the patient but attending to psychosocial factors and continuity of treatment. In recent years, there has been an increase in the demand for psychiatric emergency services attributed to various factors; this underscores the need to analyze the patterns of these emergencies in order to optimize available resources and improve patient care.
Objectives:
The present study provides information regarding demographic and clinical characteristics of the patients treated. The main goal is to identify trends, risk factors, and opportunities for improving critical situations management as well as and the effectiveness of procedures implemented in primary and specialized care.
Methods: Currently there is no standardized method for collecting data on urgent psychiatric care, thus depending on the specific methodology of each center. In our hospital, a written request from the General Emergency department (where patients are initially received and attended) is mandatory; without it, patients are not assessed. Therefore, there is a reliable computerized record of daily attendances, data that has been collected retrospectively on a weekly basis until the study period is completed (June, July, and August 2024).
The following items have been studied: time of request, age, sex, patient origin, reason for the request, prior follow-up, management in emergencies, and discharge referral. Telephone calls for specific consultations have not been included in the record or considered psychiatric care as such.
Results: There is a wealth of cross-referenced data that can be obtained form the collected information. In our opinion, the most interesting ones are those regarding referral reasons and discharging plans according to sex as well as age groups.

Image 1:

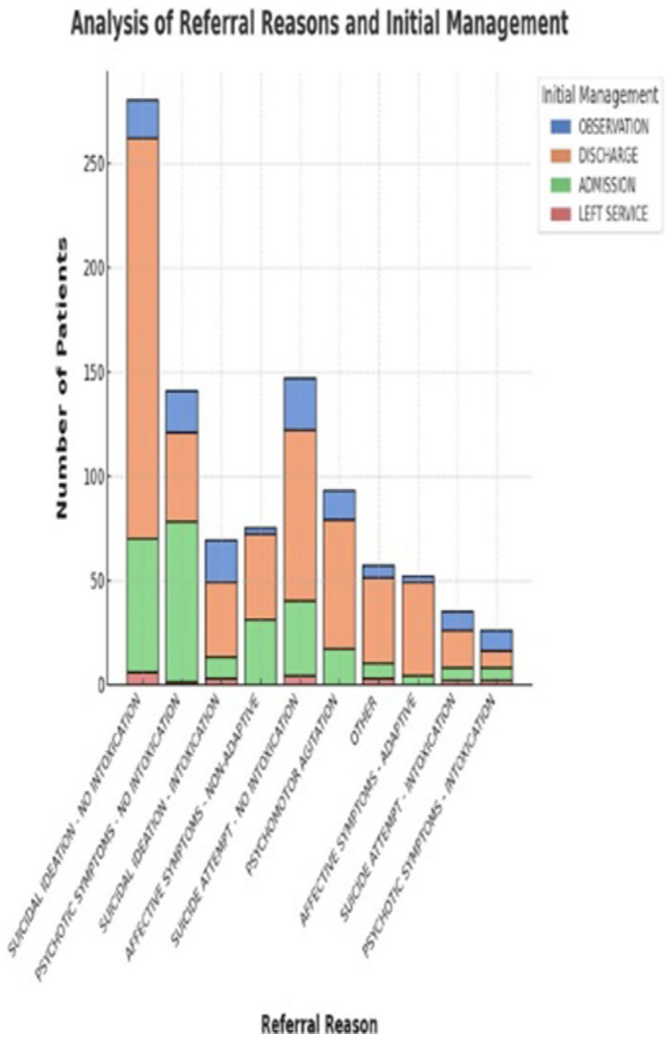

Image 2:

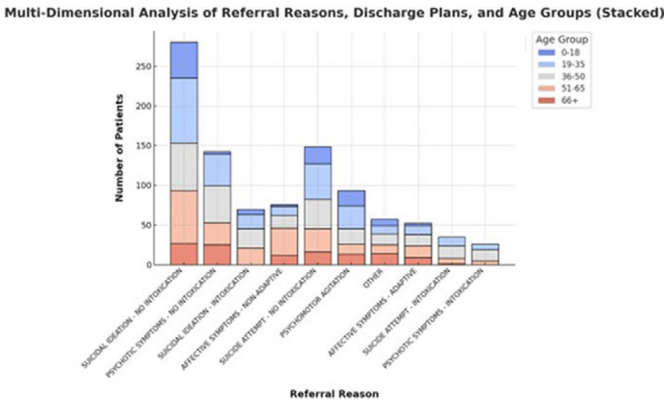

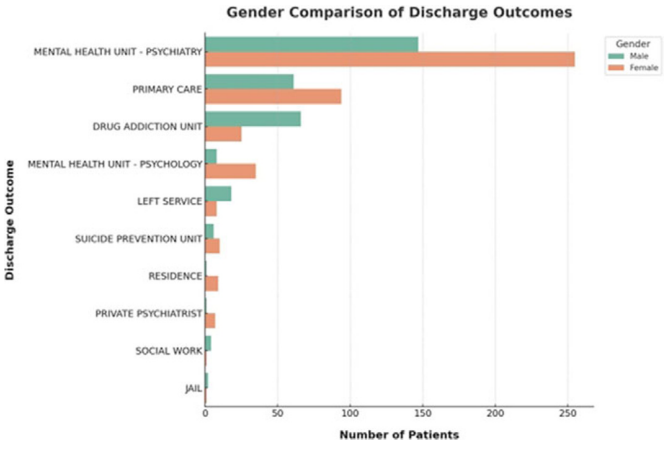

Image 3:

Conclusions: The main conclusions are:

(1) More than 55% of patients present voluntarily, which could be interpreted as a positive indicator of mental health awareness, although it may also indicate a lack of prior support to prevent these crises.
(2) Of the patients assessed, 64.3% are discharged and 22.1% are admitted, with a low rate of service abandonment (1.8%). 64.3% of the total number had prior follow-up, suggesting effective ongoing care.
(3) More than 56% of the attendances received are women. It is essential to investigate whether this gender difference is due to a greater predisposition to seek help or differences in the incidence of psychiatric disorders.
(4) Regarding the reason of consultation, there is a high prevalence of suicidal ideation without prior intoxication (22.1%), reflecting the importance of preventive strategies in mental health and early crisis intervention.

Midazolam as a Sedative in Agitated or Aggressive Patients Before Psychiatric Admission

V. Anagnostopoulou[1], P. Argitis[1], M. Demetriou[1]*, M. Peyioti[2] and Z. Chaviaras[1]

[1]Psychiatry Department, General Hospital of Corfu, Corfu and [2]University General Hospital of Alexandroupolis, Alexandroupolis, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1452

Introduction: Managing agitated or aggressive patients prior to psychiatric admission is a critical challenge in clinical practice. When verbal de-escalation fails, effective pharmacological interventions, including benzodiazepines and neuroleptics, are necessary, either orally or via injectable forms. In some cases, physical restraint is inevitable, which is challenging and distressing for both patients and staff members Midazolam, a short-acting benzodiazepine, is well-known for its rapid sedative effects and potential to minimize the need for physical restraint in such patients.
Objectives: To evaluate the efficacy of oral midazolam in providing rapid sedation in agitated patients, facilitating their pre-admission management to psychiatric units.
Methods: A review of clinical practices and relevant studies was conducted to assess the use of midazolam for sedation in patients displaying aggression or agitation prior their admission to a psychiatric unit. The evaluation focused on the drug's pharmacological profile, including its onset of action, duration, and impact on patient care and staff workflow.
Results: Oral midazolam, due to its rapid onset and short duration of action, effectively provides sedation in acutely agitated patients. Its use significantly reduces the need for physical restraints or other invasive interventions, improving patient comfort and making the admission process smoother for the healthcare staff.
Conclusions: Midazolam presents a promising pharmacological option for pre-admission sedation of agitated or aggressive patients in psychiatric settings. Its rapid sedative effect, combined with its short duration, enhances patient management and minimizes the need for physical restraints, ultimately helping both patients and staff. Further research is needed to standardize its use in psychiatric emergencies.
Keywords: Midazolam, sedation, agitation, psychiatric admission, aggression, pre-admission management.

Frequent Attenders in a Psychiatric Emergency Department: A Descriptive Analysis

R. Fernández-Fernández[1]*, L. Fontecha[1], C. Suárez[1] and C. del Álamo[1]

[1]Hospital Universitario Infanta Cristina, Parla, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1453

Introduction: Frequent attenders (FAs) are defined as patients who repeatedly visit emergency services, commonly characterized as those making ≥4 visits to the emergency department within a year (Pek et al. Ann Acad Med Singap 2022; 51:483-492). Their

identification is considered a potentially preventable misuse of resources (Pines et al. Acad Emerg Med 2011; 18).
Objectives: To identify and describe the frequent attenders of the Psychiatric Emergency Department at Hospital Universitario Infanta Cristina.
Methods: A descriptive analysis was carried out on all patients who made ≥4 visits to the emergency department at the hospital during 2023.
Results: We identified 28 frequent attenders (FAs) in our emergency department, 16 women and 11 men, who made a total of 162 visits to the emergency service. Of these, 23 patients were aged between 18 and 65 years, with a mean age of 32.87 years. The most common diagnosis was Personality Disorders, observed in 17 patients, followed by Depression in 16 patients. However, the patients with the highest number of visits on average were those diagnosed with Psychosis, recording an average of 8.30 visits per year, followed by those diagnosed with Personality Disorders, with an average of 7.76 visits per year. No patients with Bipolar Disorder were identified among the described FAs.
When analyzing temporal trends, the months with the highest number of visits from FAs were July, August, and September, with 22, 18, and 19 visits respectively. This pattern is mirrored among patients diagnosed with Psychosis, who made 30 visits during these months. In contrast, patients with Personality Disorders made 28 visits in these months, compared to 24 visits in April and 30 visits in January and February.
An additional noteworthy finding is that, out of the 162 visits made by FAs, only 20 resulted in hospital admission—14 women and 6 men. More than half of these admissions involved patients with neurotic spectrum disorders, specifically 7 cases of Personality Disorders and 6 cases of Depression
Finally, it is worth noting that of the 162 visits made by FAs, 47 were due to suicidal ideation or attempts, with 29 of these cases involving women.
Conclusions: The analysis of these patients suggests that individuals with severe mental disorders may be more affected during summer months, often requiring urgent evaluations, while those with neurotic spectrum disorders seem to be more influenced by seasonality, with a higher likelihood of requiring hospitalization. Additionally, there is a significant gender bias, with women tending to visit the emergency department more frequently, presenting with more severe conditions, and having a higher rate of hospital admissions. Accurate characterization of these patients can facilitate the prevention of potential decompensations by enhancing monitoring strategies based on the data presented.

EPV0777

Summary and review of data on psychiatric emergency care in 2023 in a hospital in the Community of Madrid

L. Fontecha[1]* and R. Fernández[1]

[1]Hospital Universitario Infanta Cristina, Parla, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1454

Introduction: The term '*psychiatric emergency*' refers to any situation in which certain psychopathological symptoms or behavioural disorders are perceived as disturbing, worrying or threatening by the patient, their family/social environment or other health/social actors, thus motivating the request for urgent care.
Objectives: The aim of this poster is to analyse the data on psychiatric emergency care in 2023 at the Infanta Cristina University Hospital in Parla.
Methods: The computer record of all psychiatric care carried out in the hospital's Emergency Department during 2023 has been reviewed.
Results: During 2023, a total of 1231 psychiatric emergencies were registered, of which 136 (11.05%) belonged to the child and adolescent population and 1095 (88.05%) to the adult population (i.e., over 18 years of age).
Of the 136 attendances in the child and adolescent population, 93 (68.38%) were of people identified as female and 43 (31.62%) as male.
Of the 1095 attendances in the adult population, 641 (58.54%) were of people identified as female and 444 (40.55%) as male.
In both the child and adolescent population and the adult population, the most frequent reason for consultation was "anxiety" (25% and 32.05%, respectively). However, it should be noted that, in both populations, two of the most frequent reasons for consultation were "autolytic ideation" (19.12% and 16.25%, respectively) and "autolytic attempt" (19.85% and 12.05%, respectively).
Conclusions: Women went to the psychiatric emergency department more frequently.
The percentage of children and adolescents who attended the psychiatric emergency department was high.
Although the most frequent reason for consultation was "anxiety", it is important to be able to reflect on the high figures of "autolytic ideation" and "autolytic attempt".

Multiculturalism, Integration, and Mental Well-being in the Context of Emergency Departments: a Comparative Analysis Across Three Hospitals in Northern Italy

E. Gambaro[1,2]*, M. Prelati[3], R. Valsesia[4], C. M. Gramaglia[1,2] and P. Zeppegno[1,2]

[1]SC Psichiatria, AOU Maggiore della Carità di Novara; [2]Medicina Traslazione, Università del Piemonte Orientale, Novara; [3]SPDC, Azienda Ospedaliero - Universitaria SS. Antonio e Biagio e Cesare Arrigo, Alessandria and [4]SPDC, Ospedale Santissima Trinità, Borgomanero, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1455

Introduction: A migrant is any person who moves or has moved across an international border regardless of the legal status of the person, whether the movement is voluntary or not, the reasons for the movement or the length of stay. In recent decades, migratory flows have increased significantly also in Italy. The migration process has highlighted the need to explore the potential challenges within the local multicultural context, as well as the difficulties that migrant patients with mental health issues may face. The assistance, diagnosis, and treatment of patients of foreign origin have become essential aspects of the pursuit of overall well-being within the community.

According to the literature, migration can represent a stress factor that leads to an increased risk of developing psychiatric symptoms or disorders. It should be emphasized that, although the organization of mental health services in Italy is strongly based on territorial outpatient services, the first contact of migrants with psychiatry occurs through the emergency room and the psychiatric wards of hospitals that usually admit patients with disorders in the acute phase.
It becomes necessary to learn more about this topic, given the limited or insufficient national and international studies on these issues.
Objectives: This study aims to investigate and describe the characteristics of migrants admitted to three Emergency and Acceptance Departments (DEA) in Northern Italy: Novara, Alessandria, and Borgomanero in comparison with natives, to investigate any differences between the two populations regarding the variables described above.
Methods: Through an electronic data acquisition research software solution (REDCap), the clinical and socio-demographic characteristics of migrants hospitalized at the three DEA will be collected. The data of migrants who received psychiatric consultation (PC) from January 2020 to December 2024 will be compared with those of natives. Data will include socio-demographic and clinical aspects, with a specific focus on mental health disorders (such as suicidal behaviours), type of intervention and outcome of the consultation. The only inclusion criterion used was the presence of PC after triage while no exclusion criteria were used except for age under 16.
Results: Ongoing analyzes will provide an in-depth description of the correlation between migrant status and the mental well-being of patients accessing the DEA who have received a PC. Particularly, the analyzes will allow us to outline the risk factors for psychiatric diagnosis and the choice of treatment strategies.
Conclusions: The data could suggest the need for prevention and intervention programs aimed at the migrant population, oriented towards cultural differences in the expression of discomfort, linguistic difficulties and/or mutual understanding between healthcare personnel and patients.

EPV0781

Neuropsychiatric symptoms in epileptic seizures. A case report

B. Lopez Abellan[1]*, P. Abril Bohórquez[1], N. Linero Rios[1], R. Justicia González[1] and N. Echeverría Hernández[1]

[1]Psiquiatría, Complejo Asistencial de Ávila, Ávila, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1456

Introduction: Epilepsy is the most common chronic neurological disease in the general population. The role of the psychiatrist in this pathology is to consider the epileptic diagnosis within the diagnostic possibilities, its psychosocial consequences and the psychological and cognitive effects of common antiepileptics. It has been reported that 30% to 50% of all individuals with epilepsy present, at some point in their lives, psychiatric difficulties.An epileptic seizure is a transient paroxysmal pathophysiological alteration of brain function caused by spontaneous excessive neuronal discharge. Symptoms will depend fundamentally on the cerebral origin of the seizure and the spread of activity in the brain. Finally, to better understand the clinical case that will be presented, it is important to differentiate between partial epileptic seizures, which involve epileptiform activity in localized brain regions, and generalized seizures, which affect the entire brain.
Objectives: The main objective of this work is to review the current scientific evidence on psychiatric symptons in epilepsy.
Methods: The case of a 75-year-old man with a neurological history and abrupt appearance of atypical psychiatric symptoms is presented. A detailed search was performed on UpToDate with the search terms “Epilepsy” and “psychiatric pathology.”
Results: This is a 75-year-old man with an organic history of repeated cerebral strokes and vascular epilepsy who attended the Emergency Department due to the onset of autolytic ideation abruptly and without a biographical trigger. After the express request by psychiatry for a neurological study, an EEG was performed, where epileptiform activity was observed in the frontal lobe and a diagnosis of right frontal focal status epilepticus secondary to a chronic cerebrovascular lesion was diagnosed. Preictal events in complex partial epilepsy include autonomic sensations (gastric repletion, flushing and changes in breathing), cognitive sensations (déjà vu, jamais vu, forced thoughts), affective states (fear, panic, depression, euphoria) and automatisms.
Conclusions: Status epilepticus constitutes one of the main neurological emergencies. Convulsive status epilepticus is a life-threatening situation that requires immediate pharmacological treatment and life support measures, as well as recognition and treatment of a possible triggering cause. It is a prolonged epileptic seizure or one that repeats itself in time intervals that are short enough so that the patient does not regain consciousness between episodes. Among the possible symptoms in epilepsy with a focus on the frontal lobe, atypical behavioral alterations are included that can go unnoticed and be referred to psychiatry.
In conclusion, this case shows the need for organic screening in those patients with atypical symptoms that do not fit into the major neuropsychiatric syndromes.

Evaluation of suicidal risk and severity in psychiatric emergency departments of different hospitals of the Autonomous Community of Madrid

A. Martínez Pillado[1]*, L. M. Navío García[2], C. BLANCO LONDOÑO[1], M. DON PEDRO MONTES[1], C. M. Rodríguez González[3] and R. ALVAREZ GARCIA[1]

[1]PSYCHIATRY DEPARTMENT, HOSPITAL REY JUAN CARLOS; [2]PSYCHIATRY DEPARTMENT, HOSPITAL FUNDACION JIMENEZ DIAZ and [3]MEDICINE, UNIVERSIDAD REY JUAN CARLOS, MADRID, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1457

Introduction: Suicide is a public health problem whose impact is increasing every year, causing more than 700,000 deaths per year globally (WHO). This includes Spain, where there is an upward trend with differences according to sociodemographic areas. The use of an appropriate suicide risk assessment scale could be a fundamental tool in psychiatric emergencies.
Objectives: The main objective: to analyze the differences in suicidal risk in different geographical areas of the CAM, using the C-SSRS in psychiatric emergencies for which patients from a capital area of Madrid (HUFJD) were compared with a peripheral area (HURJC).
Methods: Observational, analytical, cohort and multicenter study on a total of 4375 patients attended between July 2023 and January

2024 in the psychiatric emergency department of a hospital in the center of Madrid (Fundación Jiménez Díaz) and in a peripheral hospital (Hospital Rey Juan Carlos). Since the first date, these services have implemented the Columbia Scale to Assess Suicide Risk (C-SSRS) as an assessment tool in their clinical records.
Results: Of the patients, 34.95% were at high risk of suicide (moderate and high risk levels according to the C-SSRS), 8.2% were at low risk and 56.9% were not at suicidal risk. Statistically significant differences were found in high suicidal risk, being higher in the peripheral hospital (Hospital Rey Juan Carlos 40.2% vs Fundación Jiménez Díaz 30.8%; p<0.000). In addition, logistic regression shows a ratio: 1.32 times higher high suicidal risk in women, 3.26 times in patients who self-harm, 1.5 times in those without sociofamilial support and up to 1.99 times in those under 65 years of age.
Conclusions: This study confirms the importance of sociodemographic data in the incidence of increased suicide risk, among which the geographic area of residence stands out, with a difference of more than 10% in the risk of high suicide risk between the periphery (40.2% in HURJC) and the capital (30.8% in HUFJD) of the CAM, which could be related to the different socioeconomic levels in both areas.Other sociodemographic factors that increase suicidal risk are: age between 18 and 65 years (with higher incidence between 18 and 25 years), female sex, and lack of sociofamily support. In addition to these factors, self-injury and previous suicide attempts are important suicide risk factors.The availability of a tool such as the C-SSRS that can be administered to all patients attending psychiatric emergency departments seems a fundamental strategy to assess suicidal risk and severity. Its implementation in all hospitals would provide more objective data to develop lines of research, which is essential given the great impact that suicide has at a global level and its worrying trends that are continually on the rise.

EPV0783

A case report of delirium tremens in a patient with myasthenia gravis

V. Palinić[1]*, M. Krešić Ćorić[1] and N. Zovko[1]

[1]Psychiatry, University Clinical Hospital Mostar, Mostar, Bosnia and Herzegovina
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1458

Introduction: This report describes a case of delirium tremens in a 35-year-old male patient with myasthenia gravis and epilepsy. He first came to our clinic on 18th of August 2024. His complaints were of bad mood, nervousness and loss of will and appetite, he started to drink alcohol. He was advised to quit drinking and was prescribed quetiapine.
Objectives: On 20th of August he was hospitalised in our clinic as he presented with the withdrawal state. That, along with his initial blood tests, indicated a high probability of developing delirium tremens and presented us with the problem of treating this patient given his pre-existing condition.
The patient was started on saline with vitamins and glucose infusions. Low doses of quetiapine (25-50 mg) were given.
Current literature regarding MG and medications, puts diazepam in risk level 4, which means it rarely worsens MG, but symptoms must be monitored. Considering the high doses of diazepam usually required in states of delirium tremens and also not being able to predict how the strain of the delirious state will affect a patient with MG, we were cautious in administrating benzodiazepines.
Methods: A neurologist was consulted and they evaluated there was no need to transfer the patient or to adjust his medication. His chronic therapy was pyridostigmine 3x60 mg and valproic acid 2x600 mg. Blood tests showed a rise in CK level from11463 U/L to 12793 U/L in just a few hours. Myoglobin was at 630 ng/mL. Potassium levels were initially 2.9 mmol/L and were corrected to the value of 3.8 in the control test. An internal medicine specialist was called for but did not come that day. The patient was more agitated, began hallucinating, profusely sweating and trembling trough out the night. He was physically restrained.
The following day, blood test showed a further increase of CK (15578 U/L). His general state was progressively worsening, and we resorted to administering low doses of diazepam and haloperidol along quetiapine.
On Aug 22nd, test results were: urea 6.9 mmol/L, creatinin 112 umol/L, K 4.0 mmol/L, Na 149 mmol/L, Cl 111 mmol/L, CRP 91.3 mg/L, AST 381 U/L, ALT 211 U/L, LDH 653 U/L, CK 17747 U/L, CKMB 134 U/L, Mg 0.72 mmol/L, amonia 58.28 umol/L. The patient was transferred to an IC unit where he was treated for two days and during which time he was respiratory stable but in need of constant electrolyte and pH correction. His CK levels were as high as 43400 U/L and myoglobin 5542.8 ng/mL.
Results: On August 24th the patient was returned to our clinic to continue his treatment. He was hospitalised for 20 more days and released home in good health.
Conclusions: in emergency psychiatry there are sometimes cases which exceed our competences and practical possibilities to treat, but because they're psychiatric in origin, those patient are admitted in psychiatric hospitals. There is need for therapeutic guidelines for patients who develop delirium tremens and are burdened with comorbidities.

Self-induced Widespread emphysema in the first psychosis episode in a migrant worker: case report

A.-T. Rimmel[1]* and R. NEFZI[1]

[1]PSYCHIATRIE, RFSM, BULLE, Switzerland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1459

Introduction: In psychosis, self-mutilation reveals an intense alteration in body perception. This is even truer during the first psychotic episodes when one is overcome by delirium and hallucination. It often leads to physical disability particularly in ocular, genital, and limb regions.
Migrant have shown to present a higher risk of psychosis and schizophrenia. With the language barrier burden, self-mutilation may appear, as an attempt to remove from the body what cannot be verbally expressed.
Objectives: To describe the clinical presentation of an acute psychotic decompensation associated with unusual somatic symptoms (generalized emphysema), highlighting the importance of integrated psychiatric and somatic care.
To emphasize partial adherence to delusional ideas to distinguish intrapsychic thoughts from auditory hallucinations and refine the diagnosis.
Methods: Presented the case of a 25-year-old Eritrean male, living alone in Switzerland for 8 years who self-induced a widespread emphysema (Pneumomediastinum, orbital left pre- and post-

septal, intracanal extradural, pre- and retroperitoneal extending to the pelvis) by attempting to unblock his nose with his right little finger secondary to a Command hallucination in a first psychosis episode.

Results: The patient has not given news to his friends for 3 weeks. When visiting him they noticed that his apartment was unkempt and messy. The patient had a strange mystical speech and explained hearing a voice that tries to command him. He denied suicidal intent. Emergency exam revealed Subcutaneous emphysema and the A computed tomography body scan displayed a generalized soft tissue emphysema extending from the left temporal region, left pre- and post-septal orbital emphysema, throughout the neck spaces, intracanal extradural (cervical spine), dissecting

The mediastinum with scissural extension, probable emphysema component outside the parietal pleura (pneumothorax component is not excluded) extending preperitoneally and retroperitoneally to the level of the pelvic floor and extends along the iliac axes and into the left testicle. Also present, soft tissue emphysema in the left upper limb, up to the wrist. No pharyngolaryngeal, tracheal or esophageal perforation visible on CT. Otorhinolaryngology origin too small to be visualized.

The patient was hemodynamically *stable,* the laboratories were normal and no clinical evidence was found to consider an organic mental disorder. No drug history was found.

The mental status revealed mystical delusion with intrapsychic hallucination ordering him to evacuate the feeling of chest tightness he had felt with unblocking his nose. The diagnosis of schizophrenia spectrum disorder was retained.

Image:

Image 2:

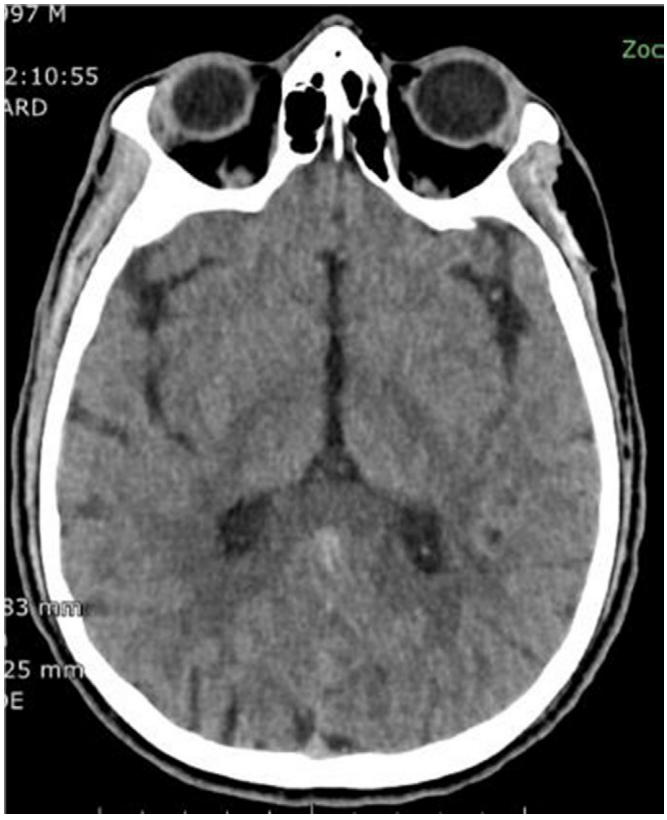

Image 3:

Conclusions: The case confirmed the importance of recognizing physical symptoms in a psychiatric context to avoid severe complications and the impact of multidisciplinary assessment.

Schizophrenic patient's preference for long-acting injectable antipsychotics in Saudi Arabia

K. A. Aljumah[1]*, N. Alzaidi[1], A. Almutairi[1], A. Duraihim[1] and I. Al-Zaagi[1]

[1]pharamcy, MOH, riyadh, Saudi Arabia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1460

Introduction: recognizing their potential impact on patients preferences towards antipsychotic treatment can guide the development of personalized and culturally sensitive treatment approaches. Gaining insight into patients' preferences regarding long-acting injectable versus oral antipsychotics has the potential to alleviate barriers to LAI utilization in schizophrenia treatment. Therefore, we aimed to identify whether patients with schizophrenia prefer LAI or oral antipsychotics in Saudi Arabia.
Objectives: Gaining insight into patients' preferences for long-acting injectable (LAI) antipsychotics could aid in mitigating potential barriers to the utilization of LAI in patients with schizophrenia
Methods: A cross-sectional descriptive study was conducted among schizophrenic patients in Saudi Arabia between June 2023 and October 2023. An analysis was conducted on the responses obtained from the Medication Preference Questionnaire.
Results: There was a subtle trend toward favouring oral antipsychotics over LAIs. Patients on oral antipsychotics commonly favoured the following outcomes: "I don't have to worry about taking medicines" (77%), "I can get back to my favourite activity" (71%), and "I feel symptoms will not come back" (65%). Most patients favoured gluteal injections over deltoid injections for the following reasons: easier use (90%), improved symptom relief (73%), lesser side effects (73%), and reduced pain (73%). Overall, 65% of patients favoured the dose once per month as opposed to three times per month (18%) or daily (17%). The common reasons cited by patients who favoured a 1-monthly dose were "less medication-related conflict" (97%) and "dislike to taking too much medication at once (93%)."
Conclusions: This study unveiled the presence of a subtle differentiation between LAI antipsychotics and oral antipsychotics in terms of their relative desirability, with a slight inclination toward an increased preference for oral medications. Patients with schizophrenia favoured the gluteal injection over the deltoid injection on account of its greater ease of use, efficacy in symptom relief, absence of adverse effects, and reduced discomfort. Furthermore, patients exhibited a greater inclination towards monthly LAI in comparison to 3-monthly LAI and oral pill antipsychotics.

EPV0789

Psychosocial risk factors among nurses at Sahloul University Hospital in Sousse (Tunisia)

J. Ben khelifa[1], N. Belhadj Chabbah[1,2,3], F. Chelly[1,2,3], I. Fki[1,2], C. Sridi[1,2,3]*, N. Ben ghadha[1] and S. ksibi[1]

[1]1- Department of Occupational Medicine, Sahloul University Hospital; [2]2- University of Sousse, Faculty of Medicine Ibn Al Jazzar and [3]3- Research laboratory LR 19SP03, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1461

Introduction: Nursing staff occupy a profession that requires significant mental, emotional, and affective demands. These caregivers are particularly vulnerable to psychosocial risks that can have significant impacts on their mental and physical health, as well as on the quality of care they provide.
Objectives: To describe the psychosocial risk factors at work among nurses at SAHLOUL university hospital.
Methods: This is a descriptive cross-sectional study conducted among the nursing staff of SAHLOUL university hospital. Data was collected using a self-administered questionnaire. Data analysis was performed using SPSS 26 program.
Results: A total of 95 nurses participated in the study. Almost all the nurses surveyed (95.8%) reported that their work constitutes a significant mental load. More than one-third of respondents (34.7%) frequently faced cases of death during their work. Most of the nurses surveyed (93.7%) felt demotivated regarding their work. Just over half of the nurses surveyed (51.6%) reported having been victims of a violent situation from a patient during their professional career. Regarding the results relative to the Karasek scale, we note that our population tends to utilize skills more than to be autonomous (35.56 vs. 34.36). Social support is generally low among our study population with an average score of 25.37±2.57.
Conclusions: There is psychosocial, and particularly professional, repercussions on the psychological state of healthcare personnel, which means that care workers' mental health needs to be addressed. Occupational health services must detect the suffering of care workers and improve the psychosocial environment.

Disclosure of Interest: None Declared

EPV0790

Burden assessment in caregivers of patients with schizophrenia

W. Bouali[1]*, W. mejai[1], R. ben soussia[1] and A. hadj mohamed[1]

[1]psychiatry, mahdia hospital, mahdia, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1462

Introduction: The role of caregiver of patients with schizophrenia is associated with an increased risk of adverse mental and physical health outcomes.
Objectives: assess the severity of the burden in caregivers of patients with schizophrenia as well as to determine the factors associated with a high burden with the overall goal of improving the quality of life of caregivers of patients with schizophrenia.
Methods: This is a descriptive mono-centric cross-sectional study with an analytical aim carried out during the period March-April

2022 on 80 caregivers of schizophrenia patients followed up at the psychiatric consultations of the University Hospital of Mahdia. The evaluation of the burden experienced by the caregiver was carried out using the "SCQ" Schizophrenia Caregiver Questionnaire Version 1.0.

Results: The average age of the caregivers was 57.1 years with 54% of them being male. 71% of the caregivers were married with 81% of them being educated and 19% being illiterate. 45% of the caregivers were still active with 58% of them having an average socioeconomic level. Parents represented 59% of caregivers, siblings 29% and spouses 14%. They lived with the patients in 96% of cases and took care of another family member in 37.5% of cases. 89% of the caregivers were taking care of the patients for a period of more than 5 years and in 77.5% of the cases, these caregivers requested specialized help. 75% of patients were completely dependent on the caregiver.

37.5% of caregivers had a severe level of burden. Four factors were found to be predictive of severe burden: low education level of the caregiver, low socioeconomic level of the caregiver, violent and aggressive behaviors of the patient, and degree of dependence of the patient ($p<0.05$).

Conclusions: Being a caregiver of a patient with schizophrenia is correlated with a great burden and deterioration of quality of life, hence the importance of assessing this burden, determining the initiating and aggravating factors as well as developing well-defined strategies for these caregivers in order to alleviate this burden and improve their quality of life.

Predictive Factors of Treatment-Resistant Schizophrenia

I. Bouamoud[1]*, N. barkallil[1], S. Belbachir[1] and A. Ouanass[1]

[1]University Psychiatric Hospital Arrazi, Salé, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1463

Introduction: Schizophrenia is a complex, chronic psychiatric disorder marked by disruptions in thought processes, perception, social interactions, and emotional regulation. Despite various therapeutic options, 20–34% of patients develop treatment-resistant schizophrenia (TRS)[1], a condition associated with a poor prognosis and significant challenges in clinical management. Early identification of predictive factors for treatment resistance may enable more targeted interventions, ultimately improving patient outcomes by allowing for tailored treatment approaches.

Objectives: This study aims to identify early predictive factors for the progression to TRS, differentiate modifiable from non-modifiable factors, and determine prognostic indicators for schizophrenia. The goal is to facilitate early intervention for high-risk cases and prevent TRS by targeting modifiable factors.

Methods: This is a descriptive and an analytical retrospective study including patients diagnosed with TRS according to NICE criteria, treated with Clozapine, and hospitalized at the Ar-Razi Psychiatric Hospital in Salé between 2022 and 2024. Included cases meet specific criteria, such as complete clinical records and the need for Clozapine treatment, with no age restrictions. Sociodemographic, clinical, evolutionary, and therapeutic data are collected using Excel and analyzed using SPSS 20 software.

Results: Among the 126 TRS cases included, several risk factors were identified. Non-modifiable factors include age, family history, and the presence of negative symptoms, while modifiable factors include the duration of untreated illness and certain comorbidities.

Conclusions: The results of this study provide valuable insights into risk factors associated with TRS and guide specific management and prevention strategies for this subgroup of schizophrenia patients.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1464

Introduction: The impact of migration on cardiovascular risk factors have been reported to be gender-specific. Obesity and cardiovascular disease are increased in those who migrate to Western countries.

Objectives: Our aim is to investigate changes in the dietary habits of women after migration, especially in schizophrenia women.

Methods: A systematic review was performed in PubMed, Scopus and PsycINFO databases from inception to October 2024 according to the PRISMA statement. Search terms: (diet OR food OR "dietary acculturation") AND migration AND women. Studies were included if they were focused on dietary changes after migration in women. In a second step, we conducted electronic searches to find additional papers on schizophrenia.

Results: A total of 2046 records were screened, of which 36 studies were included.

(1) Socio-clinical scenarios of migration: a)Latin-American (n=5), b)African (n=7), c)Asian (n=17), Europe (n=2). Results: Weight gain after migration to developed countries, reduced dietary diversity and limited access to culturally appropriate foods are common (poor traditional-food trajectories). Early stages of migration are critical. Model of dietary transition during pregnancy (3 stages) and risk of gestational diabetes.

(2) Transnational migration (rural-urban, n=5). Indian women had higher intakes of both fruit and vegetables and fat. Migration from rural-to-urban and urban-to-urban areas was associated with obesity risk. Exception: rural migrants to Mongolia's capital maintaining traditional lifestyles. Few studies focus on women with schizophrenia.

Conclusions: The dietary habits of migrant women may have implications for future chronic disease risk, particularly for those with schizophrenia. Early culturally sensitive weight-loss interventions for migrant women are recommended.
Key-words: Migration; Diet; Dietary acculturation; Schizophrenia; Women.

Exploring Societal Attitudes and Acceptance of Mental Illness in Albania: A Study on Stigma and Treatment Preferences

L. Demiraj[1]* and F. Elezi[1]

[1]"Mother Teresa" UHC, Tirana, Albania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1465

Introduction: Mental illness remains a significant issue globally, often accompanied by challenges related to stigma, stereotypes, and prejudice. In Albania, research exploring societal perceptions and the acceptance of mental illness and psychiatric treatment is limited. Understanding these views is crucial for improving mental health care and reducing stigma.
Objectives: The aim of this study was to evaluate the perception and prejudice toward mental illness in the Albanian population, with a focus on stigmatization, acceptance, and attitudes toward psychiatric treatment.
Methods: Data collection was carried out through a self-administered online questionnaire distributed to the general population in Albania. A total of 326 questionnaires were analyzed. The study population included individuals born and residing in Albania. The data was processed using the statistical program IMB SPSS v. 23.
Results: The sample showed a significant gender disparity, with a female-to-male ratio of 2.7:1. The majority of respondents were aged 21 to 40 years and had higher education. Religious individuals also showed high participation. While respondents acknowledged high levels of stigma in society, they expressed personal openness toward maintaining relationships with individuals with mental illness and integrating them into society. Despite this, there was a general lack of knowledge regarding mental illness, and confidence in the quality of mental health services in Albania was low. Psychiatrists were recommended for severe cases, though psychologists were preferred for treating depression. The most favored treatment approach was a combination of medication and psychotherapy.
Conclusions: The findings suggest that while there is an awareness of societal stigma toward mental illness in Albania, individuals personally express supportive attitudes toward integration and treatment. However, a gap in knowledge about mental illness and skepticism toward mental health services highlights the need for public education and improvements in the healthcare system. The preference for combined treatment reflects an evolving view on comprehensive care.

Risk and Protective Factors in Schizotypy, Mistrust and Anomalous Perceptual Experience: a Network Analysis

P. Do Lan[1,2]*, M. Schärer[2], M. Müller[1,3], V. Ajdacic-Gross[1,3], W. Rössler[3,4], B. Kleim[1,2] and A. Theodoridou[1,3,5]

[1]Psychiatry, Psychotherapy and Psychosomatics, Psychiatry University Hospital of Zurich; [2]Department Experimental Psychopathology and Psychotherapy, University of Zurich; [3]The Zurich Program for Sustainable Development of Mental Health Services (ZInEP), Psychiatry University Hospital of Zurich, Zurich, Switzerland; [4]Department of Psychiatry and Psychotherapy, Charité University Medicine, Berlin, Germany and [5]Faculty of Medicine, University of Zurich, Zurich, Switzerland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1466

Introduction: A resilience-based approach should be more integrated in order to get a greater understanding of the psychopathological patterns and derive prevention or intervention implications from this (Kalisch *et al. Nat Hum Behav* 2019; 1(11) 784-790). In subthreshold psychopathology, so far there is a growing body of research focusing on potential risk and protective factors while most of these studies are following an isolated focus on either of those factors. Or are using statistical methods that are not often considered the dynamic interplay of those variables (Pereira-Morales *et al.* J Ment Health 2019; 28(2) 153-160; Schäfer *et al.* Transl Psychiatry 2023; 13(1) 328). Scruitinizing the dynamic patterns enables the network approach. Mental disorders can be conceived as a complex network, involving a dynamic interplay between symptoms and protective factors (Boorsboom *et al.* Nat Rev Methods Primers 2021; 1:58*)*.
Objectives: This study investigates the role of risk and protective factors in relation to subthreshold psychosis like-experience symptoms (schizotypy, mistrust and anomalous perceptual experience) in a network structure.
Methods: This cross-sectional analysis of the prospective longitudinal ZInEP Epidemiology Survey included n = 632 participants (general population), aged 20-41 years. Dynamic relationships between potential risk factors (child hood trauma, maladaptive coping, self-stigma, perceived stress, chronic stress), potntial protective factors (adaptive coping, self-efficacy, optimism, self-confidence, self-control, spirituality) and psychopathology (schizotypy, mistrust, anomalous perceptual experience) are investigated using network analysis at baseline.
Results:

- negative association of schizotypy with optimism and self-control
- negative association between mistrust and self-control
- positive association of schizotypy with perceived and chronic stress, maladaptive coping and childhood trauma
- perceived stress highly negatively assiociated with optimism and self-efficacy
- maladaptive coping as a bridge from potential protective factors to perceived and chronic stress and schizotypy

Image 1:

Tab. 1: Clinical characteristics of the ZInEP sample

Variables	M *(SD)*
Psychopathology	
anomalous perceptual experiences	0.44 *(0.5)*
mistrust	2.01 *(0.7)*
Personality Traits	
schizotypy	6.01 *(4.3)*
Other factors	
adaptive coping	2.42 *(0.4)*
self-efficacy	3.73 *(0.6)*
self-confidence	3.35 *(0.6)*
optimism	3.70 *(0.7)*
self-control	3.14 *(0.7)*
spirituality	
maladaptive coping	1.79 *(0.4)*
self-stigma	3.67 *(0.4)*
child hood trauma	1.62 *(0.3)*
perceived stress	1.43 *(0.7)*
chronic stress	2.39 *(0.8)*

Image 2:

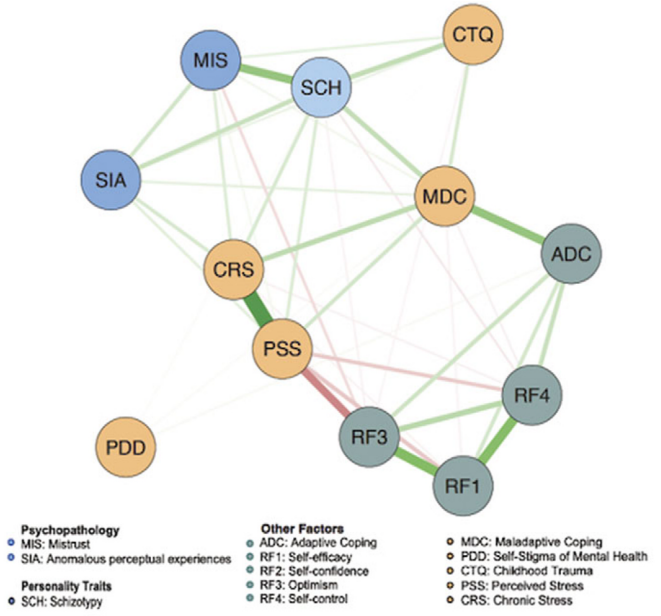

Fig. 1: **Network structure (*n* = 632).** Colors of edges: green lines indicate positive associations (red = negative) between two nodes. The wider and more saturated the edge (thickness), the stronger the association (partial correlation).

Conclusions:

- optimism and self-control as protective factors for schizotypy and mistrust
- perceived and chronic stress, maladaptive coping and child-hood trauma as risk factors associated with all psychopatho-logical symptoms
- protective factors might have more an indirect impact over risk factors on symptoms
- interventions for optimism and self-control might reduce stress

Healthcare workers and students in Bulgaria: Perspectives on Assisted Suicide

G. Dogancali Yanchev[1]*, P. G. Chumpalova-Tumbeva[1] and E. M. Dimitrova-Ilieva[1]

[1]First Psychiatry Clinic, UMHAT Dr Georgi Stranski, Pleven EAD, Pleven, Bulgaria
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1467

Introduction: This ongoing research investigates the attitudes of healthcare workers and students in Bulgaria toward assisted suicide, a practice that remains illegal and ethically debatable in the country.
Objectives: The purpose of the research is to better understand how Bulgarian healthcare workers and students deal with assisted suicide's ethical dilemmas and its potential impact on the country's ability to provide end-of-life care in the future.
Methods: Using mixed method approach including quantitative surveys, qualitative interviews, focused groups, this research seeks to capture wide range of opinions from healthcare professionals including medical doctors, nurses, laboratory assistants, midwifes, rehabilitators, medical students, nursing students, midwifing students etc.
Results: Initial findings suggests that majority of the respondents of the focused group are opposed to the legalization of the assisted suicide due to ethical concerns including adherence of the Hippocratic Oath, potential misuse, and the influence of religious beliefs. The focus group does, however, include a small but notable percentage of individuals especially younger healthcare professionals and students who recognize, value, and appreciate the significance of patient autonomy and the elevation of suffering as essential components of compassionate care.
Conclusions: This ongoing research into the views of healthcare workers and students in Bulgaria on assisted suicide uncovers a complex situation that is heavily influenced by ethical considerations and long-standing cultural and religious values. As the study progresses, it aims to dive deeper into how factors as age, duration of experience in medical field, specialty in medical field and social status contribute to these diverse views.

Cancer mortality and morbidity among patients with schizophrenia: A hospital-based cohort study, 1992-2020

M. Drevinskaite[1,2*], A. Kaceniene[2], R. Stukas[1], A. Germanavicius[3,4] and G. Smailyte[1,2]

[1]Department of Public Health, Institute of Health Sciences, Vilnius University, Faculty of Medicine; [2]Laboratory of Cancer Epidemiology, National Cancer Institute; [3]Clinic of Psychiatry, Institute of Clinical Medicine, Vilnius University, Faculty of Medicine and [4]Department of Psychiatry, Republican Vilnius Psychiatric Hospital, Vilnius, Lithuania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1468

Introduction: The inconsistency in cancer incidence and mortality rates in terms of cancer site reported among patients with schizophrenia has been an interesting topic in epidemiology, and additional studies are necessary to gain a more comprehensive understanding.
Objectives: Due to the inconsistency of the evidence about the cancer risk among patients with schizophrenia, the aim of this study was to analyse cancer mortality and morbidity in patients with schizophrenia treated in a single centre in Lithuania during the study period of 1992-2020.
Methods: A retrospective cohort study was conducted in Vilnius Republican Psychiatric Hospital, the biggest specialised psychiatric hospital in Lithuania, with approximately 5000 hospital admissions annually. The patients' cohort was established by identifying all patients with the diagnosis of schizophrenia (ICD-10 code F20) in the hospital database from 1 January 1992 until 31 December 2017. The cancer cases and cancer deaths in the cohort were identified in the Lithuanian Cancer Register through linkage procedures. The analysis of risk was based on a comparison of observed and expected numbers of cancers and deaths. Expected number of cancer cases were calculated by multiplication of the exact person-years under observation in the cohort by sex, calendar year and a 5-year age-group-specific national incidence and mortality rate. All statistical analyses were carried out using STATA 15 statistical software.
Results: During the follow-up, out of 8553 patients, 673 cases of cancer were diagnosed in both sexes. Statistically significantly lower risk for overall cancer incidence was observed in men (SIR 0.74, 95% CI 0.66-0.83), but not in women (SIR 1.07, 95% CI 0.97-1.18). We observed lower risk for pancreatic cancer (SIR 0.36, 95% CI 0.14-0.96), non-melanoma skin cancer (SIR 0.54, 95% CI 0.33-0.88) and prostate cancer (SIR 0.69, 95% CI 0.55-0.87) in men and higher risk for malignant neoplasm of liver (SIR 2.58, 95% CI 1.53-4.36) and skin melanoma (SIR 2.03, 95% CI 1.12-3.66) in men and for breast cancer (SIR 1.38, 95% CI 1.14-1.66) and corpus uteri cancer (SIR 1.56, 95% CI 1.18-2.07) in women (Table 1). Statistically significant lower overall cancer mortality risk was observed in men (SMR 0.82, 95% CI 0.70-0.96), while in the women's group, risk of cancer deaths was significantly higher compared to the general population (SMR 1.28, 95% CI 1.11-1.48).
Conclusions: The current results of our study indicate lower risk of overall cancer incidence and mortality in male patients with schizophrenia, while female patients had a higher mortality risk, alongside variations in the risk of different cancer types. This information is important not only for patients, but for healthcare specialists to develop effective disease-specific preventive interventions and programmes.

The global burden of teacher burnout: Evaluating the roles of workload and social support in diverse educational contexts

A. El Alaiki[1*], F. Hadrya[2], Z. Boumaaize[1], H. Guider[1], M. A. Lafraxo[3], A. Soulaymani[1], A. Mokhtari[1] and H. Hami[1]

[1]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra; [2]University Hassan First of Settat, Higher Institute of Health Sciences, Health Sciences and Technologies Laboratory, Settat and [3]Higher Institute of Nursing Professions and Health Techniques, Oujda, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1469

Introduction: Teacher burnout is a pervasive challenge across the global educational sector, profoundly impacting educator well-being and the overall quality of education. A robust body of research highlights the link between organizational factors and burnout, underscoring the urgent need for an in-depth understanding of these dynamics across different cultural contexts.
Objectives: This systematic review aims to delineate how workload and social support dynamically influence teacher burnout. Through a detailed examination of the complex interrelationships among these factors, we endeavor to elucidate the underlying mechanisms by which they influence teachers' emotional and psychological health, thereby providing critical insights into potential evidence-based interventions.
Methods: We synthesized findings from a total of 40 relevant studies (35 cross-sectional and five longitudinal studies), adhering to the 2020 PRISMA guidelines. We utilized the Newcastle-Ottawa Scale for quality assessment due to its rigorous criteria, examining the impact of workload and social support on teachers' stress levels across diverse educational settings.
Results: High workload and insufficient social support were identified in 75% of the studies as significant predictors of emotional exhaustion among teachers globally. Excessive workloads were correlated with increased burnout levels, which negatively affected their mental health and job satisfaction. Conversely, strong social support networks, including collegial relationships and administrative support, were found to effectively mitigate burnout, bolstering teachers' resilience and overall well-being. Furthermore, the review underlined that the quality of the evidence was moderate, highlighting the need for further, more robust research.
Conclusions: This review confirms the complex interactions within organizational dynamics that contribute to teacher burnout. It underscores the critical need for tailored interventions, such as professional development in stress management and policies that foster supportive work environments. By strategically addressing workload challenges and enhancing social support, stakeholders can significantly improve teacher well-being and reduce burnout risks globally.

Psychological burdens and resilience among Moroccan trainee teachers during the COVID-19 lockdown: A study of challenges and coping strategies

Z. Boumaaize[1], A. Bouhaba[1], H. Guider[1], M. A. Lafraxo[2], A. EL Alaiki[1]*, Y. El Madhi[3] and H. Hami[1]

[1]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra; [2]Higher Institute of Nursing Professions and Health Techniques, Oujda and [3]Regional Center for Education and Training Professions, Rabat, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1470

Introduction: The onset of the COVID-19 pandemic necessitated the declaration of a global emergency. The pervasive fear of contagion has transformed daily life practices, and lockdown measures globally implemented to mitigate virus transmission have led to a spectrum of adverse psychological effects, including anxiety, sadness, frustration, disorientation, and potential for post-traumatic stress disorder, significantly affecting mental health.
Objectives: This study aims to evaluate the psychological effects of the COVID-19 pandemic on the well-being of trainee teachers.
Methods: A descriptive analysis was conducted on a cohort of 370 Moroccan trainee teachers, with a mean age of 28.30 ± 5.99 years. Data were collected using a self-administered questionnaire designed to assess the presence and extent of psychological distress, along with sociodemographic and professional characteristics, during the lockdown.
Results: The findings revealed that 65.1% of the confined trainees experienced obsessive tendencies, and 40% reported that their daily activities were restricted, affecting their normal life pursuits. Furthermore, 68.3% expressed moderate to high stress levels due to various factors, such as financial and professional concerns, potential loss of family members, or personal hospitalization. Half of the trainees expressed concern for their future prospects and feelings of ennui during these unprecedented times.
Conclusions: The findings reveal the enduring psychological impacts of the COVID-19 pandemic on trainee teachers, with significant stress and psychological disorders noted. This emphasizes the critical need for targeted mental health support and proactive resilience-building within educational systems, not only aiding recovery but also preparing educators for future pandemics.

Beyond exhaustion: A multidimensional assessment of occupational stress and burnout among high school teachers

H. Guider[1], F. Hadrya[2], Z. Boumaaize[1], M. A. Lafraxo[3], A. El Alaiki[1]*, Y. El Madhi[4], A. Soulaymani[1], A. Mokhtari[1] and H. Hami[1]

[1]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra; [2]University Hassan First of Settat, Higher Institute of Health Sciences, Health Sciences and Technologies Laboratory, Settat; [3]Higher Institute of Nursing Professions and Health Techniques, Oujda and [4]Regional Center for Education and Training Professions, Rabat, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1471

Introduction: In the rapidly evolving landscape of contemporary education, high school teachers are increasingly confronting significant professional stress that critically undermines their mental health and overall well-being. This pervasive issue not only affects teachers but also has broader implications for the effectiveness and sustainability of educational systems.
Objectives: This study aims to elucidate the complex dynamics of occupational stress, psychosocial workplace factors, and burnout among high school teachers in Tetouan, Morocco.
Methods: A cross-sectional survey was conducted among 258 high school teachers. The study utilized the Maslach Burnout Inventory (MBI) to assess burnout levels, the Job Content Questionnaire (JCQ) to evaluate psychosocial factors, and the Perceived Stress Scale (PSS-10) to measure perceived stress levels.
Results: The MBI indicated that 43% of teachers experienced high emotional exhaustion, 46% reported low depersonalization, and 47% indicated low levels of personal accomplishment. On the JCQ, 55% of teachers faced high psychological demands, 57% had limited decision latitude, and 44% received insufficient social support at their workplace. There was a significant correlation between MBI emotional exhaustion and JCQ psychological demand scores ($r = 0.381$, $p < 0.01$), indicating a complex interplay between burnout dimensions and psychosocial factors in the workplace. Furthermore, the PSS-10 results exhibited a median stress score of 27, indicating a significant **variability in** stress perceptions among the participants.
Conclusions: This study underscores the critical need to address burnout, psychosocial workplace factors, and perceived stress among high school teachers. The prevalent emotional exhaustion, substantial psychological demands, and varied perceived stress levels revealed by this study necessitate integrated strategies that address these complex interactions to foster a more supportive and healthy professional environment. Further research should focus on operationalizing these insights into concrete, actionable policies that enhance educational professionals' well-being and productivity.

Effect of attachment styles on general psychological well-being and resilience as a mediating factor

M. A. Elgendy[1], M. Hany[1], N. Wafa[1], M. Hesham[1], A. Elsayed[1]* and D. N. K. Boulos[1]

[1]Newgiza University, Cairo, Egypt
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1472

Introduction: Attachment styles, developed through early life interactions, influence how individuals perceive relationships and manage stress. Medical students often exhibit insecure attachment styles, which are linked to increased psychological distress.
Objectives: The primary aim of this study is to explore the extent to which resilience influences the connection between attachment styles and general psychological well-being among medical students.
Methods: This cross-sectional study was conducted at New Giza University in Cairo, Egypt, and involved 437 medical students. Participants completed self-report surveys measuring attachment styles, resilience, and psychological distress. The survey instruments included the Relationship Questionnaire (RQ) for attachment styles, the General Health Questionnaire (GHQ-12) for psychological

distress (where a lower GHQ-12 score indicates less psychological distress), and the Connor–Davidson Resilience Scale (CD-RISC-10) for resilience. Participants were grouped into four attachment styles: secure (SA), fearful avoidant (FA), anxious preoccupied (AP), and dismissive avoidant (DA).

Results: The sample's mean age was 20.32 years (SD = 2.09). Females comprised 69.6% of the cohort, and single students made up 80.1% of the whole cohort. The distribution of attachment styles across females and males differed significantly ($p < 0.0001$, $\chi^2 = 25.7$), with DA being more prevalent in males compared to females (28.6% and 13.2%, respectively). GHQ-12 median scores were similar between genders ($p = 0.23$), while CD-RISC-10 scores differed ($p = 0.002$), with males having a higher median (28).

Median scores of GHQ-12 and CD-RISC-10 differed significantly across groups of attachment styles ($p < 0.0001$ and $p = 0.0002$, respectively). AP and FA had the highest GHQ-12 medians (15), while AP had the lowest CD-RISC-10 median (25).

A negative correlation between CD-RISC-10 and GHQ-12 scores was significant in the whole cohort ($p < 0.0001$, $r = -0.3227$), with FA showing the strongest correlation ($p < 0.0001$, $r = -0.3292$, CI: -0.4714 to -0.1704) and other groups showing similar reuslts (figures 1, 2 and 3).

Image:

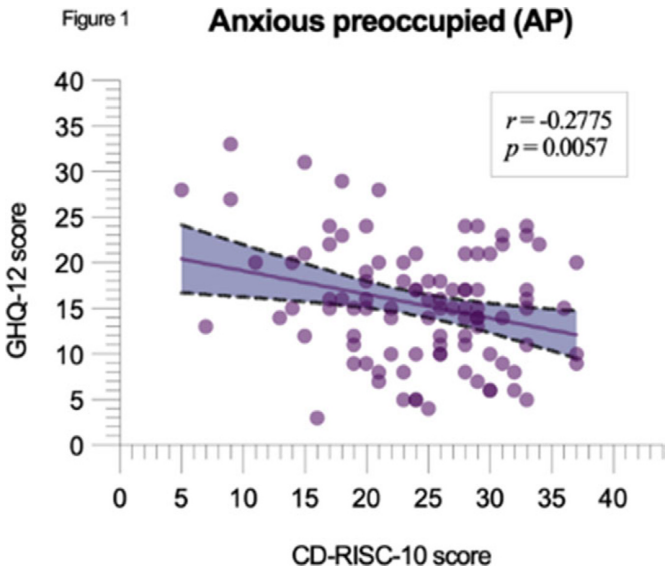

Image 2:

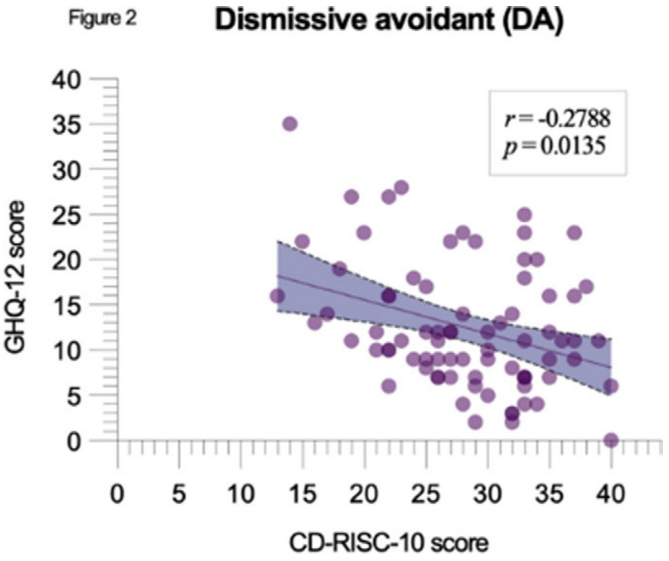

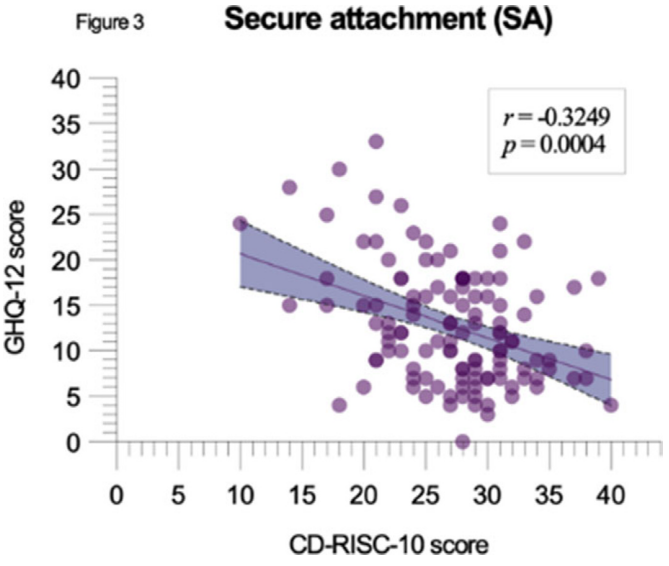

Image 3:

Conclusions: The findings underscore the critical role of resilience in buffering against the psychological impacts of insecure attachment among medical students. Approaches targeting resilience enhancement could serve as a valuable intervention target to mitigate psychological distress and improve well-being in this high-risk attachment styles. Future research is recommended to develop and test resilience-focused interventions tailored to medical students with insecure attachment styles, which may help reduce burnout and promote mental health in medical training environments.

Study of post-partum mental disorders: case of the Hospital of Mental Health and Psychiatric Diseases of the Chu Mohammed-VI of Oujda

S. Essadki[1]*, R. Hammouch[1], A. Berka[2], Y. El Aissaoui[2] and R. Boughoufa[3]

[1]Higher Institute of Nursing professions and Health Techniques; [2]THE HOSPITAL OF MENTAL HEALTH AND PSYCHIATRIC DISEASES OF THE CHU MOHHAMED-VI, Oujda and [3]Laboratory of Life and Health Sciences, Faculty of Medicine of Tangier, Tangier, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1473

Introduction: The birth of a child is a joyous event that can be accompanied by major challenges for women's mental health. It is marked by physical, hormonal, psychological, family and social upheavals. It can also be associated with an increased risk of incidence or decompensation of psychiatric disorders.
Objectives: The aim of this study is to describe the trends and characteristics of post-partum mental disorders in the Orientale region of Morocco.
Methods: 36 files of patients hospitalised or having consulted for a post-partum psychological disorder at the Mental Health and Psychiatric Diseases Hospital of the Mohammed-VI University Hospital Centre in Oujda were examined using a data collection form.
Results: The main disorders identified were post-partum depression and puerperal psychosis, with rates of 62% and 38%, respectively. 32% of them have attempted suicide, 14% have suicidal thoughts, 32% have committed infanticide, and 21% have rejected their baby. With regard to pregnancy and childbirth, a third of the women had a caesarean section, with primiparous women predominating. 57% of the women described their childbirth experience as long and painful. Similarly, the use of addictive substances was mentioned in 44% of cases.
Conclusions: It is true to say that measures need to be put in place to improve conditions for women and to raise awareness among those around them of the need for early detection of these disorders. These proposals underline the importance of taking concrete steps to support the women concerned and promote their mental well-being.

Anxiety, Depression and Quality of Life among youth in Kosovo

N. Fanaj[1,2]*, S. Mustafa[2,3] and E. Krasniqi[2,4]

[1]Alma Mater Europae Campus College Rezonanca, Prishtina; [2]PMSH, Prizren; [3]AAB College and [4]UBT College, Prishtina, Kosovo
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1474

Introduction: The literature review on anxiety/depression rates and quality of life (QoL) in youth in Kosovo are scarce. Studies on anxiety and depressive symptoms in Kosovo mostly, have revealed high prevalence rates pre and during COVID-19.
Objectives: This study aimed to explore the relationship between anxiety, depression, and quality of life in Kosovo youth. The significance of this study lies in the fact that these variables are being examined together for the first time in Kosovo after COVID-19.
Methods: Its cross-sectional study. The sample consisted of 563 students aged 18 to 25 (Mage=20.88; SD=1.52). Participants recruited online in the period of May 2023, and completed the Albanian version of GAD-7, PHQ-9 and GQOL (Global Quality of Life Scale). Data processing was done with SPSS 27.0 and Microsoft Excel 2019.
Results: The prevalence of anxiety (measured with GAD-7, ≥10) was 42.6 % while the prevalence of depression (measured with PHQ-9, ≥10) was 45.5%. Significant negative correlations were observed between anxiety and QoL ($r = -.335$, $p < 0.00$) and between depression and QoL ($r = -.326$, $p < 0.00$). A partial correlation indicated that anxiety and depression had very much influence in controlling for the relationship with QoL reciprocally; for anxiety ($r = -.133$, $p < 0.02$) and for depression ($r = -.109$, $p < 0.13$). Females and low SES emerged (but not employment status) as factors associated with higher levels of anxiety/depression and low Quality of Life.
Conclusions: Our anxiety/depression prevalence rates are mostly above those found in Kosovar youth both before and during COVID-19, and also in comparison to other European countries. Anxiety and depression, both separately and especially when co-occurring, significantly affect the quality of life of young people. Despite the fact that prevalence rates can vary depending on the specific methodology, sample size, and population demographics of each study, these findings should be taken seriously and addressed by mental health authorities in Kosovo through preventive and treatment programs. Additionally, further studies with sound scientific quality are necessary.

Unwanted Loneliness and Mental Health: Current State of Knowledge

R. Fernández-Fernández[1]*, Á. Izquierdo de la Puente[2], P. del Sol Calderón[2], M. Vizcaíno da Silva[3], M. Sánchez-Duque[1] and D. Gómez-Olmeda[1]

[1]Hospital Universitario Infanta Cristina, Parla; [2]Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda and [3]Centro de Salud San Carlos, San Lorenzo de El Escorial, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1475

Introduction: Loneliness and social isolation are frequently associated with mental health problems. In Spain, the term 'unwanted loneliness' has gained particular importance in recent years, referring to an involuntary insufficiency in social relationships. According to recent studies, this affects an estimated 13.4% of the Spanish population (Jiménez Rodríguez. Rev Esp Salud Publica 2024; 98).
Objectives: To conduct a review of the studies that address loneliness and social isolation
Methods: We searched in PubMed using the following terms: '((unwanted loneliness[Title/Abstract]) OR (loneliness[Title/Abstract]) OR (social isolation[Title/Abstract])) AND (mental health[Title/Abstract])', limiting the search to the last 30 years.
Results: We found 5,472 articles on the subject, of which 4,373 were published in recent years, confirming the growing interest in this issue. The countries with the most publications on this topic were

England (1,733 results), the United States (1,561 results), and Switzerland (894 results). Although we did not focus on this aspect, it is worth noting that the most frequently used keyword was 'COVID-19,' appearing a total of 1,229 times, which may partially explain the increase in publications over the last year.
Upon reviewing the content of the articles, we observed that many focus on demographic factors. For example, living with a romantic or sexual partner has been consistently identified as a protective factor against loneliness (Currin et al. Curr Psychol 2022; Online publication), and we also found significant associations between loneliness and being single, separated, or divorced (Ibáñez-Del Valle et al. Int J Environ Res Public Health 2022; 19:16622).
The association of this issue with social inequalities has also been highlighted (Martín Roncero et al. Gac Sanit 2021; 35:432-437). We observed a potential gender bias, with findings indicating a higher risk in women for the perception of loneliness and the evaluation of social relationships (Pavlidis et al. Aging Ment Health 2023; 27:1313-1321). Other studies have found that higher population density reduces social isolation in areas with a high proportion of people of the same race or ethnicity but increases it in areas with fewer people of the same ethnicity (You et al. Inquiry 2024; 61:469580241273127). Sexual orientation-related factors also appear to be significant: internalized homonegativity has been associated with loneliness, where it is noted that accepting and integrating a gay or lesbian identity seems particularly important for younger, non-gay-identified individuals (Berg et al. J Gay Lesbian Ment Health 2015; 19:285-302).
Conclusions: Unwanted loneliness is a complex and highly significant phenomenon, with a demonstrated association with poorer overall and mental health (Martín Roncero et al. Gac Sanit 2021; 35:432-437). This issue should be studied not only from the lens of mental health but also from a sociological perspective.

Childhood sexual abuse and dissociation: Testing the betrayal trauma theory in two Chinese samples

C. H. O. Huang[1], A. K. C. Chau[2], C. T. Y. Cheung[3], W. T. Chien[4], S. K. K. Lam[4], J. Y.-H. Wong[5] and H. W. Fung[6]*

[1]Department of Social Work and Social Administration; [2]Department of Psychiatry, the University of Hong Kong, Pokfulam; [3]Department of Social Work, Hong Kong Baptist University, Kowloon; [4]The Nethersole School of Nursing, The Chinese University of Hong Kong, Shatin; [5]School of Nursing and Health Sciences, Hong Kong Metropolitan University and [6]School of Nursing, The Hong Kong Polytechnic University, Kowloon, Hong Kong
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1476

Introduction: Childhood sexual abuse (CSA) is a major public health concern and is closely associated with dissociative symptoms. According to the betrayal trauma theory, dissociation can be interpreted as a response towards betrayal trauma (i.e., trauma perpetrated by a close person, such as a family member). No previous study has validated this theory with a focus on CSA in the Chinese context.
Objectives: We hypothesized that people with betrayal CSA, but not non-betrayal CSA, would report significantly more dissociative symptoms than people without CSA. We also hypothesized that betrayal CSA, but not non-betrayal CSA, would be significantly associated with the severity of dissociative symptoms. We tested the hypotheses in two independent Chinese-speaking samples.
Methods: Sample 1 (N = 91) consisted of participants seeking treatment in an evaluation study; while Sample 2 (N = 376) included community health service users in a survey study. In both Chinese-speaking samples, participants completed the two CSA items on the Brief Betrayal Trauma Survey and the 16-item Dissociative Features Section of the Self-report Dissociative Disorders Interview Schedule (SR-DDIS). ANOVA and regression analyses were used to test our hypotheses.
Results: Across both samples, participants with betrayal CSA reported significantly more dissociative symptoms than those without any CSA (Sample 1: M = 5.60, SD = 3.14 vs M = 3.67, SD = 3.06; F = 3.301, p = .041, Sample 2: M = 2.06, SD = 2.49 vs M = 0.93, SD = 1.32; F = 8.428, p < .001). As hypothesized, no significant differences in dissociative symptoms were observed between participants with and without non-betrayal CSA (Sample 1: M = 4.00, SD = 3.71 vs M = 3.67, SD = 3.06; Sample 2: M = 1.14, SD = 1.83 vs M = .93, SD = 1.32). Across both samples,, betrayal CSA, but not non-betrayal CSA, was significantly associated with dissociative symptoms (Sample 1: β = .250, p = .024, Sample 2: β = .189, p < .001), after controlling for age and gender.
Conclusions: This study provides cross-cultural evidence for the betrayal trauma theory. We suggest that proactive family-centered child protection is needed to prevent CSA, and screening for dissociative symptoms is also necessary in CSA survivors.

Long-Term Sick Leave for Psychiatric Disorders Among Healthcare Workers

M. makhloufi[1,2], M. Bouhoula[1,3], N. Gannoun[1,3], A. Ghenim[1,3], B. Narjes[3,4], A. Chouchene[1,3]*, A. Aloui[1,3], I. Kacem[1,3], M. Maoua[1,3], H. Kalboussi[1,3], O. El Maalel[1,3], A. Brahem[1,3] and S. Chatti[1,3]

[1]Occupational Medicine Department, Farhat Hached University Hospital; [2]Department of Occupational Medicine and Occupational Pathology; [3]Department of Occupational Medicine and Occupational Pathology, Faculty of Medicine of Sousse and [4]Occupational Medicine Department, Sahloul University Hospital, sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1477

Introduction: Absenteeism is a significant issue affecting various professional sectors, and its increase within healthcare institutions is a major concern. This phenomenon is complex and multidimensional, involving numerous factors.
Objectives: To determine the rate of absenteeism among healthcare personnel, describe the socioprofessional characteristics of employees on long-term sick leave due to psychiatric disorders, and identify the main factors associated with this absenteeism.
Methods: This is a retrospective descriptive study conducted on all healthcare personnel in a Tunisian governorate who took long-term sick leave for psychiatric reasons between 2015 and 2020. Data were collected from medical and administrative records through the Regional Long-Term Sick Leave Commission and via a questionnaire conducted by phone
Results: Among the 5067 employees in healthcare facilities in the governorate, 388 (7.65%) had taken at least one period of sick leave

due to psychiatric issues. The average age of absent personnel was 45 ± 9 years, with a range of 30 to 65 years. A significant majority of the absentees were female, accounting for 85.8%. Additionally, 78.8% of the absent employees were married. University hospitals (UHs) accounted for 75.6% of absenteeism cases, with nurses being the most affected professional group (40.5%). The duration of sick leave ranged from 1 to 60 months, with an average of 8.5 months. Depression was the most frequent psychiatric cause, accounting for 82.34% of cases. The analysis showed that depression was significantly associated with several factors, notably age (p=0.021), job position (p=0.049), and employment in UHs (p=0.027).
Conclusions: The results indicate high levels of absenteeism, emphasizing the urgent need for a comprehensive intervention plan. This plan should prioritize preventive measures, targeting both individuals and workplace organization.

Chronic and Transient Loneliness in Spanish Adults: Prevalence, Risk Factors, and Their Impact on Depression, Anxiety, and Substance Use Disorders

Í. Gete-Alejandro[1]* and J. Domènech-Abella[1]

[1]Recerca, Parc Sanitari Sant Joan de Déu, Sant Boi de Llobregat, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1478

Introduction: Chronic and transient loneliness are two clinically distinct conditions that have different impacts on mental health. However, there is limited information regarding the prevalence of chronic and transient loneliness, and their associated risk factors.
Objectives: This study aims to (1) assess the prevalence of chronic and transient loneliness among Spanish adults, (2) identify and compare the risk factors associated with both forms of loneliness, (3) examine how perceptions of loneliness contribute to its persistence, and (4) evaluate the effects of chronic versus transient loneliness on depression, anxiety, and substance use disorders.
Methods: A total of 1,503 Spanish adults were interviewed by phone from May to June 2024. Loneliness was measured with a direct question, and the three-item loneliness scale from the University of California, Los Angeles, was used for the sensitivity analyses. Chronic loneliness was defined as reported loneliness both two years ago and currently, while transient loneliness was defined as reported loneliness only two years ago. The CAGE Adapted to Include Drugs (CAGE-AID) questionnaire was used to assess substance use disorder within the previous month, anxiety symptoms were measured using the GAD-2, and depressive symptoms were assessed using the PHQ-2. Logistic regression models were constructed to examine sociodemographic and behavioral risk factors for chronic and transient loneliness, as well as the impact of loneliness perceptions on the likelihood of chronicity and the association of both types of loneliness with mental disorders.
Results: 11.4% of the sample reported chronic loneliness, while 9.5% reported transient loneliness. Risk factors associated with chronic loneliness included being a younger adult, female, living alone or with roommates, having low education level, and poor health status. In contrast, the risk factors for transient loneliness included being single or separated and frequent use of social media. Poor social support was a risk factor for both types of loneliness, though it had a significantly stronger impact on chronic loneliness (OR = 10.1, 95% CI: 5.5–18.4) compared to transient loneliness (OR = 2.2, 95% CI: 1.2–3.8). Feelings of emptiness (OR = 2.7, 95% CI: 1.4–5.4) and perceiving loneliness as insurmountable (OR = 2.6, 95% CI: 1.4–4.6) were risk factors for chronicity among individuals feeling loneliness. Sensitivity analyses showed similar results to the main findings. Only chronic loneliness was longitudinally associated with higher odds of depression (OR = 5.0, 95% CI: 3.4–7.4), anxiety (OR = 3.1, 95% CI: 1.3–4.1), and substance use disorder (OR = 3.6, 95% CI: 1.9–6.6).
Conclusions: Chronic loneliness can be identified through its risk factors and the perceptions of those experiencing it, highlighting the importance of addressing these issues to improve mental health outcomes.

Gender identity and symptoms of anxiety and depression and their relationship with sleep disorders among Polish adolescents during the Covid-19 pandemic and the outbreak of war in the Ukraine

K. Badura-Brzoza[1], P. Główczyński[1]*, D. Tatar[1] and P. Dębski[1]

[1]Clinical Department of Psychiatry, Faculty of Medical Sciences, Medical University of Silesia, Tarnowskie Góry, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1479

Introduction: For most people, gender identity is consistent with biological sex and such people are called cisgender. People in whom such a relationship does not occur or occurs to a lesser extent are referred to as gender non-conforming - and these include transgender, non-binary, agender and gender-fluid people. These groups are usually affected by minority stress, which, combined with the circumstances of the pandemic and war, may have led to mental disorders and sleep disorders in this population.
Objectives: The aim of the study was to analyze the symptoms of anxiety, depression and insomnia in a group of Polish youth during the COVID-19 pandemic and the outbreak of the war in Ukraine, taking into consideration gender differences.
Methods: The study involved 1621 secondary school students aged 14 to 19, the average age was 16.73±1.35, including 857 girls, 690 boys and 74 people who defined their gender as non-binary. A set of questionnaires for the Diagnosis of Depression in Children (CDI 2), the State-Trait Anxiety Inventory (STAI), the X-1 subscale, The Athens Insomnia Scale (AIS) and an original questionnaire of sociodemographic data were used in research.
Results: Analyzing the results obtained in the study group, the respondents scored an average of 17.99 ±9.55pts in the assessment of depressive symptoms. After division into genders, the overall score was 19.69±9.40pts for girls, 15.03±8.68 for boys and 25.86 ±9.91 for non-binary people. The difference was statistically significant in all groups. In the anxiety symptoms assessment, the respondents scored an average of 46.92± 11.67pts. After division into genders, 49.21± 11.12pts for girls, 43.39 ± 11.47 for boys and 53.39 ± 10.41 for non-binary people. The difference was statistically significant in all groups. Analyzing the results obtained in AIS, the average score was 8.31±4.58pts, which allows to evaluate sleep onset as a norm. After dividing into groups, the results were 8.95±4.55pts for girls, 7.19±4.21 points for boys and 11.35±5.43 for non-binary people, the difference was statistically significant. Statistically significant

positive correlations were found between the results obtained on the scale assessing depressive symptoms and anxiety symptoms and the results obtained on the AIS scale.
Conclusions: Among the studied group of teenagers, the highest intensity of depressive symptoms is demonstrated by non-binary people, followed by females, and finally by males. Similar results were obtained in the assessment of anxiety symptoms. The non-binary group achieved results indicating sleep disorders, while the cisgender group's results of sleep onset were borderline normal. Whatsmore, the greater the severity of depressive and anxiety disorders, the greater the sleep disorders in all study groups, regardless of gender.

EPV0814

Stigma resistance and quality of life in patients diagnosed with borderline personality disorder

A. Gmeiner[1,2]*, A. Mochty[1,2], A. Wippel[1,2] and M. Amering[1,2]
[1]Social Psychiatry and [2]Comprehensive Center for Clinical Neurosciences and Mental Health, Medical University of Vienna, Vienna, Austria
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1480

Introduction: Unlike data on public stigmatization with regard to the diagnosis of borderline personality disorder (BPD), literature concerning internalized stigma (IS) and stigma resistance (SR) is scarce.
Objectives: The objective of the present study was collecting data about SR in patients diagnosed with BPD. Furthermore, quality of life and depressive symptoms were assessed and checked for possible associations with SR.
Methods: Patients meeting the inclusion criteria with 18-65 years of age and diagnosed with BPD were included into the study after giving written informed consent. The stigma resistance scale (SRS) had been translated to German. The SRS comprises 5 subscales and measures SR on a 5-point-Likert scale (1-5). Higher values indicate higher levels of SR. Furthermore, the German versions of the depression scale CES-D (ADS) and the quality of life – BREF (QOL-BREF) were used in this study. ADS measures depressive symptoms on a scale ranging from 0-60, with higher scores indicating more severe symptoms. QOL-BREF measures values between 0-100 on 4 domains, with 100 indicating a maximum of health in each domain. The recruitment took place in specialized inpatient and outpatient units between 2019 and 2022, with some interruptions caused by COVID protective measures.
Results: 101 participants (f = 90.1%) with a mean age of 29.2 years (18-59) were included into the study. The overall mean score of the SRS was 3.6. The mean scores of the subscales showed values between 2.8 (personal cognition) and 3.9 (public SR). The 4 domains of the QOL-BREF showed the following mean values: Physical health 47.4, psychological health 30.7, social relationships 51.2, environment 62.1. The study sample had a mean ADS score of 34.8. Interestingly stigma resistance, quality of life and depressive symptoms showed no correlation. Compared to the mixed sample in the original study, the sample of the current study showed comparable values in stigma resistance.
Conclusions: The use of the German SRS is feasible in a sample of patients with a diagnosis of BPD and yielded comparable results with the original mixed diagnoses study sample. As the measure exists already in several languages, comparisons between cultural, diagnostic and otherwise defined subgroups will be possible in the future. Further conceptual as well as qualitative and quantitative research work will be informed by these findings.

Mindfulness and Perceived Stress: A Study Among Tunisian University Students

A. Guedria[1,2]*, A. Beji[1], N. Najjar[3], R. Ayoub[1,2] and H. Ben Abid[1,2]
[1]Child and Adolescent Psychiatry Departement, Fattouma Bourguiba Hospital; [2]University of Monastir, Monastir and [3]Faculté des Sciences Humaines et Sociales de Tunis, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1481

Introduction: Mental health among young people, particularly students, has become an increasing concern in contemporary society, shaped by its complexity, fast-paced nature, and hyperconnectivity. High levels of stress have been observed in numerous studies of this population. Perceived stress goes beyond merely observing stressful events, encompassing the individual's subjective evaluation of these situations. This perception involves awareness of one's emotions and thoughts, as well as awareness of the surrounding environment.
Objectives: The aim of this study was to explore the relationship between perceived stress and mindfulness levels among Tunisian students.
Methods: This was a cross-sectional study, conducted over a five-month period from August to December 2023. A questionnaire was distributed via email to 800 students, collecting sociodemographic data as well as two scales. The Perceived Stress Scale (PSS-10) was used to evaluate how participants perceive daily life situations as stressful: a higher PSS-10 score indicates greater perceived stress, categorized into three levels: low, moderate, and severe. The Five Factor Mindfulness Questionnaire-15 (FFMQ-15) assessed mindfulness dimensions: observing, describing, acting with awareness, non-judging, and non-reactivity. A higher FFMQ-15 score indicates greater mindfulness.
Results: A total of 102 students agreed to participate in the study. Their ages ranged from 19 to 30, with more than half being under 20 years old. 75.5% of participants were female.
The average PSS-10 score was 23, with significantly higher scores observed among women ($p < 10^{-3}$). Stress levels were mostly moderate (55.88%) or high (32.35%).
The mindfulness assessment revealed that the majority of participants had a moderate level of mindfulness (46 ± 8). Mindfulness scores were higher among students aged between 20 and 30 compared to those under 20 years old ($p < 10^{-3}$).
A negative correlation was observed between perceived stress and mindfulness ($p = 0.01$; $r = -0.508$), particularly in three mindfulness dimensions: describing, non-judging, and acting with awareness.
Conclusions: Mindfulness appears to play a significant role in reducing perceived stress levels. Our findings suggest that mindfulness training should be integrated into programs aimed at improving stress management among students.

Decadal trends in illicit drug-related poisonings in Morocco: Epidemiological analysis and public health implications

O. Erefai[1], S. Hmimou[2], S. Elkafssaoui[3], H. Harifi[2]*, A. Soulaymani[2], A. Mokhtari[2] and H. Hami[2]

[1]Higher Institute of Nursing Professions and Health Techniques, Rabat; [2]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra and [3]Royal School of Military Health Service, Rabat, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1482

Introduction: The impact of **illicit** drug-related poisonings on public health is a pressing global concern, necessitating focused scrutiny to mitigate adverse effects on communities. In Morocco, the prevalence of **illicit** substance abuse and its resulting emergencies pose a complex challenge to public health systems. **Particularly concerning are the poisonings induced by these substances, which not only require immediate responses but also demand a sustained, strategic approach to ensure long-term community** health **and safety**.
Objectives: This study aims to delineate trends in poisonings caused by illicit drugs, as reported to the Moroccan Poison Control Center over a decade, focusing on the annual number of cases and their proportion to overall poisoning cases.
Methods: Data spanning from 2013 to 2022 from the Moroccan Poison Control Center were analyzed to assess the annual number of poisoning cases and proportions attributed to incidents involving illicit drug use. The analysis focused on identifying long-term trends, highlighting the evolving role of **illicit** drugs in poisoning statistics.
Results: Between 2013 and 2022, a total of 109,976 poisoning cases were recorded, of which 2,284 (2.08%) were related to the use of illicit drugs. Initially, drug-related poisonings increased, peaking in 2017 at 339 cases (2% of 16,906 total cases). Notable observations included 198 drug-related cases in 2013 (1.65% of 11,968 cases) and 334 in 2016 (2.11% of 15,838 cases). However, a marked decline was observed post-2017, culminating in 2022 with 84 drug-related cases (1.99% of 4,225 total cases). The prevalence of drug-related poisonings fluctuated annually, ranging from 1.56% to 3.65%, with a significant decrease in both total and drug-related poisonings after 2017.
Conclusions: Although there was an initial increase in **illicit** drug-related poisonings in Morocco, a notable decline was observed. Despite this downturn, **illicit** drug-related poisonings continue to pose a critical public health issue. Ongoing monitoring and proactive prevention strategies are crucial to sustain this downward trend and effectively manage the challenges of illicit substance abuse.

Assessment of cannabis-related health impacts in Morocco: A decade-long epidemiological study

O. Erefai[1], A. Soulaymani[1], S. Elkafssaoui[2], S. Hmimou[3], S. Irnat[3]*, S. Saidou[3], H. Chaoui[4], R. Soulaymani-Bencheikh[4] and H. Hami[3]

[1]Higher Institute of Nursing Professions and Health Techniques; [2]Royal School of Military Health Service, Rabat; [3]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra and [4]Moroccan Poison Control Center, Rabat, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1483

Introduction: The rise in cannabis consumption in Morocco, paralleling global patterns, has heightened concerns over its potential repercussions on mental and physical health, as well as its broader societal implications.
Objectives: This study aims to delineate the demographic and clinical characteristics of individuals affected by cannabis toxicity and elucidate the details of their exposure scenarios in Morocco.
Methods: We conducted a retrospective analysis of cannabis poisoning incidents from 2008 to 2017, encompassing both occasional and habitual users. Data were sourced from the Moroccan Poison Control Center (MPCC), providing a comprehensive national perspective.
Results: During the study period, 553 cases of cannabis poisoning were reported, with a gender distribution of 19.3% female and 80.7% male. Notably, 245 individuals were identified as regular users. The mean age of those affected was 18.3 years. Findings indicate that children are particularly vulnerable to accidental poisoning from psychoactive substances, predominantly due to the ingestion of delta-9-tetrahydrocannabinol (THC), the principal psychoactive compound. The clinical manifestations vary depending on the dosage and pattern of use. Out of 438 cases with documented outcomes, six resulted in fatalities, while the remainder showed improvement following appropriate medical interventions, including gastrointestinal decontamination.
Conclusions: The escalating use of cannabis necessitates immediate and strategic public health interventions, particularly targeting the youth, to mitigate its adverse health effects and societal impact. It is crucial to develop targeted strategies to enhance preventive efforts and curb cannabis misuse among vulnerable populations.

doi: 10.1192/j.eurpsy.2025.1484

Introduction: "Sex work" refers to the provision of sexual services in exchange for monetary or material compensation. The exact number of sex workers in Germany, where prostitution is legal, remains uncertain, but estimates suggest it could be as high as 700,000. The majority of the group is female and has a migration background. Sex work covers different areas. These include work in brothels and strip clubs, street prostitution, hostess services and work in the porn industry. Previous research into sex work has mainly focused on sexually transmitted diseases. While results from Switzerland indicate elevated prevalences of depression, anxiety

disorders, and substance use among sex workers, to date, there has been no research specifically addressing mental illnesses among sex workers in Germany.
Objectives: The research project aims to fill this gap by determining the 1-year prevalence as well as risk and resilience factors for mental illness among sex workers in Berlin. The research findings aim to enhance psychosocial care services for sex workers and foster meaningful contributions to the broader social discourse.
Methods: The socio-demographic composition of the sex worker population is constantly shifting, making it difficult to obtain a truly representative random sample. Quota sampling offers the closest alternative, with interviewees being approached at various workplaces. Additionally, we ensure a diverse age range is included in the study. A total of 500 participants will be surveyed using structured interviews. The interview consists of a sex work questionnaire, standardized research instruments, and a mental health screening. The sex work questionnaire gathers data on work type and intensity, socio-demographic characteristics, and individual access to counseling and support services. Standardized instruments include assessments for personality (TIPI), coping behaviors (Brief COPE), health-related quality of life (SF-12), stigmatization experiences (PASS 24), and childhood trauma (CTQ). The mental health screening will be conducted using the Mini-DIPS.
Results: The submitted poster will offer a detailed overview of the study design and methodologies. In addition, preliminary results will be shared, shedding light on the mental health status and access to healthcare services among sex workers.
Conclusions: This pioneering study seeks to address a significant gap in current research. The final findings will form the foundation for more in-depth analysis and guide future recommendations to improve support services for this population.

Prescription of psychotropic drugs in persons with concurrent mental health and substance use disorders before and during the COVID-19 pandemic in Norway

M. Leonhardt[1]* and L. Lien[1,2]

[1]ROPforsk, Innlandet Hospital Trust, Brumunddal and [2]Faculty of Social and Health Sciences, Inland Norway University of Applied Sciences, Elverum, Norway
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1485

Introduction: The COVID-19 pandemic has had a profound impact on mental health globally, exacerbating existing mental health disorders (MHD) and substance use disorders (SUD). Various measures have been implemented to mitigate these adverse mental health consequences. Nevertheless, the significant rise in mental health challenges has underscored the role of psychotropic drug prescriptions as an important metric for assessing mental health trends in certain populations. During the pandemic, data from high-income countries, indicate an increase in the prescription of psychotropic drugs. This might reflect heightened mental health needs in the general population, but also may underscores the exacerbated vulnerability of individuals with pre-existing concurrent MHD/SUD. Prescribing psychotropic drugs can be complex due to the potential for misuse and the need for careful monitoring to balance therapeutic effects with the risks.
Objectives: This study aimed to evaluate 1) the number of prescriptions of psychotropic drugs in persons with concurrent MHD and SUD in the years before and during the two COVID-19 pandemic years (2020 and 2021) and 2) to study the impact of the COVID-19 pandemic on the consumption of psychotropic drugs among this population.
Methods: We conducted a retrospective cohort study based on a data file constructed by merging individual-level information from the Norwegian Patient Register and the Norwegian Prescribed Drug Registry, analysing data from 2019-2021. The International Classification of Diseases (ICD)-10 main diagnosis, chapter V have been used to identify persons with MHD/SUD. We recognised 35.000 individuals who received a diagnosis of co-occurring MHD/SUD between the years 2019-2021. A graphical approach and descriptives were applied to study the population. Interrupted time series analysis was used to compare changes in trends in the prescriptions dispensed by eight psychotropic drug classes, according to the consecutive COVID-19 waves during the first two years of the pandemic.
Results: Preliminary analysis show, an increased prescription rate in all eight psychotropic drugs classes in persons with MHD/SUD during the first two years of the pandemic, compared to 2019. The largest increases were shown to appear parallel with the COVID-19 waves. Antipsychotics and anxiolytics were the most prevalent prescribed drugs, followed by opiates, hypnotics & sedatives and antidepressants. Being female and older age was associated with higher odds of receiving a prescription, regardless psychotropic drug class.
Conclusions: The prescription of psychotropic drugs has gradually increased from 2019-2021. More research is needed to differentiate increases due to unmet needs versus overprescribing and further, to study the long-term effects of the pandemic regarding the utilization of psychotropic drugs in this vulnerable patient group.

The Brief Symptom Inventory-9 (BSI-9): Psychometric properties among Irish college students

C. A. Lewis[1]* and F. Houghton[2]

[1]Psychology, Leeds Trinity University, Leeds, United Kingdom and [2]Department of Applied Social Science, Technological University of the Shannon, Limerick, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1486

Introduction: The Brief Symptom Inventory-9 (BSI-9) is a recently developed short (9-item) self-report scale measuring distress. It has three Subscales measuring Anxiety, Depression, and Somatisation. The BSI-9 is based on longer scales (BSI-18, BSI-53, and SCL-90) and was developed as a brief screening tool.
Objectives: The present study examined the generalisability of the original foundational research undertaken in Germany. The present study examined the psychometric properties of the BSI-9 among a sample of Irish college students.
Methods: A sample of 763 Irish college students completed the BSI-9, and a further 18 students completed the BSI-9 on two occasions, separated by four weeks, as part of a more extensive study. Factor analyses and reliability analyses were carried out.
Results: The BSI-9 scale and the three Subscales measuring Somatisation, Anxiety, and Depression were each found to have appropriate

factor loadings, satisfactory levels of internal consistency, and satisfactory levels of temporal stability across four weeks. These findings are consistent with those reported in the original foundational research in Germany.
Conclusions: Although the sample size was small and restricted to students only, the present study does provide evidence for the reliability of the BSI-9 among a sample of Irish college students. Future work is now required to extend this work to examine the convergent validity of the BSI-9 among other English-speaking samples.

EPV0821

The influence of Stigma, Disclosure, and Self-Esteem on Quality of Life in Individuals with Mental Illness

Y.-J. Lien[1]* and Y.-H. Wang[1]

[1]National Taiwan Normal University, Taipei, Taiwan, Province of China
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1487

Introduction: Stigma not only influences the willingness to disclose mental health conditions and self-esteem but may also diminish the overall quality of life in individuals with mental illnesses. However, limited research has examined the potential mechanisms underlying this complex relationship.
Objectives: This study aims to explore the mediating roles of disclosure and self-esteem in the association between mental illness stigma and quality of life.
Methods: We utilized the meta-analytic structural equation modeling (MASEM) approach and conducted a comprehensive literature search across various electronic databases to identify relevant publications up to July 2023. MASEM was employed to derive bivariate correlation matrices for stigma, disclosure, self-esteem, and quality of life. Additionally, two simple mediation models and one serial mediation model were tested to examine the relationships between these variables.
Results: The analysis included 181 articles reporting 195 independent samples (N = 33,162) and 278 effect sizes. The single mediator model indicated that self-esteem ($\beta = -0.155$, 95% CI [−0.276, −0.070], $p < .001$), rather than disclosure ($\beta = -0.019$, 95% CI [−0.094, 0.031], $p > .05$), served as a mediator. In the multiple mediator model, disclosure and self-esteem were found to have serial mediating roles between stigma and quality of life ($\beta = -0.016$, 95% CI [−0.0546, −0.0003], $p < .05$).
Conclusions: This study makes a significant contribution to understanding how stigma attitudes impact the quality of life in individuals with mental health problems, providing a strong empirical foundation for the development of mental health interventions. Future research directions and practical implications are also explored.

EPV0823

The prevalence of adverse childhood experiences in systematic reviews of primary headache and cancer

A. Mavromanoli[1]*, C. Sikorski[2], D. Behzad[3], K. Manji[4] and C. Kreatsoulas[5]

[1]Johannes Gutenberg University, Mainz, Germany; [2]McMaster University, Hamilton; [3]Brock University, St. Catharines; [4]University of Toronto, Toronto, Canada and [5]Harvard T.H. Chan School of Public Health, Boston, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1488

Introduction: Adverse childhood experiences (ACEs) describe an array of stressful exposures that occur during childhood/ adolescence, including types of abuse and neglect. As ACEs occur during a critical period of human development, they have been associated with a range of chronic diseases in adulthood.
Objectives: We aimed to systematically analyze the prevalence of ACEs in studies in two different disease severity populations, including primary headache and cancer. The objectives of this study are to examine,
The prevalence of ACEs hypothesized to impact chronic disease
The pooled association of the presence of "disease", which consists for this study only primary headache and/or cancer, with ACEs
Methods: The inclusion criteria for the studies in the systematic reviews/meta-analyses included observational studies with a comparator group, ACE(s) occurrence at ≤18 years of age, and disease diagnosis at ≥21 years of age. Searches were conducted up to Mar 16, 2023. Two review authors independently screened articles, extracted data, assessed risk of bias using QUIPS, and conducted GRADE assessment as part of the systematic reviews. In this study, we calculated the prevalence and the odds of experiencing ACEs among those with disease compared to those without disease.
Results: Of the total 39,658 articles screened, 44 studies were eligible for synthesis of 437,852 participants from 22 countries across five continents. Among included studies, the most commonly examined ACEs were physical abuse (82% of studies), sexual abuse (77%), household substance or alcohol abuse (52%), witnessing or threat of violence (50%), having a household member with a mental illness (45%), and emotional abuse (43%).
Of the 437,852 participants in the synthesis, an estimated total of 196,587 participants (45%) reported experiencing at least one ACE. Among participants with primary headache and/or cancer, 51% (29,838/58,580) reported experiencing at least one ACE, compared to 44% (166,749/379,272) of participants without primary headache and/or cancer (crude odds ratio = 1.32, 95% confidence interval: 1.30, 1.35).
Conclusions: The prevalence of ACEs is high when hypothesized to be associated with diseases, independent of the risk for mortality (i.e., primary headache low mortality, cancer high mortality). Abuse ACEs are more commonly considered in studies than neglect ACEs, and therefore, more consistent and comprehensive reporting of ACEs is needed. There is untapped opportunity for the expertise of psychiatrists to collaborate with clinicians and researchers of adult chronic disease studies.

Myths of ADHD in the Kyrgyz Republic: Destigmatization and Challenges in Mental Health

E. Molchanova[1]

[1]Psychology, American University in Central Asia, Bishkek, Kyrgyzstan
doi: 10.1192/j.eurpsy.2025.1489

Introduction: As a neurodevelopmental disorder characterized by symptoms such as inattention, hyperactivity, and impulsivity, ADHD was once predominantly associated with Western medical discourse. However, recent years have seen a notable rise in self-diagnoses of ADHD among young people in Kyrgyzstan.
Objectives: This research aims to explore the myths surrounding ADHD in the Kyrgyz Republic, focusing on how these misconceptions contribute to the destigmatization of mental health disorders and create challenges for mental health professionals. The research also seeks to examine the gap between public awareness of ADHD and the actual resources available for diagnosis and treatment in Kyrgyzstan.
Methods: This analysis is qualitative and is based on, (1) observations of self-diagnosis trends among young people in Kyrgyzstan, and (2) anecdotal evidence from mental health professionals working in the country. In-depth interviews were conducted with 15 adolescents, self-diagnosed with ADHD, and 15 mental health care specialists working in Bishkek. Informed consent was presented before the interviews and both patients and specialists were rewarded by 15 dollars after the interview.
Results: Three key myths emerged from the analysis: (1) **ADHD as a Temporary Condition:** A prevalent belief in Kyrgyzstan is that ADHD can be easily cured by a few visits to a "good" psychologist. It reflects the unrealistic expectations of therapy and the lack of understanding that ADHD often requires long-term management. (2)**ADHD as a Fashionable Disorder:** There is a growing trend, particularly among urban youth, to romanticize ADHD as a "cool" or "fashionable" diagnosis. While this has contributed to greater awareness of ADHD, it also trivializes the disorder, promoting self-diagnosis and diluting the seriousness of the condition. (3) **ADHD as a Childhood Disorder:** Another widespread misconception is that ADHD primarily affects children and that individuals grow out of it with age. This myth prevents many from seeking early intervention.
Conclusions: The growing awareness of ADHD in the Kyrgyz Republic is a double-edged sword. On one side, it is helping to reduce the stigma associated with mental health disorders, providing people with a socially acceptable way to discuss and understand their struggles. Conversely, the myths accompanying this awareness hinder effective diagnosis and treatment, making it difficult for individuals to access proper care. Mental health professionals must not only treat ADHD but also work to correct these societal misconceptions, a task made more difficult by limited resources in Kyrgyzstan. A more nuanced public understanding of ADHD, supported by accurate information and improved mental health infrastructure, is essential for addressing these challenges

Evaluating the implementation of the community mental health program GBV: service users' perspectives

A. S. Mueller-Stierlin[1,2*], S. Reuter[2] and R. Kilian[2]

[1]Institute for Epidemiology and Medical Biometry and [2]Department of Psychiatry II, University of Ulm, Ulm, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1490

Introduction: A multi-site randomized controlled study demonstrated that the community mental health intervention GBV, when combined with standard care in the German healthcare system, led to greater improvements in empowerment, quality of life, and needs-orientation for people living with severe mental illness. However, to gain a comprehensive understanding, it is essential to include service users' perspectives alongside effectiveness data.
Objectives: This study aimed to assess the implementation of GBV from the service users' viewpoint, providing a holistic evaluation of the intervention beyond randomized trial results.
Methods: A mixed-methods approach was used to evaluate the service users' experiences with GBV. Semi-structured interviews were conducted, transcribed, and analysed using thematic content analysis. Additionally, fidelity ratings were collected after 12 months of intervention, based on a scale developed from GBV quality standards, focusing on needs orientation, relationship building, and service availability.
Results: The process evaluation revealed a greater increase in empowerment, subjective quality of life and treatment satisfaction as well as a greater reduction in unmet needs with a subjectively higher perceived manual fidelity. Qualitative interviews supported these findings, emphasizing the critical role of strong relationships with GBV staff, personalized care tailored to individual needs, and adherence to GBV's quality criteria.
Conclusions: While the effectiveness of GBV has been established, ensuring fidelity to the intervention's manual is crucial for large-scale implementation. Key factors for success include a focus on relationship building and needs-orientation, ensuring that service delivery aligns with the predefined GBV quality standards.

Psychosocial Interventions for the Caregivers of patients with Epilepsy

V. Patil[1]

[1]Neuropsychiatry, AIIMS New Delhi, New Delhi, India
doi: 10.1192/j.eurpsy.2025.1491

Introduction: Epilepsy, one of the most common neurological disorders, affects around 50 million people worldwide. It is unpredictable, intrusive illness that impacts not only the patients but also those who care for them.Caregivers are vulnerable to great burden; depressive and psychosomatic symptoms, as well as physical, emotional, and economic pressures.
Objectives: To explore the psychiatric comorbidities, attributes related to caregiver burden and psychosocial intervetions available to allivate the burden in **Caregivers of patients with Epilepsy**.

Methods: A narrative review of the relevant studies focusing on psychiatric comorbidities and psychosocial interventions for reducing the caregiver burden in caregivers of patient with epilepsy was comducted.
Results: Caregivers of patient with epilpsy have poor quality of life and are at risk of developing psychiatric illnesses.Caregiving was reported to negatively impact one's physical and mental health, overall family functioning, and financial status. Psychological interventions such as **psychoeducation, individual, group or family counselling, Interpersonal and social support networks, relaxation therapy and cognitive behaviour therapy** have been used to treat caregiver burden associated with epilepsy caregiving.
Conclusions: Caring for patients with epilepsy is challenging and it is associated with enormous burden. It can lead to mental health problems which ultimately affects the compliance to treatment and overall prognosis. Psychosocial interventions can prepare caregivers for a better role of caregiver and better management of the care process. There is increased need to focus on this unexplored area through research and to provide effective interventions as a part of clinical services.

EPV0827

The Burden of Mental Disorders in the world – a GBD 2021 analysis in the WHO regions

V. Pinheiro[1,2,3]* and J. V. Santos[2,3,4]

[1]ULS Matosinhos, Matosinhos; [2]University of Porto; [3]RISE-Health/Cintesis and [4]ULS Santo António, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1492

Introduction: The Global Burden of Disease (GBD) study has generated a plethora of worldwide data on mortality and disability, including the disease burden due to mental disorders, often amenable to interventions, essential for health planning.
Objectives: This work aims to report the burden of mental disorders in disability-adjusted life years (DALYs), from 2001 to 2021, globally and in the six World Health Organization (WHO) regions.
Methods: Retrospective descriptive study, using secondary data from the GBD 2021 Results Tool. Globally and for each of the six WHO regions, age-standardised DALY rates are reported and respective 95% uncertainty intervals, between 2001-2021, for both sexes and for males and females. All data analysis was performed using R version 4.0.5.
Results: In 2021, the both-sex age-standardised DALY rate due to mental disorders was 1909.15 (1440.16 – 2437.88) DALYs per 100,000 globally, with great heterogeneity across regions: the Americas with 2379.96 (1786.30 – 3026.74) DALYs per 100,000, the highest burden, and the Western Pacific with 1517.45 (1159.48 – 1910.43) DALYs per 100,000, the lowest. Between 2001-2021, the global both-sex age-standardised DALY rate remained relatively stable and even decreased slightly until 2019 but a sharp increase occurred in 2020 and 2021. This pattern generally held up across regions, with the Americas consistently the region with the highest burden, followed by Eastern Mediterranean, Europe, Africa, South-East Asia and Western Pacific. The European region showed the largest increase in 2001-2021 (from 1895.12 (1435.12 – 2420.97) to 2162.03 (1609.92 – 2777.89)). The same pattern occurred in females across regions, but an important difference in males was observed, with the Eastern Mediterranean region presenting the highest burden in 2021 (2012.54 (1523.41 – 2569.42), after overtaking the Americas in 2008.
Conclusions: The burden of mental disorders remained relatively stable between 2001-2019 with a sharp increase in 2020-2021 globally, and great heterogeneity between regions and some important differences between sexes. Besides opportunities for mutual learning, essential for health planning, cultural sensitivities and social/economic contexts can be important factors associated to these patterns: the COVID-19 pandemic may have been an important trigger for this sharper increase in burden. These results highlight the different patterns of disease burden due to mental disorders in the world and the need for tailored strategies.

EPV0828

Mortality Rates from Suicide in Brazil in 2021: A Comprehensive Demographic Analysis by Sex and Age Group

J. R. Pinto Nasr[1]

[1]Universidade Paulista - Campus Campinas, Campinas, Brazil
doi: 10.1192/j.eurpsy.2025.1493

Introduction: Suicide represents a significant and growing public health challenge in Brazil, reflecting a complex interplay of social, economic, and mental health factors.
The increasing rates of suicide highlight the need for targeted interventions and policies. Understanding the demographic characteristics associated with suicide, particularly in relation to sex and age, is crucial for developing effective prevention strategies and health policies. This study utilizes data from the 2024 epidemiological bulletin, "Panorama dos Suicídios e Lesões Autoprovocadas no Brasil de 2010 a 2021."
Objectives: This study aims to provide an analysis of the mortality rates from suicide in Brazil for the year 2021. The primary focus is on exploring the distribution of suicide rates by sex and age group, as well as evaluating the proportional mortality in relation to the total number of deaths in the country.
Methods: The study utilized data sourced from the Mortality Information System (SIM) and the aforementioned epidemiological bulletin, which compiles comprehensive mortality data across Brazil. We analyzed the rates of mortality from suicide, categorizing the data by age groups: 05 to 14 years, 15 to 19 years, 20 to 29 years, 30 to 49 years, 50 to 69 years, and 70 years and older. The analysis further differentiated the data by sex, allowing for a nuanced understanding of demographic variations.
Results: In 2021, Brazil reported a total of 15,507 deaths attributed to suicide. Of these, 12,072 (1.21% proportional mortality) were male, and 3,431 (0.43% proportional mortality) were female, indicating a substantial gender disparity in suicide rates. The mortality rates from suicide per 100,000 inhabitants varied significantly by age group: 0.7 for males and 0.9 for females in the 05 to 14 years age group; 9.3 for males and 4.5 for females in the 15 to 19 years group; 14.6 for males and 3.9 for females in the 20 to 29 years group; 14.9 for males and 3.8 for females in the 30 to 49 years group; 15.4 for

males and 3.8 for females in the 50 to 69 years group; and 18.1 for males and 2.9 for females aged 70 years and older. Notably, among the leading causes of death, suicide ranked 11th for the 05 to 14 years age group (3.41%), 3rd for the 15 to 19 years age group (6.90%), and 4th for the 20 to 29 years age group (5.56%). These figures underscore the significant impact of suicide on young populations.
Conclusions: The high mortality rate from suicide in Brazil underscores the urgent need for public health policies focused on suicide prevention. Effective interventions should include mental health support, community outreach programs, and increased awareness campaigns aimed at reducing the stigma around mental health issues. By addressing the underlying social and economic factors contributing to suicide, Brazil can improve health outcomes and enhance the quality of life for at-risk populations.

EPV0829

Epidemiological Trends and Hospitalization Profile of Alcohol-Related Mental and Behavioral Disorders in the State of São Paulo, the Most Populous State of Brazil, 2023

J. R. Pinto Nasr[1]*, F. H. de Oliveira Bezerra[1], N. da Silva Fonseca[1], A. J. Bras Santos[1] and T. Mosca Vidigal[1]

[1]Universidade Paulista - Campus Campinas, Campinas, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1494

Introduction: Mental and behavioral disorders resulting from alcohol use are a significant public health issue. As the nation's most populous state, São Paulo encounters distinct challenges in this domain. According to the 2022 Census, the most recent national demographic survey, the state of São Paulo's population is estimated at 44,411,238, representing approximately 21.9% of Brazil's total population of 203,080,756. Understanding the epidemiological profile of these disorders is crucial to better assess their impact on the healthcare system and to guide effective resource allocation and management strategies.
Objectives: The present study aims to analyze statistical data related to hospitalizations due to mental and behavioral disorders caused by alcohol use in the state of São Paulo in 2023.
Methods: A cross-sectional, descriptive, retrospective, and quantitative study was conducted, focusing on hospitalizations of individuals diagnosed with mental and behavioral disorders due to alcohol use in the state of São Paulo during 2023. Data were collected from the Department of Health Informatics of the Brazilian Unified Health System (DATASUS) within the "Hospital Information System of SUS" section, examining variables such as age range, gender, ethnicity, and length of hospital stay.
Results: In 2023, São Paulo recorded 5,898 hospitalizations for alcohol-related mental and behavioral disorders, with total expenditures amounting to R$ 9,215,994.94. The average length of stay was 22.9 days, and the overall mortality rate was 0.64%, with 38 deaths. The highest number of hospitalizations occurred in the 35-39 years (12.1%), 40-44 years (14.7%), and 45-49 years (15.5%) age groups, which together accounted for 42.3% of all cases. Men represented 86.1% of hospitalizations, with an average length of stay of 23.4 days compared to 19.9 days for women. The ethnic distribution showed that 52.9% of hospitalizations were among White individuals, 8.3% were Black, 37.5% were Multiracial, and 0.7% were Asian. The longest average stays were among White individuals (25.1 days), followed by Black (22.2 days) and Multiracial (20.2 days). The overall mortality rate was 0.64%, with a slightly higher rate in men (0.65%) compared to women (0.61%). Black individuals had the highest mortality rate (1.23%), particularly among men (1.25%).
Conclusions: This study underscores the public health impact of alcohol-related mental and behavioral disorders in the state of São Paulo, particularly among middle-aged men. Ethnic disparities in hospitalization duration and mortality suggest the need for targeted healthcare strategies to meet diverse demographic needs. These findings highlight the importance of tailored interventions and strategic resource allocation to reduce the burden of alcohol-related disorders and enhance health equity.

High Prevalence and Socioeconomic Inequalities of Mental Disorders Among Adults with Disabilities in Western Iran

B. Piroozi[1] and K. Qaderi Bagajan[2,3]*

[1]Social Determinants of Health, Research Center, Research Institute for Health Development, Kurdistan University of Medical Sciences, Sanandaj; [2]Department of Clinical and Health Psychology, Shahid Beheshti University, Tehran, Iran, Islamic Republic Of and [3]Psychological Diagnostics group, Department of Psychology, Humboldt-Universität zu Berlin, Berlin, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1495

Introduction: There is very little information about the mental health status of people with disabilities in Iran, while monitoring the status of this index is very necessary to properly address problems, design appropriate interventions, and evaluate the impact of interventions.
Objectives: in this regard, this study investigated the prevalence of mental disorders among adults with physical and sensory disabilities in Sanandaj City, Iran.
Methods: This descriptive-analytical and cross-sectional study was conducted on people with physical and sensory (sight, hearing and speech) disabilities over 18 years of age in Sanandaj city in 2023. A two-part questionnaire was used in order to collect data in this study. The first part consisted of age, sex, type of disability, basic health insurance status, supplementary health insurance, education, employment status, and economic status (wealth assets). The second part included Goldberg's 28-item questionnaire (GHQ-28) that was used as a screen tool for mental disorders. Data were analyzed using STATA software version 16.0 (Stata Corp, College Station, TX, USA.)
Results: Finally A total of 607 people (response rate: 99%) participated in this study that 317 were men (52.2%) and 290 were women (47.8%). The prevalence of mental disorders suspicion was 56.7% (344 people) and its prevalence based on the severity of the disorder was 29.7% mild, 16.6% moderate and 10.4% severe. Results indicated that over 56% of participants were suspected of having a mental disorder, with the most common being depression and anxiety. Females, younger participants, the unemployed, those without supplementary health insurance, and those from lower economic classes had significantly higher odds of mental disorder suspicion. An uneven distribution was observed, with a disproportionate concentration among the lower economic status group.

Conclusions: The findings highlight a high prevalence of suspected mental disorders among people with disabilities and inequalities in gender, age, employment, insurance coverage, and socioeconomic status. Addressing mental health needs is crucial through targeted screening, prevention programs, and promoting access to appropriate services for this vulnerable population.

Examining the relationship between personality traits, anxiety levels, and coping styles with stress among architecture students

C. Şahin[1,2*] and M. Karaaziz[3]

[1]Psychiatry, University of Health Sciences Şişli Etfal Training and Research Hospita, Istanbul, Türkiye; [2]Institute of Social Science Department of Clinical Psychology, Near East University and [3]Department of Psycology, Near East University, Institute of Graduate Studies, Nicosia, Cyprus

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1496

Introduction: The university period is a time during which individuals experience both physical and social changes, encounter conflicts and intense anxieties that can be categorized under various subheadings such as behavioral, emotional, sexual, social, economic, and academic.Moreover, studying in the department of architecture includes additional stressors that differ from other faculties, such as non-objective materials and educational outputs, the requirement for versatile abilities and originality, subjective evaluation processes, constant exposure to criticism, performance anxiety.The level of an individual's current anxiety and the coping methods they will develop in response to stress are determined by the fundamental analysis methods of their personality traits. In this context, the aim of our study is to determine the significance of the relationship between personality traits, anxiety levels, and stress coping styles of architecture students studying at faculties located in the Marmara region, and to identify whether these factors vary according to demographic characteristics.

Objectives: The levels of anxiety that arise due to various reasons, the coping styles developed in response to stressor factors, and the personality traits, which are often considered the key determinants of these two factors, are examined within the scope of architecture students, who are exposed to intense stressors as the study population.Analyzing the relationships between these elements is crucial both to address gaps in the existing literature and to contribute to public health.

Methods: A study was conducted with 432 architecture students, who volunteered to participate in the study, from the Faculties of Architecture in universities located in the Marmara Region of Turkey. Data were collected using Random Sampling Method (Voluntary Basis), Online Survey Application, Socio-Demographic Information Form, Big Five Personality Inventory, Beck Anxiety Inventory, Coping with Stress Lifestyle Scale. The results of the study were evaluated using SPSS, Cronbach's alpha analysis, Mahalanobis distance values, T-TEST, One-Way Analysis of Variance, LSD TEST, Pearson Correlation Analysis and Standard Multiple Regression Analysis.

Results: As a result of the study, significant relationships were found between anxiety levels and gender, personality traits, types of schools, coping styles with stress, parental education levels; between coping styles with stress and types of schools, parental education levels, personality traits, and father's education level, family income level; and between anxiety levels and coping styles with stress.

Frequency and Correlates of Anxiety Symptoms in Serbian Primary Care

M. Spasić Stojaković[1,2*] and M. Latas[3,4]

[1]Psychiatry, Kliniken im Theodor-Wenzel-Werk, Berlin, Germany; [2]Faculty of Medicine, Belgrade University, Belgrade, Serbia; [3]Psychiatry Depratment, Faculty of Medicine, Belgrade University and [4]Clinic of Psychiatry, University Clinical Centre of Serbia, Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1497

Introduction: Globally, anxiety disorders are ranked as the sixth largest contributor to non-fatal health loss (WHO, 2017). Data on anxiety in primary care patients in low- and middle-income countries are sparse.
Objectives: Determining prevalence and demographic correlates of symptoms of anxiety in primary care across Serbia.
Methods: Cross-sectional study was conducted in 100 primary care facilities from whole Serbia. Sample consisted of 10-12 consecutive patients interviewed by each of the 270 partaking general practitioners, total of 2041. The participants answered sociodemographic questionnaire, and if they were previously diagnosed with F40 or F41. GAD-7 questionnaire was used for the assessment of symptoms of anxiety (cut-off score ≥ 10). Multiple logistic regression was applied.
Results: Positive screening for anxiety was found in 22.7% of participants. It was significantly associated with gender (male OR: 0.769, 95% CI: 0.602-0.982), marital status (divorced OR: 1.901, 95% CI: 1.346-2.686; single OR: 1.573, 95% CI: 1.042-2.375), education (high school OR: 0.578 95%, CI: 0.410-0.814; university OR: 0.489, 95% CI: 0.323-0.740), employment (unemployed OR: 1.903, 95% CI: 1.355-2.672; retired OR: 1.797, 95% CI: 1.209-2.672; homemaker OR: 3.018, 95% CI: 1.842-4.945) and region of residence (Beograd OR: 0.595, 95% CI:0.430-0.824; Central Serbia OR: 0.371, 95% CI:0.231-0.597) Percentage of participants who have screened positively for anxiety without having previously established anxiety (F40, F41) diagnosis was 61.4%.
Conclusions: Anxiety is relatively prevalent among patients in primary care in Serbia and it is associated with gender, marital status, education, employment, and region of residence, with homemakers, divorced and the ones with only primary school being the most likely to have positive screening for anxiety. Even though positive screening for anxiety as measured here does not necessarily imply diagnosis of anxiety disorder, it nevertheless, means that the person experiences distress, and may need clinical attention - substantial percentage of patients with positive screening for anxiety is unrecognized and untreated.

Attachment styles among students at the faculty of medicine of Sfax and suicidality

Y. Yaich[1*], A. Bouallegui[1], N. Ben Hamed[1], H. Khiari[1], A. Hakiri[1], G. Amri[1] and R. Ghachem[1]

[1]Psychiatry B, Razi hospital, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1498

Introduction: The theory of attachment is one of the most influential theories in developmental psychology. It was formulated by British psychologist John Bowlby in the 1950s and 1960s.This theory states that early relational experiences, particularly those with primary attachment figures (usually parents), influence the formation of internal working models that guide social interactions and attitudes toward oneself and others throughout life. The theory of attachment has important implications for adult relationships. An important time to study attachment is during university years, when many young adults are on their own for the first time and must establish new relationships which represents a moment of vulnerability.
Objectives: The purpose of this study was to evaluate the prevalence of different attachment styles among medical externs using the RSQ scale and to examine the relationship between these attachment styles and suicidality.
Methods: This is a cross-sectional, descriptive, and analytical study. It was conducted over a period of five months among students at the Faculty of Medicine of Sfax using an online form that included sociodemographic data, medical history, lifestyle habits and the "Relationship Scale Questionnaire" (RSQ)
Results: The average age was 21.63 years. The distribution of students according to their attachment styles showed that avoidant attachment was the most prevalent (29%, n=150), and women exhibited more ambivalent attachment than men (p=0,031). Ambivalent attachment was significantly associated with sexual orientation (p=0,025).
Personal psychiatric history was associated with secure (p=0.008), ambivalent (p=0.005), and disorganized attachment styles (p=0.011).

A significant link was found between personal history of suicide attempts and ambivalent attachment style (p=0.005).Our results were compared with existing literature and studies on this topic agree on the importance of assessing students' attachment styles and their emotional needs.
Conclusions: This study highlights the significant relationship between attachment styles and suicidality among students at the Faculty of Medicine of Sfax.
Further research is needed to advance our understanding of the implications of these findings and how to address the emotional and psychological needs of students.

Attachment styles among students at the faculty of medicine of Sfax and parental separation and divorce

Y. Yaich[1]*, A. Bouallegui[1], N. Ben Hamed[1], H. Khiari[1], A. Hakiri[1], G. Amri[1] and R. Ghachem[1]

[1]Psychiatry B, Razi hospital, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1499

Introduction: The theory of attachment is one of the most influential theories in developmental psychology. It was originally developed by John Bowlby.This theory states that early relational experiences, particularly those with primary attachment figures (usually parents), influence the formation of internal working models that guide social interactions and attitudes toward oneself and others throughout life. This framework is particularly relevant in the context of students at the Faculty of Medicine of Sfax, where the pressures of rigorous academic demands intersect with personal histories that may include parental separation and divorce. Research indicates that parental separation and divorce can negatively impact attachment security, leading individuals with such experiences to have a higher likelihood of developing distrust in relationships.
Objectives: The purpose of this study was to evaluate the prevalence of different attachment styles among medical externs using the RSQ scale and to examine the relationship between these attachment styles and parental separation or divorce.
Methods: This is a cross-sectional, descriptive, and analytical study. It was conducted over a period of five months among students at the Faculty of Medicine of Sfax using an online form that included sociodemographic data, medical history, lifestyle habits and the "Relationship Scale Questionnaire" (RSQ).
Results: The average age was 21.63 years. The distribution of students according to their attachment styles showed that avoidant attachment was the most prevalent (29%, n=150), and women exhibited more ambivalent attachment than men (p=0,031). Ambivalent attachment was significantly associated with sexual orientation (p=0,025). A significant link was demonstrated between parental marital status and avoidant attachment style (p=0,008). Indeed, an avoidant attachment style was more frequently found among students whose parents were separated or divorced. Ambivalent and disorganized attachment styles were associated with separation from the mother during the first five years of life (p=0,004 and p= 0,011) and separation from the father during the first five years of life (p=0,034 and p = 0,010). A correlation was found between repeating a year and avoidant attachment style (p=0,018). Single students were primarily avoidant (p=0,039), while married students showed more secure (p=0,019) and disorganized attachment (p=0,029).
Conclusions: In conclusion, the attachment styles developed in childhood, particularly in the context of parental separation and divorce, have significant implications for students at the Faculty of Medicine of Sfax.By addressing the impact of attachment styles, educators and counselors can better equip students to thrive both personally and professionally, ultimately enhancing their contributions to the medical field.

EPV0839

Attachment styles among students at the faculty of medicine of Sfax and childhood trauma

Y. Yaich[1]*, A. Bouallegui[1], H. Khiari[1], N. Ben Hamed[1], A. Hakiri[1], G. Amri[1] and R. Ghachem[1]

[1]Psychiatry B, Razi hospital, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1500

Introduction: Attachment styles, which describe the patterns of interpersonal relationships formed during early childhood, play a crucial role in shaping individuals' emotional and social functioning throughout life. Among students at the Faculty of Medicine of Sfax, understanding these attachment styles is particularly relevant, as they can influence academic performance, peer relationships, and overall well-being. Students who experienced adverse childhood events may display heightened anxiety, avoidance, or ambivalence in their relationships, potentially affecting their ability to connect with peers and mentors in the demanding environment of medical education.
Objectives: The purpose of this study was to evaluate the prevalence of different attachment styles among medical externs using the RSQ scale and to examine the relationship between these attachment styles and childhood trauma.
Methods: This is a cross-sectional, descriptive, and analytical study. It was conducted over a period of five months among students at the Faculty of Medicine of Sfax using an online form that included sociodemographic data, medical history, lifestyle habits and the "Relationship Scale Questionnaire" (RSQ).
Results: The average age was 21.63 years. The distribution of students according to their attachment styles showed that avoidant attachment was the most prevalent (29%, n=150), and women exhibited more ambivalent attachment than men (p=0,031). Ambivalent attachment was significantly associated with sexual orientation (p=0,025).
Students with an ambivalent attachment were more likely to be victims of verbal aggression during childhood (p=0.002), whereas students with a disorganized attachment were more likely to be victims of sexual aggression during childhood (p=0.020).This aligns with other studies that have shown that children who have been victims of abuse are more likely to develop insecure attachment, particularly disorganized attachment.
Conclusions: Understanding these dynamics is crucial for developing targeted support systems that promote emotional resilience and healthier relationships within the educational context. The findings suggest that students with insecure attachment styles, often stemming from adverse childhood experiences, may face unique

challenges in their academic and social environments. Further research is needed in that area.

Epidemiological models for the suicide rate of the Russian population in the period 1992-2022

A. Magay[1]* and V. Mitikhin[1]

[1]Mental Health Research Centre, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.600

Introduction: Suicides remain one of the most important problems of public health and society, being the most common reason for seeking emergency psychiatric care. The suicide rate is one of the most important indicators of the mental health of the population. Epidemiological models allow you to demonstrate the scale of problems and assess the resources to solve them.
Objectives: The construction of epidemiological models for the suicide rate of the Russian population in order to analyze the relationship of this indicator with demographic and socio-economic factors in the period 1992-2022.
Methods: The work uses data from Russian socio-economic statistics, materials from medical and research institutions and results published in scientific periodicals (see, [1] and references). In the formation of epidemiological models, the methods of systematic data analysis presented in the work [1] and statistical analysis in the framework of MS Excel were used.
Results: During the period under review, for the Russian population, there is an almost linear dependence (negative) of the suicide rate on the main integral factor - life expectancy (years) (for the Russian population). The correlation coefficient of this factor with the suicide rate is 0.959. The next most important influence on the suicide rate is the unemployment rate (correlation coefficient 0.764). Using regression analysis, one-factor and two-factor epidemiological models for the suicide rate from these factors were obtained. The obtained regression models are characterized by very high reliability with a coefficient of determination R^2 equal to 0.919 for the one-factor model and, accordingly, 0.943 for the two-factor model.
These results, obtained on the basis of data for the period of large-scale socio-economic and political reforms, allow us to offer a rational explanation for the observed rapid (in the period under review) deterioration of the mental health of the population. Conservative genetic mechanisms cannot fully explain such rapid variations in the mental health of the population. Consequently, the main weight in the study of mental disorders of the Russian population is given to demographic, socio-economic and cultural living conditions of the population, psychosocial stress, environmental factors and, possibly, epigenetic changes caused by them.
Conclusions: The obtained models make it possible to quickly monitor and predict the impact of demographic, socio-economic factors and changes in the staffing of psychiatric care on the suicide rate of the Russian population. 1. Mitikhin V., Yastrebov V. et al. *Neuroscience and Behavioral Physiology*. 2019; 49(2): 233-239. doi: 10.1007/s11055-019-00720-4

Training of Psychiatry and Child Psychiatry Residents : Ethical Aspects

S. Bourgou[1], R. Ghachem[1], S. Halayem[1] and G. Amira[2]*

[1]National College of Psychiatry and Child Psychiatry, Tunis and [2]Child psychiatry Department, Mongi Slim Hospital, La Marsa, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1501

Introduction: Ethical practices are fundamental to the training and professional development of psychiatry and child psychiatry residents. However, challenges such as stigmatization, discrimination, and ethical dilemmas in clinical and research settings can impact the quality of their training experience.
Objectives:
1. To assess the degree of exposure of residents to stigmatization during their residency training.
2. To explore the level of awareness among residents regarding the practice of ethics in their clinical and research activities.

Methods: This is a cross-sectional study conducted by the National College of Psychiatry and Child Psychiatry from January 13 to January 16, 2024. An anonymous Google Forms questionnaire about ethic aspects during during residency training was sent to psychiatry and child psychiatry residents via the college email and private groups.
Results: We received 71 responses. The participants had an average age of 29.9 years, with a sex ratio of 0.1. Among them, 50.7% were child psychiatry residents, and 49.3% were psychiatry residents. Residents reported experiencing discrimination in 49% of cases, with the following breakdown: from senior staff (61.1%), paramedical staff (47.2%), and doctors from other specialties (33.3%). The primary cause of discrimination was the residency level (56.3%). Residents reported experiencing discrimination in role distribution within the department (35.2%) and in scientific work (31%).
Regarding their thesis work, 8.5% of residents felt obliged in choosing their thesis supervisor, and 16.9% felt pressured in selecting their thesis topic. Residents submitted their thesis work to the local committee in 58.5% of cases, informed participants about the study in a satisfactory manner in 75.4% of cases, and obtained oral informed consent from participants (or their parents) in 46.2% of cases. The residents felt that training in psychiatric ethics was necessary in 94.5% of cases and that specific training in research ethics in psychiatry was necessary in 91.8% of cases.
Conclusions: Taking into account the various findings of our survey and raising awareness among different stakeholders, including doctors and paramedical team members, are essential measures to ensure that psychiatry and child psychiatry residents can complete their specialty training while adhering to fundamental ethical principles.

Euthanasia for psychic suffering: the psychopathological (f)law

M. Calmeyn[1,2,3]

[1]private practice, Loppem Zedelgem; [2]Superior Health Council, Brussels and [3]Postuniversity Center KUL, Kortrijk, Belgium
doi: 10.1192/j.eurpsy.2025.1502

Introduction: In countries where euthanasia is allowed it seems natural that it can also be applied to persons with psychiatric pathologies, euphemistically called 'psychic suffering'. Is it that self-evident? In society it still raises ambivalence. In court proceedings it's almost about psychopathological cases which can't be solved rightly in a judicial context. These examples are like seismographs detecting special vibrations. Metaphorically speaking several causes are at stake to explain those oscillations. One of them is discussed below. Psychopathology.
Objectives: Psychopathology as such is dynamic – not static. It is a self-organization of complex dynamic systems. The clinical reality and the theoretical grounds corroborate this assumption. This has consequences for the application of euthanasia in case of psychic suffering. Can it still be argued that a psychiatric disease is untreatable? That in the future no change is possible anymore? The objective is to explain that these questions are rhetorical.
Methods: The exploration of two theories leads to the understanding of the proposition, namely that psychopathology is a complex dynamic self-organization.
Results: First, anthropopsychiatry – an integrative theory and praxis of modern psychiatry, philosophy and psychoanalysis with the human(e) as the heart of the matter - states that the human being is intrinsically dynamic and unpredictable. So is the broken man lost in psychopathology. Second, complex living systems are dynamic, with coincidence and uncertainty – in present and future – as core of the systems themselves.
Conclusions: These findings are essential for the theory and practice of euthanasia for psychic suffering. The law only allows it when the psychiatric disease of a person is said to be incurable and not likely to change in the future. From the previous it is clear that this isn't the case. It's the flaw of the law in case of euthanasia for psychic suffering.
The importance is to realize these findings and acting accordingly. After all it is a matter of life or death, isn't it?

Assessment of Medical Decision-Making Competence in Emergency Settings: Application of a Validated Scale in a Case Study

V. Del Rio Peña[1]*, A. Pelegrí[1], M. Boadas i Gironés[1], A. Barnés Andreu[1], D. Vegas Renom[1], C. Fernández Alcobet[1], M. Aparicio Muñoz[1], C. Tablero Nadal[1], Á. Ferrer Alberti[1], F. Estrada Coma[1], E. Aguilar Morales[1], V. Soria Tomás[1] and D. Palao Vidal[1]

[1]Consorci Corporació Sanitària Parc Taulí de Sabadell, Sabadell (Barcelona), Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1503

Introduction: The assessment of competence for medical decision-making is a critical aspect in the care of patients with mental health disorders. Since patient autonomy is a fundamental pillar of medical ethics, evaluating their capacity to make informed decisions ensures respect for their rights while safeguarding their well-being. An accurate assessment of competence not only facilitates safer and more appropriate decisions for the patient, but also allows physicians to act ethically and legally. Understanding the tools and criteria for such assessments is essential to balance patient autonomy with the protection of their health.
Objectives: Identify factors that may influence a patient's competence for specific decisions.
Familiarize with validated scales for assessing patient competence. Identify strategies to improve competence in cases where necessary.
Methods: We present the case of a 65-year-old female patient without significant medical or psychiatric history, who was evaluated in the emergency department for cardiac tamponade, requiring urgent intervention via pericardiocentesis. At the time of the procedure, the patient refused the intervention due to severe pain, requesting voluntary discharge without undergoing further tests. Psychiatry was consulted to assess the patient's decision-making capacity. An interview was conducted using the MacCAT-T (MacArthur Competence Assessment Tool for Treatment) scale.
Results: A joint interview was conducted between the emergency medicine, intensive care, and psychiatry departments. The results indicated partial competence of the patient for this medical decision (understanding of the procedure and its impact on daily life, but high risk associated with the decision). The patient's family was involved in the decision-making process, and it was decided to extend the emergency department stay for two additional days to promote better patient competence.No psychopathology was found that impaired the patient's competence. Ultimately, it was determined that the patient had the necessary competence for this specific decision, and she was discharged home.
Conclusions: Interviews assisted by validated competence assessment scales, such as the MacCAT-T, can be a useful tool in challenging decision-making contexts in emergency situations, providing a more objective and ethical evaluation of patient competence.

EPV0843

EU and UK migration policies impeding mental health justice - a critical review

C. Diefenbach[1]

[1]Department of Psychiatry, Psychosomatic Medicine and Psychotherapy, Goethe University Frankfurt, University Hospital, Frankfurt am Main, Germany
doi: 10.1192/j.eurpsy.2025.1504

Introduction: Ongoing global conflicts have led to increasing forced migration and displacement. This rising numbers' trend has fueled discriminatory policies in the EU and UK, resulting in detrimental mental health consequences for refugees and asylum seekers (RAS) caused by post-migration stressors. These policies sharply contrast ratified treaties and conventions based on the Universal Declaration of Human Rights (UDHR).

Objectives: The review examines the infringement of RAS' right to health, focusing on the mental health consequences of post-migration stressors faced upon arrival in the EU and the UK. It analyses how these post-migration stressors reflect a violation of human rights (HR), tracing the evolution of human rights theory from natural law to contemporary universal principles. It investigates how post-migration stressors exacerbate psychiatric symptoms in an already vulnerable population present in the EU and UK. It seeks to understand whether the EU faces a moral cosmopolitan duty of humanitarianism towards RAS, exploring the ethical and legal obligations of the EU and UK under key international HR frameworks.
Methods: A systematic search was conducted across several databases, including PubMed, ScienceDirect, and GoogleScholar. The search comprised keywords such as human rights, cosmopolitanism, health justice, post-migration stressors, refugees and asylum seekers, common european asylum system and mental health. Boolean Operators AND and OR were applied. Exclusion criteria included non-English/German/Italian publications, papers focused on non-european asylum policies or refugee populations outside the EU and UK, and study protocols. Studies were synthesised to provide a comprehensive overview of post-migration stressors in the EU and UK and a philosophical deduction of human rights.
Results: Both the EU and UK violate international HR law by failing to ensure the right to health for RAS. Empirical studies from Greece, Italy, and Germany document that post-migration stressors —such as inadequate housing, poor living conditions, and delays in asylum procedures—exacerbate mental health conditions like depression, post-traumatic-stress disorder, and anxiety. The recent reform of the Common European Asylum System (CEAS) demonstrates the gap between legal commitments in international law and current migration policies. This further restricts access to asylum and (mental) healthcare, subjecting RAS to violence and inadequate care.
Conclusions: The EU's and UK's political and legal responses violate basic human rights of RAS, particularly their right to health, despite legal commitments to international HR treaties. This further exacerbates mental health conditions in RAS. A human rights-based approach, integrating mental health into migration policies, is crucial to protecting RAS' dignity and mental health. Until then, the EU and UK will continue to fall short of their moral and legal obligations.

Perceived stigma in AI-generated mental health imagery: an online study

J. Grimmer[1]*, N. Khorikian-Ghazari[1], L. Schoch[1], N. L. Hartmann[1], A. Hasan[1,2] and I. Papazova[1]

[1]Department of Psychiatry, Psychotherapy, and Psychosomatics, University of Augsburg, Medical Faculty and [2]DZPG (German Center for Mental Health), partner site München/Augsburg, Augsburg, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1505

Introduction: Artificial intelligence (AI) has enriched the everyday lives of many people and is used in a variety of ways, i.e. as a resource of medical information. One of the most popular AI functions is the generation of images of real-world settings. Recent research (Mei et al. ACM FAcct 2023; 1699-1710) has shown, that AI could reinforce prejudice and can be biased in its answers leading to stigmatization in the online world as well. This has dramatic consequences as stigma is known to affect mental health negatively (Pérez-Garín et al. Psychiatry Res. 2015; 228 325-331). Little is known, however, if and to what extend AI generated images reveal bias towards people with mental illness or corresponding institutions such as psychiatric clinics.
Objectives: The aim of this exploratory study is to investigate whether AI-generated images of psychiatric institutions, scenes, and severe mental illnesses are perceived as stigmatizing compared to other hospital scenes and severe illnesses from patients, mental health experts, and the general population in Germany.
Methods: Two researchers prompted three different AIs to generate various realistic medical scenes (prompts: person suffering from a severe mental illness, person suffering from a severe illness, mental health institution, hospital, psychiatric ward, hospital ward, incident in a mental health institution, incident in a hospital, electroconvulsive therapy session, cardiopulmonary resuscitation session). For each chatbot, one image per prompt was selected randomly for the following online survey. In a mixed subject design, participants were randomly assigned to one of three groups displaying the generated images of one AI. Then, they were asked to rate the images on SAM rating scales, adjective scales, to provide a title for the image, and to decide whether the image stigmatizes specific groups. The survey starts on November 2024 and a total sample size of 100 subjects is aimed for.
Results: Preliminary results will be presented at the congress.
Conclusions: This study examines the effects of AI-generated images on patients, experts and the general population. It attempts to find out whether and to what extent AI-generated images stigmatize people with severe mental illnesses and to what extent psychiatric institutions are portrayed realistically compared to general medical institutions and severe illnesses.

A correlational study of Greek therapists' responses to sexual and erotic feelings during psychotherapy

M. Lazaridou[1]* and I. Sofroni[1]

[1]ICPS, Athens, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1506

Introduction: Erotic and sexual feelings within therapy are complex phenomena which provide important information on aspects of both the client's and the therapist's relational self and hence bear great significance for the outcome of the therapy. The present correlational study examined Greek therapists' responses to sexual and erotic feelings during psychotherapy.

Objectives: The following hypotheses arising from the relevant literature were formulated so as to explore the above aims of the study empirically.
Hypothesis 1: Women therapists experience more negative feelings than males.
Hypothesis 2: There will be a statistically significant difference between males and females in experiencing gratification feelings.
Hypothesis 3: Therapists with psychodynamic training will experience lower levels of dysphoric feelings compared to therapists of other orientations.
Hypothesis 4: The proportion of psychodynamic therapists that disclose sexual and erotic feelings towards a client in supervision will be significantly higher than that of therapists of other orientations.
Since the present is the first conducted in the cultural environment of Greece and the first one correlating quantitative data from a psychometric test with handling of erotic and sexual feelings questions, the study will investigate in addition further questions correlating years of experience, sexual orientation, therapist age, with measures of emotional reactions.
Methods: Over two months, 139 adult psychotherapists completed an anonymous online survey. The demographics and attitudes of psychotherapy participants toward sexual and erotic feelings were collected. The Therapists' Attitude toward Sexual and Erotic Feelings Scale measured emotions.
Results: Results showed that male therapists felt more enjoyment than females, who were more afraid of the erotic or sexual. When controlling for therapist age, gendered difference in terror disappears. CBT and integrative therapists, who scored high on Aversion, also experienced higher threat levels. The present investigation showed no correlation between psychotherapeutic orientation and therapist erotic or sexual disclosure to supervised clients. Additional secondary analysis was done.
Conclusions: The findings of the study imply that therapists' emotional reactions to sexual and erotic sensations in psychotherapy are multifaceted and relate to their professional and personal identities. Psychotherapeutic training, licensure, supervision, and therapist implications are examined.

Involuntay hospitalization for purpose of treatment - experiences and viewpoints from patients with schizophrenia

S. K. Linstow[1]* and A. Urfer-Parnas[1]

[1]Mental Health Center Amager, København, Denmark
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1507

Introduction: Coercive methods in psychiatry have been a matter of intense public debate for many years. Involuntary hospitalization (IH) for purpose of treatment is a major intervention with the purpose of providing care for individuals, who, during psychotic episodes, are not immanently dangerous to self or others but unable to take care of themselves and at risk of significant deterioration. The intervention is, however, not yet fully examined from patients' perspectives.
Objectives: To examine views and experiences of patients with schizophrenia, involuntary hospitalized in a psychotic state for purpose of treatment.
Methods: Nine patients were interviewed at discharge with a semi-structured instrument on the following: If IH can be justified in general and in the context of their own admission, how IH can be prevented, and finally, how they would react if confronted with a person in a similar condition as their own as described in their chart at the time of IH. The patients were reinterviewed after the interviewer had read their chart to obtain their reactions on others' descriptions of their condition.
Results: None of the patients considered their involuntary hospitalization necessary in its entirety or as an act of caregiving, and they believed that community support could have prevented it. Some described improvement in their condition attributed not to the hospitalization itself but to positive interactions with staff and other patients. They did not view their condition as psychotic but rather as angry, stressed, or even entirely well. They stressed that psychiatric patients should be able to refuse treatment in the same way as patients with somatic illnesses can.
Conclusions: We discussed the patients' experiences and negative view of IH, how their opinions can be related to the concept of psychosis and insight, possibilities of increased community support, and ethical issues concerning caregiving when the person being cared for does not feel a need. A better understanding of the role of psychopathology and patients' subjective experiences may provide a foundation for a patient-doctor dialogue on joint interventions in the future. More options for community support and acute outpatient interventions could be a possible way to reduce IH of patients, who are not dangerous to self or others.

The Hidden Dangers of Diagnostic Overshadowing in Psychiatric Patients: A Case Study

I. C. Mandras[1]*, A. L. Comsa[1] and M. M. Manea[1]

[1]Clinica Psihiatrie 3, Spitalul Județean de Urgență Cluj, Cluj-Napoca, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1508

Introduction: Diagnostic overshadowing, or the tendency to attribute physical symptoms to mental illness, poses a significant risk to psychiatric patients, significantly delaying diagnostic and treatment possibilities. This case study highlights the potentially life-threatening consequences of dismissing physical complaints in patients with a history of mental health disorders.
Objectives: To examine the impact of diagnostic overshadowing on patient care and outcomes, emphasizing the need for comprehensive, unbiased medical assessment, regardless of psychiatric history.
Methods: We present the case of a 72-year-old female patient with an extensive history of multiple psychiatric admissions, primarily

for somatization and depressive episodes. The patient's journey began with an initial admission in our psychiatric service. However, her condition rapidly degenerated, as she developed chest pain, leg numbness, and digestive issues. These symptoms were initially attributed to her psychiatric conditions by the internal medicine team, leading to a critical delay in appropriate medical intervention.
Results: As a consequence, the patient's condition deteriorated rapidly, culminating in a severe septic state. Further investigation revealed that the sepsis had a pulmonary origin, with Serratia marcescens identified as the causative pathogen. This underscores the potential for seemingly benign symptoms to mask serious underlying infections in vulnerable populations. The patient's case was further complicated by the emergence of several severe medical conditions, including toxic hepatitis, cardiomyopathy, and valvular insufficiencies, highlighting the potential for cascading health issues when initial symptoms are not thoroughly investigated. In the course of treatment, the patient experienced additional complications arising from medical interventions, most notably drug-induced hepatotoxicity, serving as a reminder of the delicate balance required in managing complex cases and the potential for treatment-related adverse events to further complicate patient care.
Conclusions: This case study underscores the critical importance of conducting thorough and unbiased medical evaluations in psychiatric settings, or in cases where psychiatric history is present. It vividly demonstrates how preconceived notions and unconscious biases regarding psychiatric patients can lead to delayed diagnosis and treatment of serious medical conditions, potentially resulting in life-threatening consequences. The case serves as a wake-up call for healthcare providers to approach each patient with an open mind, regardless of their psychiatric comorbidities.

Effects of Mental Health Stigma on Clinical Decision-Making in the Context of Digital Medicine

I. Papazova[1]*, N. L. Hartmann[1], J. Grimmer[1], A. Hasan[1,2] and N. Khorikian-Ghazari[1]

[1]Department of Psychiatry, Psychotherapy and Psychosomatics, Medical Faculty, University of Augsburg, BKH Augsburg and [2]DZPG (German Center for Mental Health), partner site München/Augsburg, Augsburg, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1509

Introduction: People with mental illness often experience stigma and discrimination, which can reduce treatment outcomes and quality of life. Numerous studies have shown that stigmatizing attitudes among physicians negatively affect both psychiatric and somatic care. Recently, technological advancements have led to the emergence of digital medicine as a new avenue for health care. However, little is known about how stigmatizing attitudes toward patients with mental illness might impact clinical decisions in the context of digital medicine
Objectives: This study aims to assess how implicit and explicit stigma against mental illness among medical students and general practitioners affects their decision for recommending treatment through a digital mHealth app.
Methods: A total of 62 general practitioners and 60 medical students participated in the anonymous online survey. After providing demographic information, participants reviewed two case vignettes: one depicting a patient with a comorbid mental and somatic illness, and the other depicting a patient with only a somatic illness. Participants rated, on a scale from 1 to 10, the likelihood of prescribing an mHealth app designed to enhance treatment of the somatic disease. The Social Distance Scale (SDS) and the Implicit Association Test (IAT) were used to measure explicit and implicit stigma, respectively. The IAT is a computer-based task that assesses implicit bias regarding the perceived incompetence associated with psychiatric disorders compared to somatic disorders.
Results: On average, participants were more likely to prescribe an mHealth app for patients with only a somatic illness than for patients with both somatic and comorbid mental illness ($p < .001$). Furthermore, implicit stigma was a significant predictor of participants' preference to treat patients with somatic over mental disorders ($p = .013$). There were no group differences in the IAT score.
Conclusions: Our findings indicate a bias against people with mental illness among both medical students and physicians, even within the context of digital medicine. Future research is needed to further examine the scope and impact of stigmatizing attitudes on patient health care outcome.

Use of Physical Restraint in Psychiatry: Attitudes of Healthcare Providers and Ethical Considerations

N. Sghaier[1]*, W. Belaguide[1], N. Kalboussi[1], S. Halleb[1], H. Ben Garouia[1] and J. Mannai[1]

[1]Psychiatry Deprtement, Ibn Jazzar university, Kairouan, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1510

Introduction: Physical restraint in psychiatry is a widely used practice intended to protect patients from harming themselves or others, guided by strict procedures and monitoring. Recent reports and legal updates aim to regulate its use more closely
Objectives: This study assesses the extent of physical restraint use and explores healthcare workers' perceptions and experiences regarding this practice, focusing on ethical issues.
Methods: Between April and May 2024, we conducted a cross-sectional descriptive study involving healthcare staff from psychiatry departments across Tunisia, including hospitals in Sousse, Monastir, Kairouan, Mahdia, Sfax, and Tunis. Participants were surveyed using a literature-based questionnaire, and data were analyzed with SPSS21 software.

Results: The study included 16 men (28%) and 43 women (72%), predominantly aged 20-30 years (72%), with most participants from Kairouan (52%). Sixty-four percent of staff viewed physical restraint as a therapeutic tool. Opinions on its impact on the therapeutic alliance and physical integrity were mixed, with 33% considering it dehumanizing. The most common emotions reported were fear (58%) and pity (39%), while anxiety was the least reported (9%). Coping strategies included rationalization (63%) and discussing experiences with colleagues. Sixty-six percent of staff reported encountering ethical dilemmas, with varying frequencies. Views on patient consent were divided, with 42% opposing seeking consent, and differing opinions on obtaining consent from patients with good insight or in relapse.
Conclusions: The study reveals diverse and complex attitudes towards physical restraint in psychiatry. It underscores the need for continuous training, ethical reflection, and efforts to align practices with ethical standards to mitigate negative impacts on staff.

Respect for Autonomy in Patients with Altered Reality Judgment

M. F. Tascon Guerra[1,2*], E. Ramos Garcia[1], M. V. Lopez Rodrigo[1], Y. D'hiver Cantalejo[1] and M. Palomo Monje[1]

[1]Psychiatry, Hospital Ntra Sra del Prado, Talavera de la Reina and [2]Psychiatry, SESCAM, Talavera de la Rein, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1511

Introduction: Bioethics is a discipline based on ethical principles aimed at guiding healthcare practice. Four fundamental principles are defined: autonomy, non-maleficence, beneficence, and justice. The first of these is autonomy, which expresses the ability of each individual to make decisions regarding their own health.
Objectives: This case presents a 47-year-old male patient diagnosed with schizophrenia, legally incapacitated and under guardianship by a Foundation. He has no awareness of his illness, is on pharmacological treatment in a controlled environment, and does not cooperate for testing or procedures. He has been involuntarily admitted to the Psychiatry Unit since 2022, awaiting transfer to a residential facility.
Methods: In recent months, the patient has exhibited dysphagia and constitutional syndrome. A tumor suspicious for malignant oropharyngeal neoplasm is identified. He is informed in simple terms, in the presence of his legal guardians, that he has a tumor with malignant characteristics, which will grow over time, eventually blocking his airway and leading to death. Testing is necessary to reach a diagnosis and propose treatment.
Results: The patient repeatedly and firmly expresses his desire not to undergo any tests or treatment. In coordination with the Psychiatry and Otorhinolaryngology services, and in consultation with the Bioethics Committee, it is decided to respect the patient's autonomy and his decision to refuse tests or invasive procedures. At all times, comfort measures and pain management are provided.
Conclusions: Autonomy is the ability to have control over one's own life. Every person has the right to make decisions about their health. Mental impairments can alter a person's autonomy, as they hinder the conscious process of decision-making.
The dignity of the person plays a key role in the protection of life, physical and psychological integrity, and the freedom of individuals with mental disorders.

The Use of Clozapine in Incarcerated Persons with Borderline Personality Disorder

N. Divac[1], S. Čekerinac[2*] and D. Sekulić[2]

[1]Dept. of Pharmacology, Clinical Pharmacology and Toxicology, University of Belgrade, Faculty of Medicine, Belgrade and [2]Dept. of Psychiatry, General Hospital of Sremska Mitrovica, Sremska Mitrovica, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1512

Introduction: Borderline personality disorder (BPD) is common in incarcerated persons. Psychiatric medications are prescribed in prisons for the treatment of psychiatric illnesses, but also for the reductions of symptomes triggered by the specific conditions and environment. The use of psychotropic medications in incarcerated persons is beneficial in terms of prevention of aggression and violent outbursts. Clozapine, as the most effective antipsychotic for aggressive and violent behavior could be very useful in forensic population, but is avoided due to adverse effects and the need for regular monitoring (Cekerinac et al. IJOPH 2024).
Objectives: The objective of this reserch is to analyze the use of clozapine among incarcerated persons with BPD, and to evaluate the incidence of adverse effects.
Methods: A cross-sectional, epidemiological survey was used to measure the prevalence of antipsychotic prescribing among adult prisoners in Sremska Mitrovica Prison (Serbia) in 2020.
Results: Of 1280 incarerated persons, (all men, average age 36.3 years), 80 (6.25%) were prescribed an antipsychotic. More than a half (N=44) were prescribed clozapine, but in doses lower than recommended for approved indications. None of them had an approved indication for clozapine, so this can be defined as off-label use. The average dose of clozapine was 51.14 mg/day, while the recommended maintenance dose is 300–450 mg/day. The other commonly used antipsychotic in this population was olanzapine (N=30). No cases of elevated white blood cells count were noted during regular monitoring. For the broader purpose of the study, metabolic parameters were assessed for the users of both antipsychotics, BMI, plasma glucose levels, plasma cholesterol levels and plasma triglyceride levels. Only the mean values of the levels of glucose and triglycerides in the plasma were slghtly elevated compared to the referent values of the Prison Hospital (Table 1.).
Table 1. Metabolic parameters in inmates prescribed olanzapine and clozapine vs. inmates who were prescribed metabolically inert antipsychotics

Metabolic parameter (mean±SD)	Treated with clozapine or olanzapine	Referent values
BMI	26.147±4.180	25.0-29.9 (healthy weight)
Glycemia mmol/L	5.783±0.849	3.9-5.6
Cholesterol mmol/L	4.413±0.953	<5.17
Triglycerides mmol/L	2.433±1.380	<1.7

Conclusions: We justify the off-label use of clozapine in prison settings due its benefits in reducing violence and aggression; however, further research would be necessary to clarify does the use of clozapine in incarcerated persons cause behavioral improvements that could reduce recidivism and improve post-imprisonment outcomes. The prevalence of adverse effects is rare; however, that is possibly due to low doses of the prescribed antipsychotics and specific prison settings in terms of dietary options and physical activity, as well as the average young age of the inmates.

Involving forensic psychiatric patients in research - experiences, challenges and lessons learnt after one year of the PART Advisory Board

E. Drewelow[1]*, M. Daum[2], K. Gerullis[1], I. Kilimann[2], O. Biernetzky[3], S. Teipel[3], P. Walde[4] and B. Völlm[1]

[1]Clinic for Forensic Psychiatry; [2]Clinic for Psychosomatic Medicine and Psychotherapy, Rostock University Medical Center; [3]Deutsches Zentrum für Neurodegenerative Erkrankungen (DZNE), Rostock and [4]LVR-Institut für Forschung und Bildung, Köln, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1513

Introduction: Participatory research can enhance the relevance, quality, and impact of studies, increase recruitment, and optimize research methods. It can also help to secure third-party funding,. The participatory inclusion of forensic psychiatric patients in research has so far primarily been implemented in the UK. With the establishment of the PART advisory board, founded in December 2023, this gap is intended to be closed in Germany by creating sustainable, previously lacking structures for the involvement of forensic psychiatric patients. The acronym PART refers to participation/ participatory. In the PART advisory board, people with lived experience and researchers actively cooperate in projects in the field of forensic psychiatry. In preparation for their role, people with lived experience received training where they were provided with knowledge and skills for their work. The board has now advised several research projects and issued recommendations.
Objectives: The purpose of this presentation is to critically reflect on the first experiences and consider how to incorporate these insights to improve the structure and working methods of the advisory board: What experiences have researchers, people with lived experience and those presenting their research projects made? How were participants involved? What impact did the advisory board have on specific research projects? What challenges arose, and how were they addressed? What are the lessons learned so far?
Methods: To answer these questions, various evaluation tools were used. These include feedback questionnaires from participants assessing each advisory board meeting and project presentation, interviews with participants at least two times throughout the project, statements from the advisory board to project presenters, and responses from the presenters on how the board's recommendations were implemented. Additionally, the perspectives of involved project staff were considered.
Results: By the time interim results are presented at the EPA Congress 2025, the PART Forensic Advisory Board will have met at least 12 times and at least five research projects will have been presented to the board and received its recommendations. It has already become clear that involving participants, especially in forensic psychiatric settings, requires specific framework conditions. These address overarching structural aspects, disease specific patient relevant needs, as well as knowledge- and method-based issues relevant to participants.
Conclusions: Even at this stage, the advisory board can be considered successfully implemented. Participatory research with people with lived experience in forensic psychiatric settings is possible, feasible, and above all, meaningful.

Disclosure of Interest: None Declared

EPV0858

Gambling among forensic psychiatric patients: A prevalence study

J. W. Eriksen[1]*, L. U. Sørensen[2,3], S. Kristiansen[4], M. D. Terkildsen[2,3,5], R. M. Hansen[5], T. Marcussen[1] and L. Frostholm[3]

[1]The Reseach Clinic on Gambling Disorder, Aarhus University Hospital; [2]Department of Forensic Psychiatry, Aarhus University Hospital Psychiatry; [3]Department of Clinical Medicine, Faculty of Health, Aarhus University, Aarhus N; [4]Department of Sociology and Social Work, Aalborg University, Aalborg and [5]DEFACTUM, Central Denmark Region, Aarhus N, Denmark
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1514

Introduction: While gambling problems are increasingly recognized as a public health concern, knowledge of the prevalence and impact within psychosocially vulnerable populations is scarce. Never before has the prevalence of gambling problems been studied in a forensic psychiatric patient population. Given the risk for gambling problems to exacerbate existing mental health conditions, cause financial strain, and contribute to criminal behavior, understanding its prevalence and associated factors within this population is critical.
Objectives: The study aims to estimate the prevalence of gambling behavior and gambling problems among forensic psychiatric patients in Denmark and compare the results to the general Danish population. Additionally, the study seeks to identify associations

between psychosocial and demographic variables and the occurrence and severity of gambling problems. Lastly, the study will explore gambling motives and their relation to gambling problems in this patient population.
Methods: This observational, cross-sectional study will include inpatients and outpatients in Central Denmark Region forensic psychiatric care and inpatients in Capital Denmark Region forensic psychiatric wards from June 1 to December 31, 2024. Participants must be 18, and speak Danish, English, or Greenlandic. Data will be collected via self-report questionnaires and electronic patient records. Key measures include gambling behavior (past year gambling, frequency, and expenditure), gambling problems (the Problem Gambling Severity Index), and gambling motives (the Gambling Motives Questionnaire-Financial).
Results: Data collection ends by December 31, 2024; preliminary findings will be presented at the conference.
Conclusions: Results will provide valuable insights into the prevalence and characteristics of gambling problems in this population, informing clinical care and potentially guiding the development of targeted interventions. By highlighting the need for attention to gambling issues in forensic psychiatric settings, the study may enhance rehabilitation and recovery efforts and successful discharge by addressing potential risk factors for recidivism.

Disclosure of Interest: None Declared

EPV0859

Smoking, Obesity, and Metabolic Syndrome in Two High Security Settings

G. Goktas[1,2*] and I. Jeandarme[1]

[1]Medical Director and [2]FPC Antwerpen, Antwerp, Belgium
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1515

Introduction: Two high security Forensic Psychiatric Centers (FPC) were implemented in the last decade in Flanders (FPC Ghent and FPC Antwerp). FPCs provide court[1]ordered treatment for forensic psychiatric patients (called "internees") that have committed a criminal offense related to their psychiatric disorder and who are at a high risk for recidivating.
Objectives: Treatment is often mandatory and lengthy, and per[1]sonal rights are highly restricted, which has an impact on treatment motivation and overall patient wellbeing (Lutz et al., 2022). While the Risk Need Responsivity (RNR) model - which focuses on risk reduction – was and still is the prominent model for offender rehabili[1]tation, other aspects are currently given more atten[1]tion. This includes the Good Lives Model (GLM) and the recovery movement, that aim at improving the achievement of skills necessary to maintain a good live and give meaning and value in one's existence (Lutz et al., 2022).
Methods: Data collection and statistical analyses The descriptive analyses of categorical and continuous variables was done using SPSS version 28. Valid per[1]centages were given. Assumption testing was per[1]formed and found that the data were not eligible for parametric examination. The significance level was set at .05.
Results: Weight and BMI At the initial measurement, the mean weight was 89.3 kg (SD ¼ 21.64, range ¼ 46–222 kg). The mean weight at second measurement was 92.6 kg, with a standard deviation of 21.90 and a range of 46.6–185.6. The second weight measurement occurred 812.2 days or 2.2 years (SD ¼ 552.39, range ¼ 7–3084 days) after the initial measurement. The weight difference between the two measurements ranged from a weight loss of 53.8 kg to a weight gain of 51.6 kg and showed a mean weight increase of 2.2 kg (SD ¼ 10.41)1
Conclusions: The overall conclusion of the study is that obesity, MetS, smoking, as well as substance misuse are highly prevalent among our high security population. These are all risk factors associated with somatic morbidity and mortality. Our study showed that obesity and MetS were found across psychiatric diagnoses and the presence of metabolic syndrome was not limited to the use of SGA.

Disclosure of Interest: None Declared

The Utility of Carbohydrate-Deficient Transferrin (CDT) Test for Regranting Driver's License After Repeat Drunk-Driving in Taiwan

M.-H. Hsieh[1*], R.-P. Lee[1] and S.-C. Huang[1]

[1]Psychiatry, Tungs' Taichung MetroHarbor Hospital, Taichung City, Taiwan, Province of China
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1516

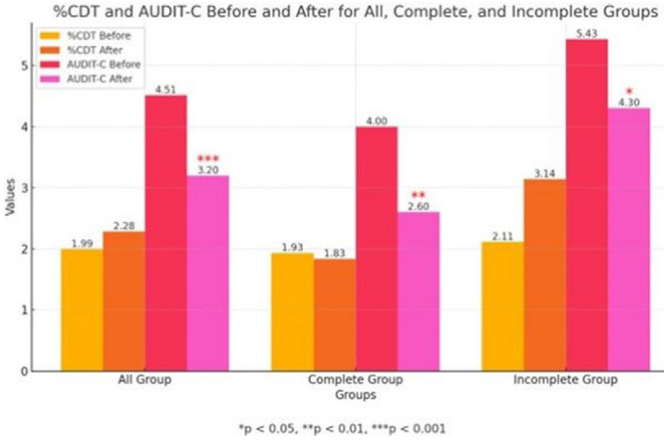
Introduction: Carbohydrate-Deficient Transferrin (CDT), a biomarker for excessive alcohol consumption, has been used in driver's license regranting programs in the UK and other European countries, but relevant data is lacking in Taiwan. This study collected % CDT data from repeat drunk driving offenders to monitor their alcohol consumption and aims to provide local data to inform policies in Taiwan.
Objectives: The objective of this study is to assess whether alcohol consumption decreases over a 12-month period, as measured by % CDT values and Alcohol Use Disorders Identification Test - Consumption (AUDIT-C) scores.
Methods: Study Design
This study was conducted from 2020 to 2023, involving 65 recidivist drunk drivers whose licenses had been revoked and who sought to reapply. Participants were referred to our hospital for a one-year, monthly evaluation and intervention program. Data were collected on gender, age, marital status, education level, employment status, years of alcohol consumption, primary type of alcohol consumed, DSM-5 severity, AUDIT, and AUDIT-C scores. Blood tests, including GGT, AST, ALT, triglycerides, cholesterol, and %CDT, along with AUDIT-C assessments, were conducted at the 1st, 4th, 7th, and 11th evaluations.

Results: Basic demographic information is shown in Image 1. There was no significant difference in %CDT before and after the intervention (p = 0.332), with values of 1.99% and 2.28%, respectively. Among 42 participants who completed the 12-month intervention, %CDT showed no significant change (p = 0.46; 1.93% vs. 1.83%). For 23 participants who did not complete the intervention, %CDT also showed no significant difference (p = 0.219; 2.11% vs. 3.14%). However, AUDIT-C scores significantly decreased across all groups. The total group's scores dropped from 4.51 to 3.20 (p = 0.00091), the completion group from 4.00 to 2.60 (p = 0.011), and the non-completion group from 5.43 to 4.30 (p = 0.025). These results are shown in Image 2, and the correlations between baseline variables are displayed in Image 3.

Image 1:

Demographics of Repeat Drunk-driving Offenders (N=65)	
Gender	Men: 61 (93.9%), Women: 4 (6.1%)
Age (Mean: 46.3 years)	20-34: 3 (4.6%), 35-49: 38 (58.5%), 50-64: 23 (35.4%), 60+: 1 (1.5%)
Marital Status	Married: 35 (53.9%)
Education Level	Elementary: 2 (3.1%), Junior High: 16 (24.6%), High School: 42 (64.6%), College: 5 (7.7%)
Job Status	Full-time: 56 (86.2%), Part-time: 2 (3.1%), Unemployed: 7 (10.7%)
DSM-5 Severity	Not meet: 15 (23.0%), Mild: 20 (30.8%), Moderate: 17 (26.2%), Severe: 13 (20.0%)
AUDIT Scores (Mean: 9.32)	Low-risk: 25 (38.4%), Hazardous: 30 (46.2%), Dependence Likely: 10 (15.4%)
Drinking Years	<5 years: 16 (24.6%), 5-10 years: 9 (13.8%), 11-15 years: 8 (12.3%), 16-20 years: 7 (10.8%), >20 years: 25 (38.5%)
Drinking Type	Beer: 36 (55.4%), Kaoliang: 11 (16.9%), Whiskey: 6 (9.2%), Paolyta: 6 (9.2%), Abstained: 4 (6.2%), Medicinal liquor: 2 (3.1%)

Image 2:



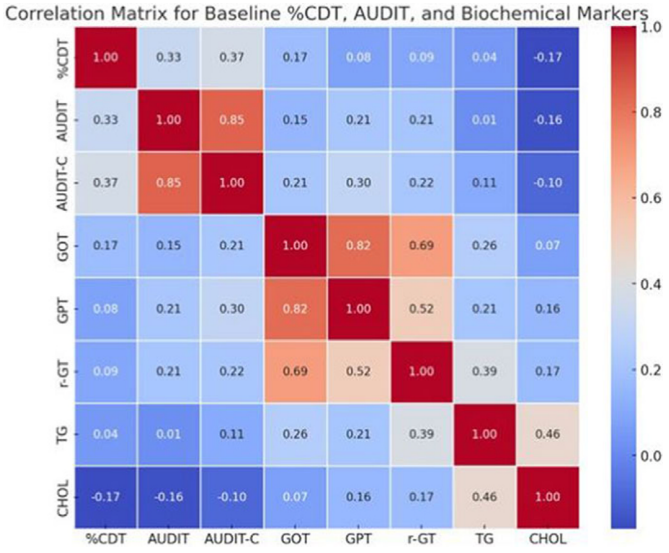


Image 3:

Conclusions: Our study found that monitoring drunk-driving recidivists with %CDT every three months did not yield a statistically significant change in %CDT, but did result in a significant reduction in AUDIT-C scores. Fleming et al. (2004) suggest that psychological pressure from long-term biomarker monitoring may have a therapeutic effect, with bimonthly CDT follow-ups potentially beneficial. Thus, using %CDT for license reinstatement is feasible, though adjustments to assessment intervals and inclusion of other biomarkers should be considered.

Fleming et al., Alcohol Clin Exp Res 2004; 28: 1347–55.

False positive urine drug test for tricyclic antidepressants attributed to quetiapine treatment

E. Routsi[1], M. Kousounadis[1], L. Lymperopoulos[1] and N. Kokras[1]*
[1]First Department of Psychiatry, National and Kadopistrian University of Athens, Eginition Hospital, Athens, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1517

Introduction: Quetiapine is a serotonin-dopamine antagonist widely used for the treatment of bipolar disorder and schizophrenia. Patients with bipolar disorder and schizophrenia are also at high risk of drug abuse. Illicit substances are often traced in such patients during manic and psychotic episodes. Urine drug tests are commonly used to detect illicit substance use during hospital admissions.
Objectives: We report a case of an adult male patient treated with 600mg o.d. quetiapine who falsely tested positive for tricyclic antidepressants in a routine urine drug test

Methods: A male patient with a prior history of alcohol, cannabis and cocaine abuse acutely developed psychotic-like symptoms (persecutory delusions, psychomotor retardation, social withdrawal) and attempted to commit suicide. He was admitted to our psychiatric hospital, and he denied illicit drug use during the last 5 months.
Results: The patient was treated with quetiapine monotherapy, progressively titrated up to 600mg o.d. As a routine procedure and because of his personal history of drug abuse, he has been subjected to a urine drug test, which revealed positive results for tricyclic antidepressants. Due to uncertainty whether he abused tricyclic antidepressants prior to this admission, a second test was ordered after two weeks of quetiapine monotherapy and close inpatient monitoring, which was also positive for tricyclic antidepressants.
Conclusions: Quetiapine has a three-ringed chemical structure which shares similarities with tricyclic antidepressants. in vitro tests proved cross-reactivity of quetiapine and tricyclic antidepressants with some commercially available immunoassays. However it is not clear if the cross-reactivity is due to quetiapine or its active metabolites. In any case, the interpretation of a urine test positive for tricyclic antidepressants should take into account the possibility of such cross-reactivity with quetiapine, especially in cases of suspected drug overdose when the urine test is used to deduct the possible offending drug. Moreover, this cross-reactivity might be eploited in cases of suspected non-adherence to quetiapine treatment.

The assessment of decision-making ability in the forensic evaluation of capacity for civil conduct in patients with schizophrenia

W. Li[1]

[1]Department of Forensic Psychiatry, Academy of Forensic Sciences, Shanghai, China
doi: 10.1192/j.eurpsy.2025.1518

Introduction: Patients with schizophrenia often require civil capacity assessments when participating in civil activities. The primary focus of the assessment involves evaluating patients' understanding of the issues at hand, their awareness of potential choices and the corresponding outcomes, and their ability to make decisions after considering the advantages and disadvantages. As such, the ability to make decisions is the fundamental neuropsychological mechanism underlying civil activities.
Objectives: This study systematically reviewed existing research on decision-making ability in patients with schizophrenia.
Methods: Both major international and Chinese databases were systematically searched. Relevant studies were summarized in aspects of the assessment, neuropsychological mechanisms, and neurobiological mechanisms of decision-making ability in patients with schizophrenia.
Results:

1. The most frequently employed experimental paradigms in studies focusing on economic decision-making include the Iowa Gambling Task (IGT) and the Game of Dice Task (GDT). Patients with schizophrenia performed significantly worse on the IGT compared to healthy individuals, often overestimating immediate gains and losses while failing to learn from the frequency of wins. There are relatively few studies utilizing the GDT, and the findings are inconsistent across studies.
2. Cognitive domains related to the decision-making ability in patients with schizophrenia could be executive function, verbal memory, and working memory. Psychiatric symptoms related to the decision-making ability include diminished motivation, lack of interest, depressive symptoms, and negative symptoms. Moreover, emotion plays a critical role in decision-making behaviors. Decision-making ability can also be influenced by medication and the overall severity of the illness; however, some studies found no association between decision-making ability and psychiatric symptoms, the illness stage, or medication usage.
3. Imaging studies consistently indicate that the prefrontal cortex is a critical brain region associated with decision-making abilities. Brain areas such as the orbitofrontal and ventromedial prefrontal cortex, amygdala, frontoparietal cortex, medial prefrontal cortex, dorsomedial prefrontal cortex, bilateral thalamus, and the left dorsal anterior cingulate cortex may play a role in decision-making processes in patients with schizophrenia. Nonetheless, some research found no association between decision-making ability and the functioning of the dorsomedial prefrontal cortex.

Conclusions: Deeply exploring the neuropsychological and neurophysiological mechanisms behind decision-making ability can help the understanding of the decision-making behavior of patients with schizophrenia in civil activities and can benefit forensic evaluation of civil capacity.

EPV0863

Outpatient compulsory observation and treatment by a psychiatrist: Russian perspective

V. V. Motov[1]

[1]Psychiatry, Social House "Stupino" (The Institution for Chronic Mental Patients with Disability) of The Department of Labor and Social Protection of the Population of the City of Moscow, Stupino, Russian Federation
doi: 10.1192/j.eurpsy.2025.1519

Introduction: Outpatient compulsory observation and treatment by a psychiatrist (OCOTP) is, according to Russian Law, a coercive measure of medical nature. It was put into effect in 1997 and may be assigned by the court to persons suffering from mental disorders who have committed criminal offenses. Forensic psychiatric examination is a mandatory condition for the court to make a decision.
Objectives: To provide an overview of (1) the purposes of OCOTP, (2) the differences between OCOTP and outpatient mandatory psychiatric treatment, (3) the basis for judicial decisions to order and terminate OCOTP, the duration of OCOTP, and its effectiveness.
Methods: An analysis of scientific publications and professional literature on the topic and my own practical experience as a forensic

psychiatrist who recommended such a measure to the court, and the treating psychiatrist who carried it out in a mental institution.
Results: OCOTP may be imposed by the court (1) in relation to defendants found NGRI, who committed socially dangerous acts primarily in a state of "temporary mental disorder", (2) following completion of compulsory inpatient treatment of an insane person, (3) as a preventive measure in conjunction with punishment when the offender is found guilty but has a mental disorder that can be treated on an outpatient basis. OCOTP is ordered for an indeterminate period, and the court considers its extension or termination annually.
Conclusions: OCOTP is an evolving concept and the topic of discussion in professional literature.

Training Police Officers how to Interact effectively with those who have Autism

V. Murphy[1]*, S. Abbott[2] and G. Gulati[3]

[1]Psychiatry, University College Cork, Cork, Ireland; [2]Co-Reponder Training, William James College, Boston, United States and [3]Medicine, University of Limerick, Limerick, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1520

Introduction: There is growing awareness of the need for Police Officers to develop skills to assist those who have Autism. The development of skills is essential for a positive outcome, be it managing an emergency call out, making an arrest or interviewing a victim of crime. This is being championed by the development of co-responder teams which consist of a Police Officer and a Mental Health Professional who are dedicated to responding to emergency calls that may have a mental health component. These teams report a high rate of call outs involving those with Autism and frequently request further training in the area.
Objectives: To develop a training pilot study in Ireland which could be expanded to an international cohort of Police Officers and co-responder teams in the United States.
Methods: We were invited to train a small group of Irish Police Officers. We used the opportunity to obtain feedback which we then used to identify common training needs and used to improve the presentation. This was then delivered to the Framingham Police, Boston, USA and a group of co responder trainees. Feedback was again sought and used to improve the presentation to better address the needs of the group. A presentation was delivered to a conference for those who co-ordinate co-responder teams in Law Enforcement, Universities and Colleges in the United States and feedback sought.
Results: In the initial training to Irish Police Officers, feedback demonstrated improvement with significant *p*-values in all domains examined with questions e.g. 'I understand the common difficulties those with Autism experience' and 'This training will help me in my day to day work'. The feedback from the conference demonstrated significant interest and engagement in the training with questions e.g. 'The program maintained my interest' and 'The presenters responded to the questions and needs of the attendees'.
Conclusions: There is growing recognition of the need for Police Officers to have the skills to recognise, communicate with and support those with Autism. Our program has demonstrated a need and interest of Police Officers and co-responder teams for training in this area. We have also demonstrated effectiveness of the training using feedback from the attendees.

EPV0865

Significance of forensic perpetrators with diagnosis of dementia

L. Mužinić Marinić[1]* and I. Marinić[1]

[1]Department of Psychiatry, Dubrava University Hospital, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1521

Introduction: Although criminal behavior is not expected in the elderly, especially those diagnosed with dementia, it is important to keep in mind the potential forensic significance of dementia. Also it is especially important to focus attention on the participation of people with dementia in the legal process, given that their cognitive impairments may impair their ability to participate in the judicial process, as well as their capacity to protect their rights and interests.
Objectives: The aim of the study is to provide an overview of the forensic meaning of dementia and the assessment of persons with a diagnosis of dementia in a legal context.
Methods: For the purpose of the research, a review of relevant studies in the PubMed database was performed, related to the field of forensic psychiatry of offenders diagnosed with dementia and criminal behavior of the elderly.
Results: During the forensic assessment of people with dementia, it is important to assess their cognitive impairment, for which purpose various psychological tests and diagnostic processing are applied in addition to diagnosing other comorbid diagnoses, especially depression or the existence of a psychotic disorder. In dementia, an important criminogenic factor can be the use of alcohol, along with the potential for committing violent crimes.
Conclusions: Depending on the severity of cognitive impairment and the existence of psychotic symptoms or a delirious state, the legal capacity of people with dementia can be significantly impaired. It is important to assess the need for security measures of psychiatric treatment, as well as the possibility of participating in the court process with regard to cognitive impairment. It is also necessary to pay attention to the protection of the rights and interests of people with dementia, as well as the ability to reason.

Disclosure of Interest: None Declared

EPV0867

Exploring the Clinical Applications and Implications of EMDR Therapy for PTSD in Forensic Settings: A Systematic Review

S. Prasad[1], G. S. Gill[2] and S. Gunturu[1]*

[1]Psychiatry, BronxCare Health System, New York and [2]Psychiatry, Case Western Reserve University, Cleveland, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1522

Introduction: There is a scarcity of research on the application of EMDR in addressing PTSD within correctional facilities, presenting varied results due to the difficulties associated with prolonged imprisonment. Prisoners encounter persistent mental health conditions such as depression, trauma, PTSD, and substance use disorders, contributing to maladaptive behaviors within the aggressive and psychologically taxing prison environment. Racial tensions and the pressure to conceal emotions further complicate matters, affecting daily life within the prison setting.
Objectives: To conduct a systematic review, following PRISMA guidelines, to assess the efficacy and evidence supporting the use of Eye Movement Desensitization and Reprocessing (EMDR) therapy for Posttraumatic Stress Disorder (PTSD) within forensic settings, in order to address the limited research available and provide insights into the outcomes and challenges related to treating PTSD in incarcerated individuals.
Methods: A review of 11 studies meeting the inclusion criteria was conducted. The study involved 156 incarcerated participants with a median age of 36.9 years, examining gender-based differences in reported trauma experiences and evaluating the effectiveness of EMDR therapy for PTSD in forensic environments. Primary assessment tools included PCL-C and CAPS scores for pre- and post-therapy evaluations. The timing of the initial EMDR session post-incarceration and symptomatic improvements over sessions were analyzed.
Results: Analysis of the study revealed significant improvements in symptoms over an average of six EMDR sessions, with no reported adverse events during therapy. The study highlighted the challenges and outcomes of implementing EMDR therapy for PTSD in correctional settings, shedding light on the effectiveness of the treatment among incarcerated individuals.
Conclusions: Despite positive initial results, it is vital to approach the interpretation of the benefits of EMDR therapy with caution, given factors such as the absence of standardized clinical trials, variability in reported outcomes, and the potential for study bias. Recognizing the need for additional investigation, further exploration is warranted to understand the lasting effects of EMDR therapy on recidivism rates, taking into account variables like the nature of the offense, length of incarceration, and frequency of reoffending.

Disclosure of Interest: None Declared

EPV0870

Differential diagnosis of disinhibited behaviors in forensic psychiatry: a report of three cases

K. Şahin Akkaya[1]*, K. Çifteci[1], B. Dizman[1], O. Uyanık[2] and E. Sönmez Güngör[1]

[1]Psychiatry, Erenkoy Mental and Nervous Diseases Training and Research Hospital and [2]Neurology, University of Health Sciences, Sancaktepe Şehit Prof. Dr. İlhan Varank Training and Research Hospital, İSTANBUL, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1523

Introduction: In forensic psychiatry, the most common diagnoses among the affected population are mood and psychotic disorders, personality disorders, or other conditions including intellectual disabilities. These individuals are either offenders or victims in criminal cases. Moreover, the tendency towards criminal behavior, disinhibition, agitation and aggression may also be associated with a neurocognitive disorder. Criminal behavior has been detected in 37.4% of frontotemporal dementia, 7.7% of Alzheimer's disease, and 20% of Huntington's disease patients.
Objectives: Raising awareness on the potential presentations of disinhibited behaviors through three case reports and on the importance of detailed clinical evaluation to differentially diagnose and appropriately manage forensic referrals.
Methods: Each case was evaluated based on a predefined procedure comprising the anamnesis, mental status examination, review of previous medical and forensic records, neurological consultation including neuropsychiatric battery, social investigation and any other relevant information. Informed consent was obtained from all patients before presentation.
Results: Case 1
A 63-year-old male, presented with a legal request of determining the need for a legal representative. The patient, who previously showed no similar behavior, repeatedly took loans under his own name, sold his assets at undervalued prices, experienced difficulties managing money, and was easily deceived. The patient was determined to exhibit frontal-type memory impairment, consistent with behavioral variant FTD (bvFTD), and it was deemed appropriate to appoint him a legal representative.
Case 2
A 52-year-old male, presented to assess his criminal responsibility regarding a theft offense. Anamnesis revealed forgetfulness, difficulties in managing money, tendency to take items from stores without paying, and repetitive behavior of cooking. Detailed examination and tests conducted led to a diagnosis of anxiety disorder, with a conclusion indicating full criminal responsibility.
Case 3
A 72-year-old male was hospitalized regarding an insult towards legal authorities. During the observation period in the inpatient ward, he exhibited similar behaviors. However, the final diagnosis was consistent with no significant psychopathology, and the patient was deemed criminally fully responsible for this act.
Conclusions: In cases where behavioral disturbances predominate, the possibility of frontal lobe dysfunction should be considered. Nevertheless, temporality relationships in symptomatology and the course of the disease, as well as where, when, and how the criminal act happened should also be taken into account. Cases which have similar initial presentations may finally lead to unrelated diagnoses.

Systematic evaluations are necessary to accurately guide the legal authorities as well as planning treatment.

Disclosure of Interest: None Declared

EPV0871

Stalking syndrome in clinical forensic psychiatry

J. Sredanovic[1], L. Cuk- Jovanovic[1], E. Novakovic[1,2]*, J. Tomasevic[2] and T. Novakovic[2]

[1]Clinic for mental disorders dr Laza Lazarevic, Belgrade and [2]Faculty of Medicine, University in Priština, Kosovska Mitrovica, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1524

Introduction: This study is probably the first study on stalking conducted in the Republic of Serbia.
Objectives: The aim of this study was to examine the stalking experiences of a sample of persons who, according to the Court's judgment, were in need of treatment.
Methods: This retrospective study was conducted from January 2020 until January 2024 and included 46 persons on the measure of treatment treated at the Clinic for Mental Disorders "Dr Laza Lazarević" in Belgrade. All obtained data were from their medical records and based on the judgment of the Court. The data were processed using SPSS version 21 to produce mainly descriptive and inferential statistics. Difference were considered statistically significant if $p< 0.05$.
Results: The participantes were mean age 49.5 ±12.9 years, and most of them 41 (89.1%) were men. The stalker was in most cases a male, he was unemployed (65.2%), unmarried (91,3%), lived with his parents (67.4%) in the city (91.3%). Stalkers were most often diagnosed with F22 (23.9%) and F23 (23.9%). The stalker with the diagnosis F22 most often pursued the desired partner (33.3%) and the stalker with the diagnosis F23 a person from the social environment (33.3%). After the treatment measure is completed, the stalker often repeats the same act (12.83%).
Conclusions: Stalking remains a major problem and insufficiently tested that must be taken seriously. It is best to look at stalkers as a heterogeneous group whose behavior can be motivated by various psychiatric illnesses, predominantly psychoses.

EPV0872

A post-tragedy psychiatric approach to violence prevention and community healing

V. Vukovic[1]*, S. Nikolic Lalic[2], J. Mitić[2], M. Jakšić[3] and A. Opankovic[4]

[1]Clinical Hospital Centre "dr Dragiša Mišović", Belgrade; [2]Special hospital for psychiatric disorders "dr Slavoljub Bakalović", Vršac; [3]Institute for mental health and [4]Faculty of Medicine, Clinic for psychiatry, Clinical Centre of Serbia, Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1525

Introduction: The world is increasingly burdened by complex, interwoven crises—economic, social, and political— and societies must examine and adapt their institutions to prevent and mitigate violence. Developing countries such as Serbia are transitioning from a history of conflict and face many difficulties in this regard. Lingering stigma around mental health, limited resources, and collective societal trauma complicate the task of responding to incidents of violence. One of these is the recent school shooting which has, on the one hand, highlighted deficiencies in early identification and intervention for at-risk adolescents, and has, on the other hand, pointed out the potential role of forensic psychiatry in transforming both prevention and post-crisis mediation.
Objectives: The aim of this study will be to propose potential pathways to redefine the Serbian forensic psychiatric landscape, through delineating interdisciplinary interventions such as implementing community-based mental health education, expanding risk assessment protocols for youth, and providing prophylactic care for vulnerable populations.
Methods: Drawing on comparative data from international practices, this paper explores several potential culturally adapted forensic models, focusing on early intervention, trauma-informed care, and interdisciplinary collaboration.
Results: The dialogue between forensics and restorative justice could help define models for facilitating community healing, as well as enabling accountability and rehabilitation for patients. This paper proposes that changes in forensic psychiatry might facilitate the development of evidence-based frameworks directed at reducing future violent incidents, if applied in an communal, distributed model which includes social workers and other persons of interest. These interventions would be crucial in aligning Serbia's forensic practices with current socio-political dynamics, potentially fostering a more effective and scientifically informed approach to justice and rehabilitation.
Conclusions: Implementing a culturally adapted, interdisciplinary forensic psychiatric model in Serbia could provide a vital framework for violence prevention, community healing, and the integration of restorative justice practices.

EPV0873

Debriefing after incidents and restrictive practices: a D-FOREST study

B. Walls[1]*, A. Lindner[2], J. Leahy[1], D. Duffy[1], P. Mc Laughlin[1], H. G. Kennedy[3,4,5] and M. Davoren[1,3,5]

[1]Central Mental Hospital, National Forensic Mental Health Service, Portrane, Co. Dublin. K36 FD79, Dublin, Ireland; [2]Johannes Gutenberg-Universität, Mainz, Germany; [3]Psychiatry, Trinity College Dublin, Dublin, Ireland; [4]Skou Professor of Forensic Psychiatry, University of Aarahus, Aarhus, Denmark and [5]Visiting Professor of Forensic Psychiatry, University of Bari 'Aldo Moro', Bari, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1526

Introduction: The Council of Europe's Model Mental Health Act places emphasis on the need for a 'debriefing' discussion with patients after incidents of restrictive practices to arrive at a common understanding concerning what happened and to consider future prevention strategies. For the patient, issues may arise that may be subjectively reinforcing or subjectively aversive and staff may feel that the incident has, or does not have, alienating consequences.
Objectives: The aim of this study was to evaluate the consequences for the patient and for staff of incidents and use of subsequent

restrictive practices, as a basis for future understanding of what debriefing might usefully include.
Methods: A prospective cohort study was completed whereby incidents were rated using the Dynamic Assessment of Situational Aggression (DASA) and DRILL tool 'consequences' scales in the Central Mental Hospital (CMH). The DRILL consequences scale consists of three ladders, 're-enforcing', 'aversive' (both rated from the point of view of the patient) and 'alienating' (rated from the point of view of ward based staff). Data were gathered as part of the Dundrum Forensic Redevelopment Evaluation Study (D-FOREST). An omnibus General Estimating Equations model (GEE) was tested with the DRILL 'consequences' as dependent prior to dismantling studies.
Results: In this study, the 384 patient-days were in scope, 411 lines of data including 326 patient-days, 85 harmful incidents and 63 incidents of seclusion. In an omnibus GEE with the three-item DRILL consequences scale as dependent variable, DASA on the day before Wald X^2=3065.9, p<0.001; DRILL behaviours scale Wald X^2=970.7, p<0.001; DRILL interventions Wald X^2=140,159.1, p<0.001; DUNDRUM-1 Wald X^2=1638.9, p<0.001. The three items of the DRILL consequences scale were individually tested as dependent variables in GEE models with DASA the day before, DRILL behaviour scale, DUNDRUM-1 and each of the eight items of the DRILL interventions scale. Only increasing observation levels were not re-enforcing, with searches and seclusion strongly re-enforcing.
Conclusions: We have shown that consequences of harmful behaviours and preventive, restrictive interventions are measurable and proportionate for patients and for staff. Short-term risk on the day prior to an incident was able to predict the re-enforcing and aversive consequences for the patient, but not the alienating consequences – or lack of them – for staff. Future research will examine the way in which the baseline need for security mediates or moderates the relationship between incidents and patients and staff views of the consequences of incidents and restrictive practices.

EPV0874

Not guilty by reason of insanity: characteristics of psychotic murders and murderers

A. Yaron Antar[1]

[1]Criminology, The Max Stern Yezreel Valley College, Yezreel Valley, Israel
doi: 10.1192/j.eurpsy.2025.1527

Introduction: Some acts of murder are committed out of insanity by individuals suffering from psychotic mental disorders. According to the law in many countries, these individuals do not have criminal responsibility. They are defined as not guilty due to insanity and therefore cannot be punished.
Objectives: This study aims to explore the sociodemographic, psychiatric, criminal and forensic characteristics/factors of insanity murders and murderers. This examination has not yet been conducted in Israel, which is a multicultural country with social, religious, ethnic complexity.
Methods: This study examined the hospital records (investigation material, indictments, admission summaries, and expert testimonies) of all 80 inpatients who had committed murder and been hospitalized in the maximum security unit from its opening in 1997 until 2021, and were found not guilty due to insanity.
Results: ***Demographics characteristics*** (at the time of the offense). The participants were men ages 18-85 (M=36.11, SD=11.84). 58.8% were born in Israel, 21.3% immigrated from the former Soviet Union, 6.3% from Ethiopia, and 13.8% from other countries. The majority (82.5%) were Jewish, 16.4% were Arab. Most lived in urban centers (86.3%). Most were not married at the time of the offense: Single (62.5%), divorced (21.3%). Only a minority was married (16%).
Psychiatric characteristics. Most participants were diagnosed with schizophrenia (90%); had at least one hospitalization prior to the offense (70%), and had a previous hospitalization due to violence. Most of them were not compliant with psychiatric treatment and follow-up (only one participant was fully compliant). In most cases (74%) pre-murder deterioration was recorded.
Criminal characteristics. At least 52.5% had a criminal record prior to committing the offense (a higher number is possible, the information is based on the medical file only, there was no access to an official criminal record).
Murder/forensic characteristics. At least 48.8% there was no prior planning. In most cases (66.6%) the motive described was paranoid delusions and only in 5% there is command hallucinations. In most cases the murders took place in the home of the victim and/or the assailant (67.5%), one person was murdered (91%) and the victim was known to the assailant (88.8%), most of them a family member (61.3%). In at least 75% of the cases there was a brutal murder with multiple stabbings, use of multiple means/actions, abuse of the body or dismemberment. Following the murder, 58.3% of the assailants remained at the site of the crime and/or called for help, 27.4% left the site (no information for the remaining subjects).
Conclusions: The findings are consistent with existing knowledge and may assist in identifying at-risk populations, develop and implement relevant prevention programs as well as improving the therapeutic continuum from hospitalization to the community.

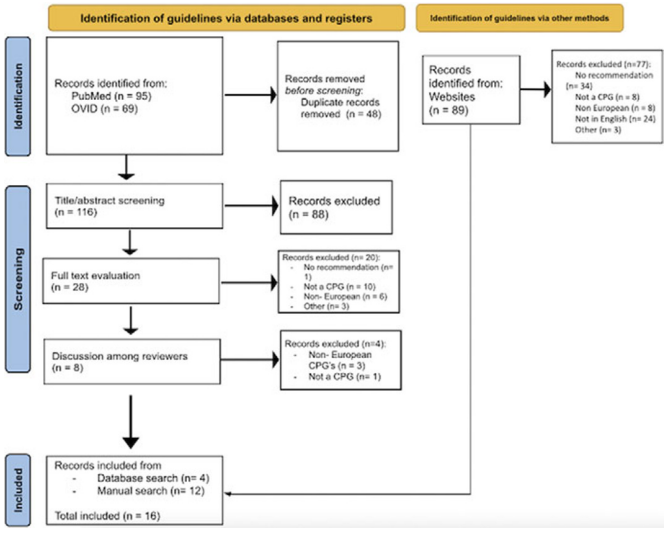
What do European guidelines say about genetic testing for people with mental disorders? A scoping review



I. Arican[1]*, J. Zinkstok[2], M. van der Horst[2] and N. Bass[1]

[1]Division of Psychiatry, University College London, London, United Kingdom and [2]Department of Psychiatry, University Medical Center Utrecht, Utrecht, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1528

Introduction: Technological advancements have identified numerous genetic variations linked to mental disorders, providing potential explanations and, in some cases, enabling targeted treatments. However, clinical genetic testing remains underutilised in psychiatric care, potentially due to inconsistent clinical guidelines across Europe.
Objectives: This scoping review aims to compile, summarise and evaluate European clinical practice guidelines (CPGs) on genetic testing in mental disorders, identifying gaps and variations in recommendations to inform current practice and future guideline development.

Methods: A scoping review was conducted across scientific databases (PubMed/MEDLINE and Ovid) and grey literature sources (Image 1. Flow diagram). Inclusion criteria centred on European CPGs published in English from 2010 onward with specific recommendations on genetic testing in mental disorders. Quality assessment was performed using the International Centre for Allied Health Evidence (iCAHE) checklist. Data extraction focused on guideline characteristics, target populations, and genetic test recommendations.
Results: Sixteen CPGs met the inclusion criteria, displaying considerable heterogeneity in quality and content, and covering a limited range of mental disorders. Six guidelines addressed neurodevelopmental disorders. Most recommended genetic testing in Autism Spectrum Disorder (ASD) when indicators such as intellectual disability (ID) or dysmorphic features were present; however, one guideline recommended routine testing. Only one guideline included recommendations for genetic testing in ID; routine access to Fragile X testing, chromosomal microarray, and whole genome sequencing was recommended as standard care.
Eleven guidelines provided recommendations on genetic testing in neurodegenerative disorders. In dementia, consensus on routine testing was generally limited to young-onset cases or those with distinct genetic profiles. APOE genotyping was generally discouraged. Guidelines for diagnostic testing for Huntington's Disease (HD) were consistent. Access to predictive testing with appropriate genetic counselling for at-risk adults was also recommended.

Image:

Conclusions: Based on our findings and the wider literature, we recommend considering genetic testing for: 1) all patients with ID, 2) patients with ASD exhibiting features suggestive of a genetic cause, such as ID and dysmorphic traits, and 3) patients with dementia with a young age of onset or a family history indicative of a Mendelian disorder. For HD, testing should be informed by phenotypic features and family history. Establishing harmonised, evidence-based guidelines is essential to integrate testing effectively. Key considerations include clinical utility, patient autonomy, and access to genetic counselling to ensure informed and supportive care.

EPV0879

Season of birth/C-reactive protein gene interaction differentially affects negative symptoms domains in patients with schizophrenia

V. Golimbet[1]*, T. Lezheiko[1], M. Gabaeva[1], N. Kolesina[1] and V. Mikhailova[1]

[1]Clinical Genetics Laboratory, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1529

Introduction: Schizophrenia is a severe psychiatric disease caused by genetic and environmental factors or their interactions that can contribute across multiple disease domains, including negative symptoms (NS), a core feature of schizophrenia.
Objectives: To study the association between season of birth (SOB), a well-replicated risk factor for schizophrenia, and NS domains avolition/apathy (AA) and diminished expression (DE) and to search for an interaction effect of SOB and rs2794521 genetic variants of the inflammatory marker C-reactive protein (CRP) on these domains.
Methods: The study included 2475 patients with schizophrenia. Patients born during the months of December to February were considered to be winter-born (n=636) and patients born in other months were considered to be non-winter-born (n=1839). Genotypes for CRP rs2794521 were obtained for 2437 patients. NS factors were calculated based on the Positive and Negative Syndromes Scale.
Results: There was a significant effect of SOB on AA scores (p=0.009), which remained after adjustment for sex and illness duration. Patients born in winter had higher scores compared with those born in other seasons. No significant effect of SOB on DE scores was observed. An association between the CRP rs2794521 *G*-allele and AA scores was found (p=0.044) in the winter-born group, with the carriers of the *G*-allele having higher scores. There was no effect of the *G* allele on DE scores in this group and on AA or DE scores in the non-winter group.
Conclusions: The results provide new evidence about the effect of SOB and SOB/CRP gene interaction on schizophrenia NS domains.

Disclosure of Interest: None Declared

EPV0880

The association between oxytocin receptor gene polymorphism, childhood adversity and negative symptoms of schizophrenia

T. Lezheiko[1], V. Golimbet[1]*, V. MIKHAILOVA[1] and M. Gabaeva[1]

[1]Clinical Genetics Laboratory, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1530

Introduction: Neurohormone oxytocin plays an important role in the pathogenesis of mental illness, and also moderates the relationship between stress factors, especially those acting in the early stages of development, and the development of mental disorders. Literature data indicate that environmental risk factors significantly increase the risk of schizophrenia and the severity of its clinical presentation.

Objectives: To study the association between the oxytocin receptor (OXTR) rs468302 and rs7632287 polymorphisms and negative symptoms of schizophrenia, taking into childhood adversity (CA), i.e. events that could adversely affect the psychoemotional state and development of the child in the period up to 18 years. CA includes abuse in the family, alcohol or drug addiction in parents, mental disorders.
Methods: The study included 592 patients with schizophrenia (items F20. according to ICD-10). Information about the presence of CA was obtained from case histories and patient interviews. Analysis of covariance was used for statistical data processing; in post-hoc pairwise comparison, Tukey's test was used.
Results: A significant effect of the interaction between CA and OXTR gene polymorphism rs7632287(G\A) on the severity of negative symptoms in patients with schizophrenia was revealed. For rs4686302 (C\T) polymorphism the association was found at the trend level. In patients without CA, polymorphisms did not have a significant effect.
Conclusions: The OXTR rs468302 and rs7632287 polymorphisms, previously associated with phenotypes related to social behavior, may be associated with negative symptoms of schizophrenia, and the association is mediated by the presence of a history of psychotraumatic events acting at an early stage of development.

Exploring genetic sources of a decreased cognitive performance in psychometric schizotypy

V. Plakunova[1], M. Alfimova[1] and V. Golimbet[1]*

[1]Clinical Genetics Laboratory, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1531

Introduction: Schizotypy is seen as subclinical part of the psychosis liability continuum. While several studies have attempted to confirm the relationship between schizotypal traits and genetic predisposition to schizophrenia using polygenic risk scores (SZ-PRS), the association of SZ-PRS with other features of schizotypal individuals resembling schizophrenia symptoms remains unexplored.
Objectives: This study aimed to assess the contribution of SZ-PRS and PRS for other relevant traits to cognitive functioning in schizotypy.
Methods: Healthy subjects (n=1468) were divided into low, negative, positive, and high mixed schizotypy groups based on a cluster analysis of the Schizotypal Personality Questionnaire data. Of them, 247 individuals had genome-wide information and completed a comprehensive cognitive battery, from which a cognitive index (CogI) was derived. PRS for schizophrenia, bipolar disorder, educational attainment, intelligence (IQ), neuroticism, and risk-taking were calculated with LDpred2-auto tool. The association of the CogI with PRSs was examined with stepwise multiple linear regression controlling for age and two ancestry-related principal components.
Results: The groups differed in the CogI (p=0.015). The high schizotypy individuals (n=49) had a lower CogI than the low (n=73, p=0.01), negative (n=54, p=0.08), and positive (n=64, p=0.09) ones. SZ-PRS (β=-0.16, p=0.012) and IQ-PRS (β=0.13, p=0.014) predicted CogI in low schizotypy; IQ-PRS (β=0.42, p<0.001) in negative schizotypy; risk-taking PRS (β=-0.27, p<0.001) in positive schizotypy; and none of the PRSs predicted cognition in high schizotypy.
Conclusions: We did not find traits whose PRS might explain the lower cognitive performance in high schizotypy. Thus, nongenetic factors deserve more attention in future research.

EPV0882

Characterization of SLC6A1 mutations associated with schizophrenia using SH-SY5Y-based cell lines Ekaterina Marilovtseva1

E. Marilovtseva[1], D. Abashkin[1] and V. Golimbet[1]*

[1]Clinical Genetics Laboratory, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1532

Introduction: SLC6A1 is a GABA transporter which, being expressed in neurons and glial cells, removes GABA from extracellular space, preventing the spread of the inhibitory transmission within the brain. Recently, A93T, R211C, and W495L *de novo* mutations in SLC6A1 have been demonstrated to be involved in schizophrenia pathogenesis. However, the mechanism of action of SLC6A1 in schizophrenia is still to be determined.
Objectives: To establish a series of SH-SY5Y-based cell lines expressing wt *SLC6A1* and its forms with single A93T, R211C or W495L mutations and their combinations, and to further characterize the properties and the subcellular localization of the resulting proteins.
Methods: The chosen variants of *SLC6A1* tagged with N-terminal FLAG were cloned into a lentiviral plasmid under the TRE promoter and used for transfection of HEK293T with further SH-SY5Y transduction. *SLC6A1* expression was initiated by adding 20 μg/mL of doxycycline to the cells. After 48 hours of treatment the cells were either used for qPCR and Western blot analysis, or stained.
Results: All cell lines expressed *SLC6A1* forms efficiently. SLC6A1 with single mutations, $SLC6A1^{R211C;W495L}$, and $SLC6A1^{A93T;\ R211C;\ W495L}$ were present by the same ≈67kDa form as wt SLC6A1, while $SLC6A1^{A93T;R211C}$ resulted in an additional band at ≈130kDa, indicating either the presence of PTM, or the formation of a homodimer. $SLC6A1^{A93T;W495L}$ gave no protein product, probably, due to its proteolytic degradation. Interestingly, wt SLC6A1, $SLC6A1^{R211C}$, and $SLC6A1^{A93T;R211C}$ were detected in neurites, while $SLC6A1^{A93T}$, $SLC6A1^{W495L}$, $SLC6A1^{R211C;W495L}$, and $SLC6A1^{A93T;R211C;W495L}$ were mainly found in cytoplasm, which might indicate that these mutations might affect the function of the protein.
Conclusions: Having established a series of SH-SY5Y-based cell lines expressing SLC6A1 with schizophrenia-associated mutations, we demonstrated the effect of the latter on the protein's subcellular localization. Based on our observations, we speculate that R211C has the mildest effect on the localization and function of SLC6A1 and can even partially compensate that of A93T, but not W495L. We also suggest that SLC6A1 with the A93T;W495L combination undergoes proteolytic degradation, most likely, due to the defects in its structure.

Shared Genetics between Depression and Cardiometabolic Disorders

P. S. Kundi[1]*, M. Syed[2], B. A. Syed[3] and D. Sahota[4]

[1]Vancouver Coastal Health, Vancouver; [2]Psychiatry, Peace Arch Hospital, White Rock, Canada; [3]Oregon State University, Corvalis, United States and [4]McMaster University, Hamilton, Canada
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1533

Introduction: Several studies have discovered associations between depression and cardiovascular disease risk factors and patients with Coronary Artery Disease with comorbid Depression have worse prognosis. There is growing evidence of polygenic overlap between depression, Coronary Artery Disease and other Cardiovascular risk factors and may suggest molecular mechanisms underlying the association between depression and raised cardiovascular disease risk.
Objectives: Depression and cardiometabolic disorders are both heritable and both are caused by a mix of genetic and environmental factors. Genetic factors contribute to 31–42 % in MDD (Sullivan et al. 2000), 30–60 % in coronary artery diseases (Marenberg et al. 1994), 26–69 % in type 2 diabetes (Almgren et al. 2011 ; Poulsen et al. 1999), 24–37 % in blood pressure (hypertension) (Van Rijn et al. 2007), 35–48 % in heart rate variability (Kupper et al. 2004), 40–70 % in obesity (body mass index) (Willyard 2014), and 58–66 % in the level of serum lipids (Knoblauch et al. 1997). Moreover, there are fairly high genetic co-heritabilities (genetic correlations) between depression and the different cardiometabolic disorders suggesting the influence of pleiotropic genes and shared biological pathways within them.
Methods: Literature search was conducted and appropriate material was then extracted to examine the hypothesis.
Results: Identification of shared molecular pathways supports a growing evidence base for cross-diagnostic treatment. Besides, further exploration of overlapping molecular pathophysiology can unveil novel targets for drug development and repurposing of existing medications. Also, cardiometabolic disorders can increase the risk of poor response to standard treatments in mood disorders. Lastly, studying shared pathways of depression and somatic disorders can untangle the clinical and genetic heterogeneity that underlies in these illnesses.
Conclusions: Genetic studies have suggested the involvement of pleiotropic genes in the comorbidity between depression and cardiometabolic disorders. While our abstract attempts to provide some insight into the common mechanisms and role of pleiotropic genes, in-depth understanding of how these genes mediate the association between depression and cardiometabolic diseases requires future larger scale comprehensive cross-disorder research. This will enable us to better understand why patients suffer from multiple diseases at a time and how multimorbidities influence pharmacological treatment response to diseases.

The Impact of Bisphenol A (BPA) on Serotonin Regulation and Its Implications for Mood

R. A. Maldonado-Puebla[1]*, N. Choudhury[2] and B. Carr[2]

[1]College of Osteopathic Medicine, Nova Southeastern University, Clearwater and [2]Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1534

Introduction: Bisphenol A (BPA), a widely used chemical in the manufacturing of plastics and resins found in everyday consumer products such as water bottles and food containers, is known to interfere with the body's endocrine system. Specifically, BPA acts as a xenoestrogen, meaning it can mimic the hormone estrogen by binding to estrogen receptors (ERs) in the body. This interaction raises concerns about BPA's potential impact on brain regions with high densities of these receptors, including the hippocampus and prefrontal cortex, which are critical for mood and cognitive functions. Estrogen plays a vital role in regulating serotonin, a neurotransmitter essential for mood stability. This review synthesizes existing literature on how BPA may disrupt serotonin regulation and its implications for mood disorders.
Objectives: To evaluate the mechanisms by which BPA interacts with estrogen receptors and serotonin in the brain with a key focus on its implications for mood disorders such as depression and anxiety.
Methods: A narrative literature review was conducted, gathering findings from relevant studies published over the past two decades. Sources were identified through database searches in PubMed, PsycINFO, and Google Scholar using keywords such as "BPA," "serotonin," "estrogen receptors," "hippocampus," "prefrontal cortex," and "mood disorders." The review focused on various types of studies that examine BPA's interaction with estrogen receptors and its effects on serotonin regulation allowing for the creation of an up-to-date integrative summary.
Results: The review reveals that BPA's interaction with estrogen receptors in the brain can lead to significant disruptions in serotonin regulation. BPA competes with endogenous estrogen for ER binding leading to altered serotonin synthesis and release. BPA exposure is associated with reduced expression of tryptophan hydroxylase, the enzyme critical for serotonin production, potentially lowering serotonin levels. BPA's interference with ERs impairs serotonin release from presynaptic neurons, particularly in the hippocampus and prefrontal cortex, which are vital for mood regulation.
Conclusions: The literature strongly suggests that BPA disrupts normal estrogenic regulation of serotonin, with significant implications for mood disorders such as depression and anxiety. The hippocampus and prefrontal cortex appear particularly vulnerable to these disruptions, which could theoretically exacerbate symptoms of mood dysregulation highlighting the importance of considering environmental factors like BPA in the treatment of mood disorders. Given the widespread exposure to BPA, these findings underscore the need for further research into its long-term effects on mental health and potential regulatory measures to mitigate exposure.

EPV0886

Plasma-based microRNA biomarkers for depression in Romanian patients: preliminary findings

I.-C. Matei[1]*, E. Milanesi[2] and M. Dobre[2]

[1]Clinica Nutrimed and [2]Institutul National de Patologie, Bucharest, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1535

Introduction: Depressive disorders are one of the most disabling mental illnesses with a significant impact on society. In Romania the mean annual total costs per depression patient are EUR 5553, a much higher figure than the mean annual total costs per patient ranged worldwide.
Even though their roles in depression have not been elucidated, a plethora of potential biomarkers in multiple body fluids for the early diagnosis of depression has been suggested. Blood circulating microRNAs (miRNAs) are potential biomarkers for several human diseases, including psychiatric disorders. Different studies have shown that micro RNAs are involved in a series of pathophysiological processes and could be useful markers for diagnosis and prognosis of depression.
Objectives: This preliminary case-control study was designed to identify putative blood circulating miRNAs associated with the diagnosis of depression in Romanian patients.
Methods: In this study, 20 patients with depression and 24 non-depressed controls were enrolled. All the individuals have been interviewed and screened using the following scales: the Hamilton Anxiety Scale (HAM-A), the Becks Depression Inventory (BDI) and the Perceived Stress Scale (PSS). The expression of 179 miRNAs in plasma have been evaluated by qRT- PCR. The difference in the expression of miRNAs between the two groups, as well as the correlations with the scores of the scales have been analyzed.
Results: A panel of 28 miRNAs was identified as differentially expressed between patients and controls. Only miRNAs showing a -2>FC>2.0 and p<0.05 have been considered significant. Seven miRNAs (miR-143-3p, miR-331-3p, let-7f-5, miR-502-3p, miR-145-5p, miR-7-1-3p, miR- 29a-3p) were found up-regulated in the depression group, while 21 miRNAs (miR-885-5p, miR-425-3p, miR-32-5p, miR-23b-3p, miR-590-5p, miR-30a-5p, miR-132-3p, miR-376a-3p, miR-223-5p, miR-133b, miR-142-5p, miR-92b-3p, miR-140-3p, miR-16-2-3p, miR-28-3p, miR-27a-3p, miR-15b-3p, miR-106b-3p, miR-877-5p, miR-30e-3p, miR-140-5p) showed a down-regulation in the group of patients compared to the controls. Some of the significant correlations between miRNA expression and the scale scores are reported: a positive correlation between let-7f-5 and miR-7-1-3p with the BDI score (p=0.003 r=0.526, and p=0.008 r=0.477, respectively) and a negative correlation between miR-425-3p with BDI (p=0.002 r=-0.502) were found.
Conclusions: The results reported in this communication represent preliminary findings. Due to the nature and heterogeneity of depression, the number of patients and controls in the two cohorts will be enlarged to correlate these miRNAs with other patient features.

Mitochondrial DNA Copy Number Changes in Mood Disorders during the Menopausal Transition

C. Meriç Özgündüz[1,2]* and D. Ceylan[2,3]

[1]Psychiatry, Acibadem University Maslak Hospital; [2]Neuroscience, Koç University Graduate School of Health Sciences and [3]Psychiatry, Koç University Faculty of Medicine, İstanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1536

Introduction: A heightened susceptibility to mood disorders among women at specific junctures throughout their reproductive lifetime has been reported. Previous studies have suggested that the probability of developing Major Depressive Disorder (MDD) during the menopausal transition is amplified from 2 to 4 times when contrasted with both premenopausal and postmenopausal periods and also increased mood symptom severity in the menopausal transition in bipolar disorder (BD) has been cited (Chen *et al.* Arch Womens Ment Health 2017; 20 463-8). A considerable body of evidence suggests that mitochondrial dysfunction plays a crucial role in the pathophysiology of various psychiatric disorders, including MDD and BD. Researchers have proposed that the mitochondrial DNA copy number (mtDNAcn) may serve as an essential marker of mitochondrial health, which is the ratio of mitochondrial and nuclear DNA (Malik *et al*. Mitochondrion 2013; 13 481-92).
Objectives: In this review, we aimed to compile and present existing data regarding mtDNAcn alterations in women during the menopausal transition by comparing the mtDNAcn numbers of the women in premenopausal, perimenopausal and postmenopausal periods thereby establishing a foundation for future research on the origins of these conditions.
Methods: A literature search was conducted on the electronic databases PubMed, Cochrane Library, Medline (OVID), Scopus, Web of Science and CINAHL to identify the relevant studies published until 14 October 2024. The search was performed using the following keywords (Menopause OR Premenopause OR Pre-Menopause OR Premenopaus* OR Perimenopause OR Postmenopause OR Post-Menopause OR Postmenopaus*) AND (mitochondrial DNA copy number OR mtDNA copy number) and limited to English language.
Results: According to the search results, 66 publications were reached in total. After detecting and removing duplicate publications, there were 21 publications left. After screening, any of the studies met inclusion criteria for the systematic review, because most of them were conducted in different patient groups and healthy controls in the menopausal transition periods, but the main findings of these studies can be summarized as; mtDNAcn varies between the patients groups and healthy controls in the menopausal transition periods with the conflicting results. Some of the studies found higher mtDNAcn in patient groups such as breast cancer and pelvic organ prolapsus, whereas some of them found lower mtDNAcn numbers in patient groups such as osteopenia and osteoporosis.
Conclusions: Considering above findings, there is mtDNAcn alterations in women during the menopausal transition. These findings may highlight the need for future studies to elucidate the link with mtDNAcn and mood disorders in the menopausal transition period by comparing the women in different menopausal periods.

Neurotrophins expression in brain regions of an anorexia nervosa mouse model, biomarkers for diagnostic and prognostic

N. Ramoz[1]*, J. Cao[1], V. Tolle[1], P. Gorwood[1,2] and O. Viltart[1,3]
[1]U1266, INSERM; [2]CMME, GHU PARIS Psychiatrie & Neurosciences, Paris and [3]Université Lille, Lille, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1537

Introduction: Anorexia nervosa (AN) is a complex mental disorder characterized by a voluntary food restriction and excessive physical activity resulting in dramatic weight loss. Neurotrophins are growth factors that play s role in the proliferation, survival and differentiation of cells in the brain. Alterations in neurotrophin factors, including the brain-derived neurotrophic factor (BDNF), have been found in patients wuth AN. Variants of genes encoding various neurotrophins and their receptors have been associated with eating disorders or with disease outcome or prognosis compared with controls. In animal, BDNF negatively modulates the central control of food intake and its injection into rodents induces weight loss and anorexia. Its receptor, the p75 neurotrophin receptor was also able to regulate the energy balance, as observed in mice lacking the p75NTR, which decreased their feeding. Thus, several neurotrophins and their receptor may have a metabolic effect, making them good candidates for biomarkers in AN for diagnostic and prognostic purposes.
Objectives: Our work measured the levels of expression of neurotrophins and their receptors in specific brain areas, taking advantage of the mouse AN-like model in food-restricted and refeed animals.
Methods: The AN-like model combining a chronic food restriction (50%) for 15 days followed by an *ad libitum* refeeding period of one week was used. Female mice have access to a running wheel to create a metabolic environment similar to that of patients suffering from AN during restriction and recovery after hospitalization. The mRNA levels of Bdnf, TrkB, Ngf, NtF3 and Ntf5 were measured in brain regions (prefrontal cortex, hippocampus, hypothalamus and dorsal striatum) using quantitative PCR in the different groups of mice (ad libitum, ad libitum with wheel, food restriction and food restriction with wheel). Statistical analysis will compare levels using one-way or two-way ANOVAs depending on the animal group or brain region.
Results: A significant decrease of the expression of *Bdnf*, *Ngf* and *Ntf5* genes was observed between *ad libitum* and food restriction groups in the dorsal striatum. The transcript level for *Bdnf* was also decreased in the prefrontal cortex in the food restriction groups compared to the *ad libitum* groups. In contrast, TrkB transcript was increased in in food restriction groups compared to ad libitum groups, in the prefrontal cortex. We expect significant differences in gene expression in the other brain regions of interest for the food restricted animals compared to the *ad libitum* animals. The levels of neurotrophic genes are ongoing for the refeeding animals.
Conclusions: Neurotrophins could represent potential biomarkers of AN for the diagnosis and prognosis in the evolution to weight recovery and will thus allow a better understanding of the aetiology of AN.

A Potential Paradigm Shift in Managing Huntington's Disease? A Meta-Analysis of the Recent Advances in Symptomatic Treatment and Gene Therapy

A. Agrawal[1], R. Walwaikar[2], J. Parmar[3], A. A. Pillai[2], A. A. Kumar[4] and F. Sheikh[5]*
[1]Humanitas University, Milan, Italy; [2]SSPM Medical College and Lifetime Hospital, Sindhudurg; [3]Government Medical College, Amritsar; [4]GMERS Medical College, Vadnagar, India and [5]Greater manchester mental health trust, Manchester, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1538

Introduction: Huntington's Disease (HD) is a serious inherited neurodegenerative disorder characterized by a progressive decline in motor and cognitive functions, along with neuropsychiatric symptoms. The pathophysiology involves extended CAG repeats in the huntingtin (HTT) gene, leading to the toxic accumulation of protein aggregates and subsequent neurodegeneration. Current treatments for HD solely provide symptomatic relief and are merely adjunctive, with no effect on disease progression. Novel gene editing technologies, such as CRISPR on the other hand, directly target mutant huntingtin at either the DNA or RNA level, and may potentially delay or halt the progression of HD through their disease-modifying effects.
Objectives: This review is aimed at critically evaluating the recent advances in gene therapy and symptomatic treatment approaches, focussing on both current treatments as well as first-generation human and preclinical studies targeting HD. The review also seeks to assess the rationale for these studies, the mechanisms of action involved, and their broader implications for clinical practice and patient care.
Methods: A systematic review of the recent literature on drug-based and non-drug-based HD treatment approaches, including symptomatic and advanced gene-editing strategies, was conducted. Data pooling was carried out with random-effects models to provide calculated standardized mean differences (SMDs) and 95% confidence intervals (CIs). The review included a comprehensive investigation of strategies such as CRISPR-Cas9, prime editing, antisense oligonucleotides, and RNA interference, yielding promising data with prudent clinical utility.
Results: Eighteen studies with a total of 2,152 participants were analyzed. A significant reduction in motor manifestations compared to controls was recorded with Tetrabenazine and Deutetrabenazine use, with an SMD of -0.65 ($p < 0.001$). Antidepressant supplementation showed promising effects on psychiatric symptoms, achieving an SMD of -0.70 ($p < 0.001$). Non-drug-related treatments moderately improved participants' quality of life, as illustrated by an SMD of 0.58 ($p < 0.001$). In gene therapy-related interventions, CRISPR-Cas9 and prime editing approaches showcased a significant reduction in the levels of mutant huntingtin protein, with a mean of -1.25 ($p < 0.001$). Additionally, antisense oligonucleotides provided encouraging results, eliciting a dose-dependent reduction in RNA levels, with a mean of -0.85 ($p < 0.001$).
Conclusions: Combining innovative symptomatic treatments with novel gene-editing technology marks a potential paradigm shift in managing Huntington's Disease. While symptomatic therapies are paramount to ensure optimal patient comfort, recent advances in gene therapy research hold tremendous potential in modifying and curbing disease progression.

Cardiovascular Risk Assessment in Psychiatric Patients

J. Barreira[1]* and S. Macedo[1]

[1]Psychiatry and Mental Health, Unidade Local de Saúde do Tâmega e Sousa, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1539

Introduction: Psychiatric patients, particularly those with severe mental illness, face an elevated risk of cardiovascular disease. This heightened risk stems from a combination of factors, including the effects of antipsychotic medications, unhealthy lifestyles, and socioeconomic disadvantages. Addressing cardiovascular risk in this population requires tailored approaches that consider both medical and mental health aspects. Traditional cardiovascular risk prediction models, such as SCORE2, often fail to accurately assess cardiovascular risk in psychiatric patients.
Objectives: This non-systematic review aims to evaluate the evidence behind the use of cardiovascular risk prediction models in patients with mental illness, assessing their applicability and limitations.
Methods: Relevant and recent studies or reviews were selected from the PubMed electronic database using search terms related to cardiovascular risk prediction and mental illness. Articles were chosen based on their relevance to psychiatric populations and their focus on prediction models.
Results: Recent cardiovascular risk prediction models, such as PRIMROSE and QRISK3, incorporate factors like the presence of severe mental illness, antipsychotic and antidepressant use, and lifestyle factors (smoking and alcohol consumption). These models are more effective than general population models in predicting cardiovascular events in psychiatric patients. Interventions based on these models, particularly pharmacological strategies such as the use of statins and metformin, have been effective in managing lipid levels and reducing cardiovascular risk in this population.
Conclusions: Psychiatric patients are at a significantly increased risk of cardiovascular disease, warranting early intervention and consistent monitoring. Tailored risk assessment models can significantly improve cardiovascular outcomes by guidind pharmacological intervention. Further studies are needed to improve and validate the available prediction models.

"Conflict-free communication skills" as a new academic course in the medical students' education

A. M. Bukinich[1]* and A. M. Konovalova[1,2]

[1]Faculty of Psychology, Lomonosov Moscow State University and [2]Department of Pedagogy and Medical Psychology, Sechenov University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1540

Introduction: The professional activity of doctors is often associated with conflict situations, so it is important for them to obtain conflict-free communication skills during their education. These skills can be formed during a new academic course in curriculum. In this paper, we describe the prerequisites of the course "Conflict-free communication skills" on the sample of teaching pediatrics students at the Sechenov University.
Objectives: To clarify the possibility and expediency integration of a new course into the curriculum of medical students.
Methods: The primary method employed is bibliographic analysis.
Results: The main purpose of a new course is the formation of universal, general professional and professional competencies in verbal and nonverbal communication for medical students. It is necessary for medical students to acquire the basic principles of communication psychology and the formation of conflict-free communication skills. In the process of organizing education for future medical staff, it is important to start from the basic concept of communication, not from the basic concept of conflicts. From our point of view, the concepts of effective communication and conflict-free communication are interrelated. To make this course more practical, classes should be held in the format of business games, case studies, and social-psychological training.
We have identified the following sections of the discipline:

The phenomenon of communication;
Business communication and its types;
Psychological boundaries and their violations;
Empathy in the work of a doctor;
Teamwork and collaboration.
Conclusions: The integration of a new course into the curriculum of medical students will allow us to develop conflict-free communication skills and teamwork, thereby simplifying business communication in the medical field.

End-of-life decision-making in the ICU: perspectives on who "should" decide and influencing factors

S. Georgakis[1,2]*, E. Dragioti[1], G. Papathanakos[2,3], M. Gouva[1] and V. Koulouras[2,3]

[1]Research Laboratory of Patient, Family & Health Professional Psychology, Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina, Greece; [2]Department of Medicine, School of Health Sciences, University of Ioannina, Ioannina, Greece, University of Ioannina and [3]Intensive Care Unit, General Hospital of Ioannina, Ioannina, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1541

Introduction: Discrepancies often arise between experts and non-experts regarding their roles in making end-of-life (EOL) decisions within the Intensive Care Unit (ICU). Such decisions are frequently contentious in clinical settings, with wide-ranging consequences in legal, ethical, psychological, social, and clinical contexts.
Objectives: The aim of this study was to systematically review the global perspectives of physicians, nurses, family members, and the general public on who "should" be involved in decision-making for adult ICU patients, as well as to identify potential influencing factors.
Methods: Adhering to the PRISMA 2020 guidelines, a comprehensive literature search was performed across PubMed, EMBASE, and CINAHL databases. A data extraction table was developed,

validated through discussion and implemented by two independent researchers. The extracted data were subsequently analyzed descriptively.
Results: Thirty-three studies were included, documenting variations in findings across different geographical and temporal contexts. Most participants in these studies were healthcare professionals. Despite evidence of paternalistic tendencies, physicians generally showed a growing inclination toward a more collaborative decision-making model. Similarly, the views of other population groups leaned towards patient and family involvement, with nurses additionally supporting their own participation. Six categories of influencing factors were identified, with legal/regulatory considerations and participant demographics emerging as the most significant.
Conclusions: The overall representation of participants' perceptions highlights a broader tendency towards collaborative decision-making. This requires coordinated efforts from both clinical practitioners and policymakers to establish a decision-making framework that is inclusive, context-sensitive, and adaptable to the legal and cultural specifics of each region. To this end, emphasis should be placed on national-level interventions that address these issues directly, as opposed to broader, supranational approaches that may lack the necessary nuance.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1542

Introduction: The risk of self-harm is highest in younger age groups, with increasing numbers of under-18s being admitted to hospital due to self-harm in recent years in the UK1,2. The National Institute for Health and Care Excellence (NICE) guidelines for self-harm in adolescents over eight was updated in September 2022 and reinforces the need for the proper initial management of adolescent self-harm3. To our knowledge, our study is the first UK national audit on the management of self-harm in adolescents presenting to the emergency department using the updated NICE guidelines.
Objectives: To assess the clinical management of children and adolescents who present to the Emergency Department (ED) following self-harm, a cross-sectional, multicentre study was conducted within teaching hospitals affiliated with nine medical schools across England, Wales and Scotland.
Methods: Data was retrospectively collected from ED records using consecutive sampling of individuals aged 8 to 17 years who presented with self-harm from 7 Sep-7 Nov 2022.
Results: Records from 328 patients were included in the final analysis. Most patients were female (82.0%) and white (68.2%), with a mean age of presentation of 14.7 (σ = 1.58). The rate of positive responses to each question is available in Table 1. A 'positive' response is defined as a 'yes' response, rather than 'no' or 'not documented'.

Table 1. Rate of compliance with audit criteria

Guideline number	Criteria	Rate of positive response (%)
1.3.1	All staff who have contact with people who self-harm should ask about safeguarding concerns.	56.4
1.2.2	Recognise the need to seek consent from the person as early as possible.	73.5
1.5.2	Do not delay the psychosocial assessment until after medical treatment is completed. *Question:* Was psychosocial assessment delayed until after medical treatment is completed?	17.8
1.5.15	Together with the person who self-harms and their family and carers, develop or review a care plan using the key areas of needs and safety considerations identified in the psychosocial assessment	68.9
1.6.6	Undertake a risk formulation as part of every psychosocial assessment.	45.5
1.9.2	If a 16-/17-year-old is admitted to a general hospital, ensure that it is to a ward that can meet the needs of young people.	26.1
1.11.12	Discuss with the person harm minimisation strategies that could help to avoid, delay or reduce further episodes of self-harm and reduce complications.	43.2

Conclusions: This is the first study, to our knowledge, that investigates the management of self-harm in under 18s across the UK using the updated NICE guidelines. Some criteria may have been adhered to but not documented. The results from this study provide support for the further improvement of clinical practice in the management of self-harming children and adolescents.

The Impact of a Digital Guideline Version on Schizophrenia Guideline Knowledge: Results from a Multicenter Cluster-Randomized Controlled Trial

T. Halms[1*], G. Gaigl[1], C. Lorenz[2], D. Güler[1], N. Khorikian-Ghazari[1], A. Röh[1], S. Leucht[2] and A. Hasan[1,3]

[1]Department of Psychiatry and Psychotherapy, Medical Faculty, University of Augsburg, Augsburg; [2]Department of Psychiatry and Psychotherapy, Technische Universität München, Munich and [3]Partner site Munich/Augsburg, German Center for Mental Health (DZPG), Munich/Augsburg, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1543

Introduction: While clincial practice guidelines are an effective means of improving healthcare, they are not always adequately implemented. A recent study of the German S3 guideline for schizophrenia (version 2019) revealed low rates of adherence among medical professionals (Khorikian-Ghazari *et al.* Eur Arch Psychiatry Clin Neurosci 2023, 1-12). The factors impeding adherence are numerous and encompass individual, contextual, and guideline-related elements. The present study (Halms *et al.* 2024 BMC Medicine 2024, 22(1) 311) examines the efficacy of a digital guideline version in comparison to print/PDF formats with respect to guideline knowledge.
Objectives: The primary aim of this study was to assess whether healthcare professionals using a digital version of the schizophrenia guideline achieved greater knowledge gains than those using traditional print or PDF formats. Secondary objectives included examining the usability of the formats, shared decision-making capabilities, and confidence in clinical decision-making.
Methods: A multicenter, cluster-randomized study was conducted in psychiatric hospitals in South Bavaria, Germany. Medical and psychological staff were divided into two groups: Implementation of the guideline via the digital MAGICapp platform or the conventional print/PDF version. The study comprised a baseline assessment (T0) and a post-intervention assessment (T1) after a six-month implementation phase. The primary outcome measure was guideline knowledge, measured by knowledge questions about the contents of the German S3 guideline for schizophrenia.
Results: A total of 217 subjects participated at the initial assessment (T0), while 120 subjects completed the follow-up assessment (T1). Both groups demonstrated notable gains in knowledge, yet no significant differences were observed between the two groups. At T0, 43.6% of the control group and 52.5% of the intervention group met the specified criterion. With regard to the primary outcome (≥ 30 of 46 knowledge questions and all five cardinal questions answered correctly), no significant difference was found at either T0 or T1 (T0: $Chi^2_{(1)} = 1.65$, $p = 0.199$, T1: $Chi^2_{(1)} = 0.34$, $p = 0.561$). Following the intervention, 58.2% of the control group and 63.5% of the intervention group met the primary outcome.
Conclusions: Overall, a significant improvement in guideline knowledge was demonstrated throughout the implementation process. The digital guideline version did not demonstrate superiority in knowledge gain, but it did show potential advantages in shared decision-making. The results may have been influenced by familiarity with conventional formats and barriers to implementing digital applications. The study highlights the importance of needs-based, structured implementation strategies, particularly for younger practitioners with less professional experience.

Comparative Effectiveness of Olanzapine Versus Haloperidol in Treating Delirium: A Systematic Literature Review and Meta-Analysis of Randomized Trials

D. Soler Lopes[1]*, I. B. De Oliveira[2], M. L. Geremias[3] and A. L. Stephany[4]
[1]Lancaster University, Lancaster, United Kingdom; [2]USP, Sao Paulo; [3]UNIVILLE, Joinvile and [4]Serviço ntegrado de Saúde, Jacareí, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1544

Introduction: Delirium, as described in the DSM-V, is a disruption in attention and consciousness that develops over a brief period, representing an acute change from baseline awareness. First-generation antipsychotics, such as haloperidol, are often advised as the first line of pharmacological treatment. In comparison to haloperidol, olanzapine appears to be more beneficial in terms of efficacy and safety, according to a 2016 systematic review and meta-analysis of randomized clinical studies. However, most of the research included were single-center investigations with tiny sample numbers, diverse study demographics, and bias potential.
Objectives: The aim of this systematic review was to identify the current best evidence on the effectiveness of olanzapine versus haloperidol in various clinical settings to guide best practices for healthcare professionals. Also, this literature review seeks to provide a up-to-date synthesis of the current evidence on this subject.
Methods: We conducted a systematic search of four databases (PubMed, PsycINFO, CINAHL, and Cochrane Central) from inception through January 31st, 2024, using keywords related to delirium (acute confusion, confusion state, confusional state), olanzapine, and haloperidol. The search was limited to randomized controlled trials comparing olanzapine with haloperidol, without restrictions on dose, route of administration, or drug exposures. When analyzing outcomes with a robust number of studies, we applied a random-effects model. For outcomes with fewer studies, we used a fixed-effects model. Additionally, we conducted sensivity and subgroup analyses. All statistical evaluations were performed using the RevMan software.
Results: Seven studies met our inclusion criteria. Haloperidol was associated with a significantly lower severity of delirium after 2-3 days of treatment compared to olanzapine, with a small effect size (g = 0.40, 95% CI [0.02; 0.78], p = 0.04) based on three studies (n = 110). However, no significant difference was observed after 4-7 days

(g = 0.09, 95% CI [-0.26; 0.44], p = 0.61) across five studies (n = 306). There was no significant difference in overall side effect rates between haloperidol and olanzapine (p = 0.29, 7 studies, n = 530), but haloperidol resulted in significantly more extrapyramidal side effects (p = 0.008). Sedation as an adverse effect did not differ significantly between the two drugs (p = 0.54, 4 studies, n = 284).
Conclusions: Haloperidol may offer superior short-term efficacy in reducing delirium severity but is associated with a higher risk of extrapyramidal symptoms. No significant differences were found in long-term efficacy or sedation rates between olanzapine and haloperidol. These findings support the need for careful consideration of drug safety profiles in the treatment of delirium.

Comprehensive Analysis of Hormone Formulations and Emotional Effects in Transgender Men Undergoing Hormone Replacement Therapy

A. Stewart[1]*, B. Carr[2] and L. Schmidt[2]

[1]College of Allopathic Medicine, Nova Southeastern Univeristy, Ft. Lauderdale and [2]Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1545

Introduction: Hormone replacement therapy (HRT) for transgender men involves various formulations of testosterone, each exhibiting unique pharmacokinetic profiles and emotional impacts. A comprehensive understanding of these variations is crucial for optimizing treatment outcomes and managing side effects effectively.
Objectives: This study aims to elucidate the differential emotional effects associated with various testosterone formulations used in HRT for transgender men.
Methods: A comprehensive literature review was conducted using databases such as PubMed, Scopus, and Web of Science. The review focused on four primary testosterone administration methods: intramuscular and subcutaneous injections, transdermal patches and gels, oral testosterone, and implantable pellets. Key metrics evaluated included pharmacokinetics, emotional effects, and nature of side effects.
Results: The review identified distinct pharmacokinetic profiles and emotional responses associated with each testosterone formulation:
Intramuscular and Subcutaneous Injections: These methods showed peak testosterone levels within 24-48 hours, followed by a decline over one to two weeks. Emotional effects included mood elevation and increased energy during the peak phase, with potential irritability or anxiety. The trough phase was marked by mood swings and depressive symptoms, particularly before the next injection. Side effects such as acne and libido changes peaked shortly after injection and decreased before the subsequent dose.
Transdermal Patches and Gels: These methods maintained consistent blood testosterone levels, resulting in stable mood and emotional states with reduced mood swings. Initial therapy adaptation caused mild mood changes, and side effects were primarily localized to skin irritation at application sites.
Oral Testosterone: Testosterone undecanoate offered stable testosterone levels with consistent mood regulation. Gastrointestinal side effects were common, and emotional stability varied based on absorption rates and adherence to dosing schedules.
Implantable Pellets: These provided the most stable testosterone levels over several months, leading to very stable emotional states with minimal mood fluctuations. Side effects included localized reactions such as discomfort or infection at the implantation site, with minimal systemic side effects.
Conclusions: The choice of testosterone formulation significantly impacts the emotional well-being of transgender men undergoing HRT. Intramuscular and subcutaneous injections were associated with emotional fluctuations tied to hormone peaks and troughs, while transdermal, oral, and implantable methods provided more stable hormone levels and emotional states. Regular monitoring and individualized modifications are crucial to optimizing physiological and emotional outcomes and enhancing the quality of life for transgender men.

Involvement of loved ones in the rehabilitation process for severe neurotrauma in children

Y. Afanasyeva[1]* and M. Bratkova[1,2]

[1]Moscow City University and [2]Clinical and Research Institute of Emergency Pediatric Surgery and Trauma (CRIEPST), Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1546

Introduction: Among children with developmental disabilities, there is a group with consequences of neurotrauma that requires comprehensive support at different age stages, with the obligatory inclusion of the family in the rehabilitation process. These children are shown both medical and psychological and pedagogical rehabilitation, the effectiveness of which is determined by the active position of the patient's relatives.
Objectives: The study the factor of involvement of close patients with neurotrauma in the rehabilitation process: manifestations of psychophysical activity.
Methods: 140 children with neurotrauma consequences with neuropsychiatric disorders (2021-2024) and 136 families. Medical and pedagogical method with observation, examination, diagnostic and typological assessment of children's mental activity; cluster analysis of the results of studying families (parents) as participants in rehabilitation.
Results: Clusters were identified based on the assessment of the activity of parents' inclusion in the rehabilitation process:

Cluster 1. Active families (40%). The patient's relatives follow all the instructions of the specialists, are an important and integral part of the rehabilitation team. Children from the families studied show both qualitative and quantitative gains in rehabilitation, predominantly in the socio-communicative and cognitive domains.
Cluster 2. Estranged families (60%). Adults formally relate to rehabilitation activities. In children from these families, the dynamics of recovery is limited to an insignificant increase in psychophysical activity indicators, without transition to a higher level.

Conclusions: The effectiveness of the rehabilitation process for severe neurotrauma in childhood is influenced by the involvement of adults close to the child. The personality traits of the parents, adaptability and resistance to stress, the severity of the child's illness - these factors turn out to be decisive. Most loved ones need medical and psychological support. Regardless of the severity of neurotrauma in children, parents become more active if they note the dynamics in improving mental health. In case of long-term, severe illness of children accompanied by disability, family members only provide care and supervision.

Categorization in different modalities as cognitive processes impairment indicator in children with developmental learning disorder

A. M. Bukinich[1]*, G. D. Vzorin[1] and A. M. Konovalova[1,2]

[1]Faculty of Psychology, Lomonosov Moscow State University and [2]Department of Pedagogy and Medical Psychology, Sechenov University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1547

Introduction: Categorization is one of the main processes representing human thinking. There is plenty of categorization study methods, but none use the same methodology to study categorization in different modalities. Notably, it is hard to compare results of such categorization directly due to the different category familiarity degree. For example, visual forms and number of visual stimuli are more familiar than number of syllables, plural or singular word form. However, it is possible to compare quality (type) of categorization errors in different modalities considering the relation to different cognitive processes.
Objectives: To explore the categorization errors in visual and verbal modalities.
Methods: A special task inspired by Bruner concept formation study was used. 49 children with developmental learning disorder had to recognize common features in series of visual or verbal stimuli (5 series of 30 stimuli in each modality).
Results: 15 error types were identified in both visual and verbal modalities indicating the impairment of working memory, executive control, nominative processes, cognitive speed and categorization level.
Conclusions: Studying types of categorization errors may indicate the cognitive processes impairment and helps to clarify the relation between categorization and modality of input information.

Psychiatric and behavioral problems in Prader-Willi syndrome: a clinical case

I. M. Marques[1]*, S. Abreu[1] and M. C. Coroa[1]

[1]Department of Psychiatry, Centro Hospital e Universitário de Coimbra, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1548

Introduction: Prader-Willi syndrome (PWS) is a rare neurodevelopmental and multisystemic disorder. This syndrome is most often caused by paternal deletion or a maternal disomy of chromosome 15. PWS is characterized by hypotonia, hypogonadism, and hyperphagia. Intellectual disability, impaired social skills, emotional regulation, sleep disorders and behavioral problems (tantrums, temper outbursts, obsessive–compulsive symptoms, skin picking) are also present. Autism spectrum disorder, mood disorders, anxiety, and psychosis are common in these individuals. (Bos-Roubos *et al.* Frontiers in psychiatry 2022; 13 897138).
Objectives: The aim of the case is providing a review of psychiartric and behavioral problems in PWS.
Methods: Clinical case description and literature review on the subject.
Results: We report a clinical case of a 23 year old man who was diagnosed with PWS. Clinical features includes intellectual disability, obesity, scoliosis bracing, probable hypoventilation-obesity syndrome [using non-invasive ventilation], hypercholesterolemia and hypogonadism. He took 3 doses of testosterone in 2017, which had to be suspended due to serious changes in behavior. Behavioral sporadic problems, reactive to the environment, are also present such as impulsiveness, stubbornness, aggressive outbursts, oppositional behavior, self-injuring behavior (placement of foreign bodies in the ear canal), card obsession and suspicious posture. This clinical condition has an impact on PWS relatives and at social level. He was medicated with Paliperidone 9mg; Topiramate 50mg; Clozapine 25mg; Escitalopram 10mg; and Haloperidol 2mg/ml (SOS). Currently, the patient is stable, with little weight gain and sporadic episodes of greater impulsivity without clinical relevance. He has participating in integrated activities at the institution.
Conclusions: The main limitations in adolescence/adulthood are psychiatric and behavioral comorbidities, in association with hyperphagia and intellectual disability, which become more prominent with age. However, these symptoms are highly variable among individuals of different ages. Antipsychotics have been used for management of psychiatric and/or behavioral comorbidities. Other medications have also been used such as antidepressants (SSRI), antiepileptics, mood stabilizers and the response may vary depending on the individual. Weight gain, due to atypical antipsychotics, can be mitigated when food has controlled access. PWS has a major impact on the individual's social and family environment, which requires an appropriate multidisciplinary strategy. A safe and constant environment as well as behavioral management programs must be ensured. (Butler *et al.* Current pediatric reviews 2019; 15 207-244).

EPV0903

Fragile X Syndrome and multidisciplinary strategy: a clinical case

I. M. Marques[1]*, S. Abreu[1] and M. C. Coroa[1]

[1]Department of Psychiatry, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1549

Introduction: Fragile X Syndrome (FXS) is a hereditary disease, linked to the X chromosome. FXS is the most common form of

inherited intellectual disability and monogenic cause of Autism Spectrum Disorder (Protic *et al*. Developmental medicine and child neurology 2024; 66,7 863-871). Other clinical features includes speech and language delay, deficits in executive functioning, attention deficit hyperactivity disorder, sensory hyperarousal, social anxiety and aggressive behaviour. Cardiac abnormalities, musculoskeletal and gastrointestinal symptoms are also present.

Objectives: The aim of the case is providing a review of multidisciplinar strategy in Fragil X Syndrome.

Methods: Clinical case description and literature review on the subject.

Results: We report a clinical case of a 25 year old man was diagnosed with autism spectrum disorder, moderate intellectual disability, associated with Fragile X Syndrome. The patient is followed up in a Psychiatry (neurodevelopment) consultation. The present clinical condition causes multiple difficulties in managing his daily life, requiring supervision to carry out most of the tasks assigned to him, resulting in dependence on a third person. Furthermore, the patient has permanent total incapacity for any employment activity. Despite the diagnosis presented, as a result of investment on the part of the clinical, school, social action teams and especially his parents, the patient does not present behavioral changes that justify, at the moment, the use of any psychotropic drug. However, it is important to have access to all non-pharmacological therapies, otherwise the patient will lose the benefits achieved to date. The patient is currently stable, taking a course to become an administrative assistant at an institution. He participates in dance groups, speech therapy and hydrotherapy.

Conclusions: The best approach involves a targeted intervention to control symptoms and improving the quality of life. The management includes non-pharmacological strategies, such as individualized educational support, applied behavior analysis, physical, occupation and speech-language therapy. A pharmacologic strategies that includes, for exemple, SSRIs and/or antipsychotics is often helpful. FXS has a major impact on the individual's social and family environment, which requires an appropriate multidisciplinary strategy that includes occupational, physical therapists, teachers, psychologists and psychiatrists. (Protic *et al.* International journal of molecular sciences 2022; 23 1935).

"Exploring Nurses' Perspectives on the Behavioral Responses of Residents with Intellectual Disabilities and Dementia in Social Welfare Centers"

E. Naki[1]*, A. L. Batiridou[1], S. Mantzoukas[2], M. Gouva[1] and Z. Konstanti[1]

[1]Research Laboratory of Psychology of Patients, Families and Health Professionals, School of Health Sciences, Department of Nursing and [2]Research Laboratory of Integrated Health, Care and Well-being, School of Health Sciences, Department of Nursing, University of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1550

Introduction: The behavioral disorders of individuals with dementia, as well as the attitudes and behaviors of people with intellectual disabilities, create challenges both in their home environment and for the nursing staff responsible for their care in Social Welfare Centers. This phenomenon is widely examined in both international and Greek literature; however, it remains a complex and multifactorial issue, not only in defining behavioral disorders but also in identifying the factors that cause them.

Objectives: This qualitative study aims to explore how nurses at Social Welfare Centers perceive behavioral disorders, the factors they associate with them, and their emotional reactions. The goal is to gain an in-depth understanding of the phenomenon, highlight its significance, and bring forward the nurses' perspectives.

Methods: A qualitative approach was adopted to explore the relationship between nurses and beneficiaries due to behavioral disorders. A relational perceptual framework was used. Eight semi-structured interviews were conducted with permanent nursing staff from Social Welfare Centers. This was followed by a literature review of behavioral disorders, focusing on both nurses and beneficiaries.

Results: The qualitative data analysis revealed three key themes: the role of the nurse and their relationship with beneficiaries in Social Welfare Centers, the behavioral disorders and emotional reactions of nurses based on their experiences, and the need for nursing staff education, along with the importance of an interdisciplinary team.

Conclusions: The onset, worsening, reduction, or elimination of behavioral disorders depends on the complex interaction between nurses and patients with dementia or intellectual disabilities. The need to focus on factors that increase the occurrence of such behaviors is emphasized, to assist nurses working in long-term care facilities in managing them without compromising the quality of care provided to the beneficiaries. More studies are required to provide guidelines for better management of behavioral disorders.

EPV0905

Comparative Efficacy of Second-Generation Antipsychotics vs. SSRIs in Managing Behavioral Symptoms in Children and Adolescents with Autism Spectrum Disorder

H. M. Nguyen[1]*, L. Schmidt[2] and B. Carr[2]

[1]University of Florida College of Medicine, Gainesville, FL, United States and [2]Psychiatry, University of Florida College of Medicine, Gainesville, FL, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1551

Introduction: Autism Spectrum Disorder (ASD) is characterized by social interaction challenges, repetitive behaviors, and behavioral issues such as irritability, aggression, and hyperactivity. These symptoms lead to significant functional impairments, placing emotional and financial burdens on caregivers. Current treatment options include second-generation antipsychotics (SGAs) and selective serotonin reuptake inhibitors (SSRIs), but direct comparisons of their efficacy in managing ASD-related behaviors are limited.

Objectives: This review aims to compare the efficacy and safety of SGAs and SSRIs in reducing behavioral symptoms in children and adolescents with ASD.

Methods: A comprehensive systematic review by Lamy et al. (2020) evaluated over 50 studies on pharmacotherapy for ASD, including randomized clinical trials (RCTs) of SGAs like risperidone and aripiprazole. Other studies focused on specific SSRIs, such as citalopram, in ASD populations. Additionally, two notable trials were

included: Ghanizadeh et al. (2014), which compared aripiprazole and risperidone, and King et al. (2009), a placebo-controlled study on citalopram.

Results: Lamy et al. reported that SGAs, particularly risperidone and aripiprazole, significantly reduced irritability scores on the Aberrant Behavior Checklist (ABC) and Clinical Global Impression (CGI) scales ($p<0.05$), aligning with their FDA approval for ASD treatment. Ghanizadeh et al. (2014) also found that aripiprazole and risperidone reduced ABC scores (12.6 points for aripiprazole and 9 points for risperidone), though both were associated with side effects, such as increased appetite (34.5% for aripiprazole and 40% for risperidone) and drooling.

In contrast, King et al. (2009) found no significant improvement with citalopram over placebo (CGI-I improvement: 32.9% for citalopram vs. 34.2% for placebo) and noted more adverse effects in the SSRI group, including impulsiveness and insomnia. The review highlighted limitations, including methodological heterogeneity, lack of direct comparisons between SGAs and SSRIs, and variability in treatment duration.

Study	Intervention	Sample Size	Outcome Measure	Key Findings
Lamy et al. (2020)	SGAs (multiple RCTs)	>50 trials	ABC, CGI	Significant reduction in irritability ($p<0.05$)
Ghanizadeh et al. (2014)	Aripiprazole, Risperidone	59	ABC	Reduction in symptoms; fewer adverse events with aripiprazole
King et al. (2009)	Citalopram, Placebo	149	CGI, CY-BOCS	No significant benefit over placebo; more adverse effects

Conclusions: In conclusion, SGAs appear more effective than SSRIs in managing ASD-related behavioral symptoms, particularly irritability. Despite limitations, SGAs show consistent benefits with a manageable safety profile. Future research should prioritize direct SGA vs. SSRI trials and longer treatment durations to inform clinical decision-making in ASD pharmacotherapy.

EPV0906

Current Treatment Approaches for Affective and Anxiety Disorders in Adults with Intellectual and Developmental Disabilities

H. M. Nguyen[1]*, D. Valle[1] and B. Carr[2]

[1]University of Florida College of Medicine, Gainesville, FL, United States and [2]Psychiatry, University of Florida College of Medicine, Gainesville, FL, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1552

Introduction: Adults with intellectual and developmental disabilities (IDD) have higher rates of psychiatric disorders, such as depression, anxiety, and bipolar disorder, compared to the general population. Unique challenges, like cognitive impairments and communication barriers, require tailored treatments. This poster reviews strategies for managing these conditions in adults with IDD, focusing on adaptations in psychopharmacology and psychotherapy.

Objectives: To outline treatment approaches for depression, anxiety, and bipolar disorder in adults with IDD, highlight limitations and necessary adaptations, and advocate for collaborative treatment models involving healthcare providers and caregivers.

Methods: A literature review identified studies and guidelines on psychopharmacologic and psychotherapeutic interventions tailored to adults with IDD, examining the effectiveness of pharmacological agents, cognitive behavioral therapy (CBT), and other adaptations.

Results: Current treatments for depression, anxiety, and bipolar disorder in adults with intellectual and developmental disabilities (IDD) often deviate from standard protocols, requiring modifications in both pharmacological and therapeutic approaches. Depression management in IDD typically relies on selective serotonin reuptake inhibitors (SSRIs), adapted with gradual dose escalation and close monitoring due to limited data on their specific effects in this population. Psychotherapy, particularly group cognitive behavioral therapy (CBT), has shown notable efficacy, with studies reporting significant symptom reduction in treated groups. For anxiety disorders, low-dose SSRIs remain the primary pharmacological option, with cautious titration to minimize adverse effects, while benzodiazepines are generally avoided to prevent paradoxical responses and disinhibition. CBT-based interventions, including graduated exposure therapy customized for specific phobias or triggers, show promise, though further randomized trials are warranted. Managing bipolar disorder in IDD is particularly challenging due to the heightened risk of severe functional impairment and symptom overlap, with mood stabilizers like lithium and antipsychotics administered sparingly given potential metabolic and neurological side effects. Given limited research, clinical strategies often rely on individualized treatment plans informed by provider expertise and patient-specific needs.

Conclusions: Treatment for psychiatric disorders in adults with IDD requires significant adaptation, with careful dosing and monitoring of medications to minimize adverse effects. Evidence supports CBT as an effective option, yet there is a critical need for more research, especially randomized trials, to develop more robust guidelines specific to this population. Close collaboration between healthcare providers and caregivers is essential for successful outcomes.

Overview of Psychiatric Conditions in Adults with Intellectual and Developmental Disabilities (IDD)

H. M. Nguyen[1]*, D. Valle[1], E. Jetter[1], A. Gomes[1], A. Lertkitcharoenpo[1], M. Liu[1] and B. Carr[2]

[1]University of Florida College of Medicine, Gainesville, United States and [2]Psychiatry, University of Florida College of Medicine, Gainesville, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1553

Introduction: Adults with intellectual and developmental disabilities (IDD) are more likely than the general population to experience

psychiatric disorders, with prevalence rates estimated at 33-40%. These individuals often display atypical symptoms, complicating diagnosis. Primary care providers are often the first to encounter these patients but face challenges due to limited training and "diagnostic overshadowing"—the misattribution of psychiatric symptoms to the IDD itself rather than recognizing comorbid mental health conditions.

Objectives: This study aims to: (1) highlight the prevalence and unique presentations of psychiatric disorders in adults with IDD, (2) discuss diagnostic challenges, particularly diagnostic overshadowing, in primary care, and (3) advocate for collaborative care models to improve diagnostic accuracy and outcomes.

Methods: A literature review across PubMed, Medline, and PsycINFO focused on studies addressing psychiatric prevalence in IDD, diagnostic barriers, and the efficacy of collaborative care models in managing complex cases in primary care.

Results: Adults with IDD show high rates of mood disorders, anxiety, ADHD, and psychotic disorders, often presenting atypically. For example, ADHD may show as prolonged attentional and behavioral difficulties, impacting social and functional skills. Anxiety may present as agitation or sensitivity to routine changes, often misinterpreted as behavioral issues. Mood disorders, especially depression, tend to appear as irritability or somatic complaints, which are frequently attributed to the IDD itself. Psychotic disorders are also prevalent, particularly among individuals with certain genetic syndromes, and complicate diagnosis due to overlapping symptoms.

Diagnostic overshadowing significantly impacts accurate psychiatric diagnosis in adults with IDD, as primary care providers often attribute psychiatric symptoms to the disability itself. Limited IDD-specific training in primary care compounds this issue. Collaborative care models, where primary care providers collaborate with mental health specialists familiar with IDD, show promise in addressing these diagnostic and treatment challenges, especially for complex cases.

Conclusions: Effective psychiatric care for adults with IDD requires specialized provider training, comprehensive evaluations sensitive to atypical presentations, and collaborative care models. Addressing diagnostic overshadowing through improved training and integrated care can enhance psychiatric outcomes for this underserved population. Further research, particularly randomized controlled trials, is needed to develop evidence-based guidelines for tailored care in adults with IDD.

EPV0908

Improving Psychiatric Care for Adults with Intellectual and Developmental Disabilities (IDD)

H. M. Nguyen[1]*, S. Joseph[1], M. Liu[1] and B. Carr[2]

[1]University of Florida College of Medicine, Gainesville, FL, United States and [2]Psychiatry, University of Florida College of Medicine, Gainesville, FL, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1554

Introduction: Adults with intellectual and developmental disabilities (IDD) often struggle to access suitable psychiatric care due to cognitive and communication challenges. Traditional mental health services are not always well-equipped for these needs, highlighting a critical need for evidence-based, IDD-specific guidelines. Expanding research, especially randomized controlled trials (RCTs), is essential to develop personalized, effective treatments for this population.

Objectives: This poster aims to outline current gaps in psychiatric care for adults with IDD, propose strategies for treatment adaptation, and emphasize research priorities to advance evidence-based care for this underserved group.

Methods: A literature review assessed studies on treatment adaptations for IDD, focusing on the effectiveness of current interventions and limitations in existing research. Priority was given to innovative care approaches and adaptations in standard mental health treatments.

Results: Psychiatric care for adults with IDD often involves adapting treatments like cognitive-behavioral therapy (CBT) and pharmacotherapy with simplified, patient-centered methods. For example, CBT adaptations may include breaking techniques into smaller steps, using visual aids, and shorter sessions, which accommodate cognitive limitations. Personalized care is essential due to varying abilities within this population. Pharmacological treatments also require careful titration and close monitoring, as the risk of side effects is higher among those with IDD. However, few RCTs assess the efficacy and safety of treatments for severe psychiatric disorders in the IDD population, underscoring the need for more rigorous research to support clinical guidelines. To overcome recruitment and follow-up barriers in RCTs, studies suggest alternative methods such as targeted outreach through day centers, provider organizations, and one-on-one approaches, which have been effective in reducing dropout rates. Furthermore, bipolar disorder treatment in IDD is particularly under-researched, despite its significant impact on quality of life, highlighting a need for focused studies in this area.

Conclusions: Enhancing psychiatric care for adults with IDD will require systemic changes, including increased research funding, IDD-specific clinical guidelines, and improved provider training. RCTs focused on adapted therapies and pharmacological interventions are crucial to build a strong evidence base. By promoting individualized, evidence-based approaches, the field can better meet the unique needs of adults with IDD, ultimately improving mental health outcomes and quality of life.

Genetic Considerations in Psychiatric Treatment for Individuals with Intellectual and Developmental Disabilities (IDD)

D. B. Valle[1], H. M. Nguyen[1]* and B. R. Carr[1]

[1]College of Medicine, University of Florida, Gainesville, FL, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1555

Introduction: Genetic testing has become an essential tool in managing psychiatric conditions among individuals with intellectual and developmental disabilities (IDD). The frequent presence of genetic syndromes within this population underscores the value of genetic insights for guiding personalized treatment. By integrating pharmacogenetics into care, clinicians enhance medication efficacy and reducing the likelihood of adverse effects.

Objectives: This study aims to elucidate the role of genetic testing in identifying specific syndromes and psychiatric comorbidities in IDD, explore the application of pharmacogenetic insights to optimize psychiatric medication management, and highlight case examples that demonstrate how genetic insights influence treatment decisions.
Methods: A targeted literature review identified relevant studies on genetic syndromes linked to IDD, the impact of genetic testing in psychiatric care, and the application of pharmacogenetic data in guiding medication management. Key studies examined the pharmacogenetic profiles of individuals with IDD and their effects on treatment outcomes, focusing on findings that can inform personalized treatment strategies.
Results: Fragile X syndrome (FXS), a prevalent genetic disorder among IDD populations, is associated with high rates of anxiety, ADHD, and autism spectrum disorder (ASD). Research shows that stimulant medications commonly used for ADHD may worsen agitation in individuals with FXS, making non-stimulant options or behavioral therapies preferable. Pharmacogenetic findings, such as variations in serotonin-related gene polymorphisms, have been linked to increased aggression and stereotypic behaviors in males with FXS, guiding clinicians toward selective serotonin reuptake inhibitors (SSRIs) or alternative behavioral approaches. In cases of DiGeorge syndrome (22q11.2 deletion syndrome), genetic testing identifies an increased risk for psychotic disorders, and genetic variants may affect drug metabolism. Findings from the IMPACT study, a Centre for Addiction and Mental Health (CAMH) project, highlight the benefits of tailoring medications based on genetic markers, such as CYP2D6 and CYP2C19 enzyme activity. These insights improve outcomes by reducing side effects like sedation and enhancing therapeutic efficacy, especially for IDD patients who may respond unpredictably to psychiatric medications.
Conclusions: Genetic testing is invaluable in the psychiatric management of individuals with IDD, offering insights that enable more personalized and effective treatment approaches. By identifying genetic syndromes and incorporating pharmacogenetic data into medication planning, clinicians can minimize adverse effects, tailor therapies, and improve patient outcomes. Ongoing research and broader access to pharmacogenetic testing are essential to further refine treatment protocols for the IDD population.

Multimodal Management of a Patient with Severe Mental Disorder: A Case of Escape and Re-admission to a Long-Term Psychiatric Care Unit

R. Albillos Pérez[1]*, C. Peláez Fernández[2], S. Castelao Almodóvar[2], A. Castelao Escobar[1], P. Sanz Sánchez[1], C. Alguacil Núñez[1] and R. González Núñez[1]

[1]Psiquiatría, Hospital Universitario Puerta de Hierro Majadahonda and [2]Psiquiatría, Hospital Universitario El Escorial, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1556

Introduction: The follow-up of patients with severe mental disorders and disruptive behaviors poses a significant challenge, particularly when there is a history of high impulsivity and risk of escape. Effective coordination among mental health teams, support institutions, and families is essential to provide a safe therapeutic environment and facilitate rehabilitation. This case illustrates the complexity of managing a patient with conduct disorder and borderline intellectual functioning following a prolonged escape from a long-term psychiatric care center.
Objectives: To describe the clinical and outpatient management of a patient who escaped from a long-term psychiatric care facility. To evaluate the importance of multidisciplinary and inter-institutional coordination in the planning and follow-up of treatment to optimize the clinical and functional stability of the patient.
Methods: We present the case of a 26-year-old male with a history of conduct disorder and borderline intellectual functioning (IQ=60), problematic cannabis use, and gambling addiction. The patient was admitted to a Long-term Psychiatric Care Unit (UCPP) due to impulsive behaviors, aggression, and threats towards family members. The patient escaped and remained missing for 8 months. After being located and returning to the clinic, an outpatient intervention was initiated in coordination with the Madrid Agency for Support to People with Disabilities (AMAPAD) and the Regional Office of Mental Health and Addictions (ORSMA), assessing his readiness for re-admission and the adequacy of the treatment plan.
Results: Upon re-admission, the patient initially appeared cooperative, minimizing the behaviors that led to his previous admission. As the intervention progressed, signs of irritability and hostility emerged, with overvalued/delusional ideas of persecution from family and UCPP staff, and limited introspective capacity. Intensive treatment at the UCPP led to better acceptance of limits and reduced impulsivity, although deficiencies in awareness of his limitations persisted. A transfer to another long-term care unit, the recently inaugurated Recovery and Community Reintegration Unit (URCC), was planned, with intensive rehabilitation goals tailored to the patient's needs.
Conclusions: Proper coordination among institutions and flexibility in the therapeutic approach are essential for managing patients with severe mental disorders and high-risk behaviors. This case underscores the importance of a multimodal approach and adapting therapeutic strategies to the patient's clinical evolution, always prioritizing the safety and well-being of both the individual and their family environment.

Association of Antipsychotic Polypharmacy VS Monotherapy with psychiatric re-hospitalization among adults with schizophrenia followed By the ACT TEAM in Bronx

O. Alli-Balogun[1]*, U. Anyeji[1] and S. Gunturu[1]

[1]Psychiatry, Bronxcare Health System, New York, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1557

Introduction: The ACT team consists of mental health professionals with a wide range of expertise, including psychiatrists, psychologists, nurses, social workers, and peer specialists. The goal of ACT is to help patients achieve and maintain stability in the community, and to reduce the need for hospitalization and other

forms of institutional care and reduce the barriers to care by bringing the care to the Patient.
Upon discharge from the Psychiatric Hospital Patients are often sent home with more than one antipsychotic oral medication and are at times on two long-acting intramuscular preparations.
This is an example of polypharmacy which refers to the concurrent use of multiple medications to treat a single patient, polypharmacy is often used to manage patients with complex mental health conditions who may require multiple medications to address their symptoms.
Objectives: The AIM of the study is to determine the number of patients followed by the ACT team in the Bronx who are on 2 or more antipsychotics as compared to those on monotherapy who were re-hospitalized within 1 year of discharge.
Methods: This is a retrospective study on patients who are followed by Bronx ACT team affiliated with the Institute for Community Living (ICL) in NYC from February 2022 to February 2023. The study compared the number of re- hospitalizations of patients on 2 or more Antipsychotics as compared to those on Monotherapy from February 2022- February 2023. were a thorough review of charts of the 68 Clients being followed by the ACT team was done.
Results: Out of 68 patients being followed by the ACT team; 9 Patients were on 2 antipsychotics/ LAI (Long Acting Injectable) of which 5 patients were on 2 oral antipsychotics, 1 Patient on 3 oral antipsychotics, and 3 Patients on two long-acting intramuscular depot preparations of which five 5(3 for psychiatric related issues and 2 for medical reasons) out of 9 (55.55%) of this population were hospitalized in the 12-month reporting period of February 2022 to February 2023. As compared to 27 (45.7%) patients on monotherapy who were also hospitalized in the last 12-month reporting period.
All remaining 32 (54.2%) clients on monotherapy had no hospitalizations in the 12 months reporting period.
Conclusions: Patients who warrant the need to be followed by The ACT are majorly those who require intensive follow-up in the community and are mostly non-adherent with their medications and prescribing multiple antipsychotics that usually not taken should be carefully considered.
Due to the nature of the study no definite conclusion could be drawn regarding causality between APP and hospitalizations within the 12- month reporting period.

An epidemiological survey of occupational stress among teachers in Tunisia

A. Aloui[1,2,3]*, M. Bouhoula[1,2,3], E. Toulgui[2,4], N. Ganoun[1,2,3], A. Chouchane[1,2,3], M. Maoua[1,2,3], A. Brahem[1,2,3], H. Kalboussi[1,2,3], W. Ouanes[2,4], O. El Maalel[1,2,3], S. Jemni[2,4], I. Kacem[1,2,3] and S. Chatti[1,2,3]

[1]Occupational Medecine Department, University Hospital of Farhat Hached, Sousse, Tunisia; [2]University Of sousse, Faculty of Medecine Ibn El Jazzar, 4000 Sousse, Tunisia; [3]Research laboratory LR 19SP03, Study of the risks and prospects for the prevention of non-communicable diseases in the workplace and [4]Physical Medecine and Rehabilitation, University Hospital of Sahloul, Sousse, Tunisia, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1558

Introduction: Stress is one of the biggest problems facing teachers today. The increasingly demanding nature of their job has also increased pressure levels dramatically. Research shows that teachers are now facing greater day-to-day problems with occupational stress than most other employees.
Objectives: Determine the prevalence and the caracteristics of the occupational stress among teachers.
Methods: This is an exhaustive cross-sectional study carried out among the teachers of a private teaching group in the city of Sousse in Tunisia between October and December 2022. The data were collected using an anonymous questionnaire in electronic format 'Microsoft Forms' distributed by e-mail. The questionnaire included socio-professional and medical data. Ocuupational stress was assessed using the Karasek questionnaire.
Results: A total of 241 questionnaires were included, representing a response rate of 90.14%. The mean age of the teachers in this study was 39.98 ± 9.14 years, with a predominance of females (56.8%) and a sex ratio (M/F) of 0.75. In this private teaching group, there were 181 higer education teachers (75.1%) and 60 school teachers (24.9%).The average seniorty in this educational group was 3.49 ± 2.95 years. Participants worked an average of 4.88 ± 1.49 hours per day and 16.92 ± 7.39 hours per week. The majority of respondents had no medical (82.6%) or surgical (71.8%) co-morbidities. Only 10 (4.1%) teachers were anaemic, 6 (2.5%) were hypertensive and 4 (1.7%) were diabetic. More than half (55.6%) of the teachers had a BMI above the normal range: 102 participants were overweight (42.3%) and 32 (13.3%) were obese. As for lifestyle habits, 12.9% of teachers were smokers, 9.5% drank alcohol and 34.4% practised a sporting activity. Referring to Karasek's two-dimensional model, 59 (24.5%) of the 241 teachers were classified in a situation of <<Jobstrain>>associating: low latitude and high professional demands. By completing this model with the third dimension of social support at work, 35 (14.5%) of the 241 teachers were classified in a situation of <<Isostrain>> combining low latitude, high professional demands and low social support.
Conclusions: Action to improve work organisation and support for teachers would be necessary to prevent the occupational stress.

The Impact of workplace Harassment on Mental Health among healthcare workers

A. Aloui[1,2,3]*, R. Ghammem[4], M. Bouhoula[1,2,3], I. Kacem[1,2,3], Y. Tebouri[1,2,5], A. Chouchane[1,2,3], A. Koubaa[6], M. Maoua[1,2,3], A. Brahem[1,2,3], O. El Maalel[1,2,3], J. Maatoug[4], S. Chatti[1,2,3] and H. Kalboussi[1,2,3]

[1]Occupational Medecine Department, University Hospital of Farhat Hached, sousse, Tunisia; [2]University of Sousse, Faculty of Medecine Ibn El Jazzar, 4000, Sousse, Tunisia; [3]Research laboratory LR 19SP03, Study of the risks and prospects for the prevention of non-communicable diseases in the workplace; [4]Epidemiology Department, University Hospital of Farhat Hached; [5]University of Sousse, Study of the risks and prospects for the prevention of non-communicable diseases in the workplace and [6]Occupational medecine Department, University Hospital La Rabta, sousse, Tunisia, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1559

Introduction: Workplace harassment is one of the main psychosocial risks, leading to suffering at work or a lack of well-being.

It can compromise one's sense of safety and dignity and leave lasting scars on mental health.
Objectives: Determine the prevalence of workplace harassment in healthcare environments and evaluate its impact on mental health.
Methods: This is across-sectional study conducted among health professionals at an University Hospital in Tunisia. Data was collected using a pre-established synoptic form on the social and professional characteristics of the participants. Workplace harassment was assessed using the LIPT questionnaire.
Results: Of the 500 healthcare workers included in this study period, 362 respended to the questionnaire representing a response rate of 72.4%. The average age of the participants was 37.3 ±8.71 years, with women predominating (59.4%). The majority of participants were paramedical staff (54.4%). Of the participants, 101 (27.9%) had at least one comorbidity. The most common medical conditions were hypertension (10.5%). As for psychiatric history, which was present in 21.8% of participants, depression was the most common pathology (53.1%). The prevalence of harassment was 19.9%. Both men and women were harassed in 47.9% of cases, 66.7% by their hierarchical superior, and 72.2% by their colleagues. Our results show that 27.4% of subjects reporting palpitations were harassed, compared with 14.8% in the group without palpitations (p=0.003). Similarly, the frequency of harassment was significantly higher in participants with a lump in the throat. Subjects with fatigue were also significantly more harassed than subjects without this complaint (25.5% vs. 12%, p=0.002). Anxiety and competition problems were 4.27 (CI95%(2.3-7.91), p<0.001) and 4.41 (CI95%(2.32-8.39), p<0.001) times more frequent in people suffering harassment.
Conclusions: The prevalence of harassment among health professionals is not negligible, and the repercussions of this phenomenon are frequent. Given the extent of this emerging concept, preventive measures must be proposed and studied in order to put an end to its harmful effects.

Managing Needs-based Inpatient Care for Young Adults: Project 'House of the Future'

U. Altunoez[1,2*], A.-C. Hergott[1], I. B. Guevercin[1], S. Akbas[1], A. Daskiewicz[1], L. Schmidbauer[1] and C. Dette[1]

[1]Department of General Psychiatry & Psychotherapy, KRH Wunstorf Psychiatric Hospital, Wunstorf and [2]Research Group for Social and Transcultural Psychiatry and Psychotherapy, Hannover Medical School, Hannover, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1560

Introduction: The transition from childhood to adulthood is a complex process and an important developmental task with many opportunities and risks. Despite the fact that almost three-quarters of psychiatric disorders begin before the age of twenty-four, adolescents and young adults are poorly represented in psychiatric research, and the data used to guide diagnosis and treatment in this group rely mainly on studies in adult populations. The mental health system in Germany is also not organized to meet the needs of this age group, and as a result, the treatment outcomes for young adults in inpatient or day-care units of adult psychiatric centers are mostly unsatisfactory. For this reason, it is crucial to implement mental health care concepts that are tailored to the needs of young adults.
Objectives: Here we present a milieu-therapeutic inpatient care concept, 'House of the Future,' which integrates different therapeutic approaches to provide holistic and targeted support for young adults in need of psychiatric care.
Methods: An innovative inpatient psychiatric care concept for young adults from a psychiatric training hospital in Lower Saxony, Germany, will be presented in detail.
Results: The concept of the ward incorporates a variety of therapeutic approaches, including milieu therapy, systemic family therapy, and psychodynamic therapy. Additionally, it incorporates safe-wards elements and numerous non-verbal, innovative techniques such as art therapy, occupational therapy, music therapy, and sports therapy adapted for this age group. We provide a structured and needs-based environment for young adults, enabling them to engage with their experiences without being defined by their disorder or solely integrated into psychiatric systems. Our holistic approach aims not only to treat symptoms but also to promote sustainable personal development and a healthy lifestyle that empowers young adults. Young adults represent the future, and the development of their future is contingent upon the efficacy of the social support system, which is itself a significant challenge. Consequently, social work and pedagogical support are among the most essential elements of the concept. In addition to the comprehensive presentation of the concept, opportunities for networking with integration support institutions, day clinics, and specific outpatient units will be provided.
Conclusions: Adolescence and young adulthood are distinct developmental stages with unique needs. To reach optimal outcomes and to build our future on a safe base, it is fundamental to implement tailored care models in psychiatric settings that are in harmony with the specific requirements of this age group. Project 'House of the Future' aims to be a best practice example to address these needs.

The correlation between socio-educational factors and the level of functionality in patients with Schizophrenia

C. Babasan[1*] and M. M. Manea[1]

[1]Psychiatry, Cluj Country Emergency Clinical Hospital, Cluj Napoca, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1561

Introduction: The level of functioning, in patients with schizophrenia, is an essential aspect in assesing and improving their quality of life. Schizophrenia is a major contributor to severe disability in adults, as it impacts patients' capacity to live independently, engage in social activities and pursue work or education. It is important to focus not only on reducing patients' symptoms, but also on improving their overall functioning. There are some factors, that can improve the functional capacity of these patients, such as: family support, level of education, being employed, treatment adherence.
Objectives: A 64 years old man, was diagnosed with Schizophrenia at the age of 20 years old (44 years ago) and he has had several hospitalizations in the Psychiatry Clinic. He is living with his 90 years old mother, has never been married and doesn't have

any children. The patient finished high school, but he doesn't have additional studies and he has never had a job. Outside the hospitalization periods, the patient has never been compliant to the amtipsychotic treatment. The mental state exam is dominated by: complex visual and auditory hallucinations; delusional ideas of interpretation and persecution; soliloquy, stereotyped speech; bizarre, desorganized behavior; diminished self-care and self-management abilities; recent and long-term memory loss.
Methods: A 65 years old man, was diagnosed with Schizophrenia at the age of 31 years old (34 years ago) and has had several hospitalizations in the Psychiatry Clinic. He lives with his wife, he has 3 children and 2 grandchildren. The patient finished high school and has post-secondary studies. He worked as an electrician until the age of 53 years old and then he retired due to his medical condition. The patient was compliant to the treatment for the majority of the time. The mental state exam of the patient, was dominated by: complex imperative auditory pseudohallucinations, complex visual pseudohallucinations and hallucinations, cenesthetic hallucinations; delusional ideas of persecution and interpretation, tangentiality and circumstantiality; emotional blunting, with an improvement of the symptoms over time.
Results: The GAF scale was applied for both patients (in 2024), and the difference between the two of them was significant, with the first patient scoring only 27 points, indicating a notable deterioration in his functionality. The second patient scored 58 points, indicating a much better level of functionality. The SQLS scale was also applied for both patients, the first one achieved a higher score, meaning a poor quality of life, whereas the second one obtained a lower score, meaning a better quality of life.
Conclusions: The socio-educational factors play a significant importance in the quality of life, in patients with schizophrenia Mental health professionals should be aware of this factors for helping their patients to improve their functionality.

EPV0919

The meaning of 'risk' in mental health care: a qualitative study of its usage in clinicians' language

H. Barker[1]*, L. Sambrook[2], P. Saini[2], C. Bu[3] and R. Nathan[3,4]

[1]School of Clinical Medicine, University of Cambridge, Cambridge; [2]Liverpool John Moores University, Liverpool; [3]CWP NHS Foundation Trust and [4]University of Chester, Chester, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1562

Introduction: Although there is good empirical data on factors that predict harmful outcomes, and standardised approaches to risk assessment have been developed, there remains a disconnect between the academic study of risk and routine clinical practice. This is exemplified by (i) the outstanding uncertainty about how to use predictive models for everyday clinical decision-making, and (ii) the use of predictive methodology to test tools that eschew prediction. The disconnect is, in part, a consequence of the varied use of the notion of 'risk' within and between academia and clinical practice.
Objectives: To derive a more nuanced understanding of the meaning of 'risk' in clinical practice.
Methods: After reading clinical vignettes, participants (all practising clinicians, n=18) took part in semi-structured interviews regarding clinical decision-making. The interview transcripts were subject to thematic analysis using a novel approach to the analysis of ideas in expressed language (in this case the idea of 'risk') which draws on philosophical and intellectual history methodologies (derived from the work of Wittgenstein, and Skinner respectively).
Results: The use of risk by participants varied according to the extent and type of its spatial location (figure 1).
In many cases, 'risk' was used in a disembodied (i.e., dislocated) way (e.g., 'what is the risk,' 'risk will increase').
When locatable, it was evident that participants located risk in:

a) the patient (e.g., '*the patient's risk*') which was sometimes qualified by the type of harm envisaged (e.g., '*his risk involved hurting staff*');
b) clinical activity (e.g., risk assessment, positive risk-taking, risk management);
c) the clinician (e.g., risk tolerances and thresholds); and
d) the system (e.g., '*our system is… quite risk averse*,' '*who holds the risk*').

Image:

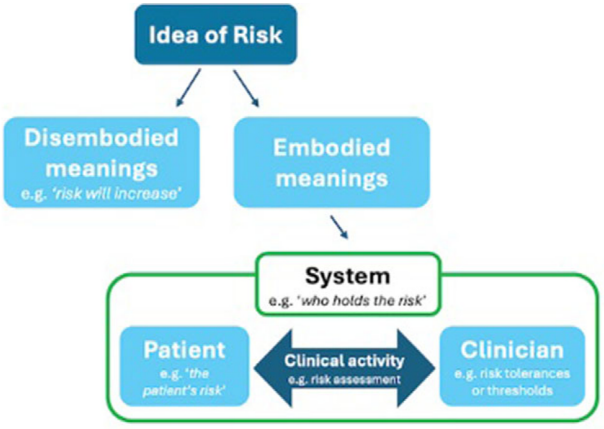

Figure 1. Meanings of the idea of 'risk' in clinicians' language

Conclusions: This study demonstrates the varied use of 'risk' in practice. By empirically delineating the different expressed forms 'risk' takes in clinicians' language (and thinking), the findings of this study can inform (i) the development of risk study methodologies that are more applicable to practice, and (ii) improvements in clinical practice by clarifying how risk can be understood and spoken about.

EPV0921

Humanitarian Love and Ethical Dilemmas in Mental Health Care: A Literature Review

A. L. Batiridou[1]*, E. Dragioti[1], S. Mantzoukas[2] and M. Gouva[1]

[1]Research Laboratory of Psychology of Patients, Families and Health Professionals, School of Health Sciences, Department of Nursing and [2]Research Laboratory of Integrated Health, Care, and Well-being, School of Health Sciences, Department of Nursing, University of Ioannina, Ioannina, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1563

Introduction: Humanitarian love, a concept grounded in compassion, emotional support, and empathy, plays a pivotal role in mental

health care, where patients often confront profound emotional and psychological challenges. This compassionate approach strengthens patient-centered care by fostering deeper therapeutic relationships between mental health professionals and patients. However, balancing this emotional engagement with professional responsibilities can give rise to complex ethical dilemmas.
Objectives: This literature review aims to: a) examine how humanitarian love influences mental health practice, and b) explore the ethical tensions between respecting patient autonomy and ensuring beneficence.
Methods: A literature review of scientific articles was conducted using databases such as PubMed, Scopus, and Cochrane, with a focus on recent research exploring the role of humanitarian love in mental health care.
Results: The findings suggest that humanitarian love enhances the quality of mental health care by promoting empathy, trust, and greater patient engagement. However, significant challenges arise when mental health professionals must navigate the balance between compassion and their ethical and legal obligations. The assessment of a patient's decision-making capacity is inherently subjective, which can potentially lead to bias or burnout among mental health professionals. Furthermore, cultural factors often add complexity to mental health care, particularly in global or cross-cultural contexts. In such situations, well-intentioned humanitarian interventions may inadvertently conflict with local traditions and human values.
Conclusions: While humanitarian love is essential in mental health care, it frequently comes into conflict with the ethical principles of autonomy and beneficence. The subjective nature of assessing a patient's decision-making capacity, combined with cultural influences, requires mental health professionals to adopt a sensitive and nuanced approach to ensure balanced and high-quality healthcare services.

Link between Quality of Life and Self-Esteem in Tunisian Women with Systemic Lupus Erythematosus

N. Mseddi[1]*, R. Ben Jmaa[1], O. Bouattour[1], I. Châari[1], L. Aribi[1], F. Charfeddine[1], F. Frikha[2] and J. Aloulou[1]
[1]Psychiatry B and [2]Internal Medecine, Hédi Chaker Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1564

Introduction: Systemic lupus erythematosus (SLE) is a chronic, multisystemic disease that can significantly impact the quality of life (QoL) and self-esteem of lupus patients.
Objectives: To study the quality of life of female patients with SLE and its relationship with self-esteem.
Methods: A descriptive and analytical cross-sectional study was conducted on 50 female patients with SLE followed at the Department of Internal Medicine at Hédi Chaker Hospital, Sfax, Tunisia, from September to November 2023. We used:

- A socio-demographic and clinical data sheet and the Lupus QoL questionnaire to assess the quality of life of lupus patients
- The Rosenberg Self-Esteem Scale

Results:

- The mean age of patients was 43.46 ± 11 years. 56% had a medical or surgical history.
- The mean age of SLE diagnosis was 33.54 years with a mean number of flares of 2.94 years ± 2.473
- **According to the Lupus QoL questionnaire:** the mean global score was 59.76± 23.496 [8.8-91.98]. The mean scores in the different domains were: physical health = 58.35 ± 32.571 [0-97], pain = 53.013 ± 33.896 [0-100], planning= 69.33 ± 32.741 [0-100], feeling of being a burden = 71.36 ± 32.694 [0-100], emotional health = 57.71 ± 26.67 [0-95.83], body image = 72.9 ± 24.6 [10-100], fatigue = 40.93 ± 24.462 [0-87.5].
- **According to the Rosenberg Scale:** a mean global score of 28.28 ± 8.572 [2-40]. Very low to low self-esteem was found in 50% of patients.
- Statistically significant correlations between low scores in the domains of quality of life and low to very low self-esteem were found:
  - Physical health: P = 0.000
  - Planning: P = 0.042
  - Pain: P = 0.002
  - Emotional health: P = 0.004
  - Fatigue: P = 0.017
  - Body image: P = 0.007
  - Global Lupus QoL: P = 0.001

Conclusions: Our results indicate that SLE can impair the QoL of lupus patients in various domains. The same is true for self-esteem. The positive relationship between the two parameters encourages a better understanding of the factors associated with each and highlights the importance of a global approach to improve the management of female lupus patients.

Well-being and job satisfaction : a study of healthcare workers at Charles Nicole Hospital in Tunis

F. E. Boujmil[1], M. Mersni[1], G. Bahri[1], S. Chemingui[1], D. Brahim[1], N. Ladhari[1], I. Besbes[2]*, A. Hakiri[2] and R. Ghachem[2]
[1]Occupational Health, Charles Nicole Hospital, Tunis and [2]Psychiatry - B, Razi Hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1565

Introduction: Job satisfaction is undoubtedly one of the concerns that has given rise to the most research since the middle of the 20th century. It is one of the particularly important concepts in the study of 'health at work' determinants. Its evaluation may appear to be necessary in order to set up relevant preventive actions. However, in Tunisian hospitals, job satisfaction remains poorly assessed. It is therefore crucial to assess it and study its factors in order to promote a balanced work environment.
Objectives: Assess the overall job satisfaction of health care workers (HCW) at Charles Nicole Hospital using a validated questionnaire in French and Arabic.
Methods: This was a cross-sectional study of consenting HCW at Charles Nicole Hospital during the period from 1st September to 31st October 2024. Data were collected by means of a 63-item questionnaire, which assessed participants' well-being and satisfaction on several aspects using a four-point Likert scale with six dimensions: Perceived superior support at work, affective commitment, emotional exhaustion, work/family conflict, extrinsic efforts and job satisfaction. The questionnaire had good internal consistency

and was validated in French and Arabic. The questionnaire was self-administered to the HCW who went to the occupational health department for a medical check-up.
Results: A total of 30 participants were enrolled. The mean age was 45.37 ± 10.3 years, with a sex ratio of 2.3 (F/H). Eighty-six percent were married and had at least one child. The most common occupational category was senior technician (34%). The average length of service was 17.27 ± 10.1 years. Laboratory departments and surgical departments were the most represented in 32% and 26% of cases respectively. Eighty percent of HCW worked full-time. Teamwork was reported in 53% of cases. The number of staff in the work team was less than 10 in 83.4% of cases. Perceived support from a superior was found in 40% of cases. Nearly 20% of cases showed emotional exhaustion secondary to their work and 34% showed extrinsic strain. Affective commitment was present in 36.7% of cases. Only 14.3% of cases showed work/family conflict. Overall, 73.3% of HCW were satisfied with their work.
Conclusions: This study highlights the importance of working conditions and organisational support in the well-being of HCW. Job satisfaction, although mainly present, is put to the test by a mismatch between professional and personal life, extrinsic efforts and a lack of hierarchical support. Emotional exhaustion is a major warning sign, showing that better care and support could improve both emotional commitment and job satisfaction.

Burnout and absenteeism: What impact on fitness for work?

W. AYED[1], M. MERSNI[1], I. YOUSSEF[2], N. MECHERGUI[3], H. BENSAID[4], G. BAHRI[1], D. BRAHIM[1], M. BANI[1], N. LADHARI[1], A. HAKIRI[5], I. BESBES[5]* and R. GHACHEM[5]

[1]Occupational medecine departement, Charles Nicolle Hospital; [2]Occupational medecine departement, Mongi Slim Hospital; [3]Occupational medecine departement, Habib Thameur Hospital; [4]Occupational medecine departement, Maternity and neonatal centre, Tunis and [5]Razi Hospital, Department B, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1566

Introduction: Burnout is a prolonged response to chronic emotional and interpersonal stressors on the job and is defined by the three dimensions of exhaustion, cynicism, and inefficacy. Burnout has a major impact on employees' health and the economy through absenteeism.
Objectives:
- To describe the socio-professional characteristics of patients suffering from burnout
- To Specify the impact of burnout on the medical fitness for work.

Methods: Retrospective descriptive study of patients with burnout who consulted the occupational pathology and fitness for work department, during the period from 17 August 2022 to 14 September 2023, as part of a medical examination for long-term absence.
Results: Of the 669 patients who presented for medical control, 222 (33.2%) suffered from burnout. The average age was 45.51 ±10.69 years. They were predominantly female, with a sex ratio (M/F) of 0.43. They belonged to the health (78.8%) and service (21.2%) sectors. The most common occupations were nurses (32.9%), manual workers (19.4%), and administrative staff (7.4%). The average length of time off work was 60.5±32.6 days. Medical decisions were to justify sick leave (73%) and return to work (24.8%).
Conclusions: Burnout is responsible for absenteeism, which is a major source of expense. Prevention based on collaboration between the occupational physician and the psychologist is essential.

Disclosure of Interest: None Declared

Psychiatric disorders during premature ovarian failure and the benefits of exerkines

N. Bouayed Abdelmoula[1]

[1]Genomics of Signalopathies at the Service of Precision Medicine, LR23ES07, Medical University of Sfax, Sfax, Tunisia
doi: 10.1192/j.eurpsy.2025.1567

Introduction: Premature ovarian failure (POF) is manifested by menstrual troubles and menopause symptoms including psychiatric burdens such as depression, anxiety, and decreased perceived psychosocial support. POF predisposes to many health risks, including decreased bone density and early progression of cardiovascular disease. Hormono-therapy of replacement of ovarian sex steroids is indicated until the normal age of natural menopause.
Objectives: The aim of our work was to study the benefits of increased physical activity and regular exercise in POF women and to show how exercise produces positive biological effects on their psychiatric health through the contribution of the exerkines network.
Methods: We conducted a comprehensive review of the scientific literature with the following keywords: Premature ovarian failure (POF), exerkines and psychiatric health.
Results: Increased physical activity and regular exercise are accompanied by the discharge of exerkines that represent an intricate network of signaling molecules or kines released into the systemic circulation during and after exercises. These molecules derived from various tissues (myokines, batokines, etc…) and organs (organokines) such as skeletal muscle, white and brown fats, liver, bones, nervous system, heart, etc…) act in different ways on the body: autocrine, paracrine or endocrine manners. Their roles in metabolic regulation, neuroprotection, and muscle adaptation highlight the importance of physical activity in maintaining health and preventing disease. Generally, it is shown that exercise can positively affect hormonal balance, homeostasis and overall health. It is also reported that physical activities promote stress reduction and hormonal regulation. Consistency and moderation are key to reaping the benefits of exercise for ovarian health. We found no human studies reporting the action of exerkines and myokines in women with POF. Some studies reporting the effects of physical exercise without further details on exerkines were found in women during and before menopause. The relationship between ovarian function and exercise, as well as exerkines levels and proteomics, was non-existent in humans and rare in animal models. Other research indicates that exercise has a positive impact on mental health, improving mood, self-esteem, and reducing stress and anxiety levels, through the improvement of the production of endorphins and neurotransmitters, the mitochondrial function and the hypophyso-hypothalamo–adrenal axis regulation interaction response to stress.

Conclusions: We conclude that human scientific studies in women with ovarian deficiency should now be carried out to investigate the types of exercise to be recommended in these women to improve their mental health. These studies should benefit from next-generation technologies such as proteomics and interactomics.

Mental Health Support in Assisted Reproductive Technology Centers

N. Bouayed Abdelmoula[1]

[1]Genomics of Signalopathies at the service of Precision Medicine, LR23ES07, Medical University of Sfax, Sfax, Tunisia
doi: 10.1192/j.eurpsy.2025.1568

Introduction: Access to genetic testing and counseling for infertile couples is essential to provide them specialized care at the genetic level. Having access to psychological support during genetic fertility assessment can be very helpful for many patient and genetic counseling offers invaluable emotional support throughout the process.
Objectives: Based on our twenty-four years' experience in genetic counseling, we present here the main psychological challenges facing couples struggling with fertility problems.
Methods: We selected all infertile couples evaluated between 2000 and 2024, who were treating their infertility with assisted reproductive technologies. Patients' psychological problems and emotional suffering, as well as the causes of these conditions, were evaluated retrospectively through our genetic counseling reports.
Results: All couples suffering from primary infertility show a more obvious decline in general well-being and satisfaction as a couple, when they are compared to couples seeking ART for secondary infertility, but having already other children. Anxiety, depression and feelings of culpability in infertile partners are the most common psychological concerns. Besides the psychological distress related to infertility, ART itself is, despite the hope it offers in terms of parenthood prognosis, a stress factor and a cause of numerous emotional and psychological problems. This distress is related to the invasive features of the ART, such as intra-testicular sperm extraction in azoospermic men and oocyte puncture, and the hormonal use in the female partners, which disturb their behaviors and moods. Other problems are associated with the lengthy, arduous and economically burdensome procedures involved in the entire treatment process. In addition, the worries of failure and the distress of failure when it becomes a reality are a crucial factor in psychological distress for the couple. Furthermore, dissatisfaction and frustration when ART is undergone for infertility affecting only one partner were noted. Many religious issues and worries about fear or phobia concerning germ cell manipulation also contribute to psychological problems. Genetic testing is another burden for the couples in our study, given the widespread ignorance of genetics and the consequent phobia of the unknown, as well as the fear of results that, once revealed as abnormal, will affect self-esteem for life.
Conclusions: This study describe the psychological concers of infertile couples undergoing ART treatment in the Tunisian Context. The improvement of the understanding of psychological needs, which are certainly provided during genetic counselling, requires a multidisciplinary consultation, involving gynecologist, reproductive biologists, geneticists, psychiatrists and psychologists. This would enable holistic and personalized psychological intervention and support.

EPV0928

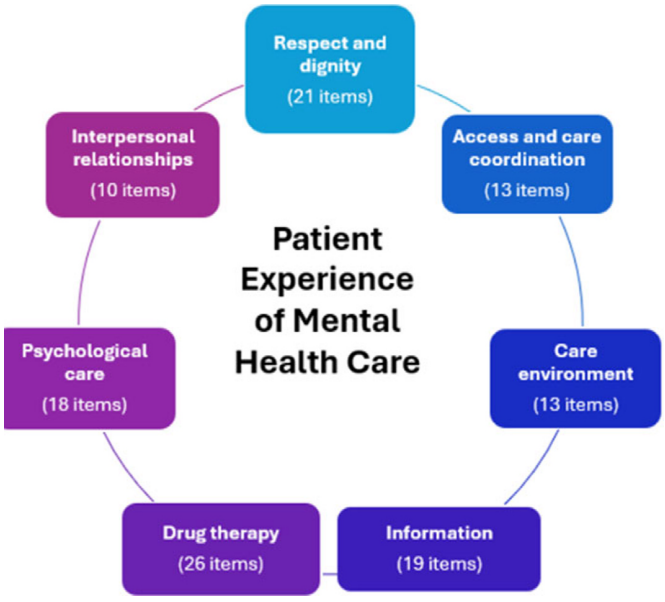
Transforming mental health care with a digital platform for adaptive PREMs and PROMs

L. Boyer[1]*, P.-M. Llorca[2], G. Fond[1], Y. Brousse[1] and S. Fernandes[1]

[1]AMU, Marseille and [2]CHU Clermont Ferrand, Clermont Ferrand, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1569

Introduction: In transforming mental health care, integrating patient perspectives is essential through Patient-Reported Experience Measures (PREMs) and Patient-Reported Outcome Measures (PROMs). PREMIUM and MyPsy&I® are two French initiatives advancing this approach by developing adaptive PREMs and PROMs and implementing a digital platform for seamless data collection, fully integrated within France's national health information systems.
Objectives: The objectives were (1) to develop eight item banks (seven PREMs and one PROM) and their corresponding Computerized Adaptive Tests (CATs) using a rigorous methodology grounded in Item Response Theory (IRT) (PREMIUM); and (2) to create a digital platform designed for multi-level use (micro, meso, and macro), enabling integration within the national health information system for enhanced patient feedback collection and analysis (MyPsy&I®).
Methods: This multicenter, cross-sectional study uses a mixed-methods approach, integrating qualitative and quantitative methodologies across three main phases: (1) development of item banks and corresponding CATs based on a standardized procedure, including conceptual work, domain mapping, item selection, item bank calibration, and CAT simulations and validation; (2) development of a digital platform tailored for multi-level use and integrated within the national health information system; and (3) a qualitative study exploring the implementation and acceptability of both the CAT and the digital platform.
Results: More than 3,000 patients with schizophrenia, bipolar disorder, and major depressive disorder were recruited from various inpatient and outpatient settings in France.
Unidimensionality, local independence, and monotonicity were verified for each item bank. Psychometric properties were satisfactory for both internal (RMSEA ≤ 0.08, CFI, TLI ≥ 0.95, and infit mean square statistic ranging between 0.7 and 1.0) and external validity. Each CAT demonstrated satisfactory accuracy and precision (standard error of measurement < 0.55 and root mean square error < 0.3), with an average administration of eight items.
The MyPsy&I® digital platform has shown strong acceptability and value across 12 French hospitals, facilitating efficient, real-time collection of patient feedback. This streamlined approach allows healthcare providers to integrate patient perspectives at various stages of care, enhancing both the quality and responsiveness of mental health services.

Image:



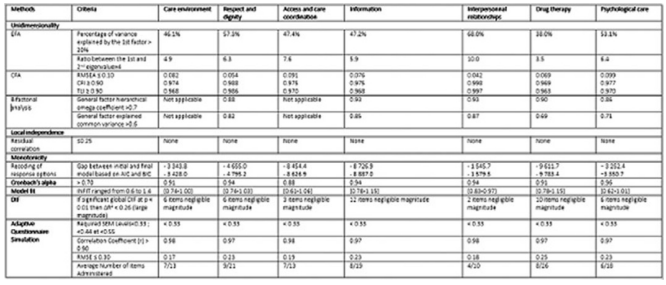


Image 2:

Conclusions: This work provides adaptive PREMs, PROMs, and a digital platform that streamline patient feedback collection, reducing burden on patients and providers. Integrating these tools into the health information flow is essential for embedding patient perspectives in modern healthcare systems, especially in a digital and AI-enhanced environment.

Disclosure of Interest: None Declared

EPV0929

Moral Injury in Healthcare Workers: Preliminary Results from a French Nationwide Survey

L. Boyer[1]*, A. Duclos[2], G. Fond[1] and P.-M. Llorca[3]
[1]AMU, Marseille; [2]HCL, Lyon and [3]CHU Clermont Ferrand, Clermont Ferrand, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1570

Introduction: Healthcare workers (HCW) face a growing crisis marked by high burnout levels (40-60%) and a rising intent to leave the profession. Current interventions focus mainly on individual resilience but have limited collective impact. Emerging evidence suggests that "Moral Injury" (MI)—a deep discord between HCW values and their practice, often worsened by organizational and economic constraints—may play a key role in this crisis.
Objectives: The primary aim of this study was to describe the manifestations of MI among HCW in France, with a healthcare system characterized by universal health coverage. Secondary objectives included the psychometric validation of the Moral Injury Inventory (MII) for HCW, analysis of organizational determinants of MI, and modeling of the underlying mechanisms of this phenomenon.
Methods: This cross-sectional, observational study was conducted nationally via an online survey. Measures included the MII, the Moral Injury Events Scale (MIES), the PHQ-9 for depression, the GAD-7 for anxiety, the Maslach Burnout Inventory (MBI), and the EuroQol 5-Dimensions (EQ-5D) for quality of life. Item Response Theory (IRT) was used to test the MII, including assessments of construct validity, and reliability. Structural equation modeling (SEM) was used to explore complex interactions between MI and other variables, including burnout, depression, and anxiety.
Results: Nearly 3,000 HCW participated in the survey. Psychometric analysis confirmed that the MII met IRT model assumptions, including unidimensionality, local independence, and monotonicity, with fit indices indicating adequate model fit (RMSEA ≤ 0.08, CFI, TLI ≥ 0.95, and infit mean square statistic ranging between 0.7 and 1.0). Differential Item Functioning analysis revealed no item biases. Over 50% of HCW reported experiencing MI, with notable variability across structural/organizational characteristics. MI and burnout emerged as distinct yet frequently associated constructs, with moderate to strong correlations observed between them. Their combined presence had a cumulative negative impact on health outcomes, with affected HCW showing higher levels of depression, anxiety.
Conclusions: This study highlights the high prevalence of MI among HCW in France, even within a robust healthcare system with universal coverage, and confirms that MI is distinct from burnout. These findings underscore the need for systemic interventions that address organizational factors, beyond the current individual-focused approaches used for burnout. Such a shift in focus would also help move away from the current tendency to over-burden and even blame HCW for systemic issues beyond their control. Given the global nature of the healthcare crisis, an international study is essential to identify systemic factors across healthcare settings, paving the way for a holistic, worldwide approach to supporting the healthcare workforce.

EPV0930

Impact of Psychiatric History on Healthcare Delivery

A. Castelao Escobar[1]*, E. Gil Benito[2], P. Sanz Sánchez[1], R. González Nuñez[1], C. Alguacil Núñez[1] and R. Albillos Pérez[1]
[1]Psiquiatría, Hospital Universitario Puerta de Hierro Majadahonda and [2]Psiquiatría, Hospital Universitario El Escorial, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1571

Introduction: A history of psychiatric disorders significantly impacts patient evaluation and treatment in healthcare. Nearly

80% of excess mortality in individuals with mental illnesses is due to physical health issues. While suicide risk is widely recognized, most mortality from mental illnesses stems from physical conditions like cardiovascular diseases, respiratory issues, and cancer, leading to a life expectancy reduction of 15-20 years compared to the general population.
Objectives: To exemplify through a case the possible impact of psychiatric history on healthcare provision.
Methods: We present the case of a 55-year-old woman with a history of severe functional neurological disorder resulting in mobility limitations, dyskinetic movements, and functional pain characterized as allodynia. She has been followed by neurology for the past year. She began mental health follow-up one year earlier due to reactive anxiety stemming from work-related issues. Her substance use history includes being a tobacco smoker for over 20 years (FTND score>50) and a former consumer of three liters of beer daily for two years, with periods of abstinence. The patient presented to the emergency department due to weight loss and low mood, worsening over the past few weeks, in the context of intense muscle pain and loss of strength. Blood tests and a brain CT scan were performed without abnormalities. She was initially admitted to Neurology for severe functional neurological disorder for symptom control, but was later transferred to Psychiatry due to suicidal threats. During her psychiatric admission, she experienced improvement in pain and subsequently in her mood. After discharge from psychiatry, the patient returned several times to the emergency department due to worsening neurological symptoms, being discharged with a diagnosis of functional disorder.
Results: Two months after her discharge from psychiatry, the patient returned to the emergency department due to rib pain. After emergency assessment, she was referred to Neurology for worsening neurological symptoms. With suspicion of paraneoplastic polyneuropathy, an MRI of the brain and spine, EMG, lumbar puncture, and CT scans of the neck, chest, abdomen, and pelvis were performed during her neurology admission. She was diagnosed with small cell lung carcinoma stage IVA and asymmetric paraneoplastic sensory neuropathy. Following the diagnosis, she was referred to Oncology, receiving one cycle of chemotherapy. However, given the unfavorable progression, it was decided, in agreement with the patient, not to continue active oncological treatment, and she was transferred to a Palliative Care Center.
Conclusions: This case emphasizes the need to recognize how psychiatric history affects medical care. Stigma and the patient's challenges in communicating symptoms can hinder the diagnosis and treatment of organic conditions, contributing to the excess mortality associated with mental health issues.

The association between Mental Health and Workaholism in Healthcare Workers

K. Imen[1], R. Nakhli[1], L. S. Chabbi[2]*, O. Ajmi[3], M. Bouhoula[1], N. Belhadj[4], A. Aloui[1], M. Maoua[1], H. Kalboussi[1], O. El Maalel[1], S. Chatti[1], A. Chouchane[1] and N. Mrizak[1]

[1]Occupational Medicine Department, University of Sousse, Faculty of Medicine Ibn Al Jazzar, Sousse; [2]D Psychiatric Department, Razi Hospital, Tunis; [3]Psychiatry Department, Psychiatry Department, Farhat Hached University Hospital Medicine Department, Sahloul University Hospital and [4]Occupational Medicine Department, Occupational Medicine Department, Sahloul University Hospital, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1572

Introduction: Workaholism, or work addiction, is a compulsive drive to work excessively, often at the detriment of personal and professional well-being. This behavior is associated with increased risk of burnout and psychosocial disorders. While understudied in healthcare workers, the constant connectivity and demands of the healthcare profession can exacerbate workaholism. Occupational health teams must prioritize addressing this issue to mitigate its negative consequences.
Objectives: To study the factors associated with workaholism among healthcare workers and to assess its impact on mental and physical well-being.
Methods: A cross-sectional descriptive study examined the determinants of workaholism and its impact on quality of life among healthcare workers at the Farhat Hached University Hospital in Sousse, from March 2022 to June 2022. The Work Addiction Risk Test (WART) was used to assess workaholism and The Hospital Anxiety and Depression Scale (HAD) to measure mental health symptoms.
Results: A total of 117 questionnaires were completed by healthcare workers, representing a response rate of 68.8%.The average age of participants was 35.45 years, with a female-dominated population (81.2%). Nurses comprised the largest group (73.5%), and most participants had less than 10 years of experience in their current department. Shift work was common, with 74.4% of participants working shifts. The Work Addiction Risk Test (WART) revealed that 18.2% of healthcare workers were at risk of work addiction, including 13.7% at moderate risk and 5.1% at high risk. The Hospital Anxiety and Depression Scale (HAD) indicated that 54.7% of participants suffered from anxiety and 35% from depression. A significant association was found between anxiety scores and a high risk of work addiction (p=0.003).
Conclusions: This study highlights the potential for workaholism among healthcare workers, particularly those facing challenging work conditions such as shift work, heavy patient loads, staff shortages, and high levels of stress. Further studies with larger and more diverse samples are necessary to better understand the prevalence and impact of workaholism among healthcare professionals mental heath.

The Impact of Working Conditions in the Public Health Sector on the Mental Health of Young Doctors in Tunisia

R. Nakhli[1], L. S. Chaibi[2]*, W. Dhaouadi[3] and M. Bouchandira[2]

[1]Occupational Medicine, Faculty Of Medicine of Sousse, Hachad University Hosiptal; [2]D Psychiatric department, Razi Hospital and [3]Faculty Of Medicine of Tunis, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1573

Introduction: Recent events in Tunisia have highlighted the severe challenges faced by young doctors, including high stress levels, burnout, and mental health issues.
Objectives: This study aims to shed light on the often-invisible realities of the medical profession in Tunisia by exploring the impact of working conditions and health policies on the mental health of young doctors.
Methods: This multicentric cross-sectional study collected data from 385 interns and residents working in four main university hospitals in Tunisia. The questionnaire included sections on sociodemographic characteristics, satisfaction with working conditions, burnout symptomatology (MBI), and anxiety and depressive symptomatology (HADS).
Results: Most respondents (82.6%) were aged 25-29, with 73% being women. Most participants (83.1%) were residents. The study \revealed widespread dissatisfaction with working conditions, including remuneration (82% dissatisfied), days off and rest periods (73% dissatisfied), and overall working conditions (78% dissatisfied). The average emotional exhaustion score was 31.883 (SD=10.2), indicating a high degree of burnout. Depersonalization scores averaged 10.176 (SD=6.3), and personal accomplishment scores averaged 23.838 (SD=8.7). The mean anxiety score was 8.776 (SD=4.2), and the mean depression score was 7.774 (SD=3.9), indicating moderate levels of anxiety and depressive symptoms.

Image 1:

Table 1: Demographic Characteristics of Participants

Characteristic	n	% (95 % CI)
Age Group		
25-29	318	82.6 % (78.5 %, 86.7 %)
30-34	50	13.0 % (9.7 %, 16.3 %)
Other	17	4.4 % (2.4 %, 6.4 %)
Gender		
Female	281	73.0 % (68.4 %, 77.6 %)
Male	104	27.0 % (22.4 %, 31.6 %)
Professional Status		
Residents	320	83.1 % (79.1 %, 87.1 %)
Interns	65	16.9 % (12.9 %, 20.9 %)

Table 2: Satisfaction with Working Conditions

Aspect	Dissatisfied (%)	95 % CI
Remuneration	82.0 %	[78.0 %, 86.0 %]
Days off and rest periods	73.0 %	[68.4 %, 77.6 %]
Social benefits and insurance	82.0 %	[78.0 %, 86.0 %]
Overall working conditions	78.0 %	[73.7 %, 82.3 %]

Conclusions: The results paint a concerning picture of the mental health status of young doctors in Tunisia, with high levels of burnout, anxiety, and depression strongly correlated with poor working conditions and work-life imbalance. These findings highlight the urgent need for comprehensive reforms in the Tunisian healthcare system, including policy changes, organizational support, and improved medical education. Limitations include the cross-sectional nature of the study and potential self-reporting bias. Future longitudinal studies are needed to understand the long-term impacts of poor working conditions on physician mental health and career trajectories.

EPV0933

Impact of Emotional Intelligence on Stress Levels Among Medical Students

K. Imen[1], R. Nakhli[2], L. S. Chaibi[3]*, C. Sridi[4], M. Bouhoula[1], N. Belhadj[4], F. Chelly[4], A. Aloui[1] and M. Kahloul[5]

[1]Occupational Medicine Department, University of Sousse, Faculty of Medicine Ibn Al Jazzar; [2]2. Occupational Medicine Department, 1. University of Sousse, Faculty of Medicine Ibn Al Jazzar, Sousse; [3]D Psychiatric Department, Razi Hospital, Tunis; [4]Occupational Medicine Department, Occupational Medicine Department, Sahloul University Hospital and [5]4. Anesthesia and Intensive Care Department, Sahloul University Hospital, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1574

Introduction: The prevalence of stress and emotional disorders among medical students has risen dramatically in recent years. In response, it is essential to develop prevention strategies, such as emotional intelligence (EI), to better manage stress and preserve mental well-being.
Objectives: To evaluate the level of EI among medical students and study its relationship with perceived stress.
Methods: This cross-sectional, analytical study was conducted among medical students at the Faculty of Medicine, Sousse, from March 2023 to February 2024. Participants completed a questionnaire assessing perceived stress using the Perceived Stress Scale (PSS10), emotional intelligence using the Schutte Emotional Intelligence Test, and lifestyle habits including sports participation and psychoactive substance use.
Results: The study included 207 students, with a majority being female (87.7%). Among them, 88.4% had no psychiatric history. Alcohol consumption was noted in 36 students, while 10 participants reported cannabis use. Regular physical activity was observed in 64.3% of cases. Students with lower EI scores generally exhibited higher stress levels, especially in the absence of sports or extracurricular activities. While correlations between EI and stress were evident, univariate analysis did not reveal a statistically significant direct association (p=0.416). Psychiatric symptoms, including anxiety and emotion regulation difficulties, emerged as significant factors in stress modulation, independent of EI levels.emotion regulation appeared to play a major role in stress modulation, independent of EI.
Conclusions: EI emerges as a critical factor in enhancing resilience against stress among medical students. By developing a more profound understanding and effective regulation of emotions, students can significantly elevate their mental and emotional well-being.

EPV0934

Relationship Between Emotional Intelligence and Burnout Among Anesthesia and resuscitation Care Staff

F. Chelly[1,2]*, I. Kacem[1,3], A. Fki[1,2], S. Chaima[1,2], N. BelHadj Chabbah[1,2], O. Ajmi[4], N. Ben Gadha[2], J. Ben khelifa[2], S. Ksibi[2], H. Ben Hamada[1,5], M. Kahloul[1,5] and W. Naija[1,5]

[1]Faculty of Medicine Ibn Al Jazzar, University of Sousse; [2]Department of Occupational Medicine, Sahloul University Hospital; [3]Farhat Hached University Hospital, Department of Occupational Medicine; [4]Psychiatry Department, Farhat Hached University Hospital and [5]Anesthesia and Intensive Care Department, Sahloul University Hospital, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1575

Introduction: Anesthesia and critical care professionals are particularly vulnerable to burnout due to the demanding nature of their work, including long hours, night shifts, high-stress situations, and the constant risk of medical errors. Emotional intelligence (EI) has emerged as a crucial factor in fostering positive professional relationships and mitigating burnout.
Objectives: To study the association between EI and burnout among healthcare workers in anesthesia and critical care settings.
Methods: This is a cross-sectional descriptive and analytical study conducted over a period of 3 months in 2024. It included 72 healthcare workers in the anesthesia and critical care departments at the Sahloul University Hospital in Sousse. The survey was based on a self-administered questionnaire, including data on sociodemographic and professional characteristics, the Maslach Burnout Inventory (MBI), and the Schutte Self-Report Emotional Intelligence Test (SSEIT).
Results: The majority of participants were female (58.3%) with an average age of 33 years. Most participants (61.1%) were nurses, and 40.3% worked in the surgical critical care unit. The average EI score was 103.26. Among the EI factors, emotion perception was the most affected, with a score of 30.69 ± 9.34. EI levels were low in 11.1% of cases. Severe burnout was present in 19.4% of participants, and 65.3% had a high emotional exhaustion (EE) score. Additionally, 70.8% had a high depersonalization score, and 58.3% exhibited low personal accomplishment. EI levels was statistically associated with time spent with family and friends ($p = 0.027$). Among the professional factors, job satisfaction was significantly associated with EI level ($p = 0.001$). The factors significantly associated with severe burnout were the absence of alcohol consumption ($p = 0.000$) and the absence of time spent with loved ones ($p = 0.033$). A significant relationship between EI and self-emotion management and EE was reported ($p = 0.040$).
Conclusions: EI is crucial for preventing burnout among healthcare workers in anesthesia and critical care. By enhancing positive attitudes, managing stress, and improving interpersonal skills, EI can improve work life and patient care. Incorporating EI training into health science curricula can equip future providers with essential tools for well-being.

EPV0935

The Impact of Psychosocial Factors on the Work Capacity of Healthcare Workers

I. Kacem[1,2], F. Chelly[1,3]*, O. Ajmi[4], A. Fki[1,3], C. Sridi[1,3], N. Belhadj Chabbah[1,3], H. Ben Hamada[1,5], M. Kahloul[1,5] and W. Naija[1,5]

[1]University of Sousse, Faculty of Medicine Ibn Al Jazzar; [2]Department of Occupational Medicine, Farhat Hached University Hospital; [3]Sahloul University Hospital, Department of Occupational Medicine; [4]Farhat Hached University Hospital, Psychiatry Department and [5]Sahloul University Hospital, Anesthesia and Intensive Care Department, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1576

Introduction: Healthcare workers, faced with increasingly demanding professional requirements, are particularly exposed to psychosocial risks. These psychosocial factors have direct repercussions on their work capacity, potentially compromising their professional performance and increasing the risk of medical errors.
Objectives: To study the influence of psychosocial factors on the work capacity of healthcare workers.
Methods: This is an analytical cross-sectional study conducted among healthcare staff at Sahloul University Hospital in Sousse over a 3-month period. Our study was based on a questionnaire that included socio-professional characteristics, Karasek's model, and the Work Ability Index (WAI).
Results: One hundred and thirty-seven staff members were included in this study, with a response rate of 72.4%. The mean age was 48.7 years, with a sex ratio of 0.57. A low work ability (WAI) was reported in 37.1% of cases. A high psychological demand at work was noted in 24.8% of cases. Job strain was reported in 18.1% of cases. Low WAI scores were statistically associated with age ($p<10-3$), female gender ($p<10-3$), lack of physical activity ($p = 0.03$), professional seniority ($p<10-3$), and high psychological demand at work ($p<10-3$). No association was found between low decision latitude, low social support, and WAI scores.
Conclusions: The results of this study highlight the significant impact of psychosocial factors on the work capacity of healthcare staff. Preventive measures in healthcare settings to improve working conditions and preserve the mental health of caregivers are essential.

doi: 10.1192/j.eurpsy.2025.1577

Introduction: There has been an increasing socio-medical discourse on the humanitarian approach to the use of restraint in psychiatric inpatient units.
Objectives: It is necessary to investigate the attitudes of psychiatric hospital staff toward the use of restraint in psychiatric inpatient units and to identify the factors influencing these attitudes.
Methods: This study examined the attitudes of psychiatric hospital staff toward the use of restraint in situations involving physical violence toward other patients, verbal violence toward other patients, physical violence toward staff, verbal violence toward staff, and disruption of the treatment environment. The study also investigated factors related to the considerations and perceived burdens (both legal and medical) associated with the use of restraint, comparing

these findings with data from a survey conducted 10 years ago. Attitudes toward restraint were not significantly associated with gender, age, or years of service. However, staffs who exhibited less prejudice toward mental illness-related crime were less likely to find restraint necessary. Compared to 10 years ago, there was little change in the need for restraint in cases of physical violence (both toward patients and staff), but the need for restraint in response to verbal violence (toward both patients and staff) had decreased. The perceived burden, both legal and medical, associated with the use of restraint had increased.

Results: Attitudes toward restraint were not significantly associated with gender, age, or years of service. However, staff who exhibited less prejudice toward mental illness-related crime were less likely to find restraint necessary. Compared to 10 years ago, there was little change in the need for restraint in cases of physical violence (both toward patients and staff), but the need for restraint in response to verbal violence (toward both patients and staff) had decreased. The perceived burden, both legal and medical, associated with the use of restraint had increased.

Conclusions: Psychiatric hospital staffs with less prejudice toward mental illness-related crime were less likely to perceive a need for the use of restraint. Compared to 10 years ago, the necessity of restraint in cases of verbal violence has decreased, which may be attributed to ongoing human rights education and increased legal and medical concerns. These findings provide important insights for future policy development aimed at promoting humanitarian approaches, such as non-restraint treatments.

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1578

Introduction: The increasing prevalence of shift work, particularly night shifts, in modern industrial settings has raised concerns about its potential detrimental effects on workers' health. Disruptions to circadian rhythms, sleep deprivation, and social isolation associated with night shift work have been linked to a range of physical and mental health problems.

Objectives: This study aims to investigate the specific impact of night shift work on the mental health outcomes of Tunisian industrial workers.

Methods: This is a cross-sectional study carried out during 3 years among active workers working in the inter-company occupational health services of Sousse. All participants had a fixed night work schedule. Data collection was based on a pre-established anonymous questionnaire. Job strain was assessed with Karazek questionnaire.

Results: A total of 453 employees were included in our study. Mean age was 32.12 ± 7.68 years. Half of the participants were women (52%). Sixty percent of participants were not married. Tobacco consumption was identified among 26% of the participants. The most affected sector of activity was the electronic one (63%). The average occupational seniority was 7.78 ± 6.407. Job strain was revealed in 23.4% of employees. High psychological demand was noted among 46.5% of cases. Low job control was identified among 57,4% of participants. Low social support was noted among 68% of participants.

Conclusions: These results underscore the need for targeted interventions to protect the health and well-being of night shift workers. Future research should explore the effectiveness of various strategies, such as scheduling modifications, workplace accommodations, and health promotion programs, in mitigating the negative impacts of night shift work.

Mental well-being of medical students and the need for mental health care in the dynamics of 2020-2024 years

E. Chumakov[1]*, I. Pchelin[2], P. Makarova[1] and N. Petrova[1]

[1]Department of Psychiatry and Addiction and [2]Department of Faculty Therapy, St. Petersburg State University, St. Petersburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1579

Introduction: Research has consistently highlighted the vulnerability of medical students to poor mental health and wellbeing. The COVID-19 pandemic has further exacerbated this issue. However, there is limited understanding of medical students' mental well-being dynamics after the pandemic.

Objectives: The aim of the study was to comparatively analyse the mental wellbeing and mental health needs of medical students in comparison with those during the COVID-19 pandemic.

Methods: An anonymous structured online survey was conducted among students of a medical institute in St. Petersburg, Russia. The sample included responses from 152 students (76.3% women) of all courses of study. The results were compared with the data of a survey conducted at the same institute in 2020 (Chumakov *et al.* Middle East Curr Psychiatry 2021;28, 38).

Results: The majority of respondents (n=145; 95.4%) reported experiencing significant stress in their lives (95.8% in 2020). The main sources of stress included education-related factors (83.6%), uncertainty about the future (72.4%), financial problems (48.0%), intimate/family relationships (46.7%), work (27.6%), and housing problems (19.1%). Thirteen students (8.6%) reported that they had been diagnosed with a mental health disorder prior to enrolling in the institute (6.1% in 2020; p=0.393). Twice as much students (n=27; 17.8%) were diagnosed with mental disorders during institute studies (15.2% in 2020; p=0.53). The mental disorders reported by the respondents were dominated by depressive disorders (n=7), anxiety disorders (5), mixed anxiety and depressive disorder (5), ADHD (5), bipolar disorder and cyclothymia (3). At the time of the study, 26 students (17.1%) were being seen by a mental health

professional (10.9% in 2020; p=0.111), the same number of students were taking any prescribed medication for mental health (10.9% in 2020; p=0.111). One-third of respondents (n=53; 34.9%) had taken non-prescription medication in the last year to improve their well-being or mood (27.3% in 2020; p=0.143), and 45 (29.6%) had taken medication in the last year to improve concentration or academic performance (38.3% in 2020; p=0.107).
Conclusions: The study showed high mental health care needs among medical students with a tendency to self-medication. Notably, mental health indicators have not improved since 2020 despite the end of the COVID-19 pandemic. Our findings highlight consistent trends in medical students' mental health and underscore the need for targeted interventions to support this vulnerable population.

Breaking the barrier: stigma, psychiatric disorders and life-threatening risks in healthcare: case report

A.-L. Comșa[1]*, I. C. MANDRAS[1] and S. A. RUS[1]
[1]Psychiatry, County Emergency Clinical Hospital Cluj-Napoca, Cluj-Napoca, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1580

Introduction: The existing studies found that stigma expands also among healthcare professionals when it comes to psychiatric patients, where a particular group is represented by substance use disorder patients, who are often perceived as manipulative, irresponsible or non-compliant.
Objectives: The aim of this case presentation is to emphasize the importance of stigma reduction especially among healthcare professionals.
Methods: A 26-year-old female patient with medical history of treatment-resistant epilepsy and misuse of cannabis and alcohol was brought into the Psychiatry ward after multiple grand-mal seizures, which occurred after weeks of daily use of alcohol and no adherence to the medical treatment.
Results: Prior to the admission, the patient was directed to the Neurology ward, where the hospitalization was declined due to her psychiatric history and the multi-drug test result, which turned positive for THC.
On the first day after admission, the patient had two seizure episodes, lasting 10 and respectively 30 minutes, after which she was transferred to the ICU department, where she was stabilized. Therefore, she returned to the psychiatric ward, where the patient enters status epilepticus, for which she underwent an neurological examination and received emergency treatment successfully.
The following day, the patient presents another episode of status epilepticus, after which she does not recover her respiratory function spontaneously and suffers cardiac arrest. The resuscitation protocol was initiated, an Emergency Medical team was requested to take over. After 4 minutes of CPR, the patient became pulmonary and hemodynamically stable.
Conclusions: Stigma is one of the factors that can influence the quality of the healthcare services provided by physicians. In the given case, stigma led to a life-threatening scenario, in which the patient was denied to receive adequate neurological treatment due to cannabis and alcohol use disorder. The impact of stigma on healthcare delivery and the barriers to receiving adequate treatment in these cases emphasize the need for training and education for all healthcare professionals.

A naturalistic study on physioterapy in acute psychiatric service

A. Di Luca[1]*, A. Tomassini[1], C. Capanna[1], S. Tozzi[2] and P. Marignetti[2]
[1]Mental Health and [2]Medical, ASL Rieti, Rieti, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1581

Introduction: There is clear evidence on the physical and psychological benefits of a bodily approach for the treatment of psychiatric disorders. They can have a significant impact on the patient's perceived suffering (Carek et al. IJPM 2011; 41(1) 15–28). In January 2024, a Physiotherapy Project started at the Acute Psychiatric Service of the Rieti ASL in collaboration with the Physical and Rehabilitation Medicine service.
Objectives: Evaluate the impact of the physiotherapy program on psychopathological dimensions and on the patients subjective well-being.
Methods: The naturalistic study was conducted on subjects consecutively hospitalized at the SPDC from January to June 2024 who voluntarily joined the physiotherapy activity. The intervention was administered with bi-weekly sessions of about 45 minutes and included: stretching, orientation exercises, active movement, coordination, muscle strengthening. The Exclusion Criteria were: sedation status, disorganization, behavioral problems. The General Health Questionnaire-12 (GHQ-12) and the Brief Psychiatric Rating Scale (BPRS) were adminstred at admission (T0) and discharge (T1). A Self-evaluation of the useful of the program was administred only to discarege (T1): participants answered by choosing between "not useful", "partly useful", "very useful" to 4 questions on the usefullness of the intervention.
Results: Thirty-five participants (17 M, 18 F; mean age 38.2±15,4) were admitted to physical activity. They recieved the following diagnoses: 48.6% Psychotic Disorder, 20% Depressive Disorder, 2.9% Bipolar Disorder, 28.6% Personality Disorder. Eleven of 35 participants had comorbid substance use disorder (14.3% alcohol, 5.7% cocaine, 5.7% cannabis, 2.9% opioids, 2.9% other substances). The hospitalization time was 11.8±4.3 and the average number of physical sessions was 1.7±0.8. The BPRS (44.4±11vs25.9±4.5; F=1024.25; p<0.001) and GHQ-12 (24.6±4.9vs15.11±5.8; F=833,43; p<0.001) mean scores significant improved in two time of evaluation (T0 and T1).

	very useful	partly useful	not useful
How useful was it for you to practice physiotherapy during your hospitalization?	46,2%	53,8%	
How much has it helped you manage anxiety?	65,4%	34,6%	
How much has it helped you muscle tension?	73,1%	19,2%	7,7%
Did participating in the group improve your mood?	61,5%	30,8%	7,7%

Conclusions: Participants showed a reduction in psychopathological severity and an increase in perceived well-being between T0 and T1. They found useful to practice physioterapy during hospitalozation and to manage anxiety, muscle relaxation and mood improvement.

Advancing resilience in healthcare professionals: A multifaceted IoMT-based strategy to combat burnout

M. A. Lafraxo[1], H. Guider[2], A. El Alaiki[2]*, Z. Boumaaize[2], I. Douelfiqar[3], Y. El Madhi[4], A. Soulaymani[2], A. Mokhtari[2] and H. Hami[2]

[1]Higher Institute of Nursing Professions and Health Techniques, Oujda; [2]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University; [3]Laboratory of Electronic Systems, Information Processing Mechanics and Energetics, Faculty of Science, Ibn Tofail University, Kenitra and [4]Regional Center for Education and Training Professions, Rabat, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1582

Introduction: The escalating burden of occupational stress and chronic health issues among healthcare professionals frequently culminates in burnout syndrome.
Objectives: This study proposes the development of a prototype mobile recommendation system that utilizes the Internet of Medical Things (IoMT) for health monitoring and burnout assessment, while simultaneously offering coping strategies for healthcare professionals.
Methods: A digital framework was conceptualized using the Unified Modeling Language (UML), **which outlined** the system's modules and graphical interfaces. The proposed system **integrates a range of** biometric sensors, including an **electrocardiogram** (ECG), a blood pressure monitor, a blood oxygen saturation monitor, and temperature sensors, complemented by a psychometric **assessment tool** to evaluate burnout syndrome.
Results: The **results of this study demonstrate that the proposed** system **can offer significant** benefits **in terms of** promoting physical and mental well-being. By **functioning** as a **continuous** health monitoring tool and a preventive measure against stress and chronic illnesses, **the proposed system can enhance** the resilience of healthcare professionals.
Conclusions: The proposed system not only facilitates proactive health surveillance but also delivers targeted interventions to alleviate burnout effects. **The implementation of** this technology could revolutionize mental health management in the workplace, paving the way for robust health policy formulation within medical institutions.

Desire for social distance towards mentally ill people

K. Evangelia[1]*, A. Argyriadis[1], S. Kotrotsiou[2] and E. Asimakopo;ulou[1]

[1]Nursing, Frederick University, Nicosia, Cyprus and [2]Nursing, University of Patras, Patra, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1583

Introduction: Familiarity with, social distance from people with mental illness and socio - demographic characteristics has been linked to conditions that lead to weaker prejudiced beliefs and a more positive opinion about mental illness.
Objectives: The relation of the attitudes and perceptions of the citizens of Larissa city towards mental illness and their desire for social distance from the mentally ill people, in relation to their familiarity with mental illness and their demographic characteristics.
Methods: A **convenience sampling survey** was conducted in Greece, **Larissa City (n=220).** The research tools which were used were: a) **Familiarity** was assessed using **the Level of Contact Report**, b) **The Social Distance Scale**, to measure the desire for social distance from people with mental illness c) Attitudes about mental illness were assessed using **The Opinions About Mental Illness (OMI) Questionnaire** and finally d) **a questionnaire for the socio - demographic information.**
Results: Univariate and multivariate analysis was applied for the statistical analysis of the data, which showed that: Desire for social distance from people with mental illness is positively related with the familiarity (with mental illness) but on the other hand is negatively related to the opinions / attitudes about mental illness.
Conclusions: The results from this study highlight and emphasize the important role of familiarity (with mental illness) and the desire for social distance (from people with mental illness) in the formation of positive/negative (prejudiced) attitudes and perceptions about mental illness.

The Relationship between Mental Health and Music Listening in the Elderly: Is There a Connection?

K. Evangelia[1]*, N. Bakalis[2], S. Kotrotsiou[2] and E. Asimakopoulou[1]

[1]Nursing, Frederick University, Nicosia, Cyprus and [2]Nursing, University of Ptras, Patra, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1584

Introduction: All older adults have a strong desire to age healthily and successfully. Because of this, the research community has extensively researched various influences on an older person's aging experience. One of those influences is music, which is associated with a positive impact on the aging experience and contributes to an individual's health, wellness, and quality of life.
Objectives: This study aims to explore the relationship between older adults' mental health and music listening.
Methods: A self-report survey was employed in this study with 168 people over the age of 65, using a convenience sample. The survey had two parts: the first part included socio-demographic information and a variety of music and listening factors, while the second part was a health-related quality of life assessment—the SF-36.
Results: The Mann–Whitney statistical test was used to examine the hypothesis that the mean total score of the SF-36 mental health subscale is different between participants who identified as enjoying

music listening and those who did not. Participants who identified as enjoying music listening had a significantly higher overall mental health total score (median = 74.5) than participants who did not enjoy music listening (median = 66.2), U (Enjoy = 38, No Enjoy = 130) = 3037, z = 2.150, p = 0.032.
Conclusions: Music has a positive influence on both mental and physical health in older adults. Listening to music or participating in music-making in late life can positively affect quality of life, particularly for older adults.

Reliability and validity of a symptom management scale in a sample of Chinese treatment seekers

H. W. Fung[1]*, T. Y. N. Tsui[2], C. H. O. Huang[3], A. K. C. Chau[4], S. K. K. Lam[5] and J. Y.-H. Wong[6]

[1]School of Nursing, The Hong Kong Polytechnic University, Kowlood, Hong Kong; [2]School of Psychology, Australian Catholic University, Melbourne, Australia; [3]Department of Social Work and Social Administration; [4]Department of Psychiatry, the University of Hong Kong, Pokfulam; [5]Nethersole School of Nursing, The Chinese University of Hong Kong, Shatin and [6]School of Nursing and Health Sciences, Hong Kong Metropolitan University, Kowlood, Hong Kong
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1585

Introduction: The Recovery Assessment Scale-Domains and Stages (RAS-DS) is a recently developed measure that builds on the original Recovery Assessment Scale (RAS). Within the RAS-DS, which measures one's recovery from mental illness, a specific domain is called "Clinical Recovery" (RAS-DS-CR). It extends the "Not Dominated by Symptoms" subscale of the original RAS, which only has three items. The RAS-DS-CR provides a more comprehensive assessment of the sense of control over symptoms and is a promising, easily-administered outcome measure for evaluating early interventions such as psychoeducation and skills training programs.
Objectives: This study examined the psychometric properties of the 7-item RAS-DS-CR in a Chinese sample of treatment seekers.
Methods: We analyzed data from 91 participants from a two-month psychoeducation program (M_{age} = 28.87; SD = 7.84, 89.0% female). At baseline, they exhibited high levels of post-traumatic (mean PCL-5 = 57.18; SD = 14.68) and dissociative (mean DES-T = 47.90; SD = 23.13) symptoms. All participants completed the baseline assessment, 83 completed the 2nd pretest, 58 completed the posttest, and 44 completed the two-month follow-up test. They completed the RAS-DS-CR and other validated self-report measures at each time point.
Results: The RAS-DS-CR revealed good internal consistency (α = .805 to .871) at each time point. Intraclass correlations of two tests taken pre-intervention (ICC = .524, p <.001) and post-intervention (ICC = .613, p <.001) indicated moderate test-retest reliability. At each time point, the RAS-DS-CR was significantly correlated with self-esteem (r = .338 to .574), depressive symptoms (r = -.402 to -.486), and PTSD symptoms (r = -.245 to -.462), indicating its construct validity. The paired sample t-test also suggested that participants scored significantly higher on the RAS-DS-CR post-intervention compared to pre-intervention (t = -4.330, p < .001; Cohen's d = 0.56), providing evidence for its sensitivity to change.
Conclusions: This study provided new evidence for the reliability and validity of the RAS-DS-CR. The RAS-DS-CR is a short and easy-to-use outcome measure of one's mental health recovery in terms of the confidence in symptom management.

The Urgency of Legal Issues Among Older Adults in the Context of the Fragmentation of Their "Good Objects"

S. Georgakis[1]*, N. Zagorianakou[1] and M. Gouva[1]

[1]Research Laboratory of Patient, Family & Health Professional Psychology, Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1586

Introduction: Conflicts concerning land ownership and inheritance disputes among older adults are prevalent and often lead to extreme and criminal behaviors. Even seemingly insignificant differences, such as disputes over a few square meters of land or a single tree, can escalate into violence or homicide.
Objectives: This study aims to examine these phenomena through the lens of the fragmentation of the "good object," as well as the accompanying sense of urgency experienced by older adults. This fragmentation refers to the loss of emotional and psychological foundations that provide a sense of security and identity. The study explores how these seemingly minor disputes, when they threaten the "good objects" of older adults, combined with their intense urgency to resolve these issues before it is too late, can turn into serious identity crises, potentially leading to extreme behaviors.
Methods: Through the analysis of case studies and a psychoanalytic approach, the psychosocial factors influencing older adults' decisions regarding the management of their property and their emotional connections to these assets are examined.
Results: The findings reveal several key factors contributing to these conflicts, including: a) Emotional attachment to property stemming from years of hard work, b) Inheritance tensions and a sense of injustice, c) Financial insecurity, which makes property the most valuable asset for survival, d) Psychological pressure and isolation, which may lead to unpredictable behaviors, e) Lack of emotional control and traditional perceptions of honor and dignity, f) A sense of loss of control as they age and the need to defend what they deem important.
Conclusions: The psychoanalytic interpretation of these phenomena reveals that the fragmentation of the good object, which may be land or other property, is closely tied to the identity and mental well-being of older adults. These individuals experience an intense sense of urgency, as delays in resolving their legal issues can mean the loss of their identity. This urgent need to protect their "good objects" often leads to reactions, frequently violent, stemming from despair and the perception that their social fabric is abandoning them. For older adults, legal and property disputes are not merely material concerns but represent their last struggle to maintain their identity. It is essential to recognize the importance of these issues and provide them with the value they deserve.

Work-Related Quality of Life in Tunisian Medical Interns: Key Influencing Factors

M. Hajji[1]*, N. Rmadi[2], A. Hrairi[2], N. Kotti[2], M. Hajjaji[2] and K. Jmal Hammami[2]

[1]Family medicine department, university of Sfax and [2]Occupational Medicine department, Hedi Chaker university hospital, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1587

Introduction: Work-related quality of life (WRQoL) is a crucial aspect of overall well-being, particularly for medical interns who face unique challenges in their demanding environment.
Objectives: This study aims to assess factors associated to work-related quality of life in a population of Tunisian Medical Interns.
Methods: A cross-sectional study was conducted from July to September 2024 among Tunisian medical interns using a Google Form's questionnaire. They were asked about their sociodemographic characteristics and their working conditions such as number of working hours per day, number of night shifts per month, and number of patients seen per day. Quality of working life was measured using the the Work-Related Quality of Life (WRQoL) Scale which covered six domains: General Well-Being (GWB), Home-Work Interface (HWI), Job and Career Satisfaction (JCS), Control at Work (CAW), Working Conditions (WCS) and Stress at Work (SAW).
Results: Our study included 141 interns with a mean age of 27.28 ± 2.42 years. Among them, 31 (22.1%) were married. The average working hours per day was 6 .42 hours, and the average number of patients seen per day was 12 patients. The average nightshifts done per month was 6. Age was statistically positively associated with all WRQoL' domains. However, GWB and HWI were negatively associated with number of working hours per day (p=0.022 and 0.026 respectively) and number of night shifts per month (p=0.001 and 0.000 respectively). Moreover, JCS, CAW and WCS were negatively associated with number of night shifts per month (p=0.007, 0.002 and 0.000 respectively).
Conclusions: This study highlights the significant factors influencing work-related quality of life among Tunisian medical interns such as working conditions. By addressing these factors, it is possible to enhance the overall quality of life for medical interns, thereby promoting their well-being and improving their capacity to provide quality patient care.

Job satisfaction among family medicine residents: A cross-sectional study

M. Hajji[1]*, N. Rmadi[2], A. Hrairi[2], F. Dhouib[2], I. Ben Hnia[2], M. Hajjaji[2] and K. Jmal Hammami[2]

[1]Family medicine department, University of Sfax and [2]Occupational medicine department, Hedi chaker university hospital, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1588

Introduction: Job satisfaction reflects on overall life quality involving social relationship, family connection and a feeling of enjoyment or fulfillment specially for family medicine residents' contentedness with their job.
Objectives: This study aims to assess factors associated to job satisfaction in a population of Tunisian family medicine residents.
Methods: We conducted a cross-sectional study from January to July 2024. Family medicine residents participated in the survey through a Google Forms questionnaire. They were queried about their sociodemographic information and work conditions, including daily working hours, the number of night shifts per month, and the average number of patients seen each day. To assess participants' job satisfaction, we used the validated physician's job satisfaction scale which covered five domains: patient care, burden, income-prestige, personal reward, and professional relations.
Results: We enrolled 108 family medicine residents (65 women and 43 men) with an average age of 26 ± 2 years [22-37 years]. The average daily working hours were 6.62 hours, with an average of 15 patients seen each day. Additionally, the average number of night shifts completed per month was 5. Positive correlations were found between age and satisfaction with time spent with family friends or leisure activities (p=0.001, r=0.3), burden's average mean (p=0.01, r=0.2) and opportunities for continuing medical education (p=0.03, r=0.1). However, a negative correlation was found between satisfaction with professional relations and the number of night shifts per month (p=0.01, r= - 0.2).
Conclusions: This research highlights the critical factors influencing job satisfaction among family medicine residents in Tunisia, with a particular focus on their working conditions. Addressing these issues is essential for enhancing the overall satisfaction of these residents. By creating a supportive work environment, we can ultimately improve patient care and treatment outcomes.

doi: 10.1192/j.eurpsy.2025.1589

Introduction: Nurses are at the forefront of patient care and are often exposed to various stressors that can impact their mental health. The mental health of nurses working in both the private and public sectors is a significant issue that requires attention.
Objectives: In this study, we propose to compare psychological distress of nurses working in private and public sectors.
Methods: It was a cross sectional study conducted among 200 nurses (100 from each of the private and public sector). We used the 6-item Kessler scale (K6) to measure symptoms of psychological distress.
Results: The average age of nurses working in the public sector was 33.24 ± 9.34 years versus 31.93 ± 7.68 years in the private sector. Most staff (33.5%), whether in the public or private sector, had

professional seniority of between 6 and 10 years. The average K6 score was significantly higher in the public sector (9.01) compared to the private sector (7.35) (p-value = 0.01). The likelihood of experiencing psychological distress was lower in the private sector compared to the public sector (p= 0.034; OR= 0.37; 95% CI [0.14-0.95]).
Conclusions: These findings highlighted potential implications for the mental health of nurses based on their employment sector, showing that prolonged daily stress could have a negative impact on their psychological well-being.

doi: 10.1192/j.eurpsy.2025.1590

Introduction: Several factors can threaten the mental health of engineers and seem to lead to anxiety and depressive disorders. Workaholism is an emerging phenomenon that has been the topic of much debate on its impact on workers' mental health.
Objectives: Determining the prevalence of workaholism among women and men engineers and screening for psychological distress among the workaholic engineers with a focus on gender differences.
Methods: This study is a descriptive-cross sectional analysis conducted on active engineers for one month. Data were collected through an online questionnaire, including socio-professional data, the WART (Work Addiction Risk Test) and the Hospital Anxiety and Depression scale.
Results: Our population consisted of 45 women and 62 men engineers with an average age of 28.62± 4.3 years and 29.61± 4.5 years respectively. A high risk of workaholism was present among 42.2% and 41.9% of women and men respectively.
Among workaholic engineers, anxiety and depression were present in 73.1% and 46.2% of cases respectively among men and in 78.9% and 42.1% of cases respectively among women.
Workaholic engineers women were likely to have anxiety (p=0.000) and reproach from their families for excessive professional commitment (p=0.007).
Among engineers men, associations were found between workaholism and anxiety (p=0.000), depression (p=0.024), the use of psychotropic medication (p=0.013), a job satisfaction less than 4/10 (p=0.024) and facing reproach from their families for excessive professional commitment (p=0.032).
Workaholism among both women and men engineers was negatively correlated with sports activities (p=0.006, p=0.042).
Conclusions: Workaholism is a significant phenomenon among engineers that can lead to anxiety and depression disorders. Therefore, the detection of early signs of workaholism and its associated symptoms seems essential among this vulnerable population in order to prevent its psychological impact.

Impact of social support on the outcomes of upper limb occupational injuries

A. Hrairi[1], N. Rmadi[1], M. Hajji[2]*, N. Kotti[1], A. Haddar[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupational medicine department, Hedi chaker university hospital, University of Sfax and [2]Family medicine department, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1591

Introduction: Upper limb occupational injuries constitute an important health problem affecting workers in their most productive years. The professional environment influences the outcomes of these injuries. The impact of social support among this vulnerable population may explain the difference in terms of outcomes of occupational injury.
Objectives: Evaluating the impact of social support in upper limb occupational injuries' outcomes.
Methods: A cross-sectional analysis was conducted during 9 months among workers victims of upper limb occupational injuries consulting for an Impairment Rating Evaluation. Socio-professional data and the accident' outcomes were collected. Social support was evaluated by the Social Support Scale. The pain was evaluated by a Visual Analogue Scale. Anxiety and depression were evaluated by the Arabic version of Hospital Anxiety and Depression scale. Unsuccessful return to work comprises all situations other than a satisfactory return to the same position held before the accident.
Results: Out of 90 injured workers, 78.9% were male. Hand and wrist injuries represented 63% of injured sites. The mean age was 43.10± 9.87 years. The mean pain scale was 5.75±2.78. The mean length of absence was 180.73±245.14 days. A proportion of 12.2 % had low social support. Unsuccessful return to work was found among 37.8% of participants. The prevalence of anxiety and depression were 31.1% and 20% respectively. Sleep disorders were mentionned by 56.7% of subjects. Low social support was associated with unsuccessful return to work (p=0.000), negative outlook of the professional future (p=0.000) and depression (p=0.002). No association was found with pain, length of absence and sleep disorders.
Conclusions: Social support may influence the outcomes of upper limbs occupational injuries. This finding highlights the need for further examination of social factors among this vulnerable population.

Efficacy of a modified remotivational program for persons with Schizophrenia in community mental health center

J. Hsiao[1]* and A.-W. Pan[2]

[1]Taipei city hospital and [2]National Taiwan University, Taipei, Taiwan, Province of China
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1592

Introduction: Patients with schizophrenia often experience deficits in motivation, which can significantly impact their functional

abilities and participation in daily life activities as the illness progresses. Motivational deficit is a key concern in the treatment and rehabilitation of schizophrenia. The remotivational program, based on the Model Of Human Occupation, is a therapeutic intervention aimed at improving the volition subsystem and addressing motivational deficit in patients.
Objectives: (1) The modified remotivational program can improve the motivation deficits, social functioning, social skills, and alleviate the psychiatric symptoms of individuals with schizophrenia in the community. (2)The experimental group, compared to the control group, can improve the motivation deficits, social functioning, social skills, and symptoms of patients.
Methods: This study is conducted at a psychiatric specialty hospital in northern Taiwan and recruits participants from a community rehabilitation center. This study included a total of 38 participants, diagnosed with schizophrenia or schizoaffective disorder. The experimental group receives a modified remotivational program twice a week for 50 minutes per session over eight sessions. This experiment employs a randomized assignment and single-blind design, with assessors unaware of group assignments. Statistical analyses involve paired sample t-tests to compare within-group differences pre- and post-intervention, and independent sample t-tests to compare between-group differences post-intervention.
Results: The experimental group underwent a four-week intervention consisting of eight sessions of themodified remotivational program. Results indicated significant improvement in addressing motivational deficits in patients (t=2.61, p=0.01). However, other outcome measures showed no significant differences between the experimental and control groups.The experimental group with average satisfaction ratings ranging from 4.12 to 4.43, and average self-assessment scores ranging from 4.12 to 4.25. Clinical feedback and observations revealed that participants in the experimental group expresses higher interest and engagement in the modified remotivational program.
Conclusions: While individuals with schizophrenia undergoing community-based mental rehabilitation generally exhibit stable psychiatric symptoms, they often overlook the pervasive impact of negative symptoms, particularly the widespread influence of motivational deficits. This study's findings demonstrate that the intervention program effectively addresses motivational issues. Therefore, it is recommended that future clinical practices integrate and utilize such interventions to provide community-based psychiatric care with individualized and diverse intervention strategies.

Caring Under Pressure: Perceived Stress Among Caregivers of Dementia Patients

O. Inanc[1]

[1]Gulhane Training and Research Hospital, Ankara, Türkiye
doi: 10.1192/j.eurpsy.2025.1593

Introduction: Dementia is a progressive neurodegenerative disorder characterized by a gradual decline in cognitive functions, such as memory, reasoning, and communication, which places a significant burden on caregivers. Dementia caregiving presents unique challenges that contribute to elevated stress levels. Caregivers of dementia patients often face increased psychological and physical strain, exacerbated by the disease's progressive nature and complex caregiving demands. This systematic review explores the perceived stress among dementia caregivers, highlighting the impact of caregiving responsibilities and identifying potential coping mechanisms. Our review seeks to offer evidence-based recommendations to support caregivers and improve their quality of life, thereby addressing a crucial gap in dementia care.
Objectives: This systematic review aims to assess the extent of perceived stress among dementia caregivers, identify associated factors, and evaluate coping mechanisms. The goal is to highlight critical stressors and propose evidence-based strategies for improving caregiver support.
Methods: We systematically reviewed eighteen studies from PubMed using the terms "Perceived Stress Scale" and "Caregivers of Dementia Patients." Our analysis included data from 3,385 caregivers, focusing on stress levels, cortisol measurements, and psychological impacts.
Results: The review consistently identified high levels of perceived stress among dementia caregivers. Cortisol levels, assessed in three studies, were significantly elevated in caregivers compared to non-caregivers (Williams et al., 2021; Kim & Park, 2022; Nguyen et al., 2023). Perceived stress showed a significant correlation with cognitive decline and sundowning behaviors. Additionally, caregivers reported elevated depressive symptoms, with stress levels showing a direct association with these symptoms (Jones et al., 2021). The review also identified that higher education was associated with reduced anxiety and depression, while female caregivers reported higher stress levels compared to males (Miller et al., 2022). Effective coping strategies included seeking information, participating in culturally adapted interventions, and enhancing social support networks (Patel & Singh, 2023).
Conclusions: Dementia caregiving imposes considerable stress due to the demanding nature of the role and the complexities of patients' conditions. Interventions should prioritize culturally sensitive support programs, expand educational opportunities for caregivers, and strengthen social support systems to alleviate caregiver stress. Future research should further investigate the influence of gender, social isolation, and healthcare access on caregiver stress, particularly in low- and middle-income countries (LMICs) and during global crises such as the COVID-19 pandemic. Addressing these factors will be crucial in developing comprehensive strategies to support dementia caregivers effectively.

EPV0953

Burnout Syndrome Among Pediatric Residents at a Children's Hospital in Madrid

S. Jaramillo[1]*, B. Martínez-Núñez[1], M. Faya-Barrios[1] and M. Graell[1]

[1]Department of Psychiatry, Hospital Infantil Universitario Niño Jesús, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1594

Introduction: Burnout Syndrome (BOS) is a state of exhaustion due to chronic workplace stress, characterized by emotional exhaustion (EE), depersonalization (DP), and a diminished sense of personal accomplishment (PA). BOS is significant among healthcare professionals worldwide, and a critical issue in medical residency, raising concerns about mental health, patient care and safety.

Objectives: This study aimed to evaluate the prevalence and severity of BOS among pediatric medical residents at a children's hospital in Madrid, Spain. The association between demographic and occupational factors, such as gender, residency year, and night shifts per month, and the presence of BOS was also analyzed.
Methods: An observational, cross-sectional study was conducted in September 2024, using a survey distributed to pediatric residents. The survey included demographic and occupational data and the Maslach Burnout Inventory Human Services Survey (MBI-HSS), which assesses burnout through EE, DP and PA. Perception of institutional burnout prevention and support programs was also evaluated.
Results: The response rate was 81.8% (45/55), the majority of respondents were female (77.8%), aged between 24-32 years (mean 26.8), from all levels of training. Burnout scores were abnormal in 55.6%, and 11.1% met criteria for high levels of burnout. Emotional exhaustion was the most affected dimension, over half (57.8%) scoring in the high-degree for EE, followed by 40% for high DP and 28.9% for low PA. No significant associations were found between gender, residency year, or night shifts and burnout levels. However, 66.7% of the respondents perceived insufficient institutional burnout prevention programs or support.
Conclusions: The study confirmed a high prevalence of BOS among pediatric residents. These results emphasize the urgent need for targeted interventions to prevent and address burnout and improve health-care professionals well-being. Further research is needed to explore factors contributing to burnout and effective strategies for mitigating burnout among medical residents.

Psychiatric comorbidities and societal demographics of population with pyromania admitted to Bronx Care: a retrospective chart review

N. Joshaghani[1], R. Hartnett[2], L. Jimenez[3], V. Sharma[4], G. Taneja[5] and S. Gunturu[6]*

[1]Psychiatry, Bronx care Health System, NewYork; [2]St. George University, Grenada; [3]Albert Einstein College of Medicine, Bronx, United States; [4]Dayanand Medical College, Ludhiana, India; [5]Tver state Medical University, Tver Oblast, Russian Federation and [6]Psychiatry, Bronx care Health System, Bronx, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1595

Introduction: Pyromania is an impulse control disorder where repeatedly setting up intentional fires provides instant gratification after failing to control the urge. Within the psychiatric population, 6% of the individuals meet the lifetime criteria of pyromania, making it a rare diagnosis of high medico-legal significance. We aimed to estimate the prevalence of pyromania, identify psychiatric comorbidities, substance use, and related sociodemographic factors in patients with a history of pyromania within a psychiatric center in South Bronx. We hypothesize that individuals with fire-setting behavior are more likely to have antisocial tendencies, substance use disorders, and psychiatric comorbidities, leading to increased mental health service use.
Objectives: The objective of this study is to estimate the prevalence of pyromania and fire-setting behavior in a psychiatric center in South Bronx, and to examine the associated psychiatric comorbidities, substance use disorders, and sociodemographic factors. By analyzing these relationships, we aim to provide insights into the characteristics and mental health service utilization patterns of individuals with pyromania or fire-setting behavior, thereby informing future treatment strategies and interventions in urban mental health settings.
Methods: We searched for patients aged 12 and older, including all genders, who were evaluated or admitted through a psychiatric center within the South Bronx between December 2013 and December 2023 for a retrospective observational study. After applying inclusion/exclusion criteria, we included 11 patients diagnosed with pyromania or fire-setting behavior (ICD-10-CM code F63.1 or ICD-9-CM code 312.33), based on evaluation notes. We extracted and analyzed the data for demographics, substance use, comorbid psychiatric, and medical diagnosis.
Results: We found that pyromania diagnosis was found in individual's age range of 12 to 59 years (Mean Age-33.36 ± 14.72 years). All individuals were single, 82% were unemployed, 72.73% were US-born, and 91% were male. Psychotic disorders, primarily schizophrenia, were diagnosed in 73%, while 64% had a substance use disorder. The group comprised 45% Hispanic and 55% African American individuals.
Conclusions: Our study, conducted over ten years in the Bronx, revealed a strong association between firesetting behavior and psychiatric comorbidities, particularly psychotic disorders and substance use. Contrary to our initial hypothesis, we found no significant link between firesetting and antisocial tendencies. These findings emphasize the need for targeted interventions addressing both psychiatric and sociodemographic factors, especially in urban mental health settings like the Bronx.

Deprescribing off label antipsychotic medications in a general adult psychiatry service: A risk management Perspective

J. Khan[1]

[1]Psychiatry, Connolly Hospital Blanchardstown, Dublin, Dublin, Ireland
doi: 10.1192/j.eurpsy.2025.1596

Introduction: Antipsychotic medications, initially designed for severe mental illnesses like schizophrenia and bipolar disorder, have witnessed a significant rise in off-label prescribing for a diverse range of conditions and at times these medications remain unchanged over long periods of time and poses a potential risk due to their side effect profile. There are different types of risks associated and depends on the dose of medication, age and comorbid physical health conditions of the patient.
Objectives: To evaluate the outcomes of tapering and discontinuing off-label low-dose antipsychotic medications in patients without psychiatric disorders, focusing on the effectiveness of the deprescribing process and any associated withdrawal symptoms or adverse effects.
Methods: The authors decided to review their caseload and identify patients who are prescribed off label use of antipsychotic medication for example for sleep issues, Axis 2 mental illness as per DSM-4 classification and on doses where there was no indication of antipsychotic medication. It was planned to have detailed discussion with patients about the impact of having off label antipsychotic

prescription and agreed to slowly tapper off and discontinue this medication. There were 18 patients identified with off label use of antipsychotic medication. In this quasi-experimental study design, we selected eighteen patients by convenience sampling method from the caseload who were identified to be on off label prescription of antipsychotic medications. These patients were explained to the purpose of the study and the course of intervention, and all agreed to participate in the intervention.
Results: Out of 40 patients prescribed off-label antipsychotic medications, 18 were identified for review, all had been receiving mental health services for over six months and had been on antipsychotics for more than eight weeks. The most prescribed medication was quetiapine (n=11), followed by olanzapine (n=4), risperidone (n=2), and haloperidol (n=1). These medications were prescribed for issues like sleep disturbance, anxiety, and agitation, not for mood stabilization in bipolar disorder or augmentation in depression or OCD. Patients were gradually tapered off antipsychotic medications, with quetiapine doses typically reduced by 50% over two months and halved again over the next two months. Olanzapine and risperidone were discontinued over 3-6 months. Those successfully deprescribed reported improved energy, reduced fatigue, and no long-term adverse effects like tremors or extrapyramidal symptoms.
Conclusions: Antispcyhtic deprescribing is an important part of clinical care that reduce the risk to patients and gradual tapering of low-dose off-label antipsychotic medications, including quetiapine, olanzapine, and risperidone, was largely successful in this study, with most patients experiencing improved energy and reduced sedation.

Kickboxing therapy in a Day hospital for non-psychotic disorders

M. Krevatin[1], S. Kocijan[1,2*], H. Matic[1], A. Jurcevic[1], E. Ivezic[1], A. Ivrlac[1], S. Caratan[1], L. Gorsic[1], M. Horvat[1] and M. Rimac[1]

[1]Day Hospital for non psychotic disorders, University Psychiatric Hospita Sveti Ivan, Zagreb and [2]Department of Psychiatry and Neurology, Faculty of Dental Medicine J.J.Strossmayer and Health, Osijek, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1597

Introduction: The limited research conducted so far suggests that kickboxing and other martial arts can positively impact psychological well-being in a psychotherapeutic setting. The study by de Vries et al. (de Vries, et al.), which focuses on the application of kickboxing with psychotic patients, suggests improvements in self-esteem, social behavior, and aggression regulation through structured, body-oriented therapy. Physical activity that is intense and structured, such as kickboxing, helps reduce stress and anxiety by increasing endorphin production, which improves mood and reduces tension.
Objectives: The aim of our study is to analyze the impact of kickboxing on non-psychotic disorders in relation to anxiety, depression, and stress levels, as well as its effect on self-esteem and the overall quality and satisfaction. To our knowledge, this research is the first of its kind in Croatia.
Methods: This study involved 11 participants who were receiving treatment at the Day Hospital for Non-Psychotic Disorders, which treats patients suffering from a wide range of anxiety disorders, mood disorders, reactions to severe stress, and adjustment disorders. The participants were a mixed group of 6 men and 5 women, aged 28 to 58, with varying levels of education and living standards. Kickboxing training has been conducted once a week for 60 minutes during consecutive 6 months. The training is conducted in a group with an individualized approach depending on the patient's condition. The assessment was conducted at two time points: the first data collection occurred before the start of therapy, and the second took place 6 months after regular kickboxing training. The comparison was made using the Wilcoxon signed-rank test.
Results: The results of this preliminary study indicate statistically significant positive changes. Compared to the results of the first assessment, participants were significantly more satisfied with their lives in the second assessment and perceived their quality of life as significantly improved in terms of physical and mental health as well as social relationships. Depression, anxiety, and stress levels were rated as significantly less pronounced, while self-liking and self-competence did not change significantly.
Conclusions: Kickboxing offers a new, innovative approach to improving mental health in the therapeutic environment of a day hospital, especially for patients suffering from anxiety and depression.

Burden among family caregivers of children and adolescents followed for diabetes

S. Kolsi[1]*, A. W. Noureddine[1], A. Bouaziz[1], A. Labyadh[1], K. Medhaffar[1], K. Zitoun[1] and W. Abbes[1]

[1]Psychiatry, University Hospital, Gabes, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1598

Introduction: Children and adolescents are a fairly vulnerable population for diabetes.
Caregivers of children and adolescents with diabetes were most involved in their care.
Measuring the burden endured by caregivers is a good indicator of the negative repercussions on caregivers when caring for their loved ones.
Objectives:
- Determine the level of burden among family caregivers of children and adolescents with diabetes.
- Identify factors associated with a high level of burden.

Methods: The study was conducted at the University Hospital of Gabès, in the pediatrics and internal medicine departments, as well as in outpatient clinics with caregivers of children and adolescents during the period from March 2024 to May 2024.
We collected sociodemographic and clinical data for each caregiver and child or adolescent followed for diabetes.
We used :
Burden scale (Zarit): explores the psychological, physical and social impact of patient care on the caregiver. The higher the score, the greater the burden. A score above 61 means a severe burden.
Results: The study included 32 caregivers. The mean age was 35.55 years with extremes of 22 and 55 years and the sex ratio (M/F) was 0.6. Workload was shared equally by 66% of caregivers (65.7%; n=21). The majority of the sample (62.5%) did not seem to have experienced family conflicts related to the caregiver's role.

Among the participants, the majority, 78.1% (n=25), presented symptoms of psychological distress. A high level of stress was perceived by 43.7% of caregivers and satisfaction was noted by 34.4%.
A mean burden score was 35.59 (SD =15.37) with extremes from 8 to 59. We reported that 40.6% of caregivers presented a moderate to severe burden and 34.4% presented a light to moderate burden.
According to our results, heavy burden was statistically more common among caregivers with unequal workload sharing (p=0.006) and family conflict (p=0.01).
We found a statistically significant correlation between burden and symptoms of psychological distress (p=0.001), daily stress level (p=0.001) and overall satisfaction (p=0.001).
Conclusions: Our study shows that the burden endured by caregivers of diabetic children and adolescents represents a real issue in the care of these patients.
Several factors seem to be inherent to the disease, the caregiver and the social context.
For this reason, it is imperative to develop specific support programs for family caregivers of diabetic children and adolescents. These programs should include interventions to reduce burden.

Disclosure of Interest: None Declared

EPV0960

Resilience among family caregivers of children and adolescents followed for diabetes

S. Kolsi[1]*, W. Abbes[1], A. W. Noureddine[1], A. Bouaziz[1], Y. Ben Ayed[1], K. Medhaffar[1] and K. Zitoun[1]

[1]Psychiatry, Hospital University, Gabes, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1599

Introduction: Diabetes is a real public health problem. Some people seem to be more vulnerable to this pathology, especially children and teenagers. To ensure their loved one's well-being, caregivers can also develop coping strategies.
Objectives:
- Assessing caregivers' resilience of children and adolescents with diabetes.
- Identify factors associated with a high level of resilience.

Methods: The study was conducted at the University Hospital of Gabès, in the pediatrics and internal medicine departments, as well as in outpatient clinics with caregivers of children and adolescents during the period from March 2024 to May 2024.
The sociodemographic and clinical characteristics of caregivers of children and adolescents have been collected using a pre-established-form.
We used :
The resilience scale (CD-RISC) is designed to measure resilience, defined as the ability to cope with traumatic events. The higher the score, the greater the resilience.
Results: Our sample included 32 caregivers. The mean age was 35.55 years with extremes of 22 and 55 years and the sex ratio (M/F) was 0.6.
Among the participants, the majority, 78.1% (n=25), presented symptoms of psychological distress. A high level of stress was perceived by 43.7% of caregivers and satisfaction was noted by 34.4%.
The mean resilience score was 59.06 (SD =10.45) with extremes of 39 and 81.
We found a significant correlation between a high level of resilience and symptoms of psychological distress (p=0.003), the level of daily stress (p=0.03) and the level of overall satisfaction (p=0.043).
Conclusions: Our study showed that a high level of resilience is linked to several factors.
Interventions targeting stress related to social events should be integrated to increase the caregivers'resilience.

EPV0961

Patient satisfaction and shared decision-making in a psychiatric ward

P. Tilelis[1], G. Papaefstathiou[1], K. Anargyros[1], E. Mpaka[1], I. Chatzidakis[1], T. Jupe[1] and D. Kontis[1]*

[1]4th Inpatient Department, Psychiatric Hospital of Attica, Athens, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1600

Introduction: In the dynamic setting of psychiatric care, patient satisfaction and shared decision-making are crucial for optimal, personalized treatment. This approach is particularly vital in the context of a psychiatric ward, where engaging patients in treatment decisions could enhance their satisfaction and the overall therapeutic outcomes.
Objectives: This study evaluated the impact of shared decision-making on patient satisfaction from services among patients treated in a psychiatric ward. Additionally, it examined whether there are differences in satisfaction between psychotic and non-psychotic patients.
Methods: 53 patients (30 women and 23 men) who were hospitalized in the 4th Inpatient Department of the Psychiatric Hospital of Attica were assessed using the Client Satisfaction Questionnaire (CSQ-8) and the 9-Item Shared Decision-Making Questionnaire (SDM-Q-9). Diagnoses were based on the Mini International Neuropsychiatric Interview (M.I.N.I.). A multiple linear regression analysis was conducted to evaluate the effect of the SDM-Q-9 total score and of the presence of psychotic symptoms on the CSQ-8 total score. The relationship of separate SDM-Q-9 and CSQ-8 items, controlling for the presence of psychosis was further analyzed through partial correlation analyses. The Bonferroni method was employed in order to adjust for multiple comparisons.
Results: The mean age of the participants was 47.49 years (SD=13,65), and the mean duration of the disease was 15 years (SD=12,36). Thirty-two patients were diagnosed with psychotic disorders (psychotic disorder=28, bipolar disorder=1, mood disorder with psychotic features=3), while twenty-one were diagnosed with non-psychotic disorders (including Major Depressive Disorder, Obsessive Compulsive Disorder, Bipolar Disorder and Substance Use disorders). Increasing SDM-Q-9 total score significantly correlated with increasing CSQ-8 total score (B=0,276, 95% CI=,177, 0.374, t=5,627, p<0.001). Partial correlation analyses showed that separate SDM-Q-9 items significantly correlated with separate CSQ-8 items, while many correlations survived the stringent bonferonni correction. The presence of psychotic symptoms was not associated with client satisfaction.
Conclusions: Our findings suggest that shared decision-making correlates positively with patient's satisfaction from services during their hospitalization in a psychiatric ward and this was independent

of the presence of psychosis. In the ongoing effort to find real-world solutions in mental health, integrating shared decision-making practices into psychiatric care can be a fundamental strategy to empower and satisfy patients suffering from mental disorders.

Disclosure of Interest: None Declared

EPV0962

Self-Compassion and Forgiveness Among Individuals in Opioid Substitution Treatment in Greece

E. Kotrotsiou[1]

[1]Nursing, Frederick University, Nicosia, Cyprus
doi: 10.1192/j.eurpsy.2025.1601

Introduction: The work of original research on opioid and heroin depedence is of great interest as it has a serious medical and social impact on society.
Self Compassion and forgiveness are important factors in helping psychosocial support and improving mental health that contributes to the development of person's character.
Objectives: The purpose of this study is to explore the relationship between self compassion and forgiveness in people who are receiving treatment for opiod depedence.
Methods: An incidental sample of 153 opioid users has been selected for the study.
Data were collected using:
- The Self Compassion Scale.
- the Heartland Forgiveness Scale.

Demographic and social background information was also gathered to complement the primary data.
Results: It has been established that there is a positive relationship between self compassion and the ability to forgive oneshelf or others among people with opiate addiction.
Participants reported appropriate levels of self compassion and forgiveness. Some of the important finding include:

- There is a notable relationship age of first use illicit drugs and the level of forgiveness afforded to others.
- In substance dependency, an inverse relatioship is noted between the level of triazolobenzodiazepine abuse and self forgiveness and self compassion.

Conclusions: There is a chance of improving self kindness and forgiveness even among opioid addicts if these factors may be effective in combating the addictions.
Suggestions for future investigation includes:
- Further evaluation of the age in which a person engages in illicit substances and the level of forgiveness extended to these individuals.

Assessing if the use of benzodiazepine that are not prescribed affects self forgiveness and self compassion.

Disclosure of Interest: None Declared

Balancing motherhood and career: The psychological effects of post-maternity leave return among Tunisian women

A. Karmous[1], H. Ktari[2*], N. Karmous[3], H. Ghabi[4], A. Hajri[1], E. Khelifa[1], A. Maamri[1] and H. Zalila[1]

[1]Emergency and outpatient department, Razi hospital, Manouba; [2]Psychiatry department, Tahar Maamouri hospital, Nabeul; [3]Department B, Charles Nicoles hospital, Tunis and [4]Department G, Razi hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1602

Introduction: Tunisia is considered one of the countries where women occupy an important place in the working society. Given the fundamental role played by women in the family, they would have to balance their family responsibilities with professional duties, especially after returning from maternity leave. In many cases, the return to work can be particularly difficult which could affect their physical and mental health and even the relationship with their child.
Objectives: Assessing the effects of returning to work on the perceotion of stress after maternity leave among Tunisian women.
Methods: A cross-sectional study was conducted over a two-month period, from February to April 2024, in the department B of gynaecology and obstetrics in Charles Nicoles hospital (Tunis). Women who were in labor before delivery, who had fully responded to the questionnaire before and after returning to work and willing to take part in the study were included. A questionnaire including socio-demographic, pregnancy and delivery and labor characteristics was filled in by the participants. The effects of returning to work on the perception of stress after maternity leave were assessed using the Perceived Stress Scale (PSS-10). Women were assessed one month and three months after the delivery corresponding to one month after the return to work (maternity leave in Tunisia lasts two months).
Results: A total of 62 women were included. The mean age was 32.45 ± 6.41. Pregnancy was planned in 56.4 % of cases, well supervised in 83.8 % of cases, and complicated by gestational diabetes in 24.1 % of participants. Most deliveries were at full term (92 %) and vaginal (66.1 %). Complications were post-partum hemorrhage (11.2 %), eclampsia (3.2 %) and puerperal infections (3.2 %). Most women worked in the public sector (69.3 %) with a salary between 500 and 1000 Tunisian dinars (42%). The mean PSS-10 before returning to work was 12.36 ± 4.79 and 19.41 ± 4.31 after. After returning to work, the PSS-10 was significantly higher among women with more than two children, whose deliveries were with complications and working in the private sector.
Conclusions: Several factors have been found to involved in the increase of stress after post-maternity leave return. Focus on the psychological aspect and on supporting young mothers throughout the perinatal period seem highly needed.

Mental health status, burden and satisfaction with social support in the portuguese family caregivers of people with mental disorders: a cross-sectional study

C. Laranjeira[1,2]

[1]School of Health Sciences and [2]ciTechCare, Polytechnic Institute of Leiria, Leiria, Portugal
doi: 10.1192/j.eurpsy.2025.1603

Introduction: Current political recommendations on mental health aim to keep people with mental illness in the community, emphasizing the need to develop a natural social support network, which includes families, giving rise to the role of the family caregiver.
Objectives: The aims of the study were: a) to identify sociodemographic variables that influence the anxiety, depression and stress of the caregiver of people with mental disorders; b) to analyze the relationship between social support and caregiver burden with anxiety, depression and caregiver stress.
Methods: We carried out a cross-sectional, descriptive-correlational study, with 274 portuguese caregivers who were recruited using a convenience sampling technique. The instruments used were the Satisfaction with Social Support Scale (ESSS); Zarit Burden Interview Scale and Depression Anxiety Stress Scales (DASS-21). Descriptive statistics and nonparametric tests were used as required. Data were analyzed using SPSS-22.0. The protocol was approved by local ethical committee.
Results: Most of participants were female (67.0%) and aged between 26 and 85 years old, with an average of 66.13 (SD=5.61) years old. Female caregivers have higher rates ($p<0.05$) of anxiety, depression and stress. Caregivers who lived in rural areas have higher levels of depression ($p=0.036$) and stress ($p=0.029$). On the other hand, the greater the perceived overload, the higher the levels of anxiety ($p<0.001$), depression and stress ($p<0.001$).
Conclusions: The results suggest the need to invest in local and community intervention strategies to promote mental health and prevent mental illnesses. In this vein, health institutions must support educational and monitoring measures that screen mental illness situations early.

Psychiatric discharge management practice in Europe – a systematic search and review

S. Lech[1]*, D. Marbin[1], C. Hering[2], R. Kohl[2], J. Supplieth[2], J. O'Sullivan[2] and S. Schreiter[1]

[1]Department of Psychiatry and Neurosciences and [2]Institute of Medical Sociology and Rehabilitation Science, Charité - Universitätsmedizin Berlin, Berlin, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1604

Introduction: Effective discharge management is essential for psychiatric inpatient care, significantly impacting patient outcomes during and after the transition from inpatient to outpatient settings. A well-coordinated discharge process ensures continuity of care, reduces readmission risks, and supports long-term recovery. However, there is a notable lack of comprehensive data on discharge practices across European countries, impeding the evaluation of their effectiveness and the development of informed improvements.
Objectives: The present study has two primary objectives: first, to systematically review current practices, challenges, and outcomes related to psychiatric discharge management across European countries. Second, to evaluate and compare existing discharge guidelines, protocols, and toolkits. By synthesizing these findings, we aim to identify best practices, highlight gaps, and offer recommendations for optimizing discharge procedures. Additionally, we will briefly present a current mixed-method research project from Germany, titled "*Evaluation of Discharge Management in Psychiatric Care*," which aims to assess discharge management practices for psychiatric inpatients. These insights will supplement the broader European review by offering a focused perspective on the practical considerations and challenges of discharge management practices within a specific national context.
Methods: We will conduct a systematic search and review by exploring multiple electronic databases (MEDLINE, Embase, Cochrane Library and PsycINFO) and grey literature sources (Google and Google Scholar) for both quantitative (observational studies, reports) and qualitative (clinical guidelines, protocols, interviews, focus groups) data related to psychiatric discharge management. Additionally, we will hand-search the references of key papers, including existing systematic reviews and included articles. The search will include documents published from 2000 to December 31, 2024.
Results: The presentation will provide an overview of the current research and literature on psychiatric discharge management practices in Europe. The review is expected to provide critical insights into advancing psychiatric care standards. Additionally, the presentation aims to engage researchers and clinical practitioners attending EPA25 by providing a platform for knowledge exchange on psychiatric discharge management, facilitating networking opportunities and fostering potential collaborations for future research in this vital field.
Conclusions: Discharge management is a critical aspect of psychiatric care that requires meticulous planning and coordination. The insights gained from this review will contribute to the development of evidence-based discharge protocols that are adaptable to diverse patient populations and healthcare settings, ultimately leading to more effective and cohesive care strategies across Europe.

The Effects of Group Integrative Arts Therapy based on Social Skill Training on the Social Adaptive Function, Empowerment and Subjective Well-Being in Inpatients with Chronic Schizophrenia

E. Lim[1]* and S.-Y. Lee[2]

[1]Psychiatry, Shinsegae Hyo Hospital, Gimje and [2]Psychiatry, Wonkwang University, School of medicine, Iksan, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1605

Introduction: The social skills of the chronic schizophrenia is an important factor in assessing the prognosis of patients with schizophrenia.

Objectives: The object of this study was to investigate the effects of group integrative arts therapy based on social skill training on communication, social adaptive function, and subjective well-being in inpatients with chronic schizophrenia.
Methods: Among the 125 patients who had been hospitalized in the mental hospital after being diagnosed with schizophrenia by psychiatrists according to DSM-5, 72 patients were selected by inclusion criteria and 48 patients were randomly assigned into an experimental group(n=16), comparative group(n=16), and control group(n=16). During this study, 4 patients from each groups dropped out. The final subjects of each groups were 12 patients. The experimental group followed a 60 minutes long social skill training based on group integrative arts therapy program for twice a week and 20 times in total. The Comparative group followed a social skill training program only for 60 minutes twice a week for 20 times in total. The control group received no treatment. To assess the social adaptive function, empowerment, subjective well-being of the subjects, Communication Competence Scale(CCS), Empowerment Scale(ES) and Korean Modification of Subjective Well-Being Scale(KmSWN) were used as subjective measuring. Assertiveness Observation Evaluation Scale(AOES), Social Adaptive Functioning Scale(SAFS), and Nurses' Observation Scale of Inpatient Evaluation-30(NOSIE-30) were also used as objective measuring that were rated by nurses or social workers at the mental hospital.
Results: There was no statistically significant difference except non-verbal communication of CCS among three groups in homogeneity test of sociodemographic and clinical variables. The group integrative arts therapy based on social skill training was found to significantly increase the communication, assertiveness, social adaptive functioning and empowerment of experimental group more than comparative group, and that of comparative group more than the control group. The group integrative arts therapy based on social skill training was found to significantly increase the NOSIE-30 of the experimental group and the comparative group more than control group. NOSIE-positive and irritability of NOSIE-30 in the comparative group was increased more than those of the experimental and the control groups.
Conclusions: The group integrative arts therapy based on social skill training is found to significantly enhance the social adaptive function and empowerment of inpatients with chronic schizophrenia than social skill training. These results suggest that group integrative arts therapy could be utilized as effective mental rehabilitation intervention program for inpatients with chronic schizophrenia.

Preliminary data from a survey about nutrition in mental health

A. Litta[1]*, A. Nannavecchia[2], V. Favia[3], M. V. Minò[4] and A. Vacca[5]
[1]Department of Precision and Regenerative Medicine and Ionian Area (DiMePRe-J) University of Bari "Aldo Moro"; [2]AReSS Puglia- Regional Strategic Agency for Health and Social; [3]Istituto Tumori Giovanni Paolo II, IRCCS, National Cancer Institute, Bari; [4]Psychiatric Rehabilitation Center "Don Tonino Bello"- Assoc. M.I.T.A.G. Onlus, Brindisi and [5]Mental Health Department, ASL Taranto, Taranto, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1606

Introduction: Diet-related support is urgently needed for people with serious mental illness underlying the role of nutrition in a biopsychosocial approach. Integrating healthy lifestyle practices such as a balanced diet and physical exercise could supplement and amplify the effects of existing pharmacotherapies and psychotherapies. Despite its considerable role, nutritional literacy of mental health professionals appears scarce. Specific nutrition training courses for mental health professionals are needed in order to increase awareness on nutrition as a well-being contributing factor in the biopsychosocial model.
Objectives: The aim of this study is to investigate insight and attitudes on nutrition in mental health among a sample of psychiatrists and psychologists resident in Italy.
Methods: The survey was conducted from May to June 2024 and the questionnaire was anonymous and self-rated, accessible via Google forms. The sample comprised 110 Italian mental health professionals (adult and child psychiatrists, psychologists) who voluntarily completed the on-line questionnaire.
Results: 110 participants (61 psychologists, 46 adult psychiatrists and 3 child psychiatrists) agreed to participate to our survey. 89.2 % (n= 91) of them worked in southern Italy.The majority of participants were female (77.98%) and reported working in a Mental Health Centre (n= 41, 37,27%), followed by psychiatric residential facilities (n=22, 20%), private practice (n= 19, 17.27%), hospital (n= 14, 12.73%), university research centre (n=4. 3.64%), other non specified institute (n=10; 9.09%). The numer of years of working as mental health professional was 19.27 ± 11.27 years. Adopting "sometimes" nutritional approach for the treatment of the patients was the answer mostly reported (n= 56, 51.4%) followed by "most of the time" (n= 28, 25.69%), "always" (n=11; 10.09%), "never" (n= 7, 6.42%), "almost never "(n= 7, 6.42%).
Conclusions: Despite the scientific evidence and some treatment guidelines in support of this relationship, the implementation of nutritional psychiatry into routine clinical practice remains limited. Integrating nutrition into the clinical practice of psychologists and psychiatrists and providing evidence-based nutritional advice represent an interesting mental health challenge to address in the coming years.

Correlation between the use of social media and the self-esteem of adults with autism in their workplace

M. M. N. Matsumoto[1]*, B. F. A. da Silva[1] and D. R. Molini-Avejonas[1]
[1]University of Sao Paulo, Sao Paulo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1607

Introduction: There is a greater inequality in employment and underemployment among adults with Autism Spectrum Disorder (ASD) compared to their peers. Aspects such as sustained eye contact, interpreting non-verbal cues, understanding non-literal language, exhibiting cognitive inflexibility, and limitations in interpreting others' perspectives impact their communication. Due to these difficulties, they are often subject to social embarrassment, isolation, and insecurity when initiating conversations. Considering that contemporary interactions have intensified through social media, these networks can be a facilitator of social inclusion, especially as they are digital environments—structured, free from unexpected stimuli, offering additional processing time, and without the need to interpret prosody and intonation. In this context, to understand its impact in

the workplace for this population, one of the factors to consider is the self-esteem of these individuals within the workplace, given that self-esteem is a fundamental indicator of self-worth and self-acceptance, impacting mental health.

Objectives: To verify the correlation between social media use and self-esteem in adults with ASD in their workplace.

Methods: This is a prospective, qualitative-quantitative study based on the Ethics Committee for Research number 65890317.9.0000. 0065. Data were collected via an electronic form. Questionnaires: personal/social questions prepared by the authors; adapted protocols: Rosenberg Self-Esteem Scale and Facebook Intensity Scale.

Results: A total of 132 adults with self-reported ASD, 68% of whom had ASD with comorbidities. Regarding gender and sexual orientation, 66% were cisgender and heterosexual women, and 62% were cisgender and heterosexual men. Concerning remuneration and education, 44.7% had completed higher education, earning between two to three thousand reais per month. Additionally, 61.4% reported not having inclusive strategies in their workplace. The overall correlation between self-esteem and social media use at work showed that 65.9% use social media moderately, of which 12.9%, 18.9%, and 34.1% have low, high, and medium self-esteem, respectively. Correlating personal/social questions with self-esteem, 34.8% never feel comfortable with group conversations, of which 11.4% have low self-esteem (p-value 0.008), 48.5% feel distressed at work (p-value 0.06), 62.9% are excessively concerned about work (p-value 0.02), and 49.2% find it difficult to assert themselves at work (p-value 0.02). (Image 1)

Image 1:

Personal/Social Questions (%)	Self-esteem (%)				
1. Are you able to have long conversations with your work team about a variety of topics?	High	Medium	Low	Total	p-value*
Always	2,3	4,5	0	6,8	
Sometimes	15,2	22,7	5,3	43,2	
Never	13,6	22,7	13,6	50	
Total	31,1	50	18,9	100	0,13
2. Do you talk to your coworkers?	High	Medium	Low	Total	p-value*
Always	21,2	24,2	6,8	52,3	
Sometimes	9,8	25	11,4	46,2	
Never	0	0,8	0,8	1,5	
Total	31,1	50	18,9	100	0,08
3. Do you ask questions to your work team when you are having difficulties?	High	Medium	Low	Total	p-value*
Always	15,9	20,5	6,1	42,4	
Sometimes	10,6	25,8	10,6	47	
Never	4,5	3,8	2,3	10,6	
Total	31,1	50	18,9	100	0,3
4. Do you deal well with unexpected events at work?	High	Medium	Low	Total	p-value*
Always	1,5	4,5	0,8	6,8	
Sometimes	16,7	15,9	8,3	40,9	
Never	12,9	29,5	9,8	52,3	
Total	31,1	50	18,9	100	0,23
5. At work, do you feel comfortable talking in groups?	High	Medium	Low	Total	p-value*
Always	3	0,8	0	3,8	
Sometimes	19,7	34,1	7,6	61,4	
Never	8,3	15,2	11,4	34,8	
Total	31,1	50	18,9	100	0,008
6. Do you feel distressed about your work environment?	High	Medium	Low	Total	p-value*
Always	10,6	25	12,9	48,5	
Sometimes	15,9	18,9	6,1	40,9	
Never	4,5	6,1	0	10,6	
Total	31,1	50	18,9	100	0,06
7. Are you afraid of new challenges at work?	High	Medium	Low	Total	p-value*
Always	14,4	29,5	15,2	59,1	
Sometimes	13,6	16,7	3,8	34,1	
Never	3	3,8	0	6,8	
Total	31,1	50	18,9	100	0,09
8. Do you feel excessively worried about work?	High	Medium	Low	Total	p-value*
Always	15,2	31,1	16,7	62,9	
Sometimes	10,6	12,1	2,3	25	
Never	5,3	6,8	0	12,1	
Total	31,1	50	18,9	100	0,02
9. Do you have difficulty positioning yourself in conflict situations at work?	High	Medium	Low	Total	p-value*
Always	9,8	25,8	13,6	49,2	
Sometimes	15,2	18,9	4,5	38,6	
Never	6,1	25,8	13,6	49,2	
Total	31,1	50	18,9	100	0,02
Legend: * = Pearson's Chi-squared test					

Conclusions: This study did not statistically demonstrate a correlation between social media use and self-esteem in the workplace. However, the challenges encountered in the workplace, such as the lack of inclusive strategies, social difficulties that generate fear, distress, and worry, corroborate the literature regarding the vulnerability this population is exposed to.

Reliability of an Assessment Method for Resilience

L. Mehl-Madrona[1,2*] and B. Mainguy[3]

[1]Native Studies, University of Maine, Orono; [2]Psychiatry Residency, Northern Light Acadia and [3]Wabanaki Health and Wellness, Bangor, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1608

Introduction: Understanding resilience becomes important given that adversity is an unavoidable fact of human life. Over 70% of respondents in a sample of 68,894 people reported at least one traumatic event in their lifetime. The neurotoxic effects of these experiences range from compromised neurocompetence, psychopathology including PTSD and depression, to adverse physical effects.

Objectives: To determine if we could reliably agree on ratings of resilience on a five point scale to aid future studies of the role of resilience in recovery and relapse.

Methods: To assess resilience we developed a five point scale with 1 being the least and 5 behind the most resilient pattern. We found a water metaphor useful to conceptualize these five levels of resilience. Resilience in an ever-changing world can be likened to navigating in a body of water. Adversity tosses us into the water. Here are our levels:

Level 1: At this level, the person sinks to the bottom and remains there. They are making no effort to change their circumstances and remain stagnant.

Level 2: At this level, the person is not sitting at the bottom, but has not yet reached the surface. They are in a place of struggle and resistance, where change is elusive.

Level 3: The person is treading water at this stage. They are working hard to stay afloat, but not making significant progress in altering their overall situation.

Level 4: They're swimming toward shore, toward a more favorable environment in which they can thrive. They're actively seeking change and adjustment to a post-adversity reality.

Level 5: At this point, they've managed to climb out of the water and change their circumstances. Their resilience allows them to overcome challenges and seek better surroundings.

We used kappa statistics to assess our level of agreement among ourselves (three raters) after studying and discussing prototypical stories for each rating level.

Results: Practicing with training videos, we found we could achieve 84% agreement on the five ratings with 3 raters.

Percent overall agreement = 84.00% Free-marginal kappa = 0.80 95% CI for free-marginal kappa [0.66, 0.94]; Fixed-marginal kappa = 0.78; 95% CI for fixed-marginal kappa [0.62, 0.93]

When we added AI, we got Percent overall agreement = 71.33% Free-marginal kappa = 0.64; 95% CI for free-marginal kappa [0.50, 0.79] Fixed-marginal kappa = 0.61; 95% CI for fixed-marginal kappa [0.51, 0.71]

Conclusions: The individuals who fit into the pattern of low resilience tended to have a high amount of childhood adverse experiences as shown through the ACE survey. The accumulation of these events in combination with external variables shape resilience. Factors including intelligence/education level, drug/alcohol use, positive role models, exposures to nature/art/spirituality, and community/family norms steer a person down a set of patterned thinking and actions which ultimately depict their overall life story.

Disclosure of Interest: None Declared

EPV0971

Comparative outcomes of two different styles of mental health practice

L. Mehl-Madrona[1,2*] and B. Mainguy[3]

[1]Native Studies, University of Maine, Orono; [2]Psychiatry Residency, Northern Light Acadia and [3]Wabanaki Health and Wellness, Bangor, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1609

Introduction: An opportunity arose to compare the outcomes of patients of one psychiatrist in two different clinical settings – a community mental health center CMHC) in which the psychiatrist saw people on average for 15 minutes every 6 weeks (range 4 to 12 weeks) and a community clinic setting (CCS) in which the psychiatrist controlled the time allotted per patients and the frequency of visits. We assumed that the psychiatrist's beliefs, attitudes, and style of practice did not change between the two settings except as influenced by time constraints. Psychotherapy was provided by social workers in both settings, with an average of 45 minutes every 3 weeks in the CMHC and 40 minutes every week in the CCS. Three optional groups existed in the CCS compared to one in the CMHC. New patients received a 30 minute evaluation in the CMHC and a 60 minute evaluation in the CCS.
Objectives: To compare the dominant style of practice in the United States with an older style of practice in which psychiatrists spent more time with clients.
Methods: The psychiatrist administered the MYMOP2 (My Medical Outcome Profile, version 2) and the Brief Psychiatric Rating Scale (BPRS) to all patients at baseline in both settings. The MYMOP2 was repeated monthly (or at the next visit in the CMHC) and the BPRS at intervals of every three months. The study lasted two years and the average length of follow-up was 31 weeks in the CMHC and 49 weeks in the CCS, which was statistically significant.
Results: No statistically significant differences appeared in demographic variables. Percent funded by Medicaid, Medicare, other insurance, gender, and age distribution were the same in both settings. Clinical improvement was not observed among patients on average on both measures in the CMHC. Clinical improvement was observed on both measures in the CCS (MYMOP-2; $p < 0.01$ on worst symptom; BPRS, $p < 0.01$). The CMHC showed higher profits than the CCS. Time spent per patient was statistically significantly greater in the CCS ($p < 0.01$).
Conclusions: Increased opportunity for contact and relationship with the psychiatrist may play a greater role than assumed by the biomedical model. A public health question arises in relation to models for provision of care that are more profitable but less health effective.

EPV0972

The Bottleneck Effect: Wait Times for Adult ADHD Assessment at a Private Clinic in Australia

R. D. Mendonsa[1*] and H. T. Jayasooriya[1]

[1]Mental Health and Wellbeing, Western Health, Melbourne, Australia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1610

Introduction: Public sector mental health services in Australia typically do not provide Adult ADHD assessment or treatment, creating a significant reliance on private sector care. Consequently, the demand for private ADHD services has surged, resulting in extended wait times for assessment and treatment.
Objectives: This study aimed primarily to evaluate the wait times for Adult ADHD assessments for patients referred by GPs to a private clinic. A secondary aim was to analyze the relationship between sociodemographic and clinical variables, including illness characteristics and timing of diagnosis.
Methods: Data were collected through retrospective file reviews of consecutive patients referred to the authors' private clinics for Adult ADHD assessment between January 2023 and October 2024. Patients included in the study met the criteria of an eventual clinical diagnosis of Adult ADHD. Data collected included sociodemographic details, ADHD subtype, psychiatric comorbidities, and wait times for initial psychiatric consultations. Total sample was 68.
Results: Wait times ranged from 10 days to 305 days, with a mean wait time of approximately 4 months (112 days). Almost 30 % of the patients referred had wait time of more than 4 months. The sample comprised nearly equal numbers of male and female patients (33 vs. 35), with ages ranging from 17 to 56 years (mean age: 28.35 years). The majority (68%) were diagnosed with Adult ADHD - Combined Presentation, while 32% had the Predominantly Inattentive Presentation. Nearly all patients received their ADHD diagnosis in adulthood, with less than 5% having a childhood ADHD diagnosis.
Conclusions: There are significant delays in acessing appropriate care for people with Adult ADHD in Australia. Improvement in mental health policy and service delivery with regard to ADHD services is essential if this barrier to access appropriate care has to be overcome.

Public perceptions of mental health and the role of nursing professionals in providing psychological support: a nation-wide, cross-sectional study from Croatia

T. Meštrović[1*], T. Ćurić[1], M. Neuberg[1], I. Herak[1] and R. Ribić[1]

[1]Department of Nursing, University North, Varaždin, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1611

Introduction: Mental health is indispensable to quality of life and social well-being, influencing economic stability, human rights and sustainable development. Despite growing awareness, the public often conflates mental health with mental illness, which means that stigma remains prevalent. Nursing professionals, who interact closely

with patients, are uniquely positioned to provide psychological support. Therefore, understanding public perceptions of mental health and the role of nurses is crucial for developing effective care strategies and improving health outcomes.
Objectives: With our research we aimed to examine public attitudes towards mental health and assess how the general population perceives nurses' roles in psychological support. The study also sought to identify demographic influences on these attitudes and highlight potential improvements in nursing education.
Methods: The study utilized a cross-sectional survey design to collect quantitative data on public perceptions of mental health and the roles of nursing professionals. An anonymous online questionnaire was distributed, reaching a diverse sample of 270 participants from various demographic backgrounds. The survey included items assessing demographic information (gender, age, educational level, and residential location), as well as specific questions on mental health perceptions, experiences with psychological challenges, and also attitudes toward nursing empathy and support. Descriptive and inferential statistics - including Mann-Whitney U tests and chi-square tests - were used to analyze responses. Significance was set at $p<0.05$.
Results: Of the respondents, 73% were female, 63.3% resided in urban areas, and 54% had completed secondary education. The majority (65%) were over 35 years old. Regarding self-assessed mental health, 48.9% rated it as "good," and 48.5% reported occasional mental health challenges. Significant gender differences were observed in perceptions of empathy among nursing professionals, with female respondents reporting more positive views compared to male respondents ($U=83.37$, $p=0.01$). The study also revealed that 53% of participants believed nurses "sometimes" showed empathy toward patients' mental health needs. A significant association was found between educational level and the perception that nurses need additional training to support mental health challenges ($U=147.00$, $p=0.01$).
Conclusions: This study highlights the vital role of nurses in mental health support and suggests that additional training on psychological support could enhance care quality, especially in the eyes of well-educated patients. While many respondents see nursing professionals as empathetic, there is room to further improve nurses' mental health literacy and communication skills to reduce stigma and improve patient outcomes.

Cultural values as determinants of psychological resilience in Tunisian women

H. Mhiri[1]*, I. Chaari[1], I. Mannoubi[1], N. Boussaid[1], F. Charfeddine[1], L. Aribi[1], N. Messedi[1] and J. Aloulou[1]

[1]Psychiatric department "B", Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1612

Introduction: Resilience, the ability to adapt and thrive amid adversity, is particularly prominent in Tunisian women, who are recognized for their strength and adaptability despite societal pressures. Their resilience appears closely linked to cultural heritage, indicating a significant connection between resilience and cultural values. This study explores how cultural values shape the psychological resilience of Tunisian women.
Objectives: To examine the influence of cultural values on resilience among Tunisian women.
Methods: A cross-sectional survey was conducted Tunisian women aged 18 and above, from June to August 2024. Sociodemographic data were gathered, while cultural values were assessed using the Individual Cultural Values Scale (CVScale) and the Centrality of Religion Scale (CRS-5). Resilience was measured with the 25-item Connor-Davidson Resilience Scale (CD-RISC 25).
Results: We collected 695 responses in our survey. Participants had a mean age of 36.72 ± 12.23 years, with 90.9% holding university degrees, 56.5% employed, 49.2% married, and 50.6% with children. The mean resilience score was 68.26 ± 14.09, with 26.3% showing low resilience. Average scores for cultural values were "power distance" (9.13 ± 3.46), "uncertainty avoidance" (20.84 ± 2.95), "masculinity" (9.55 ± 3.99), "collectivism" (21.64 ± 5.07), "long-term orientation" (25.89 ± 2.94), and "centrality of religion" (3.95 ± 0.77).
Resilience correlated positively with "uncertainty avoidance" ($p < 10^{-3}$, $r = 0.145$), "collectivism" ($p < 10^{-3}$, $r = 0.208$), "long-term orientation" ($p < 10^{-3}$, $r = 0.267$), and "centrality of religion" ($p < 10^{-3}$, $r = 0.186$). Conversely, resilience was negatively correlated with "power distance" ($p < 10^{-3}$, $r = -0.104$), and no significant correlation was observed with masculinity.
Conclusions: The findings reveal that cultural values significantly shape resilience in Tunisian women. Higher resilience was associated with uncertainty avoidance, collectivism, long-term orientation, and religious centrality, while power distance negatively impacted resilience. This emphasizes the need to incorporate cultural dimensions when designing initiatives to support resilience among women in Tunisia.

Resilience and self-esteem in Tunisian women: A study on psychological strength

H. Mhiri[1]*, I. Chaari[1], I. Mannoubi[1], N. Boussaid[1], F. Charfeddine[1], L. Aribi[1], N. Messedi[1] and J. Aloulou[1]

[1]Psychiatric department "B", Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1613

Introduction: Self-esteem, defined as an individual's overall sense of self-worth and confidence, plays a crucial role in shaping how people interact with their environment. It has been strongly linked in the literature to both mental health and resilience. Tunisian women, known for their achievements despite numerous challenges, provide a compelling population for exploring the dynamics between self-esteem and resilience.
Objectives: To assess the impact of self-esteem on resilience among Tunisian women.
Methods: This cross-sectional study surveyed Tunisian women aged 18 and above, between June and August 2024, using an online questionnaire. General health information was gathered through a structured survey. Self-esteem levels were evaluated using the Rosenberg Self-Esteem Scale, while resilience was measured with the 25-item Connor-Davidson Resilience Scale (CD-RISC 25).
Results: Data were collected from 695 Tunisian women, with participants having a mean age of 36.72 ± 12.23 years. Of the respondents,

22.3% reported using psychoactive substances: 20.4% smoked, 9.4% consumed alcohol, and 2.5% used cannabis. Additionally, 22.2% had somatic conditions, 24.5% reported a personal psychiatric illness, 28.2% had a family psychiatric history, 39.3% had seen a psychiatrist at least once, and 15% were using psychotropic medications. The average resilience score was 68.26 ± 14.09, with 26.3% of participants displaying low resilience. The mean self-esteem score was 29.38 ± 5.64, with 55.8% of participants exhibiting low self-esteem. No significant correlation was found between resilience and substance use. However, resilience was significantly associated with personal psychiatric illness ($p < 10^{-3}$), family psychiatric history ($p < 10^{-3}$), psychotropic medication use ($p < 10^{-3}$), and psychiatrist visits ($p < 10^{-3}$). In contrast, there was no correlation between resilience and somatic conditions. A strong association was found between resilience and self-esteem: only 6.8% of participants with normal to high self-esteem exhibited low resilience, compared to 41.8% of those with low self-esteem showing low resilience.
Conclusions: This study demonstrates a significant relationship between self-esteem and resilience among Tunisian women, indicating that higher self-esteem is linked to greater resilience. These findings suggest that interventions aimed at enhancing self-esteem could improve resilience, particularly for women facing psychological difficulties. Future research could explore targeted strategies to boost self-esteem as a pathway to strengthen resilience and overall mental well-being in this population.

Psychological traits as determinants of resilience: Insights from Tunisian women

H. Mhiri[1]*, I. Chaari[1], I. Mannoubi[1], N. Boussaid[1], F. Charfeddine[1], L. Aribi[1], N. Messedi[1] and J. Aloulou[1]

[1]Psychiatric department "B", Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1614

Introduction: Personality encompasses stable traits, behaviors, thoughts, and emotions that shape how individuals interact with their environment. It stands to reason that personality can influence how a person responds to life's challenges, essentially defining their level of resilience. Tunisian women, who frequently face a range of daily struggles, represent a significant group for exploring the dynamics of resilience. Understanding how their personality traits impact their ability to adapt and thrive amidst adversity provides valuable insights, making this an important area of study.
Objectives: To examine the relationship between personality traits and resilience among Tunisian women.
Methods: This cross-sectional study surveyed Tunisian women aged 18 and above using an online questionnaire between June and August 2024. Personality traits were assessed using the 10-item Big Five Inventory (BFI-10), while psychological resilience was measured using the 25-item Connor-Davidson Resilience Scale (CD-RISC 25).
Results: Data were collected from 695 Tunisian women, with a mean age of 36.72 ± 12.23 years. Among participants, 24.7% were students, 56.5% were employed, 49.2% were married, and 50.6% had children. Regarding sexual orientation, 93.4% identified as heterosexual, 0.4% as homosexual, 3.3% as bisexual, and 2.9% as undefined. The average resilience score was 68.26 ± 14.09, with 26.3% of participants exhibiting low resilience. Mean scores for personality traits were as follows: agreeableness: 6.8 ± 1.86, extraversion: 6.1 ± 1.79, neuroticism: 6.33 ± 2.01, conscientiousness: 7.16 ± 1.94, and openness to experience: 8.03 ± 1.71. Resilience was positively associated with age ($p < 10^{-3}$, $r = 0.143$), marital status ($p = 0.022$), sexual orientation ($p = 0.001$), and education level ($p < 10^{-3}$), with 80% of those with only primary education showing low resilience compared to 24.2% of those with a university education. Personality traits showed significant correlations with resilience: agreeableness ($p < 10^{-3}$, $r = 0.165$), extraversion ($p < 10^{-3}$, $r = 0.207$), conscientiousness ($p < 10^{-3}$, $r = 0.367$), and openness to experience ($p < 10^{-3}$, $r = 0.278$) were positively correlated, while neuroticism was negatively correlated ($p < 10^{-3}$, $r = -0.482$).
Conclusions: Personality traits are significant determinants of resilience in Tunisian women. Positive traits like agreeableness, openness, extraversion, and conscientiousness enhance resilience, while neuroticism has the opposite effect. Considering that personality is influenced by factors such as early childhood experiences and parenting styles, future interventions could focus on fostering these positive traits to strengthen resilience.

Resilience in Tunisian women: The critical role of social support

H. Mhiri[1]*, I. Chaari[1], I. Mannoubi[1], N. Boussaid[1], F. Charfeddine[1], L. Aribi[1], N. Messedi[1] and J. Aloulou[1]

[1]Psychiatric department "B", Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1615

Introduction: Resilience is the capacity to bounce back from adversity, and this concept has been extensively studied across various populations, especially those facing significant stress. In this context, Tunisian women have recently encountered multiple challenges related to balancing professional and family responsibilities, which require them to demonstrate strong resilience. Recent literature has highlighted a strong link between social support and resilience.
Objectives: This study aims to explore the impact of social support on the psychological resilience of Tunisian women.
Methods: This cross-sectional study surveyed Tunisian women aged 18 and above using an online questionnaire between June and August 2024. Familial and professional characteristics were collected through a structured survey. Social support was measured using the Multidimensional Scale of Perceived Social Support (MSPSS), and psychological resilience was assessed with the 25-item Connor-Davidson Resilience Scale (CD-RISC 25).
Results: Data from 695 Tunisian women (mean age = 36.72 ± 12.23 years) revealed diverse backgrounds: 24.7% were students, 35.3% worked in the public sector, 21.2% were self-employed, and 14.7% were unemployed. In terms of marital status, 42.9% were single, 49.2% married, and 5.6% divorced, with 8.5% living alone, 75.7% in nuclear families, 10.4% in extended families, and 5.5% in shared housing; additionally, 50.6% had children. The average resilience score was 68.26 ± 14.09, with 26.3% exhibiting low resilience. Social support scores were as follows: familial support

(20.06 ± 6.38), friend support (18.17 ± 6.47), significant other support (21.2 ± 6.22), and overall social support (59.42 ± 15.26). Significant associations were found between resilience and marital status (p = 0.019), with married women showing lower rates of low resilience (21.3%) than single women (31.9%). Women with children also demonstrated higher resilience (p = 0.002), while employment status had a notable impact (p = 0.005), with low resilience rates highest among unemployed women (36.3%) and lowest among public sector workers (19.6%). Resilience positively correlated with social support across all sources: familial (p < 0.001, r = 0.269), friend (p < 0.001, r = 0.260), significant other (p < 0.001, r = 0.289), and overall social support (p < 0.001, r = 0.338).
Conclusions: Our findings underscore the crucial role of social support and family connections in enhancing the psychological resilience of Tunisian women. Therefore, targeted social interventions are needed to support women experiencing loneliness or lacking social networks, aiming to strengthen their resilience and overall well-being.

EPV0978

Resilience among Tunisian women: Exploring the impact of coping Strategies and sociodemographic influences

H. Mhiri[1]*, I. Chaari[1], I. Mannoubi[1], N. Boussaid[1], F. Charfeddine[1], L. Aribi[1], N. Messedi[1] and J. Aloulou[1]

[1]Psychiatric department "B", Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1616

Introduction: Tunisian women, seen as symbols of freedom, have achieved social equality despite various challenges. This study examines the role of sociodemographic factors and coping strategies in shaping psychological resilience among Tunisian women.
Objectives: To investigate how sociodemographic factors and coping styles influence resilience in Tunisian women.
Methods: This cross-sectional study targeted Tunisian women aged 18 and above through an online survey between June and August 2024. Sociodemographic data were collected, coping styles were measured using the Brief COPE inventory, and resilience was assessed via the 25-item Connor-Davidson Resilience Scale (CD-RISC 25).
Results: Data from 695 women (mean age = 36.72 ± 12.23) showed that 90.9% had university education and 34.1% were unemployed. Personal income was the main income source for 61.7%. The mean resilience score was 68.26 ± 14.09, with 26.3% exhibiting low resilience. Higher resilience was significantly associated with university education (p < 0.001) and higher economic status; 34.3% of those in lower brackets showed low resilience (p = 0.007). Personal income also predicted resilience (p < 0.001). Regarding coping, resilience positively correlated with problem-focused (r = 0.496, p < 0.001) and emotion-focused coping (r = 0.271, p < 0.001), but was negatively associated with avoidance coping (r = -0.093, p < 0.05).
Conclusions: This study reveals that resilience among Tunisian women is linked to education, economic status, and income, with effective coping strategies (problem- and emotion-focused) enhancing resilience. Findings underscore the importance of economic empowerment and effective coping skills in strengthening resilience among women.

Factor Models as an Important Tool in Creating the Effective Quality Management System in Psychiatric Institutions

V. Mitikhin[1]*, T. Solokhina[1] and D. Oshevsky[1]

[1]Mental Health Research Centre, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1617

Introduction: Medical staff is one of the main participants in psychiatric care quality management system. At the same time, it is not enough to ensure high level of staff qualifications only. It is also necessary to determine staff satisfaction with their professional activities, levels of staff well-being and of professional burden. That's why, using factor analysis in the process of identification of factors affecting these parameters of psychiatric staff is an important task.
Objectives: To work out factor models determining the main components affecting psychiatric staff professional burden and satisfaction of staff with provided psychiatric care; to justify proposals for improving medical staff professional activities and quality of care.
Methods: Adapted questionnaire «Assessment of the burden of psychiatric staff working in psychiatric institution» (WHO, 1994); Questionnaire «Assessing the satisfaction with quality of care by medical staff of psychiatric institution» (Solokhina et al., 2014). Factor analysis (principal component analysis with quatrimax rotation and factor selection according to the Cattell criterion) was used in the IBM SPSS Statistics 27 software environment. The study involved 73 nurses (age 44,55±11,56) of Moscow psychiatric hospitals № 1 and № 4. The nurses were included in the analyses as the most representative staff category closely contacting with patients.
Results: Using factor analysis, a model identifying the most significant components affecting of the professional burden of the nurses and reflecting 50.9% of the sample variance was worked out. The parameters include: "physical and emotional problems", "interpersonal problems", "intrapersonal problems", "stigmatization", "experiencing difficult situations related to patients" (16.86%, 11.67%, 9.52%, 6.61%, 6.34 of the sample variances correspondingly).
The factor model of nurse's satisfaction with psychiatric institutions activities includes "organizational" (33.66%), "procedural" (7.44%), "logistical" (6.92%), "support" (5.14%), "alternative forms of assistance" (5.05%) factors, which in total make up 58.8% of the sample variance.
Conclusions: Factor models are a powerful tool which permits to analyze complex information and to identify factors affecting important indicators in a quality management system. Therefore, factor analysis should be carried out regularly in order to prevent different risks of care quality violation. It is also important to introduce psychological support to medical staff and to improve team methods of work.

World mental health day as an effective element of the public health system. 30 years of experience and perspectives

V. F. Lebedeva[1], E. V. Gutkevich[1,2], O. A. Pavlova[1], S. V. Vladimirova[1], N. A. Bokhan[1,3] and E. Mochalova[2]*
[1]Mental Health Research Institute, Tomsk National Research Medical Center, Russian Academy of Sciences; [2]Tomsk State University and [3]Siberian State University, Tomsk, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1618

Introduction: During Open Day at Mental Health Research Institute in Tomsk, assistance was provided to many citizens of Siberia.
Objectives: to develop its algorithm.
Methods: An analysis of experience in holding Mental Health Day.
Results: Stage 1 – Preparatory: assessment of the prevalence of mental disorders; identification of the social challenges in the population that influence the growth of various forms of mental disorders; features of the functioning of general somatic health care services and psychiatric institutions, and their interaction.
Stage 2 – Information and methodological: conducting psychoeducational activities. The main topics are understanding mental health, the main risks, the first symptoms, ways to seek help. The anonymity, the free provision of services, the date, the form and method of the project are emphasized.
Stage 3 – Formation of the volume of services. A registration is made via telephone and electronic communications for those wishing to receive this help, indicating a specific and convenient time. This form of preliminary registration turned out to be logistically successful, aesthetically humane even under the conditions of sanitary and epidemiological restrictions of the COVID-19 pandemic.
Stage 4 – Implementation of Mental Health Day: on Saturday, in the week 1 of October. Filling in the express questionnaires. Formation of the main flows by specialists: 1) with affective disorders, 2) schizophrenia, 3) psychosomatic disorders, 4) post-traumatic stress disorders, 5) with addictions to alcohol, psychoactive substances, 6) persons of gerontological age. Methods of assistance: advisory, therapeutic (inpatient, outpatient), psychological support, provision of social services.
Stage 5 – Assessing the effectiveness of logistics and the results of Open Day based on the results of a consultation, analysis of questionnaires, verification of mental disorders, assessment of the main risk factors, identification of vulnerable groups of the population for the development of mental disorders.
Stage 6 – Achieving the goal of the World Mental Health Day project.
Conclusions: An analysis of experience in holding Mental Health Day allowed us to develop its algorithm.

Audit of depot antipsychotic side-effect monitoring within a Community Treatment Team (CTT) in the North East of England in 2022

O. A. S. Mohamed[1]*, N. Ahuja[1], S. Siddiqui[1], S. Aluru[1], N. Keidan[1], F. Eissa[1] and J. Taylor[2]
[1]Psychiatry, Cumbria, Northumberland, Tyne and Wear Trust, Newcastle upon Tyne and [2]Psychiatry, Cumbria, Northumberland, Tyne and Wear Trust, North Tyneside, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1619

Introduction: This audit was undertaken to look at side-effect monitoring of patients on depot antipsychotics within the North Tyneside CTT. This was the fourth reaudit of this patient group, with the most recent one having been in 2019, highlighting a gap in re-audits during the height of the COVID-19 pandemic.
Objectives: The objective of this audit was to ensure adherence to the following standards, as per National Institute for Health and Care Excellence (NICE) guidelines and local trust guidelines pertaining to antipsychotic monitoring: 1. 100% of patients on depot anti-psychotics should have side effect monitoring, in the form of a Glasgow Antipsychotic Side-Effect Scale (GASS) form, completed every year. 2. 100% of patients on depot anti-psychotics should have a GASS form completed ever, since starting their antipsychotic medication. 3. Completed GASS forms should be accessible on RiO (online noting system).
Methods: Data collection occurred and concluded in March 2022. This involved identifying patients on depot antipsychotics within the CTT, pseudo anonymising them by patient number and basic demographics, then utilising RiO to identify whether they have had antipsychotic monitoring using a GASS questionnaire as per the guidelines outlined above. This data was then represented in excel form, allowing us to appraise adherence to guidelines and changes from previous audits performed on this topic. We then utilised a traffic light system where green represented a score of 90-100% (compliant), yellow 80-89% (partially compliant), and red 0-79% (non-compliant).
Results: 53% of patients had a GASS completed in the past year (red). 95% have had a GASS completed ever (green). 98% of GASS were recorded on RiO (green). Demographic and diagnostic data was also gathered and are available in the full body of the report and poster.

Image 1:

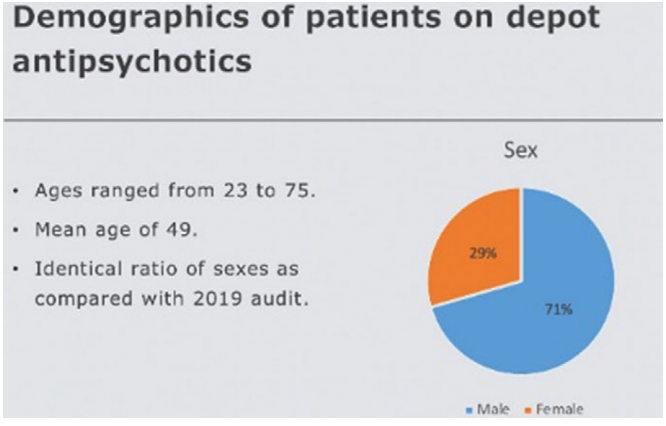

Image 2:

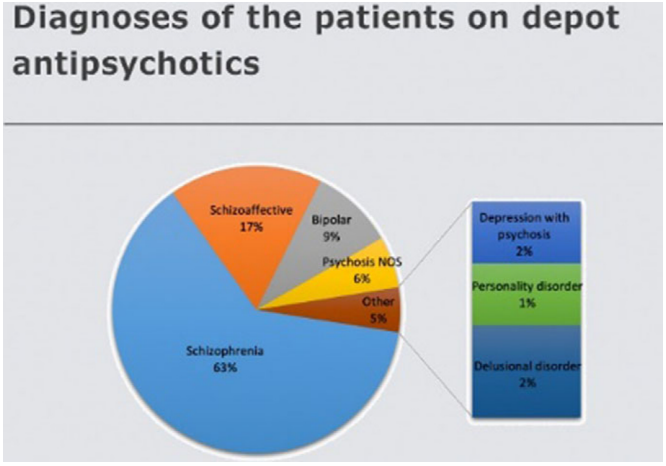

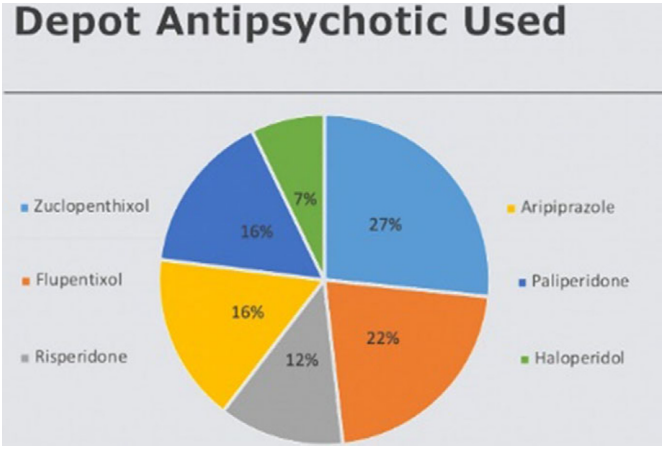

Image 3:

Conclusions: There has been a reduction in the percentage of patients having had a GASS in past year from 88% in 2019 to 53% now. This is likely to represent a disruption to services during the COVID-19 pandemic, forming obstacles to face-to-face reviews of patients. There was an increase in patients on depot antipsychotics from 90 in 2019 to 139 in 2022. There was a marginal improvement in documentation, with 98% of GASS questionnaires recorded on RiO in 2022, compared with 97% in 2019. Following recommendations being made, this will be re-audited in 2024/25.

Disclosure of Interest: None Declared

EPV0983

Ayahuasca and debut of psychosis, description of a clinical case

E. E. Morales Castellano[1]*, P. Rivero Rodriguez[1], M. Martinez Grimal[1], J. J. Tascón Cervera[1] and A. M. Morales Rivero[1]

[1]Psychiatry, Hospital universitario de gran canaria Dr Negrin, las palmas de gran canaria, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1620

Introduction: The relationship between psychosis and ayahuasca use is a topic of considerable interest and debate in the scientific and medical community. Ayahuasca is traditionally used in shamanic ceremonies in the Amazon, composed mainly of the Banisteriopsis caapi vine and the leaves of Psychotria viridis, which contain DMT (dimethyltryptamine), a powerful hallucinogen.
Ayahuasca induces altered states of consciousness, with experiences that can include visions, deep introspection, and changes in the perception of reality. The experience can be intense and emotionally overwhelming. In individuals with a history of psychosis or psychiatric disorders, ayahuasca may more easily trigger a psychotic episode. The interaction with neurotransmitters and the serotonergic system can influence their appearance.
We report a case of a patient who, after consuming ayahuasca, presented a psychotic episode that required hospitalization. After the initiation of treatment with antipsychotics, the condition had a favorable evolution towards the complete resolution of the symptoms.
Given the increasingly frequent use of ayahuasca in developed societies, the current case highlights the needs to understand, regulate and research the use of ayahuasca. Additionally, raising awareness of the potential risks of ayahuasca use through psychoeducation should be implemented.
Objectives: Describe the case of a psychotic episode induced by ayahuasca: Clinical debut, symptoms and evolution after initiation of treatment.
Methods: Description of a clinical case as well as bibliographic review.
Results: The relationship between hallucinogens and psychosis is a critical area of study due to the intense and potentially destabilizing effects that hallucinogens can have on people with this condition. Hallucinogens can trigger or aggravate psychotic symptoms, which may include hallucinations and delusions. We must keep in mind that hallucinogens can interact negatively with antipsychotics or other medications used to treat psychosis. These interactions may reduce the effectiveness of treatment or cause adverse side effects, as well as affect adherence to treatment, as it may lead to an alteration in the perception of the need for medication or the ability to follow the treatment regimen.
Conclusions: Ayahuasca use can have profound and potentially destabilizing effects, especially in people with a history of psychotic disorders. Although there is therapeutic potential, it is crucial to proceed with caution and under the supervision of trained professionals. Proper preparation and risk assessment are essential to minimize potential adverse effects.

"Peer support is the missing piece of the puzzle": An evidence-based approach to developing peer support in Jigsaw-The National Centre for Youth Mental Health

R. Murphy[1]* and A. Fitzgerald[1]

[1]University College Dublin, Dublin, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1621

Introduction: In Ireland, 1 in 5 young adults (aged 18-25) experience moderate to severe levels of depression and anxiety. To meet the growing need for mental health supports, Jigsaw – The National Centre for Youth Mental Health – provides accessible, early intervention services throughout Ireland. Building on its reputation for championing youth voices and inspired by examples set by other international integrated youth mental health services, one such strategy Jigsaw is exploring is youth peer support.Peer support offers social, emotional, and practical assistance from young people with personal experience of mental health challenges. Evidence suggests that peer support can positively impact young people by promoting a recovery-based approach to mental health. However, despite the recognized benefits, peer support is underutilized in Irish youth mental health services, and there is limited guidance available for its development.
Objectives: This research adopts a collaborative approach to intervention development, aiming to create an evidence-informed framework to guide the introduction of peer support in Jigsaw services.
Methods: This PhD project adheres to the Medical Research Council's Guidance for Developing and Evaluating Complex Interventions. The first stage of this project comprised a published scoping review of peer support in integrated youth mental health services and educational settings. The second stage of the project aimed to understand the benefits and challenges of peer support using semi-structured interviews with mental health professionals. The final stage of the project will take a participatory approach to intervention design, utilizing co-design workshops with stakeholders to identify potential intervention functions.
Results: The scoping review identified common types of peer support programs (peer-delivered one-to-one support, self-help groups, and internet support groups) and target problems addressed (depression, anxiety, and psychological distress). Interviews with fifteen professionals revealed insights into the benefits of peer support for young people, such as increased connection and empowerment, and for services, such as reduced power imbalances and increased accessibility. Challenges for implementation were also identified, including boundary management, funding, and resource allocation. The ongoing final stage focuses on developing a program theory underpinning a potential peer support intervention in Jigsaw. Key stakeholders, including Jigsaw's senior management and youth advisory panel (YAP), will be consulted to identify intervention components.
Conclusions: Recommendations regarding key components of peer support, as well as barriers and facilitators to its implementation, will be shared to support other organizations in enhancing their understanding and application of peer support for youth mental health.

Burnout Among Psychiatry Doctors in Pakistan: A Multicenter Study

G. Murtaza[1,2,3]

[1]Psychiatry, Jannat Medical Complex Rawalpindi, Rawalpindi; [2]Psychiatry, Armed Forces Institute of Mental Health Rawalpindi, Rawalpindi, Pakistan and [3]Psychiatry, North Dublin Mental Health Services, Dublin, Ireland
doi: 10.1192/j.eurpsy.2025.1622

Introduction: Burnout among medical professionals, particularly psychiatry doctors, is a pressing concern. High-stress environments, heavy workloads, and emotional demands can lead to physical, emotional, and mental exhaustion. Pakistani psychiatry trainees face unique challenges, including intensive training, high patient volumes, and limited support. Despite its implications for patient care and doctor well-being, limited research exists on burnout among Pakistani psychiatry doctors.
Objectives: To investigate burnout prevalence, contributing factors, effects, and coping strategies among Pakistani psychiatry trainees, informing evidence-based interventions to promote well-being and improve patient care.
Methods: A cross-sectional online survey was conducted among psychiatry doctors from 10 hospitals in Pakistan (July 26, 2024 – September 25, 2024). The questionnaire assessed demographic characteristics, burnout factors, effects, and coping strategies.
Results: The survey revealed significant burnout factors, including insufficient support from colleagues/administration (42.3%), high workload (23.1%), personal life stressors (19.2%), long working hours (11.5%), and lack of control (3.5%). Burnout effects included physical health issues (30.8%), mental health issues (30.8%), relationship strain (25.4%), and reduced job satisfaction (23.1%). Participants employed various coping strategies, such as having fun/leisure activities (38.5%), time management techniques (29.2%), engaging in self-care activities (26.9%), setting boundaries at work (11.5%), and seeking professional help (3.9%). Notably, the majority of participants (80.8%) were trainees, highlighting the vulnerability of this group to burnout.
Conclusions: This study highlights the alarming prevalence of burnout among Pakistani psychiatry doctors, underscoring the need for targeted interventions to promote support, workload management, and work-life balance.

A new psycho-education module for adolescents with a first episode of psychosis and their relatives

M. G. Pijnenborg[1]*, N. Boonstra[2], S. Sanches[3], D. Boertien[3], B. stavenuiter[4], B. S. Rosema[3] and C. elzinga[5]

[1]university of Groningen, groningen; [2]university of Utrecht; [3]KCPhrenos; [4]mind Ypsilon, Utrecht and [5]NHL Stenden, Leeuwarden, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1623

Introduction: Psychotic disorders typically have their onset in adolescence, a formative age that comes with many developmental challenges. The onset of mental illness in this phase of life can be very disruptive. Literacy on the nature and potential impact of psychosis can promote recovery, while family interventions have the potential to prevent relapse. Moreover, many patients and family members report a need for tools that provide guidelines to improve their communication and stimulate mutual understanding.

However, an integrated psyche-education module for both adolescents with lived experience and their relatives was lacking until now.
Objectives: The development of a new integrated psycho-education module and the content of this module will be presented,
Methods: Stakeholders (people with lived experience and family members) were interviewed on their preferences for the content, form and timing of psycho-education individually (n=15) and in focus groups (n=7). This information was used by a task force of experts composed of people with lived experience with psychosis, family members and mental health professionals. Subsequently, the intervention was piloted in two mental health care organizations.
Results: Adolescents with lived experience preferred psycho-education on communications skills and wanted to learn how to communicate with their relatives during and after the psychotic episode, adjusted to their specific situation. They prefer psycho-education together with their relatives, not separately. They also noted that the content of psycho-education may differ depending on the relationship they have with their relatives. Relatives and people with lived experience both reported they needed basic knowledge about psychosis, training in communication and problem solving skills, content with respect to self-care and content about online information. With regards to the timing of psycho-education, relatives preferred basic information as soon as possible and communication skills later on.
Both groups felt an integrated psycho-education could be beneficial. The final integrated module is composed of themes related to different dimensions of recovery, e.g. societal and social impact and spirituality. Results of the pilot were used to refine the module.
Conclusions: This new integrated psycho-education module was based on stakeholders preferences and needs and was found to be helpful to increase mental health literacy and communication between adolescents with lived experience with psychosis and their relatives.

Descriptive study of patients admitted to acute psychiatry care

P. S. Pires[1]*, C. Cunha[1], R. Cabral[1], F. Cunha[1], I. Santos[1] and A. P. Costa[1]

[1]DPSM, ULS Viseu Dão-Lafões, Viseu, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1624

Introduction: As a first-year resident doctor in specialized psychiatry training in Portugal, I have begun my inpatient internship, which is the longest component of the psychiatry residency program. At the Department of Psychiatry and Mental Health at the Viseu Dão-Lafões Local Health Unit, residents are assigned to follow patients under the supervision of specialists and rotate through cases managed by different psychiatrists. This internship focuses on acute patients, with a predominant presence of affective and psychotic disorders.
Objectives: This study aims to characterize patients hospitalized in an acute care unit, based on a sample monitored by the author.
Methods: The data for this study was obtained from electronic health records systems used in Portugal, specifically Sclinico and Alert, covering information on patients I followed during the first nine months of 2024. Additionally, we conducted a literature review on this topic using PubMed.
Results: The study sample comprised 20 female and 17 male patients. On average, the age of female patients is approximately 10 years higher than that of male patients, with women averaging 56 years and men averaging 46 years. The majority of male patients are hospitalized involuntarily under Portugal's Mental Health Law, whereas this is less common among female patients.
The primary reason for hospitalization in men is psychotic decompensation within the context of schizophrenia, while affective disorders are predominant among female patients. The average length of stay is 45 days for male patients and 30 days for female patients.
Conclusions: The longer average hospital stay for men may be linked to psychotic decompensation, often due to non-compliance with therapy. This lack of insight frequently results in involuntary hospitalization due to the risks posed to themselves and others. In contrast, affective disorders generally involve better-preserved insight, which could explain the shorter average hospital stays for women.

Gone missing or gone crazy? Key statistics about the relation between poor mental health and reports of missing people

G. N. Porfyri[1] and V. Tarantili[2]*

[1]National and Kapodistrian University of Athens, Athens and [2]General Hospital of Argos, Argos, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1625

Introduction: The definition of a missing individual includes the description of a person whose location is not known alongside alarming signs concerning his state of security and health. Despite thousands of people reportedly missing every year, limited information is available about their identity, the reason of their disappearance and their final evolving.
Objectives: To explore the relation between poor mental health and reports of missing people.
Methods: A review of 29 articles -from 2010 to 2024- on PubMed and Google Scholar regarding people suffering from mental illness who were reported missing.
Results: 1 in 5 missing children suffer from mental illness.
1 in 10 missing children is at risk of suicide.
8 in every 10 missing adults suffer from mental health problems.
4 in every 10 people with dementia will go missing eventually, in many cases involuntarily.
3 in 10 missing adults face relationship issues with their partner or relatives.
1 in 50 missing adults struggle with domestic violence.
20% of missing individuals commit suicide, with the majority of them being men who use violent methods such as drowning or hanging.
Those usually reported missing are: females aged 13-17 and men aged 24-30.
Juveniles and adults under 60s usually go missing deliberately, compared to people of different ages.
Reasons for psychiatric patients to go missing, include: disappointment by healthcare professionals; different opinions than their loved ones' concerning their health; feelings of helplessness; belief that going missing is the only solution.

Conclusions: Mental illness can be both the cause and the consequence of an individual going missing. Missing incidents in many cases represent a veritable moment of crisis and should be approached as such in someone's life. Unfortunately, when a person is found by authorities, support is rarely offered, potentially strengthening the feelings of hopelessness and despair of the previously missing person.
Mental health care professionals must be in alert after a missing's person return, ready to offer him their services.

Integrated Care Models for Severe Mental and Physical Health Disorders: A Scoping Literature Review for the EU-MIND European Initiative

M. Rahmati[1]*, U. Isayeva[2], E. TOUITOU-BURCKARD[3], C. Gandre[3], A. Kiejna[4] and M. Manchia[5]

[1]AMU, Marseille, France; [2]Unit of Psychiatry, Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy; [3]IRDES, Paris, France; [4]Department of Psychology, Faculty of Education, Psychology Research Unit for Public Health, University of Lower Silesia, Wroclaw, Poland and [5]Section of Psychiatry, Department of Medical Sciences and Public Health, University of Cagliari, Cagliari, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1626

Introduction: The co-occurrence of severe mental disorders (SMD) and physical health issues requires integrated care models that address both effectively. While interest in this area is growing, recent syntheses remain limited, particularly regarding technological advancements and the sustainability of health systems. This scoping literature review (SLR) supports the EUropean Mental and Physical Health Initiative (EU-MIND, THCS Horizon Europe) by examining integrated care for comorbid SMD and physical health conditions.
Objectives: The review aimed to identify integrated care models for SMD and physical health conditions, with a focus on technology and sustainability. Findings will inform subsequent EU-MIND phases, including a Delphi survey, financial impact assessment, and feasibility pilot studies.
Methods: Following PRISMA-ScR guidelines, we conducted a comprehensive search strategy in PubMed, Embase, Cochrane Library, and gray literature from inception to November 2024. Data were analyzed using the SELFIE framework, categorizing findings by WHO health system components (service delivery, governance, workforce, financing, technologies, and information).
Results: We reviewed over 75 studies on integrated care models, highlighting the value of coordinated mental and physical healthcare, particularly in community settings. Digital tools such as telemedicine and electronic patient-reported measures (ePREMs, ePROMs) enable sustainable care and efficient data-sharing. Challenges identified include workforce training gaps, inconsistent financing, and limited support for addressing social determinants of health (SDOH). The integration of roles like nurse practitioners and lay workers remains underutilized due to system barriers. Collaborative care models and self-management interventions, especially those involving primary care and mental health professionals, have proven effective in reducing depressive symptoms, improving quality of life, and lowering healthcare costs. Despite progress, challenges in fully integrating care systems persist across healthcare settings. Understanding these barriers requires exploring the perspectives of all stakeholders (patients, healthcare professionals, policymakers).
Conclusions: This SLR identifies key components and gaps in integrated care for individuals with comorbid SMD and physical health conditions. It highlights the importance of flexible governance, strategic integration of digital tools, and context-specific policies. Addressing these gaps can lead to more adaptive, sustainable, and patient-centered service delivery models. These findings provide a foundation for evidence-based decisions aimed at advancing multidisciplinary, integrated care approaches across European healthcare systems to better meet the complex needs of individuals with SMD.

GIS integrated Mental Health Service Delivery Mapping of Korail Slum

D. T. Rashid Soron[1]*, K. S. Azmery[1] and T. CONSORTIUM[1]

[1]Telepsychiatry Research and Innovation Network, Dhaka, Bangladesh
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1627

Introduction: About one million people in Bangladesh are living in different slums in Dhaka and Korail is the largest slum of the city with more than 250000 residents. These slums are deprived from most of the basic services and cares such as sanitation, water supply and healthcare. Moreover, the situation related to mental health care might be more disappointing. However, there is no well organized service delivery map to inform us about the existing the mental health care facilities and service provider to plan a feasible real life solution for this community.
Objectives: In this research, we aimed to fill this gap by developing Geographical Information Systems (GIS) integrated service delivery mapping of the slum and get a clear idea about the existing service institutional and individual level related to mental health care and related services to design and develop effective and acceptable real life solutions in the TRANSFORM Project for the person with serious mental disorders in the slum.
Methods: We followed stepwise apaprach starting from reviewing the literature and other docuements to gain detailed information about the geographical coverage, culture, institutions and services those were working in the Korail slum. After this, we visited the slum to get an idea of the key landmarks and conducted stakeholders and experts meeting about data collection framework design and drafting questionnaire. Based on the discussion, the questionnaire was pretested and finalized. Then this drafted questionnaire was transferred into KoBo Collect for data collection. We tested the feasibility of KOBO tools before final data collection. We recruited the data collector from the local community and trained them to collected service institutions and service providers information with GPS locations captured with 5m accuracy level in 2022. Data was organized and analyzed using Microsoft excel and a KML file was created.
Results: We found 66 Pharmacies, 50 Schools, 24 Traditional Healers, 20 Religious Institutions (mosjid mondir), 19 Madrasas, 66 medicine store, 13 health care provider chambers, 5 NGOs' office and

2 private clinics inside the slum. Among 24 traditional healers, 20 were male and all the four female traditional healers had no formal education. The 19 faith based healers (9 madrasa teachers and 10 Imam & muajjin) provide healing practice (Jhar-fook/ panipara/ tabiz/ Tadbir etc.). The community health workers of different NGOs work in the slum however, many organizations did not had their official set up in the slum. Moreover, during the service delivery mapping, we found no established mental health service in korail.
Conclusions: GIS based service delivery mapping helps us in a deeper understanding of the community and to design and implement real-life mental health solutions.

Suicidality and ADHD: which factors may influence the suicidal behavior?

M. E. Riezzo[1]*, G. Longo[1], M. Servasi[1], S. Piergentili[1], R. Volgare[1], L. Orsolini[1] and U. Volpe[1]

[1]Unit of Clinical Psychiatry, Department of Clinical Neurosciences/ DIMSC, Polytechnic University of Marche, Ancona, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1628

Introduction: Patients with Attention-Deficit/Hyperactivity Disorder (ADHD) are at a higher risk of suicidal behavior. Impulsivity, emotional dysregulation, and co-existing mental health conditions contribute to this risk. Early identification and comprehensive support are vital in mitigating these issues.
Objectives: The aims of our study are to characterize which factors promote suicide attempt in patient with ADHD.
Methods: Our study is conducted on patients (>18 years) referred to the adult ADHD outpatient service of the Psychiatric Clinic of Ancona (Università Politecnica delle Marche, Italy). The Diagnostic Interview for ADHD in adults (DIVA 5.0) was used for diagnosing ADHD. The following rating scale were administered: Temperament Evaluation in Memphis, Pisa and San Diego (TEMPS-M), Coping Orientation to the Problems Experiences-new Italian version (COPE-NVI), Temperament and Character Inventory-Revised (TCI-R).
Results: 76% (n=170) of all screened patients were diagnosed with ADHD in adulthood. 7.3% (n=12) of patients with ADHD attempted suicide. A significant higher frequency of suicide attempts was observed in those with borderline personality disorder as a comorbidity (p=0.004), in those with other psychiatric comorbidities (p=0.031), in those who are receiving treatment from the pathological addiction outpatient service (p=0.011), and in those who use stimulants (p=0.018) or opioids (p=0.019). A multivariate linear regression was observed between number of suicidal attempt (R^2=0.357; F(5,52)=5.779; p<0.001) and TCI-R transpersonal identification subscale (B=0.022; p=0.021), TCI-R harm avoidance subscale (B=-0.008; p=0.001), TCI-R impulsiveness subscale (B=0.023; p=0.012), TCI-R disorderliness subscale (B=-0.024; p=0.045) and COPE-NVI turn to religion subscale (B=-0.033; p=0.005). A logistic regression analysis was performed to ascertain the effects of all types of TCI-R subscale, on the likelihood of enacting suicide attempts. The logistic regression model was statistically significant, ▫▫ 2(1)=4.210, p=0.04. The model explained 14% (Nagelkerke R2) of the variance in patients with ADHD who committed suicide and correctly classified 90.3% of cases. Enacting a suicide attempt was significantly predicted TCI-R pure-hearted conscience subscale (exp(B)=0.843, p=0.062).
Conclusions: Comorbidities, addiction treatment, substance use, and personality traits significantly influence the likelihood of suicidal behavior. In addition, it is highlighted that impulsivity, lack of responsibility and caution, those who feel a strong connection with nature and the universe, being rigid, not having transcendental-oriented coping strategies, and being opportunistic are factors promoting suicide in patients with ADHD.

Association between wrist pain and occupational stress among sewing machine operators

N. Rmadi[1]*, A. Hrairi[1], F. Dhouib[1], I. Ben Hnia[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupational medicine department, Hedi chaker university hospital, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1629

Introduction: Given the specific characteristics of their work positions, sewing machine operators (SMOs) represent a vulnerable population to musculoskeletal symptoms such as wrist pain in the leather and footwear sector.
Objectives: This study aims to assess the association between wrist pain and occupational stress among SMOs.
Methods: A cross-sectional study was conducted among SMOs working in a shoe and leather factory. Data collection was carried out using Computer-Assisted Personal Interviews through a pre-established questionnaire. This questionnaire consisted of socio-demographic and professional data. We also assessed occupational stress using the validated French version of Job Content Questionnaire of Karasek.
Results: The average age of SMOs (n = 145) was 35.2 ± 9.9 years, with extremes ranging from 18 to 59 years. A female predominance was noted (sex ratio of 0.25). The average seniority in the current position was 14.4 ± 9.9 years. More than half of the population had high psychological demand, low decision latitude and low social in respectively 53.2%, 97.1% and 67.6%. Among SMOs, 76.3% had wrist pain. In bivariate analysis, wrist pain was positively associated to low decision latitude (p=0.033, OR=2.49, 95%IC [1.11-5.59]. Moreover, it was positively associated to professional seniority (p=0.014).
Conclusions: This study highlights a significant prevalence of wrist pain among SMOs in the leather and footwear sector. It can be exacerbated by various factors, including occupational stress. Addressing these factors is essential for enhancing both the health and productivity of this vulnerable workforce.

Associations between leadership styles and psychological distress among nurses

N. Rmadi[1]*, A. Hrairi[1], F. Ben Atia[2], N. Kotti[1], F. Dhouib[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupational medicine department, Hedi chaker university hospital, University of Sfax and [2]Higher Institute of Nursing Sciences of Sfax, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1630

Introduction: Leadership styles can either mitigate or exacerbate psychological distress, influencing job satisfaction, burnout, and overall well-being among nursing staff.
Objectives: This study aims to explore how different leadership styles impact psychological distress in nursing professionals.
Methods: We conducted a cross-sectional survey among nurses working in public hospitals and polyclinics in Sfax region. The questionnaire included socio-professional characteristics, assessment of leadership styles the Multifactor Leadership Questionnaire (MLQ) 6S and evaluation of nurses' mental health using the Kessler Psychological Distress Scale 6 (K6).
Results: A total of 200 physicians responded to the survey. The mean age was 33.24 ± 9.34 years with 70.3% being female. Mean scores of transformational, transactional and laissez faire styles were 25.6 ± 6.5, 12.8 ± 4.02 and 13.1 3.2 respectively. Psychological distress was likely to occur in 16.8% of the cases. Negative correlations were found between K6 score and transformational (p=0.00, r= - 0.81), transactional (p= 00, r=0.64) styles. However, laissez faire style was positively correlated with k6 score (p=0.024, r=0.16).
Conclusions: By emphasizing transformational and transactional leadership styles, healthcare leaders can reduce psychological distress among nurses, enhancing their well-being and improving the overall effectiveness of healthcare system.

Influence of occupational stress on job satisfaction among university workers

N. Rmadi[1]*, A. Hrairi[1], I. Makni[2], N. Kotti[1], A. Kchaou[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupational medicine department, Hedi chaker university hospital, University of Sfax and [2]Family medicine department, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1631

Introduction: Occupational stress has been identified as a significant predictor of job satisfaction among university staff.
Objectives: This paper aims to find out the relationship between occupational stress and job satisfaction among university workers in Sfax, Tunisia.
Methods: We conducted a cross-sectional study, during the period from September 2022 to October 2023. We used a self-administered questionnaire distributed to university staff. The questionnaire included socio-professional characteristics and assessment of occupational stress using the Work Stress Screener (WoSS-13). Job satisfaction was rated on a 5-point Likert scale from 1 (extremely dissatisfied) to 5 (extremely satisfied).
Results: The average age of the workers was 49.31±8. years. There is a slight female predominance (78 (53.1%)). Among the respondents, 57 (38.3%) were very to extremely satisfied. The medians of WoSS-13 subscales were 11 for WOSS-A1, 6 for WOSS-A2 and 3 for WOSS-B. Job satisfaction was positively associated with WOSS-A1 and WOSS-A2 (positive stress) but negatively associated with WOSS-B (negative stress). In bivariate analysis, being extremely satisfied was positively associated to WOSS-A1 and WOSS-A2 (p=0.000 for each respectively). However, it was negatively associated to WOSS-B (p=0.000).
Conclusions: Occupational stress has a significant impact on job satisfaction among university workers. Addressing job stress through targeted interventions can improve job satisfaction, productivity, and overall well-being among university staff.

Assessing the quality of life among victims of spinal occupational injuries

A. Hrairi[1], N. Rmadi[1]*, A. Kchaou[1], A. Haddar[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupational medicine department, Hedi chaker university hospital, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1632

Introduction: Spinal occupational injuries constitute an important health problem affecting workers in their most productive years. The outcomes of these injuries may influence the quality of life of those victims.
Objectives: Assessing the quality of life among victims of spinal occupational injuries and identifiying the associated factors to physical and mental health.
Methods: A cross-sectional analysis was conducted during 9 months (from October 2020) among workers victims of occupational injuries consulting for an Impairment Rating Evaluation. Only those with spinal injuries were included. Socio-professional data and the accident' outcomes were collected. The assessment of perceived mental health (Mental Component Summary: MCS) and physical health (Physical Component Summary: PCM) by each employee was obtained by the 12-item Short Form Health Survey. Social support was evaluated by the Social Support Scale. The pain was evaluated by a Visual Analogue Scale. Unsuccessful return to work comprises all situations other than a satisfactory return to the same position held before the accident.
Results: A total of 73 injured workers were included, 75.3% were male. The mean age was 42.78± 8.46 years. The mean job seniority was 14.44±7.86 years and the average number of working hours per week was 46.93±5.61 hours. Among the participants, 43.8% had an unsuccessful return to work, 28.1% of them had a low social support. The mean scores for MCS and PCS were 41.17± 11.89 and 29.57± 5.31 respectively.
Factors assocoiated with MCS were : the duration of absence (p=0.008), the rate of Permanent Partial Disability (p=0.025), lhe low social support (p=0.000), working in confection sector (p=0.016) and unsuccessful return to work (p=0.023).
Factors associated with PCS were : The pain score (p=0.002), the duration of immobilisation (p=0.007) and being a laborer (p=0.002). No association was found with age, job seniority, the presence of disc diseases and hospitalisation duration.
Conclusions: Victims of spinal occupational injuries are vulnerable to unfavorable outcomes from work accidents, and hence the need for special efforts to reintegrate them into professional life.

EPV0998

Occupational therapy intervention in a mental health hospitalization unit

M. Valverde Barea[1]*, M. N. Romero Muñoz[1] and L. Cerón Lorente[2]
[1]Psychiatry, H. U Jaén, Jaén and [2]Psychiatry, H. Jerez de la Frontera, Jerez de la Frontera, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1633

Introduction: Patients with severe mental disorders (SMD) often have a high number of admissions and readmissions, which leads to a loss of quality of life and functionality. The approach to patients must be multidisciplinary with the intervention of psychiatry, psychology and occupational therapy. Occupational Therapy is an important tool in acute mental health units; in the literature it has demonstrated its effectiveness in preventing suicide, offering a person-centered approach, contributing to improving their well-being and quality of life. Also noteworthy are the occupational therapy therapeutic groups for health education; sleep-wake balance; cognitive rehabilitation, social skills and relaxation that can be carried out in hospitalization units and demonstrate significant improvement in hospitalized SMD patients.
Objectives: To describe the importance of the joint approach with occupational therapy in the acute mental health unit by describing 2 clinical cases.
Methods: A 54-year-old male was admitted to the mental health hospitalization unit involuntarily due to manic decompensation. During the examination, he was in a euphoric mood and reported a decrease in the need for sleep. He spent all of his pension on compulsive shopping. The family said that in the weeks prior to admission, the patient had made abrupt decisions and had a violent attitude. He has now abandoned treatment. A 56-year-old woman, diagnosed with schizoaffective disorder, was admitted due to psychotic decompensation after being isolated at home for 1 month, with neglect of hygiene and inadequate nutrition due to thoughts of poisoning and neglect of pharmacological treatment. Upon examination, she said he was delusional about harm and poisoning, isolation, neglect of self-care.
Results: After the intervention by the therapeutic team, psychopharmacological treatment was reintroduced and daily attendance at occupational therapy groups was indicated, after which the patient showed a notable improvement. We conclude that occupational therapy has allowed a faster recovery, together with the proper intake of medication, constituting an effective therapeutic approach in the treatment. Recovering the deficient Basic Activities of Daily Living related to hygiene and personal image, adherence to treatment and social relationships. Upon discharge, both patients participate in the rehabilitation unit and continue specific programs.
Conclusions: The intervention with psychoeducational programs by Occupational Therapy and the multidisciplinary team in the acute unit improves disease awareness, health knowledge and reduces the rate of readmission in patients with SMD.

Disclosure of Interest: None Declared

EPV0999

Transcranial Pulse Stimulation (TPS) suitable add-on treatment of patients with psychiatric disorders?

V. Rößner-Ruff[1]*, C. A. Penkov[1], J. Krieger[1], K. Friedrich[1] and M. Ziegenbein[1]
[1]Psychiatry and Psychotherapy, Wahrendorff Clinic, Sehnde, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1634

Introduction: Neurostimulation procedures have also been in use for some time to treat neurological and neuropsychiatric disorders. In the field of non-invasive brain stimulation, a number of methods have been the subject of investigation, including transcranial magnetic stimulation (TMS), transcranial electrical stimulation (tES), and transcranial pulse stimulation (TPS). Although TMS and tES have been the subject of more extensive investigation, particularly in the context of Alzheimer's disease (AD) and depression, there remains a pressing need for research into TPS. Some studies have demonstrated favorable outcomes when these methods were used. Nevertheless, these methodes have yet to be incorporated into clinical practice, largely due to the inability to conclusively assess and confirm their effectiveness, which is influenced by a number of factors.
Objectives: TPS as a method of neurostimulation will be presented. Results of a recent study using TPS in patients with mild to moderate Alzheimer's disease will also be presented. The aim of the study is to investigate whether cognitive performance is significantly increased and depressive symptom severity is significantly reduced. Furthermore, a research proposal for the use of TPS in patients diagnosed with a depressive disorder will be presented.
Methods: The cognitive performance (MoCA) and depressive symptoms (GDS) of patients with early- or late-onset, mild or moderate AD will be assessed at baseline (t1), three months (t2) and six months (t3) following treatment with TPS. In the context of this longitudinal study, which is designed with a single center, the participants will be recruited in an outpatient setting within a specialized psychiatric-psychotherapeutic clinic in Lower Saxony, Germany.
Results: Repeated measures ANOVA; Mean scores MoCA t1 = 13,9 vs. t2 = 14,1 vs. t3 = 14,5 ($F(2, 66) = .749$, *n.s.*). Mean scores GDS t1 = 9,5 vs. t2 = 7,6 vs. t3 = 6,8 ($F(2, 32 = 4.410$, $p < .05$). n = 34. Preliminary data for the study of TPS in AD, study is being continued. Research proposal for the use of TPS in patients diagnosed with a depressive disorder will also be presented.
Conclusions: As in other studies, remarkable effects were shown with the use of TPS in patients with a mild to moderate AD. The results may indicate that the cognitive performance can be stabilized and the depressive symptom severity can be reduced. It is important to note that the results are based on a relatively small sample size and lack control conditions, which may limit the generalizability of the findings. Further research is required to evaluate the effectiveness of treatment of TPS in AD and to assess the potential suitability of neurostimulation as an add-on therapy, complementing previous drug and non-drug approaches. Further research is also required in the use of TPS in depression given the dearth of scientifically reliable findings on this topic.

Behavioral Variant Frontotemporal Dementia as a Catalyst for Caregiver Stress Syndrome: A Neuropsychiatric and Sociopolitical Examination

V. H. Santos[1,2*], I. A. Silva[3], C. Oom[4], R. P. Andrade[5], Z. C. eSá[1], B. Sousa[1], T. Carvalhão[1] and S. Fontes[1]

[1]Department of Psychiatry and Mental Health, Cova da Beira Local Health Unit; [2]Faculty of Health Sciences, University of Beira Interior, Covilhã; [3]Department of Psychiatry and Mental Health, Norte Alentejano Local Health Unit, Portalegre; [4]Department of Psychiatry and Mental Health, Estuário do Tejo Local Health Unit, Vila Franca de Xira and [5]Department of Psychiatry and Mental Health, Viseu Dão-Lafões Local Health Unit, Viseu, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1635

Introduction: Behavioral variant frontotemporal dementia (bvFTD), characterized by profound personality changes, impulsivity, and disinhibition, is a neurodegenerative disorder that imposes a significant burden on caregivers. This condition is increasingly recognized as a standalone factor contributing to the onset of caregiver stress syndrome (CSS). This case explores the intricate interplay between bvFTD's neurobehavioral manifestations, its effect on caregivers, and the systemic insufficiencies in offering support.
Objectives: To highlight the correlation between behavioral variant frontotemporal dementia (bvFTD) and caregiver stress syndrome, emphasizing the systemic limitations in social and financial aid for caregivers.
Methods: A 68-year-old female presented with significant behavioral alterations, including disinhibition and impulsivity. These manifestations, coupled with frontal and temporal lobe atrophy confirmed via CT scan, pointed to a diagnosis of bvFTD. Her daughter, the primary caregiver, developed significant psychological distress in response to the escalating caregiving demands. The daughter's request for caregiver status, and subsequent efforts to obtain financial and psychosocial support, were met with significant systemic barriers.
Results: In line with broader data, caregivers of individuals with dementia—especially bvFTD—exhibit disproportionately high levels of psychological distress. The daughter's subsequent psychological symptoms mirrored national trends of caregiver overload, exacerbated by insufficient systemic response and support. Studies show that caregiver burden tends to increase over time, with upward stress trajectories due to increased caregiving demands and reduced social support. This burden can precipitate mental health problems, such as mood disorders, and increase caregiver mortality risk significantly.
Conclusions: The behavioral disturbances characteristic of bvFTD intensify the psychological burden on caregivers, who must contend with the rapid cognitive and functional decline of their loved ones. The absence of sustained financial and psychosocial support exacerbates this strain, pointing to a critical need for reforms in caregiving policies. Understanding the clinical trajectory of bvFTD and its unique caregiver challenges is paramount for developing targeted interventions to prevent caregiver burnout, improve patient outcomes, and mitigate the psychosocial and health risks for caregivers.

Emotional intelligence among Tunisian medical residents

H. Daoud[1], I. Sellami[1,2*], A. Feki[3], M. L. Masmoudi[1], K. Jmal Hammami[1] and M. Hajjaji[1]

[1]Department of Occupational Medicine, Hedi Chaker Hospital; [2]LR/18/ES-28, Sfax university and [3]Department of rheumatology, Hedi Chaker Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1636

Introduction: Emotional intelligence (EI) has gained increased attention in medical education and research. EI is often defined as the ability to perceive, express, understand, and manage émotions making it a crucial skill to cultivate during medical school.
Objectives: This study aimed to explore levels of global EI among Tunisian medical residents based on their demographic characteristics.
Methods: This cross-sectional study was carried out with medical residents in training at hospitals across Tunisia. We gathered data anonymously through a Google Forms survey conducted from October 2023 to January 2024. Participants first completed a sociodemographic questionnaire, followed by the Trait Emotional Intelligence Questionnaire-Short Form (TEIQue-SF). This 30-item assessment measures overall trait emotional intelligence and evaluates four specific dimensions : Well-Being, Self-Control, Emotionality, and Sociability.
Results: Our study included 127 participants, with men comprising one-fourth (25.2%). The mean age was 27.24±1.34 years with majority aged under 30 (93.7%). The majority of participants were single (81.8%). Most participants (71.7%) were pursuing a medical specialty. First-year medical residents represented 39.4%, while fifth-year residents made up only 1.2%. The total EI score was 4.6 ±0.68. The mean scores for the four EI traits factors were as follows : well-being 4.81±1.07, self-control 4.34±0.9, emotionality 4.86 ±0.73, and sociability 4.45±0.85.
Univariate analysis showed that higher levels of global EI, self-control, and sociability were associated with the male gender, with p= 0.027, p=0.00 and p=0.02 respectively. Also, final-year residents demonstrated significantly lower emotionality scores compared to first-year medical residents. Moreover, participants in medical specialties were significantly associated with higher well-being scores (p = 0.017).
Conclusions: It is crucial to further investigate the factors contributing to these variations in EI and to develop tailored strategies that can effectively enhance EI among medical professionals and to support its development in the next generation of physicians.

Attitudes of Psychiatric Hospital Staff Toward the Risk of Criminal Behavior in Individuals with Mental Disorders

I. Sohn[1*] and I. CHO[2]

[1]Psychiatry, Keyo Hospital, Uiwang and [2]Psychiatry, WIM psychiatric clinic, SeongNam, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1637

Introduction: Recently, there has been an increase in media reports regarding crimes committed by individuals with mental disorders, leading to a deterioration in public opinion on this issue. Misconceptions about the dangerousness of individuals with mental disorders can negatively impact the prevention, treatment, and social reintegration of these patients.
Objectives: Public attitudes toward crimes committed by individuals with mental disorders are influenced by media and public opinion, and psychiatric hospital staff are not exempt from these influences. Since the prejudices of these staff members can directly affect psychiatric patients, it is crucial to assess their attitudes.
Methods: This study surveyed the attitudes of psychiatric hospital staff regarding the risk of criminal behavior in individuals with mental disorders and compared these attitudes with those of the general population.
Results: The findings revealed that psychiatric hospital staff exhibited less prejudice than the general population across six dimensions related to crimes by individuals with mental disorders: recent increase in crime, cruelty, impulsivity, violence, criminal tendency, and crime rate. Additionally, psychiatric hospital staff displayed less prejudice regarding specific disorders (schizophrenia, depression, bipolar disorder, panic disorder, post-traumatic stress disorder, dementia, attention-deficit/hyperactivity disorder, intellectual disability, and developmental disorders) compared to the general population.
Conclusions: Psychiatric hospital staff demonstrated less prejudice toward the criminal behavior of individuals with mental disorders than the general public. This difference may be attributed to their direct contact with psychiatric patients. The findings suggest potential directions for policy development aimed at reducing public prejudice toward mental disorders and associated criminal behavior.

Enhancing Patient Engagement and Positive Step-Down Discharges Through Co-Production: A Quality Improvement Initiative in an In-Patient Rehabilitation Psychiatric Unit

H. Tahseen[1]*, D. A. Hassoulas[1] and K. Umla-Runge[1]

[1]Cardiff University, Cardiff, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1638

Introduction: This Quality Improvement (QI) programme aimed to integrate co-production principles into rehabilitation psychiatry to enhance patient-centred care and facilitate positive step-down discharges. The initiative was developed in response to suboptimal audit results, revealing low patient attendance and limited positive discharges within an in-patient psychiatric unit. Recognising the critical role of rehabilitation psychiatry in supporting recovery and reintegration, the programme sought to transform patient engagement through equitable partnerships between patients and healthcare professionals.
Objectives: The programme's primary objectives were to:

1. Implement and evaluate co-production within the Care Programme Approach (CPA).
2. Increase patient attendance at CPA meetings and improve positive step-down discharges.
3. Enhance engagement, communication, and shared decision-making to achieve better patient outcomes, including reduced anxiety.

Methods: A phased approach was employed, encompassing diagnostic, problem-solving, and evaluation stages. Root cause analyses were conducted using fishbone cause-and-effect diagrams and the 5-Why Technique. The Model of Improvement guided the programme, with change ideas developed and refined through Plan-Do-Study-Act (PDSA) cycles. Interventions included distributing patient information leaflets, staff training sessions, and introducing a structured CPA agenda template. Quantitative analysis using paired t-tests evaluated changes in attendance, discharge rates, and Hamilton Anxiety Rating Scale (HAM-A) scores. Qualitative data were gathered from a co-produced CPA questionnaire, with emerging themes integrated into the project's evolution through narrative synthesis.
Results: The implementation of co-production yielded significant improvements in patient engagement and discharge outcomes, resulting in a 50% increase in CPA meeting attendance and a 70% positive step-down discharge rate. Interventions were associated with reduced anxiety levels, evidenced by improvements in HAM-A scores. Qualitative analysis highlighted key themes, including challenges during community transitions, empowerment through shared decision-making, and enhanced communication with healthcare professionals. The structured CPA agenda template further improved patient-centred communication and care experiences.
Conclusions: The integration of co-production within rehabilitation psychiatry fosters transformative partnerships that enhance patient engagement and clinical outcomes. This QI programme demonstrates the efficacy of patient-centred interventions, supported by structured communication tools, in empowering individuals, reducing anxiety, and improving transitions to community care. Co-production provides a robust framework for advancing rehabilitation psychiatry and optimising patient care pathways.

Community-based care provided by home-visiting nurses for families of individuals with mental illness, aimed at promoting family recovery in Japan

M. Tanoue[1]*, M. Suzuki[1], S. Teraoka[2], S. Okubo[3,4] and A. Watanabe[5]

[1]Graduate School of Nursng, Chiba University, Chiba; [2]Faculty of Medical Technology, Teikyo University, Tokyo; [3]Institute of Ars Vivendi, Ritsumeikan University, Kyoto; [4]BMS Yokohama Inc., Kanagawa and [5]School of Nursing, Tokyo Health Care University, Chiba, Japan
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1639

Introduction: Families of patients with mental illness in Japan face the stigma and the significant burden of caregiving. The average hospital stay for psychiatric patients in Japan was 276.3 days in 2022. Strengthening community support for patients with mental illness and their families requires targeted support that promotes recovery for both patients and their families.
Objectives: To clarify the attitudes and perceptions of psychiatric home-visiting nurses toward family support in the community,

aiming to empower families of patients with mental illness and identify key support issues for family recovery.

Methods:

1) A 30-item, web-based, anonymous questionnaire survey was conducted involving psychiatric home-visiting nurses who care for patients with mental illness The survey measured respondents' background information and perceptions regarding the frequency and importance of family care practices.
2) Simple tabulations of the questionnaire items were performed, and the frequency of implementation was examined and related. 3) Items perceived as important but infrequently implemented were identified.

Results: Sixty-six home-visiting nurses participated in the survey. The findings showed that 97% of respondents expressed interest in family support, 74% had family support experience, and 52% had attended family support training programs.

A significant correlation was observed between the perceived importance of family support and its perceived frequency of implementation across all items. The four items identified as important but less frequently implemented were:

Q08. Referring to other professional organizations for unresolved issues (22.7%).

Q11. Encouraging active participation from each patient and family member (20.6%).

Q12. Informing family members about the patient's situation, so that they can work together to ensure the patient's well-being (40.6%).

Q13. Encouraging patients to express appreciation to the family when needed (36.7%).

Conclusions: The survey results indicate that family care items requiring patient engagement or collaborative decision-making, such as referrals to other agencies, were implemented less frequently. Home-visiting nurses face challenges in enhancing their skills and knowledge in areas such as family engagement, interagency collaboration, and discerning the appropriate scope and timing of interventions.

Strengthening these competencies will support more effective connections between patients with mental illness, their families, and community resources.

Mental Health Challenges in Primary Health Care: Assessing Anxiety, Stress, and Psychological Distress Among Medical and Nursing Staff

M. Theodoratou[1,2*], P. Sklirou[1], E. Toki[3] and M. Argyrides[2]

[1]Social Sciences, Hellenic Open University, Patras, Greece; [2]Psychology, School of Health Sciences, Neapolis University Pafos, Pafos, Cyprus and [3]Speech Therapy, University of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1640

Introduction: Work-related mental health issues are becoming increasingly prevalent, particularly in professions involving direct communication and care, such as healthcare. Primary Health Care (PHC) plays a critical role in prevention, health promotion, and the management of emergency situations. The mental and emotional well-being of healthcare professionals in PHC is essential for maintaining high levels of performance and work effectiveness. However, there is limited research on the psychosocial conditions of healthcare staff in PHC settings, particularly regarding anxiety, stress, depression, and psychological distress.

Objectives: The objective of this study is to evaluate the prevalence of anxiety, stress, depression, and psychological distress among medical and nursing staff working in primary healthcare units in Peloponnese. Additionally, the study aims to examine the associations between these mental health indicators and various individual and professional characteristics, such as age, gender, and professional role.

Methods: An online survey was conducted to gather data from a final sample of 103 healthcare professionals. A questionnaire was constructed ad hoc and comprised two well-established measurement tools. The Depression, Anxiety, and Stress Scale (DASS-21) was employed to assess anxiety, stress, and depression, while the K6+ was used as a self-report measure to evaluate psychological distress.

Results: The results demonstrated that the participants exhibited generally low levels of anxiety, stress, and depression. As indicated by the DASS-21 scale, approximately 75% of respondents reported minimal to no anxiety, with only 7.8% reporting severe anxiety. Similarly, 75% of respondents indicated minimal to no stress, with only 4% reporting severe stress. Regarding depressive symptoms, 76% of participants exhibited minimal to no depressive symptoms, while only 4% demonstrated severe depressive symptoms. However, approximately 20% of the sample exhibited signs of psychological distress, which may indicate a significant mental health concern. Significant correlations were found through statistical analysis: older employees exhibited lower levels of anxiety, while nursing staff demonstrated higher levels of anxiety compared to medical staff. Additionally, women reported higher anxiety levels than their male colleagues.

Conclusions: In conclusion, while anxiety, stress, and depression levels are generally low among healthcare professionals, a notable portion of the workforce is at risk of serious psychological distress. These findings indicate the need for targeted mental health interventions, particularly for younger staff, nurses, and female employees, to ensure the well-being of healthcare professionals and maintain the efficacy of primary healthcare services.

The Link Between Problematic Internet Use, Physical Activity, and Mental Health: Implications for Depression and Anxiety

M. Theodoratou[1*], I. Patiri[2], D. Katsarou[3], E. Efthymiou[4], M. Sofologi[5], G. A. Kougioumtzis[6] and S. Papadopoulou[7]

[1]Social Sciences; [2]Hellenic Open University, Patras; [3]Psychology, University of Aegean, Aegean, Greece; [4]Psychology, University of Zayed, Emirates, United Arab Emirates; [5]Psychology, University of Ioannina, Ioannina; [6]Turkish studies, National Kapodistrian University of Athens, Athens and [7]Speech Therapy, University of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1641

Introduction: The Internet has become an indispensable component of contemporary life, enabling communication, work, and leisure activities. However, with its increasing use, concerns are emerging

regarding problematic internet use (PIU) and its effects on physical and mental health. PIU has been associated with a range of adverse outcomes, including reduced physical activity, depression, and anxiety. It is of paramount importance to gain insight into the complex relationship between internet use, physical activity, and mental health in order to develop effective interventions that can mitigate the adverse effects associated with these factors.
Objectives: The objective was to quantify the extent of internet usage among participants and to analyze its potential association with physical activity, depression, and anxiety.
Methods: The study sample consisted of 119 individuals from Patras. The data were collected using a set of validated questionnaires, including:
The Problematic Internet Use Questionnaire was employed to ascertain the extent of problematic internet use (PIU).
The International Physical Activity Questionnaire (IPAQ) was employed to assess the frequency and intensity of the participants' physical activity.
The Patient Health Questionnaire (PHQ-9) was employed to evaluate the presence and severity of depressive symptoms.
The Generalized Anxiety Disorder (GAD-7) scale was employed to assess the levels of anxiety experienced by the participants.
Results: The results indicate that a moderate level of problematic internet use is prevalent among the participants, with the majority spending more than four hours online daily. The analysis demonstrated that while increased internet use did not significantly impact the frequency or intensity of physical activity, there was a significant positive correlation between problematic internet use (PIU) and both depression and anxiety levels. As problematic internet use (PIU) increased, so did the symptoms of depression and anxiety.
Conclusions: The study highlights the potential mental health risks associated with problematic internet use. Despite no observed impact on physical activity levels, the strong association between PIU and elevated depression and anxiety symptoms suggests a need for targeted interventions. Addressing PIU could play a crucial role in improving mental health outcomes, emphasizing the importance of developing strategies to manage internet usage effectively.

Enhancing Therapeutic Collaboration in the Care of Substance-Dependent Mothers and Their Children

I. Farmakopoulou[1], S. Kosmopoulos[2] and M. Theodoratou[3]*
[1]Sciences of Education and Social Work, University of Patras, Patras; [2]Medical School, National and Kapodistrian University of Athens, AthensPatras and [3]Social Sciences, Hellenic Open University, Patras, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1642

Introduction: Treating substance-dependent mothers and their children presents unique challenges in psychiatric and psychotherapeutic practice. These cases require intensive, coordinated interventions that span mental health, social support, and medical care. Substance dependence in mothers can disrupt early attachment, increase psychiatric risk in children, and challenge the therapeutic alliance. Effective intervention demands seamless interdisciplinary collaboration to provide holistic care that supports recovery and strengthens maternal-infant bonds.
Objectives: This study examines the role of interdisciplinary collaboration in psychiatric and psychotherapeutic care for substance-dependent mothers and their children. Specifically, it aims to assess how collaborative frameworks between psychiatrists, psychotherapists, and allied mental health professionals impact therapeutic outcomes, focusing on reducing burnout and enhancing resilience among care providers.
Methods: A cross-sectional survey was conducted with 91 mental health professionals across 12 agencies involved in the care of substance-dependent mothers and their children. Participants completed an electronic questionnaire assessing demographic data, collaboration experiences, and perceptions of treatment effectiveness. The Maslach Burnout Inventory (MBI-22) and Resilience Evaluation Scale (RES) were utilized to measure burnout and resilience, exploring their influence on therapeutic collaboration and patient outcomes.
Results: Findings show that interdisciplinary collaboration positively correlates with enhanced resilience and lower burnout among professionals, factors crucial in maintaining therapeutic efficacy. Significant associations were found between demographic factors —such as age, gender, and years of service—and both resilience and burnout. Increased resilience appeared to support deeper therapeutic engagement, while low burnout levels were associated with sustained therapeutic consistency.
Conclusions: Interdisciplinary and interagency collaboration is essential in the psychiatric and psychotherapeutic treatment of substance-dependent mothers and their children. Resilience fosters more effective therapeutic engagement, while low burnout levels support sustainable practice. These findings underscore the value of collaborative, resilient mental health teams in achieving positive psychotherapeutic outcomes for this vulnerable population.

The Impact of the Telephone Crisis Support Role on the Mental Health of Workers in the Psychosocial Support Line "10306"

E. Denazi[1], T. Skali[2,3], M. Theodoratou[4,5]* and V. Sapouna[1]
[1]National & Kapodistrian University of Athens, Department of Psychology; [2]School of Medicine, National & Kapodistrian University of Athens; [3]Project Scientist in Charge of RRF "Helpline 10306", Athens; [4]Social Sciences, Hellenic Open University, Patras, Greece and [5]Psychology, Neapolis University Pafos, Pafos, Cyprus
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1643

Introduction: Workers on helplines such as the "10306 Support Line" play a critical role in offering confidential, empathetic support to individuals in crisis, providing a secure environment for those grappling with anxiety, depression, or suicidal ideation. However, the high level of responsibility, extended hours, and often distressing nature of the calls can place substantial strain on the mental and physical health of these support line professionals.
Objectives: The primary aim of this study is to examine the psychosocial risk factors and resulting physical and psychological impacts on employees of the "10306 Psychosocial Support Line", with the intention of contributing to strategies for managing employee challenges, preventing stress-related symptoms, and promoting best practices for the mental and physical wellbeing of staff.

Methods: This cross-sectional quantitative study will involve all health professionals working on the 10306 Support Line, using survey methods to evaluate psychosocial and physical impacts. The following validated psychometric tools were used:
- Copenhagen Burnout Inventory (CBI): measuring burnout levels and the emotional toll associated with support line work.
- Sense of Coherence Scale (SOC): assessing individuals' capacity to manage stress and maintain well-being.

Results: The study results indicate burnout levels among "10306 Support Line" workers. CBI scores reveal that 55.3% of participants experience personal burnout, 47.4% report work-related burnout, and 39.5% face burnout related to caller interactions. A strong negative correlation was found between burnout and the Sense of Coherence (SOC) scores, suggesting that a higher SOC is associated with reduced burnout. Additionally, younger participants reported higher personal and work-related burnout levels than their older counterparts, highlighting age as a potential risk factor for increased burnout symptoms among support line professionals.
Conclusions: The high prevalence of burnout among 10306 Support Line employees highlights a critical need for ongoing mental health support and targeted stress management. Strengthening the Sense of Coherence (SOC) and addressing age-related risk factors may enhance resilience and well-being among support line professionals, supporting both their health and the quality of psychosocial care provided to those in need.

Late Autism Spectrum Disorder (ASD) Diagnosis: A New Perspective on Life

K. Tolvaišaitė[1]*, K. Butkutė-Šliuožienė[1] and A. Kizienė[2]

[1]Psychiatry, Lithuanian University of Health Sciences and [2]Psychiatry, Kaunas Hospital of the Lithuanian University of Health Sciences, Kaunas, Lithuania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1644

Introduction: Autism Spectrum Disorder is usually diagnosed in early childhood, but an increasing number of adults are identified as autistic later in life (Huang et al., 2020). Many experience frustration due to missed early intervention opportunities. The lack of recognition of their condition during childhood or adolescence may have contributed to secondary mental health issues, such as anxiety, depression or low self-esteem, complicating the adjustment process after diagnosis (Bargiela et al., 2019). However, providing appropriate support can enhance their quality of life and promote better mental health outcomes.
Objectives: To assess the patient's clinical case to identify autism spectrum disorder in older adulthood.
Methods: A 23-year-old male patient complained of an inability to concentrate, stress and fear when around people, and difficulties in social situations. Objectively observed: stereotyped movements, noticeable anxiety, avoidance of eye contact, non-compliance with social rules, specific language use and slow thinking. The patient had no history of diagnosed psychiatric illness. Since childhood, he has disliked the feeling of clothes touching his body, physical contact with others, making eye contact. The patient also exhibited impaired social development, being unable to initiate and maintain relationships with peers. Stereotypical, repetitive movements, sensory processing deviations have been observed since childhood. The patient has various phobias from a young age. Psychological examination revealed insufficient attention with observed fluctuations, impaired attention-shifting ability. The pace is very slow, the thinking is characterized by an average level of generalization, concreteness, and stereotypy. Personality traits included rigidity, depression, compulsiveness, internal tension. Based on the clinical picture and psychological tests, the patient was diagnosed with F84.0 Autistic Disorder, according to the International Classification of Diseases, 10 th Revision. In this case, the following methods were used in the assessment: Kraepelin's and Schulte's methods, pictograms, the 4-1 method, the Childhood Autism Rating Scale.
Results: The literature highlights that ASD involves difficulties in social interaction, repetitive behaviors, sensory sensitivities, and distinct thinking patterns. Up to 90% of individuals with ASD experience sensory irregularities, which is consistent with this case, as the patient shows social challenges, repetitive movements, slow thinking, and sensory issues. Diagnosing autism in adulthood can improve quality of life by fostering understanding and access to support. In this case, the patient's past social and workplace difficulties may be attributed to autism, guiding the development of effective support strategies.
Conclusions: In conclusion, while a late autism diagnosis can be life-changing, it also comes with unique challenges that must be addressed through appropriate support.

Disclosure of Interest: None Declared

EPV1017

Empathy toward others' distress and its determinants among psychiatry trainees in Tunisia

Y. Trabelsi[1]*, Z. Bouzaabia[1], B. N. Saguem[1] and N. Jaafar[1]

[1]Psychiatry Department, Farhat Hached Hospital, sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1645

Introduction: Empathy, a key component of an effective physician-patient relationship, is understood as a multifaceted socio-cognitive ability influenced by various cognitive, emotional, social factors. While it has been extensively studied in medical students and healthcare professionals overall, there is limited research on empathy skills among psychiatrists, whose profession especially demands a strong capacity for empathy in their practice.
Objectives: This study aimed to explore the different facets of empathy among Tunisian psychiatry trainees and assess their connections with demographic, occupational, emotional, and social variables.
Methods: Across-sectional study was conducted. An online survey was proposed to 120 Tunisian psychiatry trainees. In addition to sociodemographic and work-related variables, it comprised the Davis's Interpersonal Reactivity Index, a 28-item tool used for a multidimensional assessment of empathy with four distinct subscales: Perspective taking(PT), Empathic concern(EC), Personal distress(PD) and Fantasy scale(FS). The survey also included the Difficulties in Emotion Regulation Scale(DERS), the Perceived Stress Scale(PSS), the Social Support Questionnaire(SSQ) and the General Self-Efficacy Scale(SE). Factors associated with empathy were evaluated using t test/ANOVA for categorical variables and correlation for continuous predictors.

Results: The total participation rate was 71% and the mean empathy subscores were as follows: 19.04 ± 3.95 for PT, 20.41 ± 3.71 for EC, 12.67 ± 4.41 for PD and 16.40 ± 4.91 for FS. Empathy dimensions' scores were significantly associated with the rank in the siblings, mother's level of education, satisfactory relationship with the mother, extra-professional activities and personal psychiatric history. They also were associated with work-related factors such as the year of residency, the desired choice of specialty, the training in a general hospital with a consultation-liaison psychiatry and the perceived verbal aggression from colleagues.
Empathy dimensions' scores, mainly those of PT and PD, were correlated with emotion regulation difficulties. In fact, PT scores were negatively correlated with five of the six emotion regulation difficulties and PD scores were positively correlated with all the six emotion regulation difficulties of the DERS. EC scores were positively correlated with PSS total score and the number of social supports. PT scores were positively correlated with SE total score and PD scores were negatively correlated with SE total score.
Conclusions: Our findings underscore empathy's complexity, revealing that in psychiatry trainees, it is shaped by contextual, emotional, and social factors. Without assessing these dimensions and mediators, empathy remains a theoretical concept rather than a teachable and improvable skill.

Disclosure of Interest: None Declared

EPV1018

Do difficulties with emotion regulation influence the empathic skills of Tunisian psychiatry trainees?

Y. Trabelsi[1]*, B. N. Saguem[1], Z. Bouzaabia[1] and J. Nakhli[1]

[1]Psychiatry Department, Farhat Hached Hospital, sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1646

Introduction: Empathy is essential in psychiatry, and emotion regulation significantly influences it. This study investigates the link between emotion regulation difficulties and empathic abilities in Tunisian psychiatry trainees.
Objectives: This study aimed to explore the connection between empathic abilities and challenges in emotion regulation among Tunisian psychiatry trainees.
Methods: A cross-sectional study was carried out involving an online survey proposed to 120 Tunisian psychiatry trainees. The survey included the Interpersonal Reactivity Index, which features four subscales: Perspective Taking (PT), Empathic Concern (EC), Personal Distress (PD), and Fantasy Scale (FS). A cut-off score of 14 was set to differentiate between low and high empathy levels for each subscale. Additionally, the survey included the Difficulties in Emotion Regulation Scale (DERS), which evaluates six types of emotion regulation challenges.
Results: The proportion of responses was 71% and the mean empathy subscores were: (19.04 ± 3.95) for PT, (20.41 ± 3.71) for EC, (12.67 ± 4.41) for PD and (16.40 ± 4.91) for FS. Eleven participants showed low levels of PT and 30 showed high scores of PD. Empathy dimensions' scores, mainly those of PT and PD, were correlated with ER difficulties. PT scores were negatively correlated with five ER difficulties and PD scores were positively correlated with six ER difficulties of the DERS.
Lower levels of PT were associated to difficulties engaging in goal-directed behaviors (p=0.038) and impulse control difficulties (p=0.004) furthermore higher scores of PD were associated to difficulties engaging in goal-directed behaviors ($p=10^{-3}$), impulse control difficulties ($p=10^{-3}$), strategy (p=0.003), non-acceptance (p=0.001) and clarity (p=0.001).
Conclusions: Difficulties with emotion regulation were positively associated with personal distress and negatively associated with perspective-taking abilities. Our findings highlight the significance of emotion regulation processes in improving empathic skills.

Quality of life: the perspective of neurodivergent university students

I. S. Tsalamatas[1]*, M. E. N. Santos[1], D. Cardilli-Dias[1] and D. R. Molini-Avejonas[1]

[1]Department of Physiotherapy, Speech Therapy and Occupational Therapy, Faculty of Medicine of the University of São Paulo, São Paulo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1647

Introduction: Neurodevelopmental disorders are prevalent worldwide, with an increase in diagnoses in recent years (Faraone et al. Neurosci Biobehav Rev. 2021; 789-818; Russel et al. J Child Psychol Psychiatry 2022; 674-682). Individuals diagnosed with conditions such as Autism Spectrum Disorder (ASD), Attention Deficit Hyperactivity Disorder (ADHD), Specific Learning Disorder (SLD) and Language Development Disorder (DLD) are considered neurodivergent and constitute the so-called neurominorities (Doyle, N. British medical bulletin 2020; 108-125). Studies have shown that adults with ADHD and ASD have lower scores when assessed for quality of life, compared to neurotypicals (Pinho et al, J Atten Disord 2019; 1736-1745; Sáez-Suanes & Álvarez-Couto, Rev J Autism Dev Disord 2022; 307-319).
Objectives: The present study aims to describe the quality of life of neurodivergent students.
Methods: The research was cross-sectional, prospective and quantitative. The project was approved by the Research Ethics Committee. A total of 79 neurodivergent university students from public and private universities in the State of São Paulo participated in the research. The study was carried out remotely through the Google Forms platform with application of the TCLE and WHOQOL-DIS instruments.
Results: It was observed that 30% of the participants had a diagnosis of ASD, while 48% had ADHD, 8% had ADD, 14% had ASD with ADHD and none had a diagnosis of DLD or SLD. It is worth mentioning that in the questions about quality of life and health, 18% were dissatisfied. Regarding the ability to perform tasks, 13% reported that physical pain prevented them and 70% reported needing medical treatment. Regarding levels of personal satisfaction, 37% said they were dissatisfied with their sleep, 20% were not satisfied as a person and 28% scored completely dissatisfied with access to health services. Regarding well-being and neurodivergence, 30% of the participants were completely unhappy and 15% stated that their limitation had a negative effect on their life. Regarding autonomy, belonging, and self-perception, 23% reported total dissatisfaction with their communication skills and 41% stated that they were

completely dissatisfied with their involvement in social activities. Finally, regarding strengths and weaknesses, 32% of the subjects reported not being at all satisfied with their work opportunities, 29% were in the same situation regarding the adaptations of the environment to their limitations, and 14% reported dissatisfaction with study opportunities.

Conclusions: This study was able to analyze the perspective on the quality of life of neurodivergent university students. However, due to the various biases that involve this population, it is necessary to seek broader answers, looking at the national scope to provide a better understanding of quality of life, including in the academic environment.

Disclosure of Interest: None Declared

EPV1023

Burnout and intent to stay among nurses in a private tertiary hospital

C. I. C. Uy[1]

[1]Department of Psychiatry, The Medical City, Pasig, Philippines

doi: 10.1192/j.eurpsy.2025.1648

Introduction: Burnout is an occupational phenomenon that may be a risk factor for several mental health disorders. It is defined by three dimensions namely emotional exhaustion (EE), depersonalization (DP), and personal accomplishment (PA). The nursing workforce experiences high levels of burnout taking a toll not only on their mental state but also their intent to stay leading to issues on shortage.

Objectives: This study aims to assess association of burnout and its dimensions to intent to stay of medical nurses working in a private tertiary hospital in the Philippines.

Methods: Analytical cross-sectional study using secondary data conducted by the Nursing Services Group of the private tertiary hospital last March 2023. A survey was done on nurses' perceptions of their working condition using Maslach Burnout Inventory and McCain's Intent to Stay tools. Variables were assessed through simple and multiple linear regression analyses.

Results: On simple linear regression, burnout, civil status, years of experience, and years of tenure revealed significance in their respective categories. EE and DP dimensions showed negative association to intent to stay. On multiple linear regression, only burnout ($p < 0.000$ and -0.028) and those married with children ($p < 0.000$ and -0.028) had significant association. EE consistently showed negative association however, DP and PA had positive association to intent to stay. In most literatures, DP is associated to lower intent to stay as it is equated to cynicism or detachment in interpersonal relations which can manifest as negative or inappropriate attitudes towards clients, irritability, loss of idealism, and withdrawal (Maslach et al. World Psychiatry 2016; 15 103-11). However, in this study, nurses who were more detached had surprisingly higher intent to stay which may show how cynicism can be protective. It is a cognitive method of creating a protective distance to prevent them from letting their job performance suffer especially when dealing with the physical and emotional exhaustion, and feelings of ineffectiveness caused by excessive and prolonged stress (Akyurt et al. Medical Science and Discover 2023; 10 918-928).

Gen X (43 to 58)	1.782	0.18
Educational Status		
Ongoing Masters	-1.038	0.457
Masters	0.837	0.524
Civil Status		
Married with children	-2.619	**0.006**
Married with no children	0.646	0.358
Separated / Widow	-0.677	0.794
Years of Experience prior to TMC	-0.118	0.523
Years of Tenure in TMC	-0.17	0.296

Conclusions: Consistent with global studies, burnout is associated to lower intent to stay among nurses. However, it is beneficial to have more research looking further into the comprehensive role of cynicism in burnout. In this study, nurses have built some level of cynicism that is able to preserve themselves in negative situations. However, with no proper management, depersonalization can aggravate ultimately leading to feelings of inadequacy and lower intent to stay. A deeper and more contextualized understanding about this phenomenon may help administrators improve existing operations and policies that can help foster a healthier working environment for the nurses.

Impact of Pandemics on Primary Care: Changes in GP Antidepressant Prescriptions and Mental Health Referrals During Lockdowns in England, UK

G. Yu[1]*, Y. Fu[2] and E. Y. Tang[3]

[1]King's College London, London; [2]The University of Liverpool, Liverpool and [3]Newcastle University, Newcastle, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1649

Introduction: The COVID-19 pandemic disrupted primary healthcare services, affecting mental health support and antidepressant prescriptions in England. This study examines shifts in GP referrals and antidepressant prescribing patterns during different phases of lockdown.
Objectives: This research aims to (1) analyze changes in the rates of antidepressant prescriptions across lockdown periods, and (2) investigate how GP referrals to mental health services, including social prescribing, evolved, with a focus on disparities among ethnic groups.
Methods: Using a retrospective design, we analyzed electronic health record data from GP practices in North England, covering March 2018 to June 2023. We employed a two-level negative binomial-logit hurdle model for antidepressant prescriptions and a multinomial logit regression model for referral types.
Results: Antidepressant initiation decreased during lockdowns, while ongoing prescriptions showed minor increases. GP referrals to social prescribing rose significantly, especially among ethnic minorities who also had fewer medical treatments. Lockdown phases influenced referral patterns, with reductions in secondary care referrals and growth in community-based support.
Conclusions: The study highlights a shift towards social prescribing amid the mental health strains of the pandemic, suggesting its role in a social model of health. Ethnic disparities in mental health care access emphasize the need for culturally inclusive, non-clinical mental health support.

Innovative Strategies in Precision Psychiatry: Merging Artificial Intelligence with Psychoneuroimmunology for Enhanced Mental Health Outcomes

A. Hakimjavadi[1]

[1]Psychology, Universitat Rovira I Virgili, Tarragona, Spain
doi: 10.1192/j.eurpsy.2025.1650

Introduction: The paradigms of diagnosis and evaluation in mental health are changing due to the incorporation of artificial intelligence (AI) into other fields. Understanding mental health conditions is greatly aided by insights from neuroscience, immunology, social and clinical psychology, and cultural theories. According to Martyn Evans' commentary, interdisciplinary work generates new issues and solutions while multidisciplinary work preserves unique viewpoints. In this sense, the interdisciplinary field of psychoneuroimmunology has contributed significantly to our understanding of mental health. It has also contributed significantly to the interplay between the immune system, the endocrine system, and the nervous system. This field could rapidly emerge as a key component of integrative diagnosis and assessment.
Objectives: This review emphasizes the need for comprehensive biopsychosocial assessment frameworks and the importance of harmonizing disciplines through multidisciplinary and interdisciplinary methodologies to enhance diagnostic possibilities via AI.
Methods: A critical review of clinical psychology was conducted, as well as a discussion of the necessity of using integrative methodologies in order to address the interconnected nature of both medical diseases and mental disorders, in light of recent advancements in artificial intelligence.
Results: It has been explored how PNI can serve as an interdisciplinary ground for cross-disciplinary dialogue and how stakeholder perspectives may resolve complexities in clinical assessment and psychiatric diagnosis through extending PNI with AI and applications. Integrating AI into PNI is crucial for revolutionizing mental health care, utilizing machine learning to consolidate diverse data streams and predict outcomes.
Conclusions: Lastly, it was outlined some pragmatic frameworks for clinical assessment, taking into account time, budget constraints, and stakeholder interests. Ethical, governance, and practical challenges of AI integration are discussed. The paper proposes innovative AI-driven enhancements in psychiatric assessment, diagnosis, and treatment, fostering transformative developments in clinical psychology and promoting a humanistic approach to mental health care.

The "Polo Cassia" project: a mental health service for integrated treatments of co-occurring disorders in adolescents and young adults

S. Navari[1]*, R. Carpentieri[1], S. Ceccucci[1], A. Picello[1], F. Di Nicola[1], L. D'Agostino[1], D. Giovannetti[1], D. DeLuca[1], L. Ferrara[1], C. Riitano[2], M. L. Carenti[1], A. Correale[1], S. D'Andrea[1], L. Marcellini[1], S. Oprea[1], F. Summa[1], A. Demaggi[1], I. Zappino[1], M. R. Barbera[1], V. Trincia[1] and G. Ducci[1]

[1]Dipartimento di Salute Mentale, ASL Roma1, Roma and [2]Dipartimento di Salute Mentale, ASL Roma, Rome, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1651

Introduction: The term "co-occurring disorders" (COD) refers to the coexistence of two or more psychiatric disorders especially substance use disorder (SUD) and other psychiatric disorders. In particular, the prevalence of COD increases globally and is linked to a higher risk of worse outcome. Furthermore, especially in adolescence, the goal is to provide an early and proper answer both in terms of care and prevention. On the opposite, there is a lack of integrated management strategies requiring an effective collaboration of different mental health disciplines in order to receive appropriate care. Although European countries have established mental health policies, a lack of comprehensive and structured

mental health intervention programs remains.To answer these needs we developed an Integrated Mental Health Service for patients with co-occurring disorders aged up to 30 years, lining varied challenges, including both the interception of patient's needs and the practical organization of interventions.
Objectives: This study aims to identify the impact of an Integrated Mental Health Service, "Polo Cassia", coordinated by a team of professionals based in the same physical location, on the outcome of co-occurring disorders in patients aged up to 30 years at their first contact with mental health services. Furthermore, we aim to identify which transversal clinical dimensions and risk factors might benefit from an early integrated and tailored treatment.
Methods: The project is carried out at the Community Mental Health Center (CMHC) of District 15th, ASL Rome 1. The final study sample will include all the patients referred in one year to "Polo Cassia". Clinical and socio-demographic parameters are collected in details, Global Assessment Functioning (GAF), and Quality of Life Enjoyment and Satisfaction Questionnaire (Q-LES-Q) are administered at baseline (To), after 6 months (T1) and 1 year (T2).
Results: Among the study sample referred to Polo Cassia (53% male, mean age 20,33 ±4,47), 50% of the patients comes directly from a first triage evaluation, 35% from other mental health services and 15% from other health services (e.g. diabetes centre). The 60% of the patients have SUD coexisting with other psychiatric disorders. From updated results, we expect to be able to verify the impact of an early integrated treatment on global function and quality of life in our sample of patients. Furthermore, we expect to characterize the transversal clinical dimensions which will actually respond to an early integrated treatment with positive clinical outcomes and subjective satisfaction.
Conclusions: The experience of structured integrated models of care for co-occurring psychiatric disorders is necessary to inform the future development of Mental Health Services.

EPV1031

Brazilian Psychiatric Reform: Evolution and Challenges (2001-2024)

M. A. Rodrigues[1]
[1]Universidade Anhembi Morumbi, São Paulo, Brazil
doi: 10.1192/j.eurpsy.2025.1652

Introduction: The Brazilian psychiatric reform, initiated by Law 10.216 in 2001, brought a significant shift in the treatment of individuals with mental disorders. Focusing on deinstitutionalization and psychosocial care, the reform aimed to replace the hospital-centered model with a community-based services network. Over the past 23 years, this transformation has faced challenges, including the implementation of public policies, the guarantee of human rights, and the effective integration of mental health services.
Objectives: To analyze the advances, challenges, and impacts of the Brazilian psychiatric reform from 2001 to 2024, with a focus on deinstitutionalization and psychosocial care.
Methods: A documentary and bibliographic review was conducted, including legislation, government reports, scientific articles, and data from the Unified Health System (SUS). The research covered publications from 2001 to 2024 in the PubMed, Scielo, and Lilacs databases. The search terms used were "Brazilian psychiatric reform," "deinstitutionalization," and "psychosocial care." The qualitative analysis highlighted legislative changes, service implementation, and challenges.
Results: The psychiatric reform led to significant advances in the structuring of the Psychosocial Care Network (RAPS), including Psychosocial Care Centers (CAPS) and therapeutic residential services. There was a substantial reduction in psychiatric hospital beds and an expansion of community-based services. However, challenges persist, such as regional disparities in service provision and a shortage of qualified professionals.
The implementation of RAPS varied between regions, with the Southeast and South being more developed compared to the North and Northeast. Deinstitutionalization brought benefits, such as social reintegration of patients, but also revealed gaps, including the lack of support for families and strategies for managing crisis situations.
There is an ongoing need for public policies to support the reform, including adequate funding and a focus on human rights. Recent debates on the reintroduction of psychiatric hospitals indicate tensions in mental health policy, underscoring the need to reinforce the principles of the reform.
Conclusions: From 2001 to 2024, the Brazilian psychiatric reform made progress in mental health care, emphasizing deinstitutionalization and the creation of a community-based network. However, challenges such as unequal service provision, a shortage of professionals, and political tensions indicate the need to strengthen the reform's principles. Public policies should ensure humanized, integrated care based on the rights of individuals with mental disorders, ensuring the expansion of RAPS across the country.

EPV1032

Equitable Access to Mental Health Services in Brazil

M. A. Rodrigues[1]
[1]Universidade Anhembi Morumbi, São Paulo, Brazil
doi: 10.1192/j.eurpsy.2025.1653

Introduction: Equitable access to mental health services is a challenge in Brazil, marked by socioeconomic and regional inequalities. Despite advances in policies such as psychiatric reform and the Psychosocial Care Network (RAPS), barriers persist, especially for vulnerable populations. Issues such as the unequal distribution of resources, stigma, and a lack of professionals impact both access and the quality of care.
Objectives: To analyze the inequalities in access to mental health services in Brazil and identify strategies to promote equity.
Methods: A systematic review was conducted using the PubMed, Scielo, and Lilacs databases, covering studies published between 2015 and 2023. The keywords used were "mental health access," "health equity," "Brazil," and "mental health inequalities." Inclusion criteria focused on studies addressing access to mental health services in Brazil, highlighting barriers, facilitators, and strategies to promote equity. Data were qualitatively synthesized to identify trends and challenges.
Results: The review revealed significant disparities in access to mental health services, influenced by socioeconomic, geographic, and cultural factors. Remote regions, such as the North and Northeast, suffer from a lack of infrastructure and specialized professionals. While urban centers offer more services, rural areas face

considerable limitations. The unequal distribution of professionals, such as psychiatrists and psychologists, exacerbates these inequalities. Stigma surrounding mental illness and a lack of awareness further hinder help-seeking behavior. Vulnerable populations, including Indigenous peoples and residents of favelas, face additional barriers such as discrimination and a lack of culturally adapted services.
The Unified Health System (SUS) provides a model of universal access but faces challenges related to funding, infrastructure, and capacity to meet the growing demand. Despite the efforts of RAPS, many services are overwhelmed, resulting in long waiting times and insufficient care. Strategies like integrating mental health into primary care have shown effectiveness but require more support and expansion.
Conclusions: Equitable access to mental health care in Brazil is impacted by various barriers, including regional disparities and stigma. To promote equity, it is crucial to invest in expanding the mental health care network, focusing on underserved areas and vulnerable populations. Effective policies should include professional training, stigma reduction, and culturally sensitive services. Integrating mental health services with primary care, strengthened by the SUS, is essential to ensure more accessible and comprehensive care.

EPV1033

Equitable Access to Mental Health Services in Europe

M. A. Rodrigues[1]
[1]Universidade Anhembi Morumbi, São Paulo, Brazil
doi: 10.1192/j.eurpsy.2025.1654

Introduction: Equitable access to mental health services is essential for the well-being of European citizens. Despite advancements in health policies, significant disparities in access to care persist. Socioeconomic, geographical, cultural, and institutional factors contribute to these inequalities, disproportionately affecting vulnerable groups.
Objectives: To analyze the inequalities in access to mental health services in Europe and identify effective strategies to promote equity in these services.
Methods: This study conducted a systematic literature review using PubMed, Scopus, and PsycINFO databases to identify studies published between 2015 and 2023. The keywords used were "mental health access," "health equity," "Europe," and "mental health inequalities." Inclusion criteria focused on studies addressing access to mental health services in Europe and strategies to promote equity. Extracted data were qualitatively synthesized, highlighting trends, barriers, and facilitators to equitable access to mental health services.
Results: The review revealed significant inequalities in access to mental health services in Europe, primarily due to socioeconomic and geographical factors. Low-income individuals face major barriers, such as high costs and lack of coverage by health systems. Rural areas suffer from a shortage of specialized professionals and inadequate infrastructure, making continuous quality care challenging.
Cultural and linguistic factors add further complexity, particularly for migrants and ethnic minorities. The lack of culturally adapted services and sensitivity in therapeutic approaches often leads to inadequate care. Stigma surrounding mental health remains a significant barrier, preventing many from seeking help.
Variations in mental health policies and investments across European countries further exacerbate these inequalities, creating a fragmented landscape of care access. While some countries have robust strategies, others lack consistent policies and adequate funding. Addressing these disparities requires integrated policies, culturally sensitive professional training, and effective stigma-reduction programs.
Conclusions: There is an urgent need to address inequalities in access to mental health services in Europe. Integrated strategies are essential, including policies that promote equity, improvements in rural infrastructure, and culturally sensitive professional training. Reducing stigma through awareness programs is crucial to encourage help-seeking behavior. Harmonizing policies and investments among European countries can contribute to more equitable and effective access, ensuring equal opportunities for mental health treatment and support.

EPV1034

Legal Issues and ADHD: Risk Factors and Temperamental Characteristics

F. Soricaro[1]*, G. Longo[1], M. Servasi[1], L. Orsolini[1] and U. Volpe[1]
[1]Unit of Clinical Psychiatry, Department of Clinical Neurosciences/DIMSC, Polytechnic University of Marche, Ancona, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1655

Introduction: Adult Attention Deficit Hyperactivity Disorder (ADHD) has been recognized as a condition with profound psychosocial implications, including a higher likelihood of encountering legal problems.
Objectives: To characterize temperamental characteristics and risk factor for legal problems in a group of ADHD patients.
Methods: The study involved patients (>18 years) from the adult ADHD outpatient service of the Psychiatric Clinic of Ancona. ADHD was diagnosed using the Diagnostic Interview for ADHD in adults (DIVA5.0). The following rating scale were administered: Temperament Evaluation in Memphis, Pisa and San Diego (TEMPS-M), Coping Orientation to the Problems Experiences-new Italian version (COPE-NVI), Temperament and Character Inventory-Revised (TCI-R).
Results: 76% (n=170) of screened patients were diagnosed with ADHD in adulthood. Among them, 10.2% (n=17) reported legal problems. Men with ADHD were more likely to have legal issues (χ^2=7.851; p=0.005). These patients often reported school failures (χ^2=3.033; p=0.082) and being tutored by a support teacher (χ^2=15.165; p<0.001). Legal issues were more common in those with a childhood diagnosis of ADHD (χ^2=4.880; p=0.027) and in those who were admitted to a psychiatric ward (χ^2=7.205; p=0.007). Additionally, those who smoked (χ^2=6.695; p=0.035) or used substances (χ^2=16.399; p<0.001) had more legal issues. Higher use of cannabinoids (χ^2=14.311; p<0.001) and stimulants (χ^2=12.445; p<0.001) in those who had legal problems are also reported. Generally, those with legal problems have lower schooling (p=0.005), more high school failures (p=0.047), smoke more cigarettes per day (p=0.008) and have higher scores in the problem-solving subscale of the COPE-NVI (p=0.024), the ambitious subscale of the TCI-R (p=0.058), and the self-transcendence subscale of the TCI-R (p=0.078) and lower mean score in the self-acceptance subscale

of the TCI-R (p=0.054). Logistic regression analysis showed to ascertain the effects of all TCI-R subscales, on the likelihood of developing legal problems. The logistic regression model was statistically significant, ▫▫ 2(1)=4.020, p=0.045. The model explained 14.6% (Nagelkerke R2) of the variance in patients with ADHD who have legal problems and correctly classified 91.9% of cases.Having legal problems was significantly predicted by TCI-R spiritual acceptance subscale (exp(B)=1.150, p=0.045).
Conclusions: The study highlight the significant psychosocial burden of ADHD in adulthood, particularly the increased likelihood of legal problems.Key risk factors include lower educational attainment, substance use, and specific temperamental traits, such as elevated problem-solving and self-transcendence tendencies, alongside lower self-acceptance.

EPV1035

Integration of mental healthcare into primary healthcare: a European perspective

R. Wernigg[1]*, C. Phellas[2], C. Lionis[3], K. Fountoulakis[4], E. Kovács[5] and P. Theodorakis[6]

[1]Department for Primary Caree Planning and Development, National Directorate-General for Hospitals, Budapest, Hungary; [2]Medical Sociology, University of Nicosia, Nicosia, Cyprus; [3]Medical Faculty, University of Crete, Crete; [4]Medical School, Aristotle Universit of Thessalonikiy, Thessaloniki, Greece; [5]Institute of Healthcare Management, Semmelweis University and [6]Country Office Hungary, World Health Organization, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1656

Introduction: The 2009 WHO and WONCA report (Integrating Mental Health in Primary Care: A Global Perspective) outlined best policies and practices for the integration of mental health into primary care. The arguments in favor are reduced stigma, improved access to care, holistic management of comorbidities, improved prevention and early detection of mental disorders, reduced losses to follow-up, lower costs, easier communication, improved social integration, protection of human rights, and improved uptake of the healthcare system (Greenhalgh T, 2009; Petersen et al, 2016). Nevertheless, mental health care in many countries remains separate from primary care, limiting access and equitable distribution. However, since the COVID-19 pandemic, the global need for mental health services have surged, causing a 25 to 27 per cent increase in the prevalence of depression and anxiety around the world, accelerating the demand for integrated care (Bower et al, 2023). So, the process of integration outlined in the 2009 WHO and WONCA report warrants an updated discussion.
Objectives: International experts from Hungary, Greece, and Cyprus and of WHO, WONCA and WPA present different models of integration of mental health into primary care with special respect to public health crises.
Methods: Challenges, opportunities and best practices of each country will be presented, including policy recommendations, capacity building and advocacy strategies for mental health integration and public health crises, and monitoring, evaluation, and research for integrated services.
Results: In all three countries, stigma, insufficient training of primary care providers, and inadequate policy frameworks present problems. In Greece, the dominance of a medically oriented health policy has hindered interdisciplinary integration (Lionis et al., 2019). Cyprus grapples with stigma surrounding mental health issues, which affects service utilization (Nikolaou & Petkari, 2021). Opportunities are leveraging community resources and enhancing collaboration among stakeholders to foster inclusive health services (Pinaka et al., 2022). Best practices involve training programs for primary care providers, promoting awareness, and developing evidence-based policies that prioritize mental health (Ashcroft et al., 2021). Advocacy strategies should focus on engaging policymakers and the community to address mental health needs, particularly in light of public health crises like COVID-19, which have exacerbated mental health issues (Galanis et al., 2020; Maulik et al., 2020). Monitoring and evaluation are crucial for assessing the effectiveness, ensuring accountability, and adapting strategies based on research findings (Glover-Wright et al., 2023; Saxena & Kline, 2021).
Conclusions: The need of updating the 2009 WHO and WONCA report is considered to include the latest evidence, experiences, and recommendations on mental health integration into primary care.

Disclosure of Interest: None Declared

EPV1036

Barriers to Effective Implementation of Mental Health Policies in India: A Comprehensive Analysis of Challenges and Solutions

N. Yadav[1]

[1]Psychiatry Social Work, Institute of Human Behaviour and Allied Sciences, Delhi, India
doi: 10.1192/j.eurpsy.2025.1657

Introduction: India is facing a growing mental health burden, with significant disparities in access to services despite the introduction of the National Mental Health Program (NMHP) and the Mental Healthcare Act (MHA). While these policies aim to improve mental health care, their implementation remains inconsistent due to a range of challenges. Understanding these barriers is crucial to enhancing mental health services across the country.
Objectives: This study aims to identify the key challenges impeding the effective implementation of existing mental health policies in India, with a focus on rural-urban disparities, resource constraints, and sociocultural factors.
Methods: A comprehensive literature review was conducted, examining peer-reviewed articles from databases such as PubMed, Scopus, and WHO policy documents, and reports from government and non-governmental organizations. Data was analysed to assess the primary obstacles related to funding, workforce shortages, stigma, policy integration, and infrastructure issues. Qualitative insights from key stakeholders in mental health services were also included.
Results: The review revealed five primary challenges. Firstly, the insufficient financial allocation for mental health programs, leading to limited-service availability; secondly, a shortage of trained mental health professionals, particularly in rural areas; thirdly, a pervasive stigma surrounding mental health, hindering service uptake; fourthly, the poor integration of mental health care into primary health systems; and lastly, the bureaucratic inefficiencies and lack of infrastructure. These challenges disproportionately affect rural

populations, exacerbating the urban-rural divide in mental health care delivery.
Conclusions: The effective implementation of mental health policies in India is undermined by systemic challenges such as inadequate resources, workforce gaps, and sociocultural barriers. Addressing these issues requires targeted interventions, including increased investment in mental health services, enhanced training programs, stigma reduction campaigns, and better integration of mental health care into general healthcare frameworks. A coordinated, multi-level approach is essential to overcoming these barriers and achieving meaningful improvements in mental health outcomes across India.

EPV1037

Enhancing the cost-effectiveness of mental health services in Georgia-research proposal

N. Zavradashvili[1]* and G. Matiashvili[1]

[1]School of Health Sciences, The University of Georgia, Tbilisi, Georgia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1658

Introduction: In Georgia, the psychiatry system is predominantly institutionalized, with limited community-based services and inadequate funding for psycho-social rehabilitation. Government finds it challenging to refocus psychiatry care towards deinstitutionalization, often failing to understand the high importance of such a step and the reasoning behind turning it. This research proposal aims to explore strategies to enhance the cost-effectiveness of mental health services in this context.
Objectives: Assess the current landscape of psychiatry services in a middle-income country, focusing on institutional care versus community-based services. Identify barriers and challenges faced by key actors in transitioning towards community-oriented psychiatry care. Investigate the cost-effectiveness of community mental health interventions compared to institutional care, considering long-term outcomes and societal impacts. Develop evidence-based recommendations to advocate for policy changes and resource allocation towards community-oriented services.
Methods: Literature Review: Conduct a comprehensive review of existing literature on cost-effective analyses and community interventions in middle-income countries.Policy Analysis: Examine existing mental health policies and budget allocations to identify gaps and opportunities for reallocating resources toward community-based care. Stakeholder interviews: interview policymakers, mental health professionals, and patients to collect information from different perspectives. Quantitative Analysis: Use health economics methods to analyze the cost-effectiveness of community-based mental health services compared to institutional care.
Results: Insights into the economic impact of transitioning towards community-oriented mental health services in middle-income countries. Policy recommendations aimed at increasing investment in community-based interventions and resocialization programs. Increased awareness among key actors about the long-term benefits and cost savings associated with community-oriented mental health care. Improved understanding of societal attitudes and barriers towards mental health reform.
Conclusions: Key discussion points include: How can advocacy efforts be reinforced to persuade governments that community mental health care is more affordable and beneficial? What obstacles might stand in the way of expanding community-based services, and how might they be overcome? How can stakeholders work together to guarantee resocialization programs receive ongoing financing and support? What role can international partnerships and collaborations play in supporting mental health reform in Georgia? By addressing these critical questions, this research proposal seeks to provide a roadmap for enhancing the cost-effectiveness and accessibility of mental health services in Georgia and similar middle-income contexts.

Migration and Mental Health of Immigrants

EPV1038

Hypnosis and Virtual Reality in the treatment of a MSNA (unaccompanied foreign minor)

S. Bellissima[1]* and G. Pellegrino[1]

[1]Medicina della Migrazione e delle Emergenze Sanitarie, ASP 3 Catania, Catania, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1659

Introduction: 11 years old, Syrian, he arrives alone in Italy after disembarking in Lampedusa, coming from Libya where he reports having stayed for a year. He is assigned to a community by the Juvenile Court of Catania.
A few days later, he exhibits multiple episodes of chest pain, difficulty breathing, drooling, muscle rigidity and tremors, and in the most severe case, he is taken to the emergency room and then hospitalized in pediatric neuropsychiatry.
Diagnosis ICD 10: Dissociative disorders (Code F44); Post-traumatic stress disorder (Code F53.1). Trazodone hydrochloride (60 ml) is prescribed, 5 drops three times a day.
Objectives: Care of the person and resolution of symptoms through psychotherapeutic management by the "Medicina delle Migrazione e delle Emergenze Sanitarie" of ASP 3 Catania (Italy).
Methods: Hypnosis combined with virtual reality, a technique already experimented with by the writer, the procedure consists of: trance induction; awakening; application of the visor; re-induction of the trance through conditioning, simultaneously with the departure of the virtual stimulus; continuous feedback with peripheral device. The stimulus situations transmitted by the viewer have as object setting such as: Abstract: lights, colors, geometric shapes; Concrete: naturalistic and aquatic landscapes, animals, guided tours, etc.
Results: He is a good hypnotic subject, responds well and after initial disorientation, benefits from psychotherapy, showing a slow but continuous improvement in behavior: anxiety progressively decreases, oppositional and rebellious behavior in the community wanes, conduct at school becomes appropriate where there were previously conflicts, sleep changes from disturbed to regular, and he interacts positively with adults and peers.
Marked interference is noted via phone from the family of origin, urging him to go to Germany where a half-sister resides (the procedure is feasible but very complex), leading to a resurgence

of symptoms and feelings of guilt in the minor, who perceives himself as unable to meet the demands of his relatives.
During Ramadan (he is Muslim), there are difficulties with concentration and lack of energy due to the lack of food and water, leading to a temporary delay in the work.
In an advanced phase of treatment, the minor categorically refuses to come to the clinic, probably due to being mocked by peers in the community, and it is decided to discontinue the sessions, especially since the work had progressed effectively and there was already an intention to gradually discontinue it.

Image 1:

Conclusions: It is believed that the use of hypnosis combined with virtual reality represents an appropriate treatment for post-traumatic stress disorder (PTSD), as it reduces anxiety, strengthens the ego, accelerates the process of change, and directs life in a positive direction. The Juvenile Court has granted family reunification in Germany, and at present, the minor is awaiting departure.

Migration risk factors and their impact on psychological distress among Unaccompanied Migrant Minors in Spain

P. Cristóbal Narváez[1,2*], M. Franch-Roca[1], R. el Hafi[1], I. Giné[1], L. Aparicio[3], M. Febas[4], H. Sainz Elias[1], Y. Osorio[3] and J. M. Haro[1,2]

[1]Research, Innovation and Teaching Unit, Parc Sanitari Sant Joan de Déu, Barcelona; [2]Centre for Biomedical Research on Mental Health (CIBERSAM), Madrid; [3]Servicio de Atención a la Migración en Salud Mental (SATMI), Parc Sanitari Sant Joan de Déu, Barcelona and [4]Children and Youth Integration Area, Sant Joan de Déu Terres de Lleida, Lleida, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1660

Introduction: Unaccompanied Migrant Minors (UMMs) who travel alone and live apart from their families are particularly vulnerable to mental health issues and social exclusion in Spain. Risk factors related to the migratory cycle, including travelling alone, living away from family, and experiencing discrimination, can negatively impact their mental health and increase the risk of social exclusion.
Objectives: This study aims to describe the profile of newly arrived UMM and identify the relevant health risk factors among them, considering factors before, during, and after migration and their impact on psychological distress.
Methods: The study involved face-to-face interviews with 230 minors in foster care placements. The interviews covered sociodemographic information, education and employment situations, factors related to the migratory process (before, during, and after migration), health status, and psychological distress. They were conducted in Arabic or French and translated into Spanish.
Results: The findings revealed that UMMs generally perceived themselves as having good health before migration. However, they often held unrealistic expectations about their new life. Upon arrival, they had to cope with post-migration stressors such as stress ($\beta = 0.468$, SE = 0.142, $p = 0.001$) and discrimination ($\beta = 0.357$, SE = 0.121, $p = 0.003$), which adversely affected their mental health.
Conclusions: The study highlights the impact of post-migration factors on psychological distress among newly arrived UMM. It underscores the need for comprehensive mental health care that considers the different stages of the migratory cycle. Additionally, it advocates for promoting cross-cultural mental health care models and developing policies and services to address and mitigate the effects of post-migration factors, including discrimination against UMMs in Spain.

Closing the Cultural Gap: An Intercultural Day Clinic Experience

P. S. Sirin[1*], L. Yükseltan-Hahn[1] and S. D. Thakkar[1]

[1]Zentrum für Seelische Gesundheit, Groß- Borstel, Asklepios Klinik Nord- Ochsenzoll, Hamburg, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1661

Introduction: Globally, the number of international migrants has been rising, with Europe seeing a significantly higher increase compared to other regions. Migration has been frequently identified in the literature as a risk factor for various mental health issues (Schouler-Ocak et al. Indian J Psychiatry 2020; 62 242-6). Despite this, migrant populations often encounter significant challenges in accessing mental health care services, primarily due to language and communication barriers and cultural differences (Forray et al. BMC Public Health 2024; 24 1593). To improve mental health treatment for migrant populations, it is essential to not only provide cultural competence training for healthcare professionals and ensure access to professional interpreters but also to establish and maintain multicultural treatment teams (Machleidt W. Der Nervenarzt 2022; 73 1208-12). Addressing these needs, we have been operating a multicultural treatment team at our day clinic in Hamburg for the

past year, providing care to Turkish-speaking migrants and native-born patients together.
Objectives: To describe our efforts in developing a cross-cultural center and facilitating effective communication between migrant patients and native-born patients.
Methods: A descriptive overview of our efforts to establish a day clinic model adapted to the cultural and linguistic needs of the migrant (Turkish) population in Germany with a brief review of the relevant literature.
Results: At our day hospital, we provide care for patients with psychiatric disorders who do not require inpatient treatment but for whom outpatient care is insufficient. Our multicultural treatment team is composed of healthcare professionals whose native languages are German and/or Turkish.In our day hospital, patients with a migration background receive psychotherapy and medical consultations in their native language, ensuring they can access the treatment they need without language barriers. Additionally, we aim to improve cultural understanding through collaborative activities. This approach facilitates the development of cross-cultural communication among patients and healthcare professionals from different backgrounds, while also contributing to equal opportunities in psychiatric treatment. The program addresses linguistic, cultural, and religious communication difficulties, aiming to build and sustain meaningful relationships.
Conclusions: The migrant population in Europe continues to grow each day, and mental health care services must adapt to this heterogeneous population and their diverse treatment needs. We advocate for the establishment of treatment centers where migrant populations and native-born patients are considered together, as such centers can play a role in bridging the intercultural communication gap.

Common brain activation patterns in schizophrenia patients with auditory verbal hallucinations: A conjunction analysis

L. Barbosa[1], P. Fuentes-Claramonte[1,2], P. Salgado-Pineda[1,2], F. Neuhaus[1], P. Del Olmo[1]*, B. Hoyas-Galán[3], P. McKenna[1,2] and E. Pomarol-Clotet[1,2]

[1]FIDMAG Germanes Hospitalàries Research Foundation; [2]CIBERSAM, ISCIII, BARCELONA and [3]Hospital Benito Menni, CASM, GRANOLLERS, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1662

Introduction: Auditory verbal hallucinations (AVH) are one of the primary symptoms of schizophrenia, but the biological mechanisms underlying them remain uncertain (1,2). Theoretical approaches have proposed that AVH are caused by abnormal activity in the auditory cortex; or that they represent misinterpreted cognitive activity such as inner speech. Recently, our group found, using a symptom capture task, that AVH did not trigger activity in the auditory cortex, but instead in language-related areas, thus shifting the focus towards cognitive theories of AVH (3). To date, cognitive approaches have only been preliminarily investigated, and mostly in psychological studies (1,2).
Objectives: Our aim was to test the theory that a disturbance in inner speech processes underlie AVH. We used conjunction analysis to examine common activation patterns between the experience of AVH and phonological encoding.
Methods: Eleven patients meeting DSM-5 criteria for schizophrenia or schizoaffective disorder with near-continuous AVH underwent fMRI during symptom capture and during a phonological encoding task. In the symptom capture task, the patients were instructed to press their left index finger when they begin to hear an AVH, wait three minutes, mentally repeat what they heard, and then press their right index finger. The phonological encoding task required them to indicate, via button press, whether the names of two objects shown in line drawings rhymed.
Pre-processing and analyses were carried out with FSL software using linear models. Activation maps were thresholded at $p<0.05$, cluster-corrected for multiple comparisons. To find regions of common activation between the two tasks, the activation maps from the contrasts of interest were binarized and entered into a conjunction analysis. Regions showing significant activation in both tasks simultaneously were considered activated in the conjunction analysis.
Results: The conjunction analysis showed common activation in several regions involved in phonological encoding, such as Broca's area and its right homologue, supplementary motor area bilaterally, Wernicke's area and cerebellum, in patients with AVH.
Conclusions: These results support a non-perceptual origin of AVH and link them to brain areas related to the phonological loop and working memory in schizophrenia.

Behavior and psychological symptoms in dementia: could be predictors of biology?

D. Castro[1]*, S. Orrego[1], M. Sava[1], M. Delso[1], M. P. García[2], A. M. Hualde[3], C. Terrón[4] and M. D. S. Manzano Palomo[5]

[1]Psychiatry, Infanta Leonor University Hospital; [2]Nuclear Medicine, Getafe University Hospital; [3]Nuclear Medicine, Gregorio Marañón University Hospital; [4]Neurology, Nuestra Señora del Rosario Hospital and [5]Neurology, Infanta Leonor University Hospital, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1663

Introduction: Neuropsychiatric symptoms (NPS), prevalent in individuals with mild cognitive impairment (MCI), are linked to functional decline, accelerated dementia progression, and reduced quality of life. In clinical practice, molecular imaging plays a key role in diagnosing cognitive and behavioral issues with high accuracy.
Objectives: This study aims to analyze the correlation between NPS and molecular imaging findings in MCI-diagnosed patients.
Methods: A retrospective, descriptive study was conducted with MCI patients who had undergone Amyloid PET scans (APscan) between January 2019 and October 2024 at Infanta Leonor Hospital in Madrid. Data included demographics, neurological diagnoses, Global Deterioration Scale (GDS) scores, NPS (e.g., depression, psychosis, behavioral and sleep disturbances, anxiety, suicidal thoughts), and PET-FDG/APscan results. Statistical analysis was performed using Dataset and SPSS 22.0.

Results: A total of 72 patients were included. The main characteristics of the sample are shown in table 1. Among these patients, 65.28% exhibited NPS; notably, 49.3% had depression, 23.61% behavioral disturbances, 19.44% sleep disorders, 16.67% anxiety, 4.17% psychosis, and 2.82% suicidal ideation. In patients with a positive APscan, 29.79% had NPS, including 34.29% with depression and 66.67% with psychosis. Patients with abnormal FDG-PET scans showed higher NPS prevalence (65.96%), particularly behavioral disturbances (64.71%), sleep disorders (57.14%), and depression (62.86%).

Image:

Mean of age	61,75 years	
Gender	Male	45,83%
	Female	54,17%
Global deterioration scale	3	75,71%
	4	12,86%
Cognitive tests	MOCA	25,41%
	MMSE	26,07%
Neurological Diagnosis post PET	Alzheimer Disease (AD)	25,00%
	Lewy Body Dementia	5,00%
	Frontotemporal Dementia	10.00%
FDG- PET Scan Pattern	Alzheimer-like	16,67%
	Altered no AD Pattern	51,39%
	Non Conclusive	15,28%
Amyloid PET Scan Pattern	Positive	36,11%
	Negative	63,89%

Table 1. Main characteristics of the sample

Conclusions: This study underscores the high incidence of NPS in MCI patients, noting that NPS may exacerbate patient distress, contribute to autonomy loss, and increase institutionalization risk. Furthermore, molecular imaging patterns can help predict MCI progression to dementia and highlight NPS as potential predictors and outcomes of these biological changes.

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1664

Introduction: Apathy is a common non-motor symptom in Parkinson's disease (PD), and its presence constitutes a risk factor for the development of cognitive impairment in this population (Burchill et al. Lancet Reg Health Eur 2024; 39:100870). β-amyloidopathy has been associated to shorter interval to dementia in PD and may also be a determinant of apathy.

Objectives: We aimed to investigate β-amyloid burden in non-demented PD patients based on the presence or absence of apathy, and how both factors influence the rate of progression to mild cognitive impairment or dementia over a 3-year period.

Methods: Forty-eight PD patients underwent clinical and comprehensive neuropsychological evaluation, as well as [18F]-flutemetamol positron emission tomography. They were classified as apathetic (n=22) or non-apathetic (n=26) based on their score on the Starkstein Apathy Scale. Brain imaging analysis was conducted using the SPM software package.

Results: We found statistically significant differences in disease duration when comparing clinical and demographic variables. Upon neuropsychological evaluation, apathetic patients performed significantly worse in attention domain (Digit Span and Trail Making Test A), executive function (Stroop Word-Colour Test and Trail Making Test B) and verbal memory (CERAD Total Word Recall). At follow up, 47.4% of apathetic patients progressed to dementia or MCI, compared to 12% of non-apathetic patients (χ^2 = 6.81, p <0.05). Brain imaging analysis revealed higher β-amyloid deposition in several cortical areas in apathetic PD patients (adjusted for disease duration and global composite cognitive z-scores).

Conclusions: The presence of apathy in PD patients is associated with greater cortical β-amyloidopathy and indicates a higher conversion rate to a worse cognitive diagnosis within a 3-year period.

EPV1046

Gray matter macrostructure and brain aging in unhealthy alcohol users

M. Hermesdorf[1]* and K. Berger[1]

[1]Institute of Epidemiology and Social Medicine, University of Münster, Münster, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1665

Introduction: In view of recent global trends in alcohol use, it becomes increasingly relevant to characterize health outcomes related to unhealthy alcohol use. Previous studies found that self-reported alcohol use was related to poor brain health. However, these studies remain inconclusive since they limited their analyses to very narrow demographic strata, considered only a subset of cortical regions, or didn't validate self-reported alcohol use with biomarkers such as gamma-glutamyltransferase (gamma-GT).
Objectives: This study aimed to comprehensively examine several aspects of brain health (cortical thickness, gray matter volume, and brain age gaps) in participants regularly exceeding the recommended limits of moderate alcohol use versus those who don't, and to validate self-reported alcohol intake by comparing gamma-GT levels across groups.
Methods: This analysis was based on cross-sectional data from the population-based cohort of the BiDirect Study conducted in Münster (Germany). Individuals aged between 35 and 65 years were randomly selected from the local population register and invited to participate in the assessment that included a 3 Tesla magnetic resonance imaging (MRI) of the brain and a blood collection. Unhealthy alcohol use was defined as the regular consumption of at least three units of alcohol (one unit = 0.2L beer or 0.1L wine or 2cl spirits) per occasion at least twice a week. Regional cortical thickness and subcortical gray matter volumes were extracted from T1-weighted images in participants who underwent MRI. In addition, brain age gaps were estimated using an elastic net algorithm based on the imaging-derived phenotypes. Associations between unhealthy alcohol use, cortical thickness, subcortical gray matter volumes, and brain age gaps were analyzed using multiple regression models adjusted for age, sex, lifetime smoking status, education, and childhood trauma.
Results: Participants engaging in unhealthy alcohol use had significantly higher gamma-GT levels. In addition, unhealthy alcohol use was associated lower regional cortical thickness across all four lobes of the brain. No differences in subcortical gray matter volumes were detected. In addition, we observed a significantly higher brain age gap (+ 1.11 years) in unhealthy alcohol users.
Conclusions: The results of this study indicate that the regular exceedance of the recommended levels of alcohol use is associated with poorer brain health as reflected by lower regional cortical thickness and advanced brain aging. The findings underscore the potentially adverse effects of alcohol on brain health, which are increasingly relevant in view of recent global trends in alcohol use.

EPV1047

How Follow-Up Neuroimaging Techniques Enhance Care for a Veteran with Combat-Related TBI and PTSD

O. Inanc[1]*, D. Erbek[1] and B. Garip[2]

[1]Gulhane Training and Research Hospital, Ankara, Türkiye and [2]Psychiatry, Gulhane Training and Research Hospital, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1666

Introduction: As traumatic brain injury (TBI) is a significant concern among military veterans, ongoing neuroimaging is a beneficial tool for monitoring functional brain changes and evaluating the progression of symptoms.
Objectives: Highlighting the importance of follow-up neuroimaging assessments in guiding treatment adjustments and understanding the evolving relationship between TBI, post-traumatic stress disorder (PTSD), and neurocognitive dysfunction.
Methods: A 27-year-old male veteran injured by an IED experienced trauma to the right side of his body, resulting in 80% vision loss in the right eye and 20% in the left. He reported memory gaps and sleep disturbances. After inpatient and outpatient rehabilitation, he was prescribed Olanzapine (5 mg/day), Quetiapine (150 mg/day), and Venlafaxine (75 mg/day). On his second admission for increased sleep disturbances and anxiety, Quetiapine was increased to 200 mg/day. One year later, the patient developed new cognitive impairments and reported memory deficits and anterograde amnesia, concurrently PET scans revealed hypometabolism in the frontal lobe.
Results: Neuropsychological Evaluation: The Raven Standard Progressive Matrices Test indicated potential issues in reasoning and problem-solving, while the Verbal Fluency Test suggested difficulties with cognitive flexibility and memory, and the Trail Making Test revealed problems with attention and sequencing. Imaging Findings: The initial CT scan demonstrated displaced linear fractures in the right temporal bone and two brain contusions shortly after the incident. On his visit nine months later, SPECT imaging showed relative hypoperfusion in the right posterior parietal cortex and bilateral temporal lobes. An EEG revealed slow wave anomalies in the right temporooccipital area and sharp spasms in the left temporal region. One year later, a follow-up PET scan revealed diffuse hypometabolism in the left frontal lobe, parietal lobes, and cerebellum.

Image:

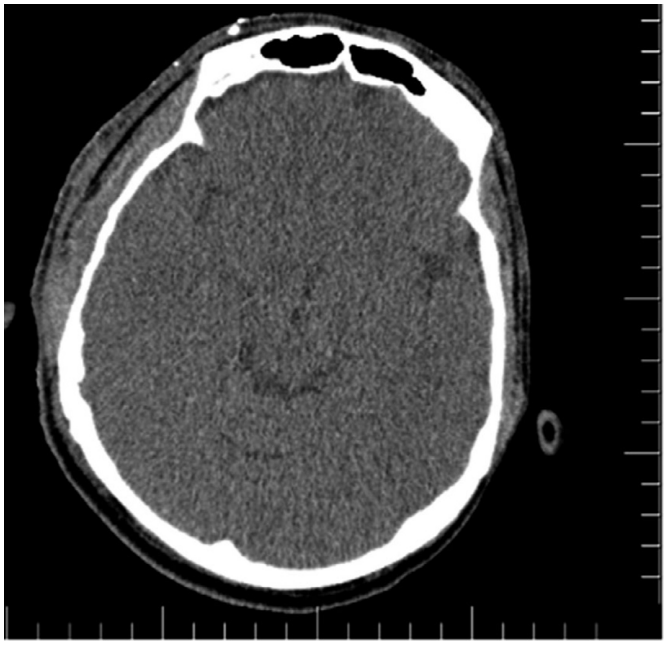

Image 2:

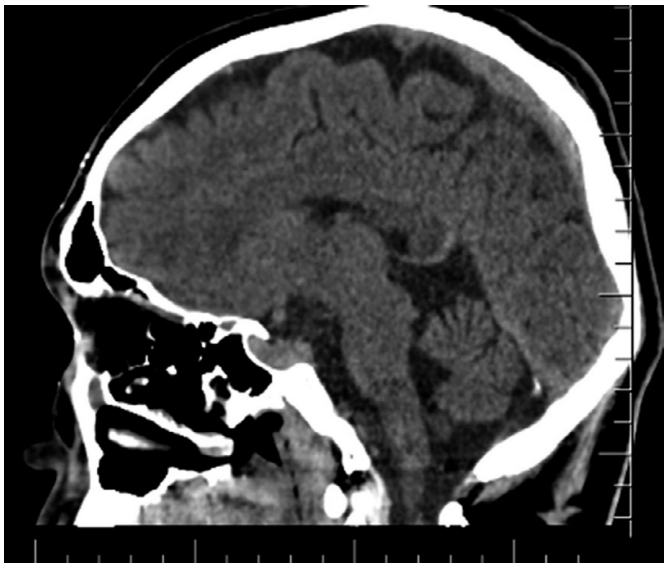

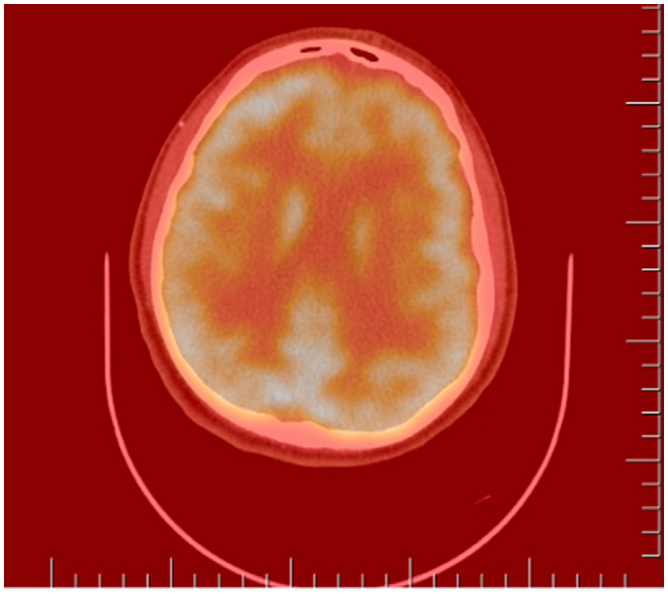

Image 3:

Conclusions: This case emphasizes the role of follow-up neuroimaging in managing complex cases of combat-related TBI and PTSD. The progression from structural damage to later functional changes like hypometabolism in the frontal and parietal lobes illustrates how neuroimaging helps track the long-term impact of brain injuries and provides a comprehensive understanding of the evolving neurocognitive challenges. Continued neuroimaging is crucial for monitoring neurodegenerative processes and guiding adjustments in treatment (Koerte et al., 2015b). This approach supports a more targeted treatment plan, improving the veteran's long-term prognosis (Wilde et al., 2015). Future studies should prioritize large, multi-site longitudinal research to track long-term neurotrauma effects through imaging, providing insights into neurodegeneration, recovery, and neuroplasticity.

MRI structural alterations in schizophrenia patients with prominent first rank symptoms

A. S. Tomyshev[1], M. M. Magomedagaev[2], A. Y. Komarova[1]*, A. N. Dudina[1], G. P. Kostyuk[3], R. V. Dmitry[2,4] and I. S. Lebedeva[1]

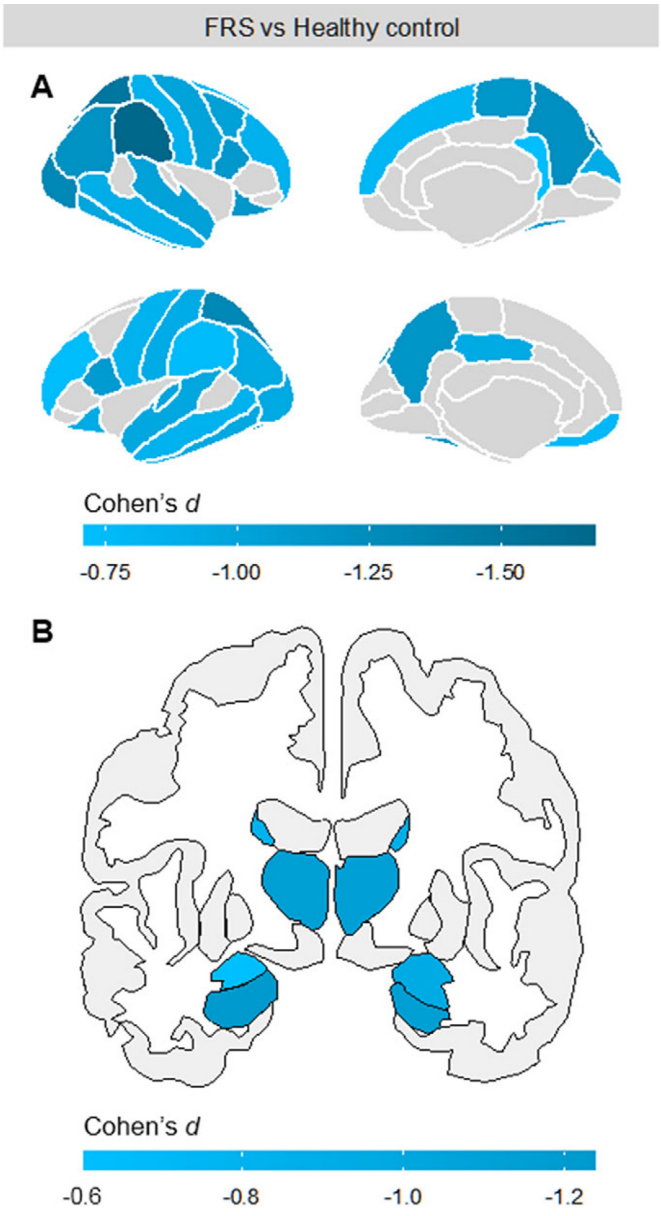
[1]Laboratory of neuroimaging and multimodal analysis, Mental Health Research Center; [2]Department of Psychiatry and Psychosomatics, I.M. Sechenov First Moscow State Medical University; [3]Mental-health Clinic No.1 named after N.A. Alexeev and [4]Department of borderline mental pathology and psychosomatic disorders, Mental Health Research Center, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1667

Introduction: There is an evidence that the presence of first rank symptoms (FRS) in psychotic patients is associated with structural brain alterations and that the FRS severity is correlated with abnormal brain functioning. However, whether the severity of first rank delusions (FRD) or first rank hallucinations (FRH) correlates with structural alterations remains unclear.

Objectives: We aimed at exploring correlations of FRS severity with structural brain alterations in schizophrenia patients with prominent first rank symptoms.



Methods: Twenty one right-handed patients (21.2-47.6 years, mean age 35.2±8.8, 2 females) with schizophrenia, presenting with prominent FRS and 21 one-to-one matched healthy controls (21.4-47.7 years, mean age 34.6±9.0, 2 females) underwent structural MRI at 3T scanner. MRI images were processed via FreeSurfer 6.0 to quantify cortical thickness and volumes for subcortical and brainstem (midbrain, pons, superior cerebellar peduncle and medulla) structures. The presence of FRS were diagnosed by professional psychiatrist (M.M.) using clinical interview and clinical-psychopathological method, severity of FRD and FRH were assessed with PANSS (P1 and P3 items accordingly). PANSS total for all patients: 88.1±20.6; PASNSS positive: 23.7±5.2 (P1: 4.9±1.3; P3: 4.6±1.3); PASNSS negative: 21.9±8.7.

Results: Compared to healthy controls, patients with FRS showed widespread cortical gray matter thickness reductions (Image 1, A), and decreased volumes of hippocampus, amygdala, thalamus, caudate and nucleus accumbens bilaterally (Image 1, B). Patients with FRS also showed decreased volumes of whole brainstem and all of its substructures (midbrain, pons, superior cerebellar peduncle and medulla: Cohen's d from -0.74 to -1.2).

No correlations between structural alterations and severity of FRD or FRH (PANSS P1, P3, P1+P3) were found.

Image 1. A: Clusters of decreased cortical thickness according to atlas of Desikan et al. (2006) in patients with FRS compared to healthy controls. B: Decreased volumes of subcortical structures in patients with FRS compared to healthy controls (nucleus accumbens are not shown).

Image 1:

Conclusions: The results suggest that schizophrenia patients with prominent FRS have a pronounced widespread cortical and subcortical structural alterations consistent with findings in general schizophrenia research. However, the lack of correlations with clinical scores do not allow to conclude definitely whether the revealed structural abnormalities underlies FRD or FRH, which should be elucidated via further research.

Disclosure of Interest: None Declared

EPV1049

Cortical alterations in patients with mild cognitive impairment who converted to Alzheimer disease compared to non-converters and correlations of these alterations with mild behavioral impairment

A. S. Tomyshev[1], N. S. Cherkasov[2], A. Y. Komarova[1]*, E. G. Abdullina[1], I. V. Kolykhalov[2] and I. S. Lebedeva[1]

[1]Laboratory of neuroimaging and multimodal analysis and [2]Department of gerontological psychiatry, Mental Health Research Center, Moscow, Russian Federation

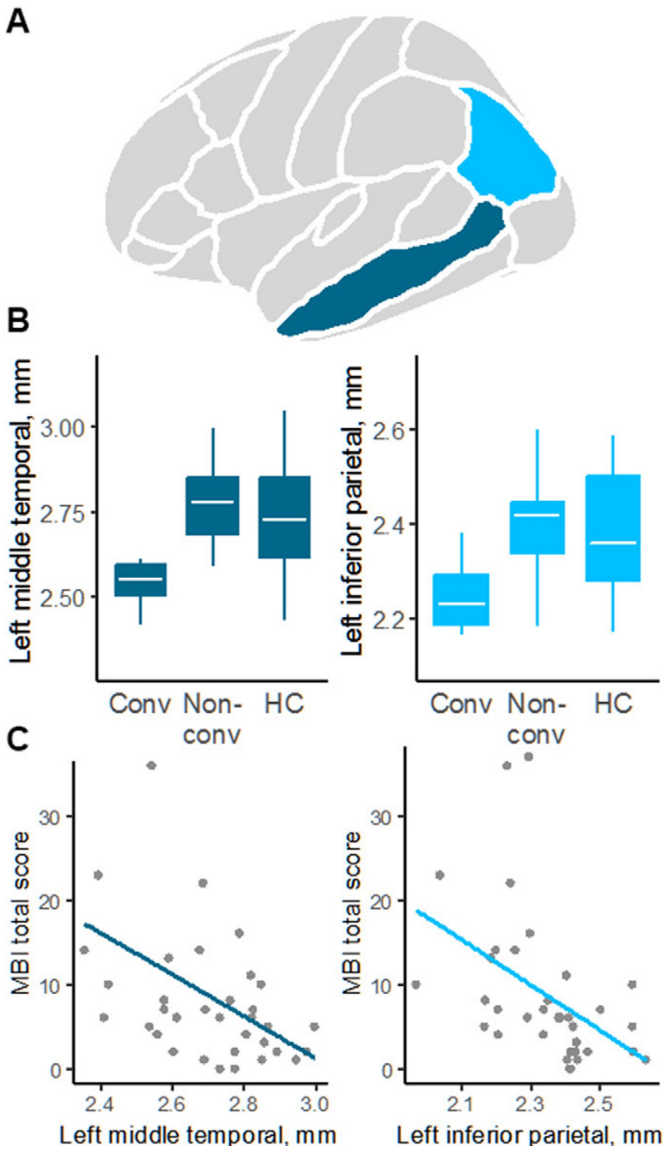
*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1668

Introduction: There is a growing evidence that a presence of mild behavioral impairment (MBI) in geriatric patients with mild cognitive impairment (MCI) increases the risk of Alzheimer disease. However, neurobiological patterns underling such additional risk remains unclear.

Objectives: We aimed to investigate structural cortical patterns in MCI patients that differentiate converters from non-converters to Alzheimer disease (AD) and to explore correlations of such patterns with mild behavioral impairment.

Methods: Thirty five right-handed geriatric patients with amnestic type of MCI (aMCI) were followed up during the period of 11.3 ±6.9 months and divided into converters to AD (n=11, mean age 74.6±7.5, 10 females) and non-converters (n=24, mean age 72.6 ±8.1, 18 females). Patients and matched healthy controls (n=17, mean age 72.3±7.2 years, 14 females) underwent structural 3T MRI at baseline. MRI images were processed via FreeSurfer 6.0 to quantify gray matter thickness for 68 cortical areas according to Desikan atlas. Cognitive status was assessed using the Montreal Cognitive Assessment (MoCA) scale, and the severity of mild behavioral impairment was assessed using the MBI-C (Mild Behavioral Impairment Checklist) at baseline.



Results: Cortical thickness in the left inferior parietal lobe (IPL) and left middle temporal gyrus (MTG) were decreased in converters compared to both non-converters (IPL: $F(1,30)=12.8$, $p=0.0012$, Cohen's $d=-1.30$; MTG: $F(1,30)=12.8$, $p=0.0012$; Cohen's $d=-1.30$) and healthy controls (IPL: $F(1,24)=11.4$, $p=0.0025$, Cohen's $d=-1.33$; MTG: $F(1,24)=8.3$, $p=0.008$; Cohen's $d=-1.15$) (Image 1A,B).

Converters also showed larger baseline MBI-C scores compared to non-converters (13.8±12.0 vs 7.8±6.6; GML $t=2.1$, $p=0.045$) and no difference in baseline MoCA (21.8±4.0 vs 23.2±2.8; GML $t=-1.4$, $p=0.19$).

Baseline MBI-C scores in the whole aMCI group correlated negatively with cortical thickness both in the left IPL ($R=-0.53$, $p=0.0011$) and left MTG ($R=-0.48$, $p=0.004$) (Image 1C). No correlations between MoCA scores and cortical thickness were observed.

Image 1. A: Clusters of decreased cortical thickness according to atlas of Desikan et al. (2006) in converters compared to non-converters and healthy controls. B: Box-plots of cortical thickness in the left inferior parietal lobe and left middle temporal gyrus. C: Scatter plots of MBI-C scores and gray matter thickness in the left inferior parietal lobe and left middle temporal gyrus in the whole aMCI group (n = 35).

Image 1:

Conclusions: The findings suggest that the decreased baseline cortical thickness in the left inferior parietal lobe and middle temporal gyrus with associated greater severity of mild behavioral impairment could be potential marker of increased risk of conversion to AD in aMCI patients.

The study was supported by RSF grant 24-15-00220

Framework proposal for training set of low-shot medical image data in cerebrovascular disease and comorbid depression

A. Starcevic[1]*, B. Vucinic[2], F. Starcevic[2], B. Starcevic[3] and M. Stojanovic[4]

[1]Anatomy; [2]University of Belgrade; [3]University Clinical Center of Belgrade, Belgrade and [4]Private practice Ortodent, Paracin, Serbia
*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1669

Introduction: Cerebrovascular diseases, including white matter hyperintensities (WMLs), are the leading cause of functional disability and comorbid depression. Accurate and timely detection of WMLs is crucial for understanding their pathophysiology, progression, and treatment outcomes of both vascular and depressive symptomatology. Recent advancements in artificial intelligence (AI) and machine learning have facilitated the development of automatic WML detection methods, enhancing efficacy and accuracy in quantifying, localising, and evaluating lesion characteristics.
Objectives: The aim of this pilot study was to propose the framework for training set of low-shot medical image data in cerebrovascular disease and comorbid depression as novel artificial intelligence (AI) neuroimaging techniques, combined with quantitative measurements can be used to investigate and understand the implications of WMLs on brain structure and function.
Methods: We included 25 subjects, 15 with WMLs and 10 controls. Depressive symptoms were assessed by psychiatrist using Hamilton Depression Rating Scale (HDRS) and clinical interview. The neuroimaging data were collected from Magnetic Resonance Department University Clinical Center, Medical faculty, University of Belgrade, Serbia. All images were aligned with MNI space to normalize their intensity. Manual delineation and brain segmentation was performed with 3D slicer software using structural T1v and T2FLAIR images. Statistical analysis was performed to determine the correlation of lesion volume with the total brain volume (TBV) and to compare the TBV in patients with lesions and controls, in an effort to find possible morphometric correlates that may aid in automatic lesion detection and predicting the spacial pattern of WMLs.
Adding to the proposed framework, we have investigated statistical correlates in subjects with WMLs and controls. A statistical analysis was conducted to compare TBV in subjects with WMLs and controls and correlation between WML volume and TBV. The significance of the observed differences is determined, providing insights into the impact of WMLs on TBV.
Results: The average WML volume was 197±154.18 mm^3, with the smallest volume measured at 28.92 mm^3 and the largest at 552.8 mm^3. A significant difference in TBV was observed between patients with WMLs and controls (p-value=0.00216, $p<0.05$), and a weak negative correlation was found between WML volume and TBV ($\rho=-0.167$).
Conclusions: Our findings demonstrate reduced TBV in patients with WMLs and depression and emphasize the importance of considering parameters such as TBV in evaluating WMLs. Assessing the impact of WMLs on TBV can provide valuable insights into the progression and severity of cognitive decline and functional impairment but also impact on training dataset preprocessing preparation for AI framework on low shot medical images in cerebrovascular disease.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1670

Introduction: Alzheimer's disease (AD) is characterized by the abnormal accumulation of amyloid-β and tau proteins. Previous studies have demonstrated that early-onset AD (EOAD) has more rapid and significant tau accumulation compared to late-onset AD (LOAD). Particularly, postmortem analyses have shown greater tau accumulation in the nucleus basalis of Meynert (nbM) in EOAD. However, there is a lack of clinical studies that directly compare tau pathologies in EOAD and LOAD or explore their associations with clinical symptoms.
Objectives: To evaluate the tau accumulation patterns in the nbM and other brain regions defined by Braak stages (I/II, III/IV, V/VI) in EOAD and LOAD using 18F-florzolotau PET imaging. Additionally, to analyze the relationship between tau accumulation in the nbM and cognitive function.
Methods: The study included 38 amyloid-positive AD patients (15 EOAD, 23 LOAD) and 46 healthy controls (HCs). PET scans with 18F-florzolotau were performed, and the standardized uptake value ratios (SUVRs) of tau accumulation in the nbM and Braak stage regions were calculated using the cerebellum as the reference. Cognitive assessments were conducted using the Mini-Mental State Examination (MMSE) and other neuropsychological tests. Postmortem brain tissue from six AD patients and two HCs was histologically analyzed to validate PET findings.
Results: EOAD patients showed significantly higher tau accumulation in the nbM than LOAD patients ($p = 0.004$). The SUVRs in Braak stage regions also tended to be higher in EOAD (I/II: $p = 0.244$, III/IV: $p = 0.120$, V/VI: $p = 0.079$). Correlation analysis revealed no significant relationship between nbM SUVR and Braak stage SUVRs in EOAD, whereas LOAD patients exhibited positive correlations in Braak stages I/II ($r = 0.50$, $p = 0.014$) and III/IV ($r = 0.43$, $p = 0.043$). In LOAD, nbM tau accumulation correlated negatively with MMSE scores ($r = -0.55$, $p = 0.006$). In EOAD, higher Braak stage tau was associated with a stronger negative trend in MMSE (III/IV: $r = -0.37$, $p = 0.178$; V/VI: $r = -0.41$, $p = 0.126$). Histopathological examination confirmed the presence of ghost tangles in advanced AD and intracellular tau in early-stage AD, supporting the PET imaging results.
Conclusions: The study highlights distinct tau pathology differences in the nbM and their impact on cognitive function between EOAD and LOAD. The findings suggest that while nbM tau pathology in LOAD is linked to disease severity, EOAD is influenced more by cortical tau pathology. PET imaging of tau provides a promising approach for enhancing diagnostic and therapeutic strategies for Alzheimer's disease.

doi: 10.1192/j.eurpsy.2025.1671

Introduction: Treatment-resistant schizophrenia patients have the worst clinical outcomes and poor quality of life, despite the administration of clozapine. Currently, the definition of resistance is based on treatment response, but evidence differentiating resistance remains unclear. The dysconnectivity theory suggests that disrupted brain interactions contribute to schizophrenia pathology. Advances in functional and structural neuroimaging allow exploration of connectivity patterns that may characterize treatment-resistant schizophrenia.
Objectives: This study aimed to describe functional and structural connectivity patterns in schizophrenia patients on clozapine.
Methods: Patients taking clozapine (CLZ) or other antipsychotic (nCLZ) were recruited from the Hospital of the Medical School of Ribeirão Preto. Healthy controls (HC) were recruited from the Hospital database. Seventy-seven participants were selected: CLZ = 35, nCLZ = 27, and HC = 27. Functional connectivity (FC) was assessed via resting-state functional magnetic resonance imaging (rs-fMRI) and ROI-to-ROI analysis using the CONN toolbox. Structural connectivity was analyzed with diffusion tensor imaging and tractography using TRACULA toolbox. ANOVA and Tukey test were used for three-group comparisons, and the t-tests for two-group comparisons. Functional analysis was performed with a significance threshold of $p < 0.05$ and false discovery rate (FDR) set to $p < 0.01$.
Results: Reduced frontotemporal FC and increased FC in the frontal-occipital were common in CLZ and nCLZ compared to HC. An increased FC between sensorimotor and the cerebellum was notable in CLZ compared to HC. Structural findings included increased axial diffusivity (AD) and mean diffusivity (MD) in 8 of 10 tracts in CLZ compared to HC. The corticospinal tract and inferior longitudinal fasciculus exhibited increased AD and MD in CLZ compared to nCLZ. The cingulum angular bundle showed significantly altered diffusion measures in nCLZ: increased AD, MD, and radial diffusivity (RD), and reduced fractional anisotropy (FA).
Conclusions: This study described a widespread functional and structural dysconnectivity in CLZ, characterized by reduced frontotemporal FC and increased frontal-occipital and sensorimotor–cerebellum FC. Altered AD and MD measures in the corticospinal tract and inferior longitudinal fasciculus were observed in the CLZ. Alterations in AD, MD, RD, and FA measures in the cingulum angular bundle, particularly noted in nCLZ, may be associated with antipsychotic administration. Further studies are necessary to establish whether these dysconnectivity patterns consistently characterize these patient groups.

Sex-Based Classification of Grey Matter Volume Using SVM: Implications for Early-Phase Psychotic and Mood Disorders

M. F. Urquijo[1*], A. Riecher-Rössler[2], P. Falkai[1], D. Dwyer[3], P. Consortium[1,2,4,5,6,7,8,9,10] and N. Koutsouleris[1,11,12]

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1672

Introduction: Understanding sex differences in brain structure is crucial for advancing personalized medicine. However, the alterations of sex-based neuroanatomical differences during the early phases of mood and psychotic disorders remain largely underexplored.
Objectives: This study aimed to evaluate neuroanatomical sex-based differences in a healthy cohort and assess potential alterations in clinical populations from the early psychiatric spectrum using a machine learning approach.
Methods: For this, we developed a Support Vector Machine (SVM) model trained to classify sex based on grey matter volume from a cohort of healthy controls (HC, n = 521), aged 15 to 40 years. After optimization and cross-validation, the model was applied to three distinct clinical populations from the same age range: individuals at clinical high risk for psychosis (CHR, n =334), those with recent onset psychosis (ROP, n = 351), and those with recent onset depression (ROD, n = 309).
Results: The model achieved a robust balanced accuracy (BAC) of 85.1% ($p < .01$) in the HC cohort. When applied to the CHR group, the model maintained a BAC of 85.5%, whereas its performance decreased in the ROP (75.8% BAC) and ROD (79.3% BAC) groups. In contrast to previous literature, female participants in the ROP group exhibited a masculinization of brain patterns, while male participants showed no such reversal. In the ROD group, both sexes revealed a slight tendency toward patterns typical of the opposite sex.
Conclusions: These preliminary findings suggest that sex-based neuroanatomical structures remain preserved at high-risk stages but undergo alterations with disorder progression. Future research will investigate the observed performance decline in relation to other phenotypic factors. These findings offer novel insights into sex-specific neurobiological mechanisms underlying psychotic and mood disorders and their early markers.

Uncovering Fahr's Disease Through Psychotic Symptoms: A case report

J. ZAOUALI[1*], I. DRIDI[1], S. ELLINI[1], M. CHEOUR[1], W. CHERIF[1], S. HALLIT[2] and F. FEKIH-ROMDHANE[1,3]

[1]Psychiatry, Razi Hospital, Tunis, Tunisia; [2]Research, School of Medicine and Medical Sciences, Holy Spirit University of Kaslik, P.O. Box 446, Jounieh, Lebanon and [3]Psychiatry, Tunis El manar university, faculty of Medicine of Tunis, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1673

Introduction: Bilateral pallidodentate calcinosis (BPC), also known as Fahr's disease, is an uncommon neurodegenerative disorder that may be either genetic or sporadic. It is distinguished by bilateral and symmetrical deposits of calcium in the basal ganglia and occasionally in the cerebral cortex, impacting the regulation of motor and cognitive functions.
Objectives: To underline the diagnostic pitfalls faced in Fahr's disease when psychotic manifestations are predominant, thereby emphasizing the need to integrate neuroimaging and diagnostic assessments in differenciating this disease from a primary psychotic disorder.
Methods: We present a rare case of Fahr's disease with an atypical initial presentation, where the condition was initially misdiagnosed due to predominant psychiatric symptoms.
Results: The patient, a 34-year-old man, displayed significant behavioral disturbances and cognitive decline since the age of 30. Initial psychiatric assessments identified a delusional syndrome, hallucinatory episodes, and psychomotor agitation, leading to a provisional diagnosis of a primary psychotic disorder. However, neuroimaging subsequently revealed bipallidal calcifications characteristic of Fahr's disease, and further diagnostic evaluations (neurological examinations, a determination of parathyroid hormone (PTH) levels along with a comprehensive calcium-phosphate evaluation) confirmed the condition.The patient was treated symptomatically with second-generation antipsychotics, alongside supportive therapy, resulting in partial symptom alleviation.
Conclusions: This case underscores the challenges of diagnosing Fahr's disease when psychiatric manifestations predominate, which can delay appropriate diagnosis and treatment. Continuous, multidisciplinary follow-up is essential for optimal management of psychiatric symptoms.

Neuropsychiatric Manifestations in Systemic Lupus Erythematosus: Psicosis as a Clinical Challenge in a Case Report and Updated Literature Review

E. Abalde García[1,2*], E. Lanchares Balboa[1], K. Muñoz Rodriguez[2] and L. C. Ortega Sandoval[1]

[1]Hospital Álvaro Cunqueiro , Vigo, Spain and [2]Psychiatry, Hospital Álvaro Cunqueiro, Vigo, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1674

Introduction: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease that affects the central nervous system (NP-SLE) in approximately 30-40% of patients, with psychosis being one of the less common yet very serious manifestations, occurring in about 2-3.5% of cases. Diagnosing psychosis in SLE can be challenging, requiring careful integration of medical history with appropriate complementary tests (immunological, CSF, neuroimaging…) while considering other possible differential diagnoses.

Objectives: To highlight the importance of considering this condition (as well as other rare causes of neuropsychiatric involvement) in patients presenting with atypical psychotic symptoms accompanied by cognitive and behavioral disturbances.
Methods: Presentation of a clinical case and literature review.
Results: A 69-year-old female presents with a complex medical history, including melanoma, meningioma, and cerebral microangiopathy. Since 2019, prolonged activated partial thromboplastin time (aPTT) and lupus anticoagulant have been observed. In 2020, she developed neurological symptoms such as blurred vision, diplopia, dizziness, and instability. In December 2022, she consults for depressive symptoms and memory problems. June 2023, she was admitted to Psychiatry ward for a psychotic episode characterized by poorly structured and apparently fluctuating delusional symptoms. There was also evident disorganization, confusion, incoherent behavior, memory deficits, and functional decline. During the hospitalization, her condition initially worsened, with bizarre behaviors fluctuating, requiring mechanical and pharmacological restraint on several occasions. Blood tests showed bicitopenia (leukopenia and thrombocytopenia), along with renal insufficiency. Antiphospholipid syndrome was confirmed. Subsequently, her delusional symptoms remitted, and she was discharged. A second scheduled admission in internal medicine followed for diagnostic clarification during which SLE (ANA+, SSA, SSB, anti U1RNP, anti Sm D, and anti-DNA+) and antiphospholipid syndrome were confirmed. Hydroxychloroquine and anticoagulation (Sintrom) were initiated.
She currently remains under follow-up in both Internal Medicine and Psychiatry with functional, cognitive, and emotional improvement, allowing for the reduction of antipsychotic and antidepressant medication without relapse. A cognitive decline has been ruled out by the dementia unit.
Conclusions: In the case of SLE and its neuropsychiatric manifestations (NP-SLE), there are no specific markers, making detailed medical history, thorough screening, and differential diagnosis essential. Appropriate use of complementary tests and close coordination with other medical specialties are crucial, requiring a multidisciplinary and holistic approach.

A New Hope: Can we estimate a clinical diagnosis by using eye-tracking technology?

M. Alijotas Capdevila[1]*, M. Martínez-Ramirez[1], P. Querol Clares[1], I. Setién Ramos[2], J. Lugo Marin[3], J. A. Ramos-Quiroga[1] and L. Gisbert Gustemps[1]

[1]Psychiatry; [2]Neuropsychology and [3]Psychology, Hospital Vall d'Hebron, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1675

Introduction: Eye-tracking technology is a sensitive and direct method of measuring social-cognitive abilities regardless of language, causing minimal cognitive strain and with the advantage of its passive presentation of stimuli to participants, which allows observation without requiring verbal interaction nor explicit responses.
Objectives: Our aim was to study variations in social attention among adults diagnosed with ASD, ADHD, comorbid ASD and ADHD, and non-clinical individuals using eye-tracking technology.
Methods: We recruited a total of 80 participants over the age of 18 from the Psychiatric External Ward of Vall Hebron University Hospital, resulting in approximately 20 participants in each group. Social attention was assessed using vignettes from the Autism Diagnostic Observation Schedule-2 (ADOS-2).
Results: Preliminary results revealed significant statistical differences among the groups in the variables analyzed, indicating that individuals with ASD display distinct patterns of visual attention toward Areas of Interest (AOIs) containing social information compared to the other groups. No differences were found in the duration of fixation on the characters' eyes among the groups. However, participants diagnosed with ASD and ASD+ADHD tended to spend more time looking at regions with lower social information density, such as the characters' hands in the third vignette.
Conclusions: These findings shed light on social attention profiles across clinical and non-clinical populations, indicating specific patterns associated particularly with ASD, and highlight the importance of considering multiple aspects of social cognition. By employing eye-tracking technology, this study provides valuable insights into the underlying mechanisms of social attention across different neurodevelopmental conditions. Furthermore, the lack of significant differences in eye fixation duration on the eyes among clinical groups challenges conventional beliefs regarding social attention deficits in ADHD compared to ASD.
Using objective measures like eye-tracking can enhance our understanding of these complex neurodevelopmental conditions, potentially aiding in diagnosis and guiding the development of targeted interventions to address social cognition challenges in populations with neurodevelopmental disorders.
Our findings may contribute to a better understanding of social attention differences between ASD, ADHD, comorbid ASD +ADHD, and non-clinical individuals, paving the way for the design of more tailored and effective interventions.

Anger, Aggression and Violence: Towards an integrative, 'transdiagnostic' treatment paradigm

S. Anand[1]*, S. Kapoor[2], S. Rizvi[3], R. Varanasi[4], Z. Abbas[5], I. Arora[6] and H. Chhatwal[7]

[1]Ashburn Psychological and Psychiatric Services, Ashburn, United States; [2]Windsor University School of Medicine, Cayon, Saint Kitts and Nevis; [3]Medics International, New Jersey; [4]Willis-Knighton Health System, Shreveport; [5]University of Texas - Houston, Houston; [6]SABA Unversity School of Medicine, Devens and [7]George Mason University, Fairfax, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1676

Introduction: Using a 'transdiagnostic' paradigm for psychopathology, we review the evidence-base for the different treatment interventions for anger, aggression and violence (AAV). We aim to more accurately link the range of psychopathology associated with AAV to underlying brain structures and functional neurocircuitry. Building upon these findings, we propose a working model that may have greater clinical utility than reliance upon a purely 'disorder-based' paradigm for addressing AAV. This will permit greater understanding of when anger (which has also conferred

evolutionary survival advantages) can become maladaptive and destructive. This comprehensive, 'interventionist' model will hopefully lead to better clinical conceptualization of AAV, especially since most AAV presents more commonly in the context of interpersonal/situational stressors and to non-forensically trained clinicians.

Objectives:

1. To identify biological, cognitive, disorder-based, developmental and personality predispositions to AAV
2. To link neuroanatomical and functional brain circuitry with onset and maintainence of AAV
3. To identify *how* pharmacological and non pharmacological interventions work, and 'where' in the brain,
4. To review the evidence-base supporting various treatment interventions

Methods: Database review of PUBMED, PsychINFO, Google Scholar and treatment guidelines dating back 15 years (review articles, treatment guidelines, meta-analyses and randomized controlled trials).

Results: This will be visually depicted in an electronic slide (or >1 slide, if permitted) to identify:

1) The inter-relationship between contextal factors, the psychopathology of AAV and undelying brain 'circutry'
2) The specific nature of the impulsive anger, 'reactive' aggression and violence response 'cycle' and where in this cycle various interventions can be effectively utlized
3) Which patient populations respond best to which types of interventions

Conclusions:

1. AAV are hyperarousal states, with outcomes that can be successfully managed
2. The evidence-base for the role of medications is more limited
3. The evidence-base for the role of various psychotherapies is greater, with specific therapies being particularly useful across psychiatric disorders and populations
4. Psychodynamic approches remain curently underutilized and underappreciated
5. Both medications and therapy influence brain neuroplasticity separately and synergistically

Title: Identifying Neuropsychiatric Symptoms in Lewy Body Dementia: A Revealing Case Report

S. Aouadi[1]*, H. Ghabi[1,2], Y. Rebei[1], M. Karoui[1,2], H. Nefzi[1,2], R. Kammoun[1,2] and F. Ellouze[1,2]

[1]Psychiatry G , Razi Hospital and [2]Faculty of Medecine of Tunis, El Manar university, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1677

Introduction: Lewy body dementia (LBD) is characterized by a range of complex neuropsychiatric symptoms that can initially mimic other psychiatric disorders, particularly melancholic depression. Failure to recognize these symptoms can lead to delayed diagnosis and inappropriate management.

Objectives: This case report highlights the importance of a thorough evaluation of neuropsychiatric symptoms in the diagnosis of Lewy body dementia (LBD).

Methods: This case report was compiled through clinical observations, patient history from family members, and medical testing. Literature on LBD was reviewed to assess treatment strategies in light of this patient's condition.

Results: Mr. T.C., 75 years old, followed for hyperthyroidism and benign prostatic hyperplasia, was admitted for a severe depressive episode with melancholic features. Despite treatment with fluoxetine, mirtazapine, and olanzapine, his clinical condition did not improve. The patient exhibited food refusal, active suicidal ideation, and thoughts of incurability, along with a delusional syndrome. The Mini Mental State Examination (MMSE) revealed cognitive impairment with a score of 21/30. An initial brain MRI showed no abnormalities. The treatment was adjusted with the introduction of paroxetine alongside olanzapine and mirtazapine, but there was no significant improvement. A follow-up brain MRI revealed periventricular vascular leukoencephalopathy and moderate cortical atrophy, directing the diagnosis towards Lewy body dementia. The appearance of additional neuropsychiatric symptoms, including visual hallucinations, cognitive fluctuations, and mild parkinsonian signs, further supported the diagnosis of LBD. Treatment was then adjusted with the introduction of quetiapine, which is better tolerated in the context of LBD due to its favorable therapeutic profile.

Conclusions: This case emphasizes the importance of accurately diagnosing neuropsychiatric disorders in Lewy body dementia. Appropriate management, based on a thorough clinical evaluation, can prevent treatment errors and improve the patient's quality of life.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1678

Introduction: The lack of accessible plasma biomarkers to identify target populations limits the promise of precision medicine for Alzheimer's Disease (AD). Amnestic mild cognitive impairment (aMCI) is an important risk for AD and often occurs years before the onset of AD.

Objectives: Based on an emerging mechanistic model of mitochondrial mechanisms of brain plasticity, we studied the role of

acetylcarnitine and free-carnitine levels assayed in plasma as potential markers of cognitive dysfunction in subjects with aMCI or early-AD.
Methods: We used available samples from two independent cohorts well characterized for clinical and neuropsychological characteristics together with ultraperformance liquid chromatography-tandem mass spectrometry and computational approaches. Cerebrospinal fluid (CSF) measures of b-amyloid accumulation and t-Tau levels were also available and used in computational modeling.
Results: Within the primary cohort, our data showed decreased levels of carnitine in relation to cognitive function as assessed by using the Mini Mental Status Exam (MMSE) in women but not men with CI as compared to age- and sex-matched HC. Furthermore, the magnitude of carnitine deficiency reflected the severity of cognitive dysfunction in a sex-specific manner (women: p = 0.015; men: p = 0.441). Our data also replicated the prior finding of decreased LAC levels in both women and men with AD, supporting the robustness of the study samples assayed in our new study. Using computational approaches, we found that the integration of these mitochondrial measures with canonical CSF biomarkers improves diagnostic accuracy. A second cohort provides a validation of the sex-specific relationship between free-carnitine deficiency and the severity of cognitive dysfunction.
Conclusions: Taken together with prior mechanistic studies in rodents, the current findings support future research on the development of individualized treatment models targeting sex-specific changes in mitochondrial metabolism.

EPV1064

fNIRS and behavioral measures of inhibition are correlated with different aspects of impulsivity

A. D. S. Afonso Junior[1], W. Machado-Pinheiro[2], A. G. Seabra[1], M. A. Munoz[3] and L. R. R. Carreiro[1]*

[1]Universidade Presbiteriana Mackenzie, São Paulo; [2]Univeridade Federal Fluminense, Rio das Ostras, Brazil and [3]Universidad de Granada, Granada, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1679

Introduction: Impulsivity implies difficulties in control, leading to non-premeditated actions, and troubles resisting distraction and remaining focused on a goal. It is a transdiagnostic construct that is associated with several disorders, including Attentional Deficit and Hyperactivity Disorder (ADHD), Borderline Personality Disorder and Obsessive-Compulsive Disorder (OCD). It is possible to divide impulsivity between impulsive actions, associated with the ability to inhibit actions, and choice impulsivity, that involves decision-making. It is also common to differentiate between trait impulsivity, that involves more stable characteristics, and state impulsivity, in which the impulsive behavior is more transient.
Objectives: To investigate the association between action impulsivity as a trait (using self-report measures) and as state (using different level of analysis in a computerized task, i.e., behavioral and neuroimaging measures).
Methods: 52 university students (mean age = 21.4; standard deviation = 3.33) filled the BIS-11 self-report questionnaires and completed a Stroop-matching/stop-signal task while they had their behavioral and hemodynamic brain activity collected using Functional Near- Infrared Spectroscopy (fNIRS). The Stroop-matching/stop-signal task had three conditions varying the inhibitory demands: Congruent/Unrelated; Incongruent/Unrelated and Incongruent/Related. Spearman correlations were performed between scores of the BIS-11 subscales (Attentional, Motor and Non-planning impulsivity) and the reaction time (RT) and hemodynamic responses (β) of the Stroop-matching/stop-signal task. Alpha level = 0.05.
Results: RTs in all conditions of the task were positively correlated with Motor Impulsivity scores (Congruent/Unrelated, rho = .31, p = .025; Incongruent/Unrelated, rho = .27, p = .049; Incongruent/Related, rho = .38, p = .005). Brain activity in the left temporoparietal region was positively correlated with Attention Impulsivity scores (rho = .29, p = .033).
Conclusions: Motor and attentional aspects of trait impulsivity can be differently correlated with behavioral and neurophysiological measures of state impulsivity. In this study, motor impulsivity was correlated with more peripherical measures of inhibition (reaction times) while attentional impulsivity was correlated with activity in temporoparietal regions commonly associated with inhibition of distractive stimuli. Greater levels of motor and attentional impulsivity were associated with slower responses and greater brain activity, respectively.

The effectiveness of an add-on postbiotic to antipsychotic drugs for prevention of metabolic disturbances in patients with first-episode psychosis and schizophrenia spectrum disorder. A double blind clinical trial

J. Chato Noriega[1]*, E. Giné Servén[2], A. Ballesteros[2], M. Araña[3], M. Barajas[3], D. Yavorov[4], I. Iturria[4], J. Ayo[4], J. García[5], G. Núñez[5], M. J. Cuesta[2], E. Rosado[1], A. M. Sánchez Torres[3], G. Gil[6], X. Ansorena[6] and I. J. Encio[3]

[1]Instituto de Investigación Sanitaria de Navarra (IdiSNA),; [2]Department of Psychiatry, Hospital Universitario de Navarra; [3]Universidad Pública de Navarra; [4]Genbioma Aplicaciones SL; [5]Intelligent System Vitale SL and [6]Instituto de Investigación Sanitaria de Navarra (IdiSNA), Pamplona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1680

Introduction: Atypical antipsychotics (APs) are the drugs of choice for the treatment of the acute episodes and for relapse prevention in schizophrenia (SZ) and psychosis. Nevertheless, these drugs have side effects and particularly increase the risk to develop metabolic syndrome. Moreover, it has been reported that first-episode psychosis (FEP) patients have significant trends to insulin resistance, a higher body mass index and a higher rate of obesity, compared to the healthy subjects. Changes in gut microbiome have been linked to increased systemic inflammation, which could be associated with metabolic disturbances and the development of SZ. In this context, some previous studies have explored the efficacy of probiotic supplementation in SZ, showing benefits in gut regulation and in improving the metabolic effects of APs.

Objectives: The purpose of this study is to evaluate the effectiveness of an add-on postbiotic to Aps on metabolic disturbances and psychopathological variables in patients diagnosed with FEP or schizophrenia spectrum disorder (SSD). , as well as to determine whether the addition of postbiotics can improve biomarkers related to compensatory immunity and the endocannabinoid system.
Methods: A randomized, double-blind, placebo-controlled clinical trial, in which postbiotic or placebo will be administered for 12 weeks as add-on APs. The study comprises two branches: FEP branch, patients recently diagnosed with first psychotic episode; and SSD branch, patients with long-standing psychotic disorder. Five follow-up appointments will be conducted along the 12 weeks to carry on clinical assessments. Patients will be monitoring with a glucose sensor, and blood and microbiota will be analysed.
Results: This is a study protocol that is currently underway. No results are available at this time.
Conclusions: Over the past few decades, it has been abundantly evident how important the human microbiota is to both short-term and long-term human health. In this regard, postbiotics seem to have higher benefitial effects and lower risk than probiotics and they offer a promising approach to improve metabolic disturbances and amelioration of psychopathological symptoms in FEP and SSD patients.

Disclosure of Interest: None Declared

EPV1067

Emotion recognition and self-versus-other referential learning in mood disorders and schizophrenia

C.-D. Chiu

Department of Psychology, Chinese University of Hong Kong, North Territory, Hong Kong
doi: 10.1192/j.eurpsy.2025.1681

Introduction: Patients of depression and psychotic disorders are often troubled by unsatisfactory interpersonal relationships. While an inability to maintain a stable sense of self restricts one's understanding another's emotional state, whether disrupted self-versus-other referential processing is a transdiagnostic predictor of increased emotion misreading across diagnostic groups has not been explicated.
Objectives: We tested whether weakened differential learning between self and other may account for impoversihed emotion recognition accross mood and psychotic disorders.
Methods: Inpatients admitted for major depressive disorder (MDD), bipolar disorder (BD), and schizophrenia (SCZ; ns = 59, 32, and 43) and 40 healthy controls were recruited. Aside from ratings of depressive and schizophrenic symptoms by psychiatrists, participants were assessed on self- versus other- referential learning, emotion recognition, emotion sharing.
Results: Regression analysis indicates lower effectiveness of self-other tagging to be a predictor independent from symptom severity for increased emotion misrecognition across MDD, BD and SCZ ($F(8, 160) = 8.52$, $p < 0.001$). Clinical groups showed lower accuracy for other-referential recall and emotion recognition, but comparable emotion sharing and self-prioritization to healthy controls.

Image:

	Emotion recognition		
	β	*t*	*p*
Age	0.114	1.470	0.144
Sex	0.250	3.530	0.001
Years of education	0.086	1.080	0.282
Intellectual quotient	0.231	2.480	0.014
Depression (T2)	0.053	0.690	0.490
Positive symptoms (T2)	-0.025	-0.190	0.847
Negative symptoms (T2)	-0.122	-0.970	0.335
Efficiency of SOT	-0.066	-0.970	0.334
Effectiveness of SOT	0.309	3.290	0.001

Conclusions: Heightened emotion misrecognition in MDD, CD, and SCZ patients can be traced back to the weakened ability in coordinating self- and other-representations according to task-demands. Future examinations on whether interventions on brain regions pertaining to self-versus-other learning might enhance emotion recognition in different patient groups would be clinically relevant.

Disclosure of Interest: None Declared

Molecular Mechanisms of Hypericin and Hyperforin in Modulating Mammalian Neurotransmitter Systems: A Review

D. J. Cox[1]*, R. Maldonado-Puebla[1] and B. Carr[1]

[1]Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1682

Introduction: Hypericin and hyperforin, key secondary metabolites of *Hypericum spp.*, commonly known as St. John's Wort, are known for their ability to modulate neurotransmitter systems in the mammalian brain. These compounds, which evolved as plant defense chemicals, have significant implications for their interaction with mammalian neurobiology, particularly concerning serotonin, dopamine, and norepinephrine pathways.
Objectives: This review aims to elucidate the precise molecular mechanisms by which hypericin and hyperforin influence mammalian brain function. The focus is on understanding how these compounds interact with neurotransmitter transporters and receptors, and how these interactions may lead to both therapeutic and adverse neurobiological outcomes.

Methods: A comprehensive review of neurobiological and pharmacological literature was conducted, focusing on studies that detail the molecular interactions of hypericin and hyperforin with key components of neurotransmitter systems in mammals. in vitro binding assays, in vivo neuropharmacological studies, and molecular dynamics simulations were reviewed to understand these compounds' binding affinities, receptor modulation, and downstream signaling effects.
Results: Hypericin, with its planar polycyclic structure, exhibits a strong affinity for serotonin transporters (SERT), where it acts as a non-competitive inhibitor, leading to increased synaptic levels of serotonin. This mechanism mirrors that of selective serotonin reuptake inhibitors (SSRIs) but also introduces the potential for serotonin syndrome when combined with other serotonergic agents. Additionally, hypericin's ability to generate reactive oxygen species (ROS) under light exposure contributes to neurotoxicity, particularly in regions of the brain exposed to higher oxidative stress.
Hyperforin, characterized by its phloroglucinol core and multiple prenyl groups, exerts its effects primarily through modulation of synaptic vesicle function and ion channel activity. It non-selectively inhibits the reuptake of several neurotransmitters, including serotonin, dopamine, and norepinephrine, through a mechanism involving transient receptor potential (TRP) channels. This broad-spectrum inhibition can lead to significant changes in synaptic plasticity and neurotransmission, impacting mood regulation, anxiety, and cognition.
Conclusions: The interaction of hypericin and hyperforin with mammalian neurotransmitter systems underscores their potential as both therapeutic agents and neurotoxins. The molecular mechanisms by which these compounds modulate neurotransmitter transporters and receptors reveal a delicate balance between beneficial and adverse effects. Understanding these mechanisms is critical for evaluating the safety and efficacy of *Hypericum* extracts in clinical contexts, particularly regarding their impact on brain function and the potential for neurotoxicity.

doi: 10.1192/j.eurpsy.2025.1683

Introduction: Chronic mental illness is a significant risk factor for developing neurocognitive disorders. Advanced molecular imaging techniques, such as amyloid PET and FDG-PET, provide critical insights into the neurobiological mechanisms that link psychiatry and neurology, enhancing our understanding of the continuum between these fields.
Objectives: This study aims to describe the clinical history of chronic mental illness in a sample of patients with diagnosis of dementia, using molecular imaging to investigate the relationship between psychiatric history and neurodegenerative pathology.
Methods: We conducted a retrospective, descriptive analysis of patients who underwent amyloid PET imaging at the Neurology Department of Infanta Leonor University Hospital from January 2019 to October 2024. Inclusion criteria mandated a documented history of chronic mental illness, irrespective of psychiatric hospitalization. Collected data included demographic variables (age, sex), cardiovascular risk factors, psychiatric diagnoses according to DSM-5, years of mental illness, neurological diagnoses, and results from FDG and amyloid PET imaging. Ethical approval was obtained, and statistical analyses were performed using SPSS 22.0.
Results: A total of 25 patients were included. The main characteristics of the sample are shown in Table 1.
Among those with a chronic mental illness history exceeding ten years (N=8), the diagnostic distribution was as follows: 20% Alzheimer's disease, 20% Lewy body dementia, 20% major depressive disorder, 10% post-traumatic stress disorder, and 10% indeterminate. Notably, 75% of Alzheimer's patients and 66.6% of those with Lewy body dementia had a history of major depressive disorder. Patients with frontotemporal dementia often presented with neurocognitive behavioral disorders or obsessive-compulsive disorder. Among four patients with psychiatric hospitalization, only one received a definitive neurological diagnosis (frontotemporal dementia).

Image:

Total of patients	**25 patients**	
Mean of age	**62.6 years**	
Gender	Male	34 %
	Female	64 %
Vascular Risk Factors	High Blood Pressure	52 %
	Diabetes Mellitus	20 %
	Dyslipidemia	64 %
Mean years of mental chronic disease	11.64 years old	
Psychiatric Diagnosis (DSM V)	Major Depressive Disorder	60 %
	Neurocognitive Disorder	8 %
	Adjustment Disorder	16 %
	Anxiety	4 %
	TOC / Agoraphobia	4 %
	Delusional Disorder	4 %
Psychiatric Hospitalization	20 %	
Neurological Diagnosis	Alzheimer's disease	16 %
	Frontotemporal dementia	16 %
	Lewy Body Dementia	24 %
	Non conclusive diagnosis	16 %
FDG- PET Scan Pattern	Alzheimer-like	12 %
	Non-conclusive	24 %
AP Scan	Positive results	16 %

Table 1

Conclusions: These findings highlight the importance of considering chronic mental illness histories in the cognitive assessment of patients. The neurobiological links between depressive disorders and Alzheimer's disease emphasize the need for interdisciplinary approaches in clinical practice. Molecular imaging serves as a

pivotal tool in refining diagnostic accuracy, complementing both psychiatric and neurological perspectives, and enabling therapeutic strategies to improve patients' quality of life.

Depression as the main manifestation of central pontine myelinolysis : A case report

S. Walha[1], N. Halouani[1], S. Elloumi[1]*, S. Ellouze[1], M. Turki[1] and J. Aloulou[1]

[1]Psychiatry « B » department, Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1684

Introduction: Centropontine myelinolysis (CPM) is an acute demyelinating neurological disorder that primarily affects the central bridge and is frequently associated with rapid correction of hyponatremia. Common clinical manifestations of CPM include spastic quadriparesis, dysarthria, pseudobulbar palsy and encephalopathy of varying degrees. In addition, CPM could be accompanied by neuropsychiatric manifestations, such as personality changes, thymic symptoms, acute psychosis, paranoia, hallucinations or catatonia, usually associated with additional brain damage, described as extrapontine myelinolysis (EPM).
Objectives: Study the nature of comorbidity between CPM and mood disorders, particularly depression.
Methods: We present the case of a patient hospitalized in the psychiatry department B of the Hedi Chaker hospital in Sfax in July 2024. He was been admitted at the request of a third party for behavioral disorders such as agitation and refusal of treatment.
Results: This is Mr. S.BH aged 68, with a psychiatric family history of follow-up for unspecified psychiatric disorders in a niece. He has no psychiatric history, but has a somatic history, unmonitored high blood pressure as well as chronic constipation causing hyponatremia, which was quickly corrected 1 month ago. The latter was responsible for CPM objectified on the brain MRI requested by a free practice neurologist who consulted him for agitation. Our patient is married. He has been retired for a few months and previously worked as a farmer for 35 years. According to the family, the history of his illness dates back to March 2024, following professional stressors when he began to present multiple somatic complaints, with anorexia and weight loss as well as a tendency towards isolation. Since June 2024, following the CPM, he believed that the police wanted to harm him. As a result, he became anxious and agitated. At the interview: Slowed down on the psychomotor level, the contact was superficial, the mood was sad, his speech was provoked, poor and conveyed in a low voice verbalizing anhedonia, he presents congestive disorders and he refuses treatment and diet at the beginning. The patient obtained a score of 12 on < < the Geriatric Depression Scale GDS >> and a score of 12 on < <the mini-mental state examination MMSE >>.
Conclusions: This case demonstrates that depression might represent the main manifestation of CPM, especially in the early stages of the disease, which should be taken into consideration when evaluating patients with acute abnormalities of sodium metabolism.

The Mediating Role of Cortical Atrophy on the Relationship between the Resilience Index and Cognitive Function: Findings from the Healthy Brain Initiative

R. Ezzeddine[1]*, D. Oshea[2], S. Camacho[2], L. Besser[2], M. Tolea[2], J. Galvin[2], C. Galvin[2], L. Wang[3] and G. Gibbs[2]

[1]Psychiatry; [2]Neurology and [3]University of Miami, Miami, United States

doi: 10.1192/j.eurpsy.2025.1685

Introduction: Background: Lifestyle factors are linked to differences in brain aging and risk for Alzheimer's disease, underscored by concepts like 'cognitive reserve' and 'brain maintenance'. The Resilience Index (RI), a composite of 6 factors (cognitive reserve, physical and cognitive activities, social engagement, diet, and mindfulness) provides such a holistic measure.
Objectives: This study aims to examine the association of RI scores with cognitive function and assess the mediating role of cortical atrophy.
Methods: Baseline data from 113 participants (aged 45+, 68% female) from the Healthy Brain Initiative were included. Life course resilience was estimated with the RI, cognitive performance with Cognivue®, and brain health using a machine learning derived Cortical Atrophy Score (CAS). Mediation analysis probed the relationship between RI, cognitive outcomes, and cortical atrophy.
Results: In age and sex adjusted models, the RI was significantly associated with CAS (β= -0.25, p = 0.006) and Cognivue® scores (β= 0.32, p < 0.001). The RI-Cognivue® association was partially mediated by CAS (β= 0.07; 95% CI [0.02, 0.14]).
Conclusions: Findings revealed that the collective effect of early and late-life lifestyle resilience factors on cognition are partially explained by their association with less brain atrophy. These findings underscore the value of comprehensive lifestyle assessments in understanding the risk and progression of cognitive decline and Alzheimer's disease in an aging population.

doi: 10.1192/j.eurpsy.2025.1686

Introduction: Children with Noonan syndrome, the most prevalent RASopathy, exhibit a characteristic neurocognitive phenotype. Specific difficulties in learning, memory, and executive function are among the most frequently observed manifestations documented in the scientific literature.
Objectives: The present study aimed to measure specific learning difficulties and intelligence in children with RASopathies.
Methods: A total sample of 47 patients (55.3% male) aged 3–16 years (M = 8.6, $S.D.$ = 3.1) was recruited from various Spanish regions (Murcia, Alicante, Gandía, Valencia, Castellón de la Plana, Tarragona, Cantabria, Asturias, Zaragoza, Madrid, Badajoz, Huelva, Sevilla and Cádiz), within the framework of The Grey Matter project. Most patients were diagnosed with Noonan syndrome, and some had Cardiofaciocutaneous syndrome. The most frequent mutations were PTPN11 (72.3%), RIT1 (6.4%), and unknown mutations in 12.8% of patients. Patients were assessed using the Spanish version of the Wechsler Preschool and Primary Scale of Intelligence, Fourth Edition (WPPSI-IV) or the Wechsler Intelligence Scale for Children, Fifth Edition (WISC-V) according to age; the Spanish Reading Processes Evaluation Battery (PROLEC) according to the appropriate age range (from 6 years); and the Spanish Writing Processes Evaluation Battery (PROESC), from 8 years.
Results: On the one hand, 32.3% presented with severe difficulty in reading words. In turn, 30% of the children showed severe difficulty in reading comprehension of texts when they were read by an examiner, and 29% after reading by themselves. On the other hand, 56% of the children presented severe orthographic difficulty in writing words and 50% presented severe difficulty in written expressions. Finally, regarding intelligence, the mean total IQ of the children was 84.7 points ($S.D.$ = 15.1), with better scores on the Verbal Comprehension Index (M = 89.4; $S.D.$ = 16), Visual Spatial Index (M = 87.7; $S.D.$ = 13.8), and Fluid Reasoning Index (M = 88.6; $S.D.$ = 11.9), in contrast with the Working Memory Index (M = 84.3; $S.D.$ = 13.2), and the Processing Speed Index (M = 83.2; $S.D.$ = 14.4). In turn, 42.6% of children had low global intelligence scores (IQ ≤ 79).
Conclusions: In conclusion, children with RASopathies, particularly those diagnosed with Noonan syndrome, need educational support to compensate for all these significant academic difficulties.

Everyday Executive Functioning in Paediatric Patients Awaiting Solid Organ or Haematopoietic Stem Cell Transplantation

J. Garrido-Bolton[1,2], M. F. Bravo-Ortiz[1,2,3,4], R. de la Vega[5,6], A. Pérez-Martínez[2,7,8,9] and E. Fernández-Jiménez[1,2,10]*

[1]Department of Psychiatry, Clinical Psychology and Mental Health, La Paz University Hospital; [2]Hospital La Paz Institute for Health Research (IdiPAZ); [3]Department of Psychiatry, Universidad Autónoma de Madrid (UAM); [4]Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red de Salud Mental (CIBERSAM), Madrid; [5]University of Málaga, Department of Personality, Evaluation and Psychological Treatment; [6]Instituto Biomédico de Málaga – IBIMA Plataforma Bionand, Málaga; [7]Department of Pediatric Hemato-Oncology, La Paz University Hospital; [8]Spanish National Cancer Research Center (CNIO), CIBERER-ISCIII. IdiPAZ-CNIO Pediatric Onco-Hematology Clinical Research Unit; [9]Department of Pediatrics, Universidad Autónoma de Madrid (UAM), Madrid and [10]Faculty of Social Sciences and Communication, Universidad Europea de Madrid, Villaviciosa de Odón, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1687

Introduction: Paediatric patients with severe diseases awaiting solid organ or haematopoietic stem cell transplantation are known to experience cognitive impairments, particularly in executive functioning. Neuropsychological pre-transplant evaluation serves as a baseline for identifying executive functioning deficits that may affect the medical and psychosocial aspects of care. This is clinically relevant because patients with poorer executive functioning may show decreased adherence to medical treatments, face greater challenges in coping with their illness, and be more likely to require educational adaptations, including curricular or methodological adjustments based on pedagogical criteria.
Objectives: This study aimed to assess everyday executive functioning in paediatric patients awaiting transplantation using an ecologically valid measure.
Methods: A total of 49 patients (59.2% male) aged between 6 and 18 years (M = 11.4, $S.D.$ = 3.5) were recruited from La Paz University Hospital (Madrid, Spain). Patients were awaiting for various types of organ transplants (kidney: 26, heart: 4, lung: 4, hepato-renal: 3, or liver: 2 patients) or haematopoietic stem cells (10 patients). Patients were assessed using the Spanish parent-reported version of the *Behavior Rating Inventory of Executive Function, Second Edition* (BRIEF-2) with age- and sex-adjusted norms from the Spanish general population. The three BRIEF-2 composite scores were analysed (the Cognitive, Emotional and Behavioral Regulation Indexes), and clinically relevant scores were set at $T \geq 65$ points.
Results: Clinically significant levels of executive deficits were observed in 33.3% of patients regarding cognitive regulation problems, in 32.7% regarding emotional regulation difficulties and in 26.5% regarding behavioural regulation problems.
Conclusions: Between 1 in 4 and 1 in 3 patients have shown some type of executive regulation difficulties. The early identification of executive functioning deficits in paediatric transplant candidates is crucial. Incorporating standardised ecologically valid measures, such as the BRIEF-2, into routine assessments can help detect neuropsychological impairments at an early stage, allowing timely therapeutic or preventive interventions (e.g., psychological prehabilitation). This approach can improve medical outcomes and quality of life and guide educational adaptations to support academic performance.

Cognitive function and cannabis use in first episodes of psychosis

P. Fuentes-Pérez[1*], P. Cordero Andrés[1,2], C. Ovejas-Catalán[1], R. Pérez Iglesias[1,2,3], P. Suárez Pinilla[1,2,3], C. Flor Gómez[1,2], D. De la Sierra Biddle[2], M. L. Ramírez Bonilla[1,2] and J. Vázquez-Bourgon[1,2,3]

[1]Valdecilla Biomedical Research Institute - IDIVAL; [2]Psychiatry Department, University Hospital Marqués de Valdecilla and [3]University of Cantabria, Santander, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1688

Introduction: The association between cannabis use and cognitive functioning in individuals experiencing a first episode of psychosis (FEP) is inconsistent, with some studies reporting deterioration (Bogaty et al. J Psychiatr Res 2018; 99:22-32), others indicating improved performance (Rodríguez-Sánchez et al. Schizophr Res 2010; 124:142-151), and some finding no difference.
Objectives: This study aims to evaluate the effect of cannabis use on cognitive functioning among individuals diagnosed with FEP.
Methods: A cross-sectional study was conducted on FEP patients enrolled in the ITPCan Program (Santander, Spain) between January 2020 and July 2024. A total of 207 participants (57 cannabis users and 145 non-users) with a FEP diagnosis were included. A descriptive-univariate analysis was performed on clinical, analytical, and cognitive variables. A Student's t-test compared baseline cognitive performance between cannabis users and non-users, while a multivariate general linear model (GLM) assessed differences related to cannabis consumption, adjusting for sex, age, and educational level. Statistical analyses were performed using SPSS.
Results: Out of the 207 FEP participants, 53.6% were women, with an average age of 36.8 years. Cannabis users comprised 28.1% of the group, and present at baseline a lower mean age at intake (27 years; $p < 0.001$). Cannabis users exhibited significantly higher scores in mania and positive psychotic symptoms. Cognitive assessments, completed by 148 patients (39 users and 108 non-users), revealed that cannabis users performed better than non-users on "processing speed" task; however, after adjusting for sex, age, and educational level, these differences were attributed to educational level and sex.
Conclusions: In consonance with some previous studies (Sánchez-Gutiérrez et al. Eur Psychiatry 2020; 63(1)), cannabis use does not appear to be a determining factor in cognitive performance in early psychosis.

EPV1077

Neuropsychiatric Effects of HIV and Toxoplasma Gondii Encephalitis: A Case Study

T. Incekurk Kizilca[1*] and B. Yildirim Cinek[1]

[1]Psychiatry, Health Sciences University Erenkoy Mental Health and Neurological Diseases Training and Research Hospital, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1689

Introduction: HIV infection can lead to neurological and psychiatric disorders by affecting the central nervous system. Toxoplasma gondii can cause encephalitis in immunocompromised individuals, particularly damaging brain regions such as the frontal cortex and basal ganglia. These neuroanatomical disruptions can influence dopaminergic and serotonergic neurotransmitter pathways, resulting in severe neuropsychiatric symptoms like behavioral disinhibition, personality changes, and psychotic manifestations (Vidal JE. J Int Assoc Provid AIDS Care 2019; 18:2325958219867315).
Objectives: This case seeks to demonstrate the neuropsychiatric effects of HIV and Toxoplasma gondii infections on neuronal function and behavior, emphasizing the importance of continuous assessment and integrated treatment approaches.
Methods: A 49-year-old male patient, with no known medical history, developed Toxoplasma gondii encephalitis after being diagnosed with HIV. Following discharge from the infectious disease ward, the patient exhibited increased irritability, impulsivity, hypersexuality, visual hallucinations, disorganized speech, and risky behaviors, along with cognitive dysfunction and social norm violations. The patient's symptoms partially improved with a treatment regimen of 15 mg olanzapine and 1000 mg valproic acid. However, the patient's ongoing course, parkinsonism symptoms emerged, prompting the discontinuation of valproic acid and the consideration of quetiapine. The patient's follow-up treatment is ongoing.
Results: HIV and Toxoplasma gondii disrupt neuronal function through inflammatory responses and microglial activation in the central nervous system. HIV does not directly damage neurons, but inflammation from cytokines released by microglia can lead to neurodegenerative conditions. Dopaminergic dysfunction is linked to psychotic symptoms, while serotonergic disruptions contribute to depression and anxiety. Frontal lobe and basal ganglia damage impair executive functions (planning, decision-making, impulse control), causing increased impulsivity, risky behaviors, emotional dysregulation, irritability, lack of empathy, behavioral disinhibition, hypersexuality, and cognitive dysfunction. These changes are tied to structural damage in the frontal cortex, necessitating long-term follow-up and comprehensive treatment. Diagnostic imaging often shows white matter lesions, basal ganglia damage, and frontal cortex atrophy. Treatment involves antiretroviral therapy, low-dose antipsychotics, mood stabilizers for managing symptoms (Bartolomé Del Pino LE *et al.* Actas Esp Psiquiatr 2024; 52(2):149-60).
Conclusions: HIV and Toxoplasma gondii infections induce significant central nervous system impairment, leading to neuropsychiatric disorders. This case illustrates their impact on neurotransmitter systems, manifesting as psychosis, cognitive dysfunction, and behavioral disturbances. Continued monitoring and comprehensive treatment are essential.

Relationships between parameters of EEG and glutamate-ergic system activity in patients with depressive-delusional disorders

A. F. Iznak[1*], ?. V. Iznak[1], A. F. Beresneva[1], O. K. Savushkina[2] and I. S. Boksha[2]

[1]Laboratory of Neurophysiology and [2]Laboratory of Neurochemistry, Mental Health Research Centre, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1690

Introduction: Activity of the glutamate neurotransmitter system contribute to the development of many mental disorders, in particular of depression and schizophrenia. While the glutamate is the principal excitatory neurotransmitter in the brain there are poor data on its relationships with EEG.
Objectives: The aim of the study was to search for possible relationships between parameters of EEG and glutamate dehydrogenase (GDH) activity in patients with depressive-delusional disorders.
Methods: The study involved 28 female in-patients aged 16-35 years (mean age 22.0 ± 8.1 years) with depressive-delusional disorders in the frames of schizophrenia (F20.01, by ICD-10). Pretreatment multichannel resting EEG recordings with spectral power analysis in narrow frequency sub-bands were performed in all patients. Patients were divided into two groups with relatively "normal" (n=18) and "slow" (n=10) EEGs. "Slow EEG" group statistically differed (p<0.05) from "normal EEG" group by greater spectral power values in theta2 (6-8 Hz) EEG sub-band in frontal-central-temporal regions of the left hemisphere. GDH enzymatic activity was measured in platelets' extracts from blood samples by spectrophotometric kinetic method and was assessed by the rate of NAD•H absorption decrease at 340 nm. The descriptive statistics and the rank correlation analysis (Spearman) were used for statistical processing of EEG and neurochemical data.
Results: "Slow EEG" and "normal EEG" groups did not statistically differ (p>0.05) in age, HDRS and PANSS scores, while the clinical severity was somewhat greater in "slow EEG" group. Nevertheless, "slow EEG" and "normal EEG" groups apparently differed in correlation structure between EEG and GDH activity parameters. Thus, in "slow EEG" group values of GDH activity correlated positively (p<0.05÷0.01) with values of spectral power in delta (2-4 Hz), theta1 (4-6 Hz) and theta2 (6-8 Hz) EEG sub-bands. In "normal EEG" group values of GDH activity did not correlate with any studied EEG parameters.
Conclusions: Greater GDH activity in "slow EEG" group of patients with depressive-delusional disorders have to provoke the glutamate mediated excitation deficit reflected in EEG slowing. The predominance of this phenomenon in the left hemisphere may underlie some features of the clinical conditions in these patients and need further studying.

Temporal-lobe functional connectivity in future converters to Alzheimer's disease

Y. R. Panikratova[1], A. Y. Komarova[1]*, E. G. Abdullina[1], O. V. Bozhko[2], N. S. Cherkasov[3], I. V. Kolykhalov[3] and I. S. Lebedeva[1]

[1]Laboratory of neuroimaging and multimodal analysis; [2]Department of radiology and [3]Department of gerontological psychiatry, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1691

Introduction: Preclinical stages of Alzheimer's disease (AD) are characterized by structural and neurochemical abnormalities in temporal lobe and temporoparietal junction (T-TPJ; Popuri *et al.* Hum Brain Mapp 2020; 41 4127-4147; Jagust. Nat Rev Neurosci 2018; 19 687-700). However, the role of functional characteristics of T-TPJ in conversion to AD is understudied.
Objectives: Our aim was to clarify whether any patterns of functional connectivity (FC) within T-TPJ differentiate patients with amnestic mild cognitive impairment (aMCI) and future conversion to AD from stable aMCI and healthy controls.
Methods: Patients with aMCI and future conversion to dementia due to AD (converters, $n = 15$; mean age 74.31 ± 7.86), patients with stable aMCI (non-converters, $n = 12$; mean age 66.77 ± 9.54), and healthy individuals without cognitive deficits ($n = 29$; mean age 64.17 ± 11.30) underwent resting-state fMRI (3T Philips Ingenia scanner). Eighteen T-TPJ cortical ROIs in each hemisphere were defined according to Harvard-Oxford atlas (Desikan *et al.* Neuroimage 2006; 31 968-980). FC between these ROIs was compared between groups separately for each hemisphere (one-way ANCOVA with connection threshold $p[FDR] < 0.05$ and *post hoc* between-group comparisons). Age, sex, and number of outlier scans due to motion were included into the models as covariates of no interest. The analyses were implemented via CONN (RRID: SCR_009550; www.nitrc.org/projects/conn).
Results: FC between the posterior parts of left middle and inferior temporal gyri was different between converters, non-converters, and healthy individuals ($p[FDR] = .0256$). Converters demonstrated an increased FC between these regions compared to other groups ($p = .0003$ for both tests). We also observed a trend for inverse correlation between this FC and delayed recall of words (MoCA) in the entire sample ($p = .055$).
Conclusions: An increased FC between the temporal brain regions may reflect either pathological processes that have already started, or compensatory mechanisms, or both in future converters to AD. The posterior part of left middle temporal gyrus is critical for auditory verbal memory, whereas the posterior inferior temporal cortex in the left hemisphere stores visual images associated with a word. The observed trend-like correlation might indicate that patients with worse auditory verbal memory rely on visual images associated with a word, however, this assumption should be supported in further studies.
The study was supported by RSF grant 24-15-00220.

Central effects of soluble factors derived from human macrophages, polarized to M2 phenotype, in depression

E. Markova[1]*, E. Serenko[1], M. Knyazheva[1], E. Shevela[2], M. Tikhonova[3] and T. Amstislavskaya[4]

[1]Neuroimmunology Lab; [2]Cellular Immunotherapy Lab, State Research Institute of Fundamental and Clinical Immunology; [3]Neurobiological mechanisms of neurodegenerative processes Lab and [4]Experimental models of neuropsychiatric disorders Lab, State Research Institute of Neurosciences and Medicine, Novosibirsk, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1692

Introduction: In depressive disorders caused by chronic psychological stress, cognitive decline is produced by neuroinflammatory and neurodegenerative changes in the brain. M2-type macrophages possess high pronounced regenerative potential due to high production of neurotrophic, neuroprotective and angiogenic factors. We have previously shown that M2 macrophage-derived soluble factors (M2-SFs) edit stress-induced depressive-like behavior.

Objectives: The aim of the study was to investigate the central effects of soluble factors derived from human macrophages, polarized to M2 phenotype (M2-SFs) involved in the mechanisms underlying the editing of depressive-like behavior.
Methods: Human macrophages were polarized polarised to M2 phenotype under serum deprivation conditions. Stress-induced depression-like male mice were undergoing intranasal administration of M2-SFs during 7 days. After which an immunohistochemical analysis was performed assessing the expression of the microglial marker Iba1. The levels of brain-derived neurotrophic factor (BDNF) and cytokines in separate structures of the brain were assessed by ELISA. For histological examination Nissl staining was applied.
Results: Depressive-like behavior editing after the M2-SFs administration was registered against the background of some structural and functional changes in the brain. It was found an increase in the density of pyramidal neurons in the frontal cortex and augmented level of BDNF in this brain structure and also in the hippocampus. After the introduction of the M2-SFs in depressive-like mice the decreased expression of the microglial marker Iba1, accompanied with decreased levels of pro-inflammatory cytokines IL-1β, IL-6, TNF-α, INF-γ in pathogenetically significant structures of the brain was also observed.
Conclusions: The data obtained indicate that the depressive-like behavior-editing effect of M2 macrophage-derived soluble factors is mediated by stimulating neurogenesis, neuroplasticity and reducing neuroinflammation.

EPV1085

Efficacy of Left Prefrontal Transcranial Direct Current Stimulation in Improving Negative Symptoms and Acutely Enhancing Attention Functions

H. Noyan[1]*, G. Eskikurt[2], A. Verkhovets[3], N. Zeren[4], H. Yeşilkaya[5] and A. Üçok[4]

[1]Department of Psychology, Ankara University, Ankara; [2]Department of Psychology, Istinye University Faculty of Humanities and Social Sciences; [3]Master Degree Programs of Clinical Psychology , Beykoz University Institute of Graduate Programs; [4]Department of Psychiatry, Istanbul University Istanbul Medicine Faculty and [5]Bakirkoy Training and Research Hospital for Psychiatry, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1693

Introduction: Negative symptoms and cognitive deficits in schizophrenia (SZ) significantly affect patients' quality of life and functionality, but show limited response to antipsychotic treatment.
Objectives: The present study aims to investigate the acute (n=32) and one-month (n=25; active-tDCS:13 vs. sham-tDCS:12) effects of repeated transcranial Direct Current Stimulation (tDCS) on negative symptoms and executive attention in recent-onset SZ.
Methods: In this study, 32 clinically stable SZ patients (age:24.7 ±4.5, 65% male) with a disease duration under 5 years were included in a single-blind, randomized sham-controlled trial. Patients received 10 sessions of either active-tDCS (n=17) or sham-tDCS (n=15) (anode: left dorsolateral prefrontal cortex, DLPFC; cathode: right orbitofrontal region) at 2 mA for 20 minutes, twice daily, across 5 consecutive days and were followed up after the 10th tDCS on day 5 (acute effect), and at weeks 2 and 4. Pre- and post-tDCS assessments included the Brief Negative Symptom Scale (BNSS), Brief Psychiatric Rating Scale (BPRS), Calgary Depression Scale for SZ (CDSS), Global Assessment of Functioning (GAF), Clinical Global Impression Scale, Verbal Fluency Test (VFT), and the Penn Computerized Neurocognitive Battery's Letter N-Back and Continuous Performance Test (CPT). One-way ANCOVA was used to assess between-group changes over time, controlling for pre-tDCS measurements, while mixed-design ANOVA explored time × tDCS-group interactions, followed by repeated measures ANOVA to assess within-group effects. Pairwise comparisons over time within each group were examined using a post-hoc Bonferroni test.
Results: The active-tDCS group showed significant acute improvements in Avolition-Apathy (AA) ($F_{(1,29)}$=13.55, p<0.001, pη^2=0.319) and Expressive Deficit (EXP) ($F_{(1,29)}$=4.66, p=0.039, pη^2=0.138) domains, BNSS-total ($F_{(1,29)}$=25.12, p<0.001, pη^2=0.464), BPRS-General Psychopathology ($F_{(1,29)}$=19.68, p<0.001, pη^2=0.404), CDSS ($F_{(1,29)=}$8.16, p=0.008, pη^2=0.22) scores, VFT-phonemic fluency ($F_{(1,29)}$=11.98, p=0.002, pη^2=0.292) and CPT ($F_{(1,29)}$=5.29, p=0.029, pη^2=0.154) performances compared to sham-tDCS. Time-group interactions were significant in BNSS-AA domain ($F_{(1,21)}$=16.44, p<0.001, pη^2=0.701), BNSS-total ($F_{(1,21)}$=15.77, p<0.001, pη^2=0.693), and BPRS-General Psychopathology ($F_{(1,21)}$=6.42, p=0.003, pη^2=0.479). Following the mixed-design ANOVA, repeated measures analyses showed significant score decreases over time in the active-tDCS, while the sham group showed no significant changes or a slight increase (only for BNSS-total scores) (Fig. 1).

Image 1:

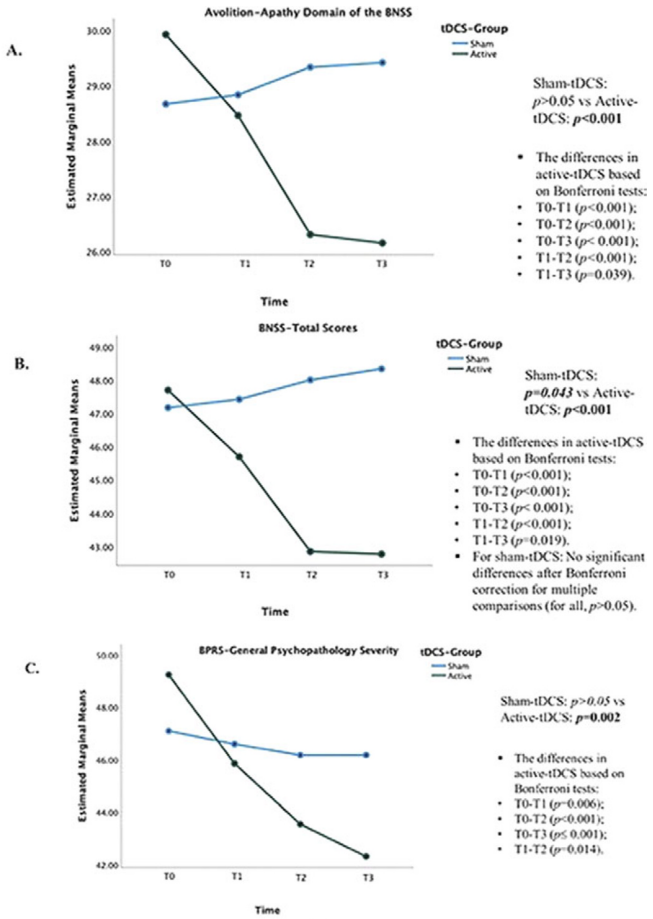

Fig. 1. Changes in Clinical Subscale Scores of tDCS Groups Over Time: Results of repeated measures ANOVA and post-hoc Bonferroni test. **A.** Changes in Avolition-Apathy domain; **B.** Changes in BNSS-Total scores; **C.** Changes in BPRS-General Psychopathology severity. **Notes:** T0 = Baseline/Pre-tDCS assessments; T1 = Post-tDCS assessments on day 5; T2 = Post-tDCS assessments at the 2nd week; T3 = Post-tDCS assessments at the 4th week. Abbreviations: BNSS, Brief Negative Symptom Scale; BPRS, Brief Psychiatric Rating Scale.

Conclusions: The present results suggest that anodal tDCS over the left DLPFC may be effective in alleviating negative symptoms, reducing general psychopathology severity, and acutely enhancing complex attention functions and working memory in recent-onset SZ.

Neuropsychiatric manifestations of Brain Sagging Syndrome. Case report and Literature review

L. C. Ortega Sandoval[1]*, E. Lanchares Balboa[1], E. Abalde Garcia[1] and J. I. Vizoso[1]

[1]Hospital Alvaro Cunqueiro, Vigo, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1694

Introduction: The presentation of psychotic symptoms in adults requires a global medical assessment, especially in cases of atypical presentations or if warning signs are present. The presence of cognitive symptoms and behavioral changes requires screening for various neurological diseases.
Objectives: Underline the importance of neurological evaluation in atypical psychotic conditions with cognitive and behavioral symptoms. Describe Brain Sagging Dementia as a possible etiology of these conditions.
Methods: Presentation of clinical case and bibliographic review.
Results: The clinical case of a 59-year-old female patient brought to the emergency department for psychiatric evaluation due to behavioral alterations is described. During the evaluation, paranoid symptoms were detected, with marked suspicion towards her family, which led to her admission for psychiatric hospitalization. During observation, the clinical history was completed, revealing marked changes in behavior, apathy, perseveration, and decreased functionality for more than five years. Neuropsychological tests were performed, where cognitive and visuospatial alterations were evident. A consultation with the neurology service was requested, who initially considered the diagnosis of behavioral-variant frontotemporal dementia.
Given the history of orthostatic headaches secondary to cerebrospinal fluid hypotension due to a dorsal fistula, a new brain MRI was performed, which found evidence of cerebrospinal fluid hypotension without frontotemporal atrophy. Given all the clinical and radiological findings, a possible diagnosis of Brain Sagging Dementia was considered.
Brain Sagging Dementia is a rare syndrome caused by spontaneous intracranial hypotension (SIH), which mimics the behavioral clinical findings of frontotemporal dementia (bvFTD), excluding it due to the absence of frontotemporal atrophy. It is insidious in nature, with gradual cognitive and behavioral alterations.
The first-line treatment is an epidural blood patch, with partial resolution of symptoms in up to 81% of cases and complete resolution in up to 67%.
In this case presented, the patient is awaiting evaluation by neurosurgery.
Conclusions: In case of suspected neurological origin of psychiatric symptoms, a complete evaluation is essential with special attention to potentially reversible causes.
It is important to keep in mind the neuropsychiatric manifestations that can occur in dementia and other neurology conditions, to avoid delaying a correct diagnosis. These include behavioral alterations, psychotic symptoms, eating disorders, as well as affective disorders ranging from apathy and depression to expansiveness with signs of disinhibition.
Brain sagging dementia is a reversible condition with symptoms of bvFTD, whose early diagnosis and treatment significantly improve the medical prognosis.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1695

Introduction: Neuroimaging studies show that schizophrenia is linked to reduced grey and white matter volumes and increased cerebrospinal fluid. Cannabis use, a widely known risk factor for psychosis, is associated with poorer clinical outcomes, although the mechanisms underlying this association remain unknown.
Objectives: This study aims to explore the effect of cannabis use on brain volumes in individuals with a first episode of psychosis, comparing users and non-users.
Methods: A cross-sectional study with 207 participants was conducted at the Cantabria Early Psychosis Intervention Program (ITPCan) in Santander, Spain, from January 2020 to July 2024. Clinical, sociodemographic, and cannabis use data were collected. Structural magnetic resonance imaging (sMRI) scans were obtained using a Philips 3.0T MRI machine with T1-weighted sequences. Voxel-based morphometry (VBM) analysis was conducted using the CAT12 toolbox to assess relative volume measures of white matter (WM), gray matter (GM), and cerebrospinal fluid (CSF), accounting for individual differences.Statistical analyses were performed by SPSS 23.0, with a significance of 0.05, including mean comparisons and multivariate analysis of covariance controlling for age, sex, and educational level.
Results: Out of the total sample, 106 patients underwent sMRI, including 44 men and 62 women, with an average age of 36.9 years. In terms of education, 47.2% had achieved basic level, while 52.8% had higher education. Regarding cannabis-related variables, 28 participants (26.5%) were identified as users; the average age of initiation was 17.1 years, with consumption occurring around 6.5 days per week and 6. 7 joints per day.
Non-user group showed slightly higher mean CSF and WM volumes compared to users (CSF=18.65 vs. 17.56; WM=36.49 vs.35.99), but these differences did not reach statistical significance ($p= 0.154$; $p = 0.265$). In contrast, cannabis users showed a significantly greater relative mean GM volume (46.37 vs. 45.12, $p = 0.037$).

However, these differences did not reach statistical significance after adjusting for age, sex, and education.
Conclusions: Cannabis use is associated with greater GM volumes among individual with a first episode of psychosis. However, these differences did not remain significant after adjusting for age sex and education. GM differences could largely be attributed to the age disparity between both groups, with cannabis users being significantly younger than non-users (27 vs. 40.8 years).
Further research into the underlying mechanisms and long-term studies are needed to provide a clearer understanding of how cannabis use affects brain structure over time.

Urinary nighttime and first morning cortisol levels in patients with Prolonged Grief Disorder (PGD) and healthy controls: early outcomes

V. Pedrinelli[1,2*], V. Dell'Oste[1,2], S. Fantasia[1], A. Bordacchini[1], B. Rimoldi[1], L. Parrini[1], D. Andreoli[1], D. Gravina[1], L. Palego[1], G. Giannaccini[1], L. Betti[1] and C. Carmassi[1]

[1]University of Pisa, Pisa and [2]University of Siena, Siena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1696

Introduction: Prolonged Grief Disorder (PGD) has been recently included in the "Trauma and Stressor-Related Disorders" chapter of the latest edition of the DSM (DSM-5-TR), being fully acknowledged among mental disorders. PGD extend the period of acute grief and increase the risk for a wide range of health impairments. The availability of biomarkers for mental disorders is thought to be crucial in the development of precision psychiatry. The hypothalamus-pituitary-adrenal (HPA) axis activity and cortisol reactivity have frequently been investigated in mental disorders. Data on neurobiology of PGD is lacking. Some studies found that PGD might be associated with increased HPA axis activity and impaired autonomic nervous system regulation.
Objectives: Aim of the present study was to examine the levels of cortisol excreted in urine during the night and first morning and to assess any differences and specificity of HPA axis functioning in a group of individuals with PGD and in one of healthy controls.
Methods: Thirthy-three subjects, comprising 16 subjects diagnosed with PGD (PGD group) and 17 controls (CTL group), were recruited at the Psychiatric Clinic of the University of Pisa (Pisa, Italy). Psychometric assessments included: the Structured Clinical Interview for Mental Disorders-Clinician Version (SCID-5-CV), the Inventory of Complicated Grief (ICG) and the Impact of Events Scale-Revised (IES-R). Enrolled subjects, previously informed on collection procedures, delivered urine samples to the health care providers the same day of the clinical evaluation. Urine cortisol levels were measured by indirect enzyme-linked immunosorbent assays (ELISAs). Analyses were carried out at the Department of Pharmacy of the University of Pisa. Between-groups differences were performed by the non-parametric Mann-Whitney (MW). A p-value <.05 was considered statistically significant.
Results: Descriptive results showed a higher variability (SDs and interquartile ranges) of urinary cortisol levels (total
μg) in the PGD group in respect to the CTL one; by inferential statistics, MW comparisons showed significantly higher urinary cortisol levels in PGD group vs CTL one (p< .05).
Conclusions: Results report that PGD patients had impaired cortisol outputs with respect to control subjects, suggesting a different pattern of production of the hormone during the night and the sleep-wake shift. If this prelimary data will be confirmed in wider samples, there will be a need to understand whether the increased cortisol profile reported in PGD may be due to increased production of the hormone at night (sleep alterations), to an increased peak on awakening (hyperarousal) or both conditions. Such findings might help to define more accurate patient-tailored therapeutic interventions.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1697

Introduction: The Locus Coeruleus (LC), the first brain region affected by TAU aggregates in Alzheimer's disease (AD), is the primary source of noradrenaline (NA). Given the importance of NA in cognitive functions, noradrenergic interventions may benefit patients with AD pathology.
Objectives: This study aims (i) to examine memory delay and related fMRI activations in brainstem and midbrain regions in healthy aging and amnestic mild cognitive impairment (aMCI); and (ii) to explore the impact of atomoxetine on memory delay and inhibitory control in aMCI.
Methods: For aim (i), event-related fMRI was used. Fifty-three subjects (28 healthy older adults and 25 with aMCI) completed an incidental recognition memory task with emotional and neutral images. Memory tests were administered four hours later, brain BOLD fMRI activations for remembered versus not remembered images were assessed. For aim (ii), seven participants attended the lab over four days. On visit 1, they received either a placebo or atomoxetine, followed by a stop signal task and an incidental memory task. On visit 2, they completed a recognition memory

task. Visits 3 and 4 repeated this protocol. T-tests were used to compare results between groups and visits.
Results: For aim (i), a greater activation in the left caudate nucleus was observed in older adults compared to aMCI when contrasting remembered items with not remembered ones (SVC, cluster-level pFWE-corr = 0.08). A significant increase in activation was also found in the locus coeruleus (SVC, cluster-level pFWE-corr = 0.018). However, after adjusting for LC integrity and global grey matter volume (GMV), these differences were no longer significant, suggesting structural changes contribute to LC activation differences between healthy controls and MCI participants. For aim (ii), inhibitory control improved slightly but was not statistically significant, while delayed memory decreased during the atomoxetine visit compared to the placebo visit ($p<.05$).
Conclusions: Our findings highlight the caudate nucleus's role in memory encoding in healthy older adults versus those with aMCI, linking LC dysfunction in aMCI to reduced LC integrity. The lack of improvement in executive functions and decreased memory during the atomoxetine visit may stem from individual differences in aMCI. Studies suggest atomoxetine is more effective in patients with high apathy and reduced LC integrity. In future analyses we will stratify participants by apathy and LC integrity to explore atomoxetine's potential benefits. This study contributes to understanding neural mechanisms in aging and aMCI and informs personalized interventions for cognitive decline in AD.

Queipo de Llano de la Viuda[1]

[1]Hospital Clinico Universitario de Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1698

Introduction: Lewy Body Dementia (LBD) is the second most common neurodegenerative disease, after Alzheimer's disease. Initial neuropsychiatric manifestations such as depression, delusions and hallucinations are frequently observed and sometimes make it difficult to diagnose the neurocognitive disorder underlying the symptoms, so it is important to perform a proper clinical examination, as the use of certain neuroleptics may worsen neurological symptoms.
Objectives: This case aims to investigate the psychiatric clinical features of Lewy body dementia from a clinical and therapeutic perspective.
Methods: A comprehensive search on psychiatric manifestations that may cover up dementia.
Results: 71-year-old female with depressive symptoms for the last 8 years. She is admitted to a psychiatric inpatient unit due to worsening of depressive symptoms despite correct adherence to treatment. Her psychiatric history includes a diagnosis of specific phobia, obsessive-compulsive disorder and depressive episodes with inhibitory symptomatology.
During her stay at the hospital, the patient is inhibited, perplexed and experiences feelings of embarrassment and guilt, along with persistent insomnia and poor response to different lines of treatment. Initially, there is notable intolerance to antipsychotics, resulting in worsening of motor and cognitive functions, as well as hypotension, using risperidone and olanzapine. After the withdrawal of treatment, the patient begins to exhibit delusional ideas and visual hallucinations, leading us to consider that she may be suffering from depression associated with an undiagnosed organic brain pathology. Clinical tests (MoCA,MMSE) reveals cognitive symptoms which, along with the motor symptoms, suggests a Parkinson's-dementia complex.
A PET-CT scan with fluorodeoxyglucose-F18 reveals severe hypometabolism in the left parietotemporal and prefrontal regions. These findings are consistent with LBD.
Treatment is initiated with rivastigmine and quetiapine. However, due to the presence of hypotension, quetiapine is replaced with clozapine 25 mg, resulting in a slight improvement in rest and affective responses to the psychotic symptoms.
Conclusions: This case illustrates how depression and psychotic symptoms can serve as early indicators of dementia, stemming from the loss of dopaminergic and acetylcholinergic pathways as part of the neurodegenerative process.
These patients may present with a range of cognitive, neuropsychiatric, sleep, motor, and autonomic symptoms. Depression is prevalent in approximately 28% of these patients. Currently, clinicians diagnose LBD based on the presence of core clinical features and indicative biomarkers. Treatment can be complicated by patients' sensitivity to certain medications, needing careful evaluation of potential side effects. Current guidelines recommend the use of antipsychotics such as quetiapine or clozapine at low doses, as these have a reduced risk of extrapyramidal effects.

doi: 10.1192/j.eurpsy.2025.1699

Introduction: Depression is a prevalent disease and 30% of affected patients are resistant to pharmacological treatment. Home-Based

transcranial Direct Current Stimulation (HB-tDCS) has been proposed as a treatment option due to its low cost, minimal invasiveness, and scalability.
Objectives: We present preliminary results on safety, feasibility and efficacy of a remotely supervised HB-tDCS intervention in patients with treatment-resistant depression.
Methods: 7 patients (5 women, age =55.67 ± 6.93) underwent a psychiatric evaluation, pre and post stimulation, that included the Montgomery-Asberg Depression Rating Scale (MADRS), the Beck Depression Inventory (BDI), and the Quick Inventory of Depressive Symptomatology (QIDS). HB-tDCS intervention consisted of 42 daily sessions administered through the Sooma tDCS™ device by a patients' companion, trained by the research team. The anode was placed on the left prefrontal cortex, the cathode on the right prefrontal cortex, and 2mA current was delivered for 30 minutes. After each session participants fulfilled an on-line survey for monitoring safety and feasibility.
Results: 86.73% of the sessions were completed. Due to impedance 7.84% of the sessions could not start on the first attempt, while 7.45% of the session were temporarily interrupted. Adverse effects included headaches (9.67%), sensations under electrodes (24.89%), and scalp dryness (7.88%).
We observed a significant reduction in depressive symptomatology as measured by the MADRS (-33.56%; t=-7.99, p<0.001). All patients showed partial response (>25%), and two a relevant response (>50%).
Self-reported scales indicated a reduction in symptomatology (QIDS:-21.66; t=-3.139, p=0.010; BDI:-13.92%; t=-1.780, p=0.063).
Conclusions: In line with previous studies, these results indicate that HB-tDCS is a feasible, safe, and potentially effective intervention for treatment of resistant depression.

Simultaneous G9a inhibition and histamine H3 receptor antagonism modulate autism-like behaviours and neuroinflammation in BTBR T+tf/J Mice

M. Hajar[1], H. Stark[2] and B. Sadek[1]*

[1]Pharmacology and Therapeutics, College of Medicine and Health Sciences, Al Ain, United Arab Emirates and [2]Institute of Pharmaceutical and Medicinal Chemistry, Heinrich Heine University Düsseldorf, Düsseldorf, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1700

Introduction: Autism Spectrum Disorder (ASD) is a complex neuropsychiatric disorder characterized by deficits in social interaction, anxiety and the presence of repetitive-ritualistic behaviours. Recent studies suggest that epigenetic mechanisms, such as histone methylation, play a crucial role in the etiology of ASD by regulating gene expression linked to neuronal differentiation and proliferation. The enzyme, G9a is responsible for histone H3K9 methylation, and its inhibition has shown promise in altering epigenetic pathways associated with ASD onset and progression. Similarly, histamine H3 receptor (H3R) has long been recognized as a potential therapeutic target for ASD treatment
Objectives: This study aimed to investigate the dual action of A-366, a potent G9a inhibitor with high and selective H3R antagonistic affinity, on the ASD-like behaviours and neuroinflammation of male BTBR T+tf/J mice model.
Methods: Male BTBR T+tf/J mice were housed under standard conditions and treated chronically with A-366 (0.5-2 mg/kg, i.p.) for 21 days. ASD-like behaviors were assessed using the Marble Burying Test, Nestlet Shredding Test, Self-Grooming Test, Spontaneous Alteration Test, Elevated Plus Maze, Light Dark Box, and Three-Chamber Test. Following behavioral testing, cerebellar and hippocampal brain tissues were analyzed using ELISA to quantify pro-inflammatory markers (TNF-α, TNF-β, IL-6, IL-1β, TGF-β) and immunohistochemistry for Iba-1 expression to evaluate neuroinflammation.
Results: A dose dependent decrease of repetitive and anxiety-like behaviours as well as amelioration in social deficits was observed in response to the chronic systemic treatment of A-366 (0.5-2 mg/kg, i.p.). Moreover, A-366 decreased neuroinflammation in cerebellar and hippocampal brain tissues of treated BTBR mice, as evidenced by the reduction in proinflammatory markers TNF-α, TNF-β, IL-6, IL-1β and TGF-β, as well as the decrease in Iba-1 expression.
Conclusions: This in vivo study demonstrates the potential therapeutic value of A-366 as a dual-targeting agent for G9a and H3Rs, with modulatory role on epigenetic, neuroinflammation, and brain histaminergic neurotransmission. Therefore, A-366 is expected to provide a lead template for future design and synthesis of a novel, potent and selective class of drugs to target ASD features.

Quality of life in patients with pituitary tumors: features of diagnostics

Y. Sidneva[1,2]*, L. Astafyeva[3], P. Kalinin[4], A. Shkarubo[4], M. Kutin[4], I. Voronina[5], D. Fomichev[4], D. Andreev[4], O. Sharipov[4], I. Chernov[4], A. Donskoy[4], I. Klochkova[3] and I. Badmaeva[3]

[1]neuropsychiatry, N.N.Burdenko National Medical Research Institute of Neurosurgery; [2]neurorehabilitation, Clinical and Research Institute of Emergency Pediatric Surgery and Trauma; [3]neuroendocrinology; [4]neurosurgery and [5]neurology, N.N.Burdenko National Medical Research Institute of Neurosurgery, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1701

Introduction: The term "quality of life" is widely used in the world community, has an interdisciplinary concept that characterizes the effectiveness of all aspects of human life. But it should be understood that its main component is the psychological and psychiatric part, which is based on self-perception. And in this regard, it is obvious that the degree of quality of life of patients with pituitary tumors, manifested by a complex clinical picture, sometimes a multi-component treatment strategy, is important for understanding, diagnostics and correction.
Objectives: to assess and compare the degree of quality of life in patients with pituitary tumors.
Methods: 120 patients (18-79 years old) after surgery for diencephalic tumor, 2019-2022. The following scales were proposed: 1) assessment of the severity of cognitive impairment and social maladjustment - the Global Deterioration Rating (GDR) scale (stages 1 to 7, where 1 is no impairment/deficit); 2) assessment of the general condition of cancer patients - the Karnofsky index (from 0% to 100%, where 100% is normal condition, no

complaints); 3) a short version of the quality of life assessment (SF-12, 2000). All patients were examined dynamically by a psychiatrist.
Results: The quality of life was assessed during treatment, when the degree: improves, remains unchanged, worsens. Different dynamics were noted with different tumor morphology, volumes of surgical intervention, and course of recovery after surgery. Thus, after surgery, the number of patients with severe disorders in large and giant tumors, especially with spread to the third ventricle (according to the Karnofsky and GDR scales), increased, respectively, they were found to have a low degree of "quality of life". The use of questionnaires (SF-12) showed the inappropriateness of their use, since 33-78% of patients (with different tumor morphology) showed personality changes, they were not fully aware of their condition. Assessment by scales revealed the following features: 1) A large sample, no universal; 2) Mostly self-questionnaires, which is questionable due to the high percentage of patients with lack of criticality, inadequate assessment of the situation and themselves; 3) Conducted by different specialists; 4) To interpret the results, an assessment by a psychiatrist is necessary. Patients with pituitary tumors were divided into: 1) with pronounced health problems - sufficient quality of life; 2) with minimal symptoms - deeply "unhealthy".
Conclusions: In assessing the "quality of life", the primary factors are not the symptoms of the disease and their manifestations, but the perception of oneself and the ability to feel "happiness". In the case of pituitary tumors, non-specific scales and self-questionnaires should be used with reservations; for the adequacy of the interpretation of the results, it is worth comparing the data with the psychiatric report.

Contribution of EEG in analyzing the intraregional « disconnectivity » in schizophrenia

L. triki[1], N. Smaoui[2], D. Jardak[2]*, R. Feki[2], I. Gassara[2], M. Bou Ali Maalej[2], N. Charfi[2], J. Ben Thabet[2], M. maalej[2], S. omri[2] and L. Zouari[2]

[1]Functional Explorations, Habib Bourguiba University Hospital and [2]psychiarty C, Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1702

Introduction: « Disconnectivity » in schizophrenia seems to be subsequent to abnormalities of the white matter and distorted functional connectivity. That would explain the cognitive impairment, including the slowing of information processing, observed in these patients that could be one of the risk factors for conversion into clinical psychosis and a significant predictor of functional outcome.
Objectives: This study aimed to search for signs of « disconnectivity » in quantitative electroencephalograms (EEG) in schizophrenic patients compared to healthy controls.
Methods: It was a case-controlled study involving 15 schizophrenic patients and 15 healthy controls. The study was carried out at units of Psychiatry Department "C" and Functional Explorations Department Sfax' hospital in Tunisia. Participants underwent a standard wakefulness EEG recording with a resting state period and a mental calculation test.The spectral density analysis for each frequency band was studied. The absolute spectral densities (ASD) of the following frequency bands were analyzed at resting state and after calculation moment: delta [0,5 – 3,5 Hz], thêta [4 – 7,5 Hz] alpha 1 [8 – 10 Hz] alpha 2 [10,5 – 12,5 Hz] and bêta 1 [13 – 20 Hz] in bilateral frontal and occipital regions. The Pearson's correlation was applied between the two moments in the same region (for the same electrode). Good connectivity was found if p <0,05, the inverse meant « disconnectivity ».
Results: Good connectivity was found for schizophrenics in the frontal region (for alpha1 band in the right one (r=0,721 ; p=0,002) and in the left one (r=0,597 ; p=0,019), for beta1 band in the left one (r=0,616 ; p=0,014), and for thêta band in the right one (r= 0,569 ; p=0,027) and the left one (r=0,661 ; p=0,007)) and in the occipital region (for alpha2 band in the right one (r=0,726 ; p=0,002), for bêta1 in the right one (r=0,565 ; p=0,028), and for thêta band in the right one (r=0,836 ; p<0,001) and in the left one (r=0,829 ; p<0,001)). Disconnectivity was admitted for other bands in the same regions. However,for healthy controls, highly significant correlations (p<0.001) were observed in the right and left frontal and occipital regions for all frequency bands.
Conclusions: These results support the « disconnectivity » theory in which it seems that relay neurons connecting the nerve cells between the thalamus and the cortex could not control the thalamic neurons. A dysfunction of these relay neurons, mainly GABAergic, is known as one of the main etiopathogenesis of schizophrenia.

Involvement of inflammation in pathogenesis of autism spectrum disorders: experimental model of postnatal valproic acid administration

A. Stakhanova[1]*, O. Voskresenskaya[2], S. Zozulya[1] and N. Kost[1]

[1]FSBSI "Mental Health Research Centre" and [2]Lomonosov Moscow State University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1703

Introduction: Autism spectrum disorders (ASD) are developmental deviations that cause social, communication and behavioral problems. Valproic acid (VPA) works as an inhibitor of histone deacetylases. One of the presumed causes of ASD development is neuroinflammation. A low-grade inflammatory process in nervous tissue can cause serious disorders, leading to the death of neurons, impaired myelination and anatomical and biochemical changes in brain structures. Currently, there are known inflammatory markers that are detected in the blood and used to assess the level of inflammation in the brain, for example, leukocyte elastase.
Objectives: To investigate the effect of postnatal administration of VPA on the behavioral manifestations of ASD and the activity of leukocyte elastase in blood serum in male white rats.
Methods: The study was performed on male rat pups. The conditions for keeping animals and the experimental procedures used were approved by the Bioethics Commission of Moscow State University (registration No. 12.3 of 17.11.2022). The animals were administrated intraperitoneally with water (H2O) or VPA at a dose of 150 mg/kg from the 6th to the 12th day of life. The study used standard behavioral tests: weight monitoring from 6-12 days of life, "Social behavior" in the sibling/stranger modification on 55 day. The animals were decapitated on the 57th day. Blood was collected

into tubes with serum separating gel (BD Vacutainer® SST™II Advance), centrifuged at 2000 g, serum was frozen -78°C. The activity of leukocyte elastase in blood serum was measured spectrophotometrically by the rate of hydrolysis of the substrate BOC-Ala- ONp (Biomedical, Inc.).
Results: An important physiological indicator for ASD in the model used is a slowdown in weight gain. As a result of the study, it was revealed that the weight of males after 6 days of VPA administration was lower compared to control individuals ($p = 0.003$). In the "Social Behavior" test, in males who received VPA, the latent period for leaving the starting compartment was significantly longer than in the control ($p = 0.019$); also, experienced males later approached a stranger as if they were a stranger ($p = 0.037$), compared to controls. In this study, the activity of leukocyte elastase in the rat's blood serum receiving VPA was significantly higher than in control individuals ($p = 0.04$). Similar deviations are observed in patients with ASD.
Conclusions: These results allow us to conclude that the administration of valproic acid to rats in the early postnatal period causes changes in physiological and behavioral characteristic typical for ASD. This confirms the validity of the created experimental model. The increase of leukocyte elastase activity in the rat receiving VPA indicate the role of inflammation in pathogenesis of ASD.

Reflection of Burnout Severity in a EEG Frequency Pattern

S. Tukaiev[1]*, S. Mushta[2], A. Popov[2], J. M. A. Ferreira[3], B. Palamar[4], M. Makarchuk[5] and I. Zyma[5]

[1]Institute of High Technologies, Taras Shevchenko National University of Kyiv; [2]Department of electronic engineering, Igor Sikorsky Kyiv Polytechnic Institute, Kyiv, Ukraine; [3]Faculdade de Medicina, Universidade de Coimbra, Coimbra, Portugal; [4]Department of Social Medicine and Public Health, Bogomolets National Medical University and [5]Institute of Biology and Medicine, Taras Shevchenko National University of Kyiv, Kyiv, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1704

Introduction: The burnout develops gradually, unnoticed by the person, and its symptoms may appear after several years and leads to serious mental and behavioral changes. The processes underlying burnout are largely unknown due to the lack of specialized studies aimed at identifying specific biomarkers. Based on this, it is necessary to detect the first, critical moment - the first symptoms of burnout.
Objectives: We aimed to examine the EEG frequencies changes relating to severity of Anxiety Tension stage of Emotional Burnout.
Methods: In this study 752 participants, students and staff of Taras Shevchenko National University of Kyiv (Kyiv, Ukraine) were involved (209 males, mean age = 19.2, 543 females, mean age = 18.28). We used the 84-item Boyko's Syndrome of Emotional Burnout Inventory to measure the emotional burnout formation. We analyzed separate artefact-free EEG segments in all frequency bands from 0.2 to 45 Hz during resting state (3 min, closed eyes condition). In order to identify the EEG signs of emotional burnout the normalized power spectral densities (PSD) were calculated on the segment from 61 to 70 seconds of recordings.
Results: The revealed burnout-related (Anxiety Tension stage) variables in the spectral characteristics of the EEG characterized by the significant changes in the theta 2 (frontal area and left temporal-parietal cortex), alpha 2 (right parietotemporal cortex) and beta 1 subbands (left frontal-central-right parietal axis).
Conclusions: These data pointed to the influence of Anxiety Tension development mostly on the processes associated with short-term memory and focused attention.

Neuroprotective effect of HLDF-6-H peptide in Parkinson's disease

Y. Zolotarev[1]*, O. Dolotov[1,2], D. Markov[1], S. Shram[1], A. Dadayan[1], N. Kost[3], O. Sokolov[3], S. Zozulya[3] and E. Shubina[4]

[1]NRC «Kurchatov Institute»; [2]Lomonosov Moscow State University, Faculty of Biology; [3]FSBSI "Mental Health Research Center" and [4]All-Russian Charitable Foundation "Movement - Life", Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1705

Introduction: The pathogenesis of Parkinson's disease (PD) is associated with simultaneous damage to the nervous, endocrine and immune systems. Therefore, drugs that have a regulatory effect on all of these systems should be used to treat PD. Similar properties are possessed by the synthetic analogue of fragment 41–46 Human Leukemia Differentiation Factor (Thr-Gly-Glu-Hse-His-Arg-NH2, HLDF-6-H)
Objectives: To study the effects of HLDF-6-H in an experimental model of PD and its impact on the severity of motor and non-motor symptoms in patients with PD
Methods: The study used a preclinical PD model based on the administration of moderate doses of MPTP toxin (18 mg/kg) and chronic intranasal administration of HLDF-6-H peptide (300 μg/kg) to C57Bl/6 mice. Mice behaviour was assessed in the Grid test and the Forced Swim (FS) test. After 3 weeks of peptide administration, mRNA of neurotropic factors (BDNF and NGF) and key cytokines (IL-1β, IL-6, IL-10, gamma interferon, tumour necrosis factor α and transforming growth factor β1) was analyzed in five brain regions (striatum, hippocampus, hypothalamus, pituitary gland, cortex). Serum levels of 10 steroids, including testosterone, estradiol, progesterone, and corticosterone, were determined using MS analysis. The activity of inflammatory markers leukocyte elastase (LE) and α1-proteinase inhibitor (α1-PI) was determined using kinetic methods. Patients (24 people) with a disease duration from 1 to 16 years received HLDF-6-H intranasally as part of the balm "Rinohealing" (9-31 μg/kg per day, up to 6 months) in addition to standard pharmacotherapy for PD. The effectiveness of therapy was assessed based on the patients' subjective assessment of their condition according to the MDS-Unified Parkinson's Disease Rating Scale (MDS-UPDRS)
Results: HLDF-6-H blocked motor disorders (Grid test) and depressive-like syndrome (FS test) caused by MPTP in mice, restored the level of neurotropic factors and cytokines in the brain of animals ($p<0.05$). In the model used, a decrease in the level of estradiol and cortisol in the blood was reversible by the peptide ($p<0.05$). The development of the inflammatory process under MPTP action is indicated by an increase in the activity of α1-PI,

the anti-inflammatory effect of HLDF-6-H is expressed in a decrease in the serum activity of LE and α1-PI ($p < 0.05$). A decrease in the severity of a number of motor (rigidity, tremor, movement and balance disorders) and non-motor (anxiety-depressive state, impairment of memory, cognitive functions, sleep, etc.) pathological symptoms of PD was noted with chronic use of "Rinohealing" as an additional therapy.
Conclusions: HLDF-6-H peptide has antidepressant, neuroprotective and anti-inflammatory activity. This has been demonstrated both in the experimental model of PD and when used as an additional therapy for PD. The obtained results indicate the prospects for further studies of HLDF-6-H for the treatment of PD.

Schizophrenia and OCD association, psychopharmacological intervention and cognitive-behavioral therapy

S. Ben Aissa[1]*, N. Chaima[1], R. Khouloud[1], L. Amine[1] and M. Wahid[1]

[1]Psychiatry D, Razi Hospital, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1706

Introduction: Global epidemiological research suggests that approximately 1% of the global population is affected by schizophrenia, with 2 to 3% experiencing obsessive-compulsive disorder (OCD). Additionally, a noteworthy proportion of individuals with schizophrenia also exhibit comorbid OCD. This overlap often complicates differential diagnosis, especially as many schizophrenia patients display obsessive and/or compulsive symptoms akin to those seen in OCD.
Objectives: This literature review is designed to examine how frequently schizophrenia and OCD co-occur and to summarize the treatments reported in various studies.
Methods: A comprehensive literature review was carried out focusing on the co-occurrence and treatment of schizophrenia and OCD. This review involved an extensive search of scientific publications, selecting articles pertinent to the subject from databases such as Scopus and PubMed using keywords like "schizophrenia and OCD" and "schizophrenia and OCD treatment," yielding over 1500 articles from 1988 to 2024. Additional sources included Google Scholar and various grey literature sources. After applying specific exclusion criteria, 44 recent articles were selected that addressed the frequency of co-occurrence and the treatment modalities used for schizophrenia and OCD. These articles were categorized by country, frequency of co-occurrence, and treatment methods.
Results: The review revealed that roughly 14.5% of individuals with schizophrenia also suffer from OCD. Among treatments, Clozapine was commonly associated with the worsening of OCD symptoms, while Haloperidol showed better tolerability. Other antipsychotic medications like Olanzapine, Risperidone, and Quetiapine were noted to either aggravate existing OCD symptoms or initiate the onset in some cases. In contrast, some antipsychotics, such as Amisulpride and Aripiprazole, helped reduce symptom severity. Non-pharmacological treatments, particularly Cognitive Behavioral Therapy (CBT), have proven effective in reducing symptom severity with favorable outcomes noted in numerous cases. The integration of pharmacological and psychotherapeutic strategies is generally recommended to maximize therapeutic outcomes, underscoring the potential of combined modalities in treating OCD.
Conclusions: Our literature review investigated the prevalence of comorbidity between schizophrenia and obsessive-compulsive disorder (OCD), as well as the pharmacological and non-pharmacological treatments utilized. The significant overlap between these disorders highlights the complexity of managing patients with these co-occurring conditions, underscoring the need for systematic screenings and integrated treatment approaches.

Obsessive-Compulsive Disorder and Myoclonic Movements Following Streptococcal Pharyngitis: A Rare Pediatric Neuropsychiatric Case

J. P. Carrasco Picazo[1]*, J. Esteve[2], C. Conde-Pumpido[2] and B. Herraiz[2]

[1]Hospital Provincial Castellón, Castellón and [2]Hospital Clínico Universitario de Valencia, Valencia, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1707

Introduction: Pediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal infections (PANDAS) typically describe the sudden onset of neuropsychiatric symptoms, such as Obsessive-Compulsive Disorder (OCD), following streptococcal infections. However, cases that present with comorbid motor abnormalities, such as myoclonic jerks, are rare and pose diagnostic challenges. We report the case of a child who developed severe OCD accompanied by myoclonic movements after a streptococcal pharyngitis infection, representing a rare neuropsychiatric syndrome with an atypical clinical course.
Objectives: To present a rare case of post-streptococcal OCD in a child with comorbid motor myoclonus, highlighting the unusual presentation and the multidisciplinary therapeutic approach.
Methods: An 11-year-old male presented to the emergency department with sudden-onset severe compulsive behaviors, including repetitive prayers and ritualistic actions. These symptoms were accompanied by involuntary, rapid, jerky movements in both upper and lower limbs, consistent with myoclonus. Two weeks prior, the patient had been treated for streptococcal pharyngitis. A comprehensive evaluation was performed, including throat culture, elevated antistreptolysin O (ASO) titers, and electroencephalogram (EEG) to rule out seizures. The Yale-Brown Obsessive-Compulsive Scale (Y-BOCS) was used for assessing OCD severity.
The patient was managed with a multidisciplinary approach involving pediatricians, neurologists, and psychiatrists. A combination of antibiotics, selective serotonin reuptake inhibitors (SSRIs), and clonazepam for myoclonus was prescribed, alongside Cognitive-Behavioral Therapy (CBT).
Results: ASO titers were elevated, indicating recent streptococcal infection, and the EEG showed no epileptiform activity. The initial Y-BOCS score was 32, reflecting severe OCD. After four weeks of antibiotic therapy, CBT, and pharmacological treatment, the Y-BOCS score decreased to 18. Myoclonic movements also reduced

by 70% with clonazepam. Symptomatic improvement continued over the next three months, with residual mild OCD symptoms and no recurrence of myoclonus.

Parameter	Initial Evaluation	After 4 Weeks	After 3 Months
Y-BOCS Score	32	18	10
Myoclonic Movement Frequency	15/hour	5/hour	0/hour
Compulsive Behaviors (0-10)	10	6	2

Conclusions: This case illustrates a rare and complex presentation of PANDAS, where post-streptococcal OCD is accompanied by myoclonic movements. The integration of antibiotics, SSRIs, clonazepam, and CBT significantly improved both OCD and motor symptoms. This highlights the importance of recognizing and treating atypical neuropsychiatric manifestations following streptococcal infections in pediatric populations.

Repetitive Transcranial Magnetic Stimulation in Severe OCD: A Case Report

C. Chen Yee

General psychiatry, Institute of Mental Health, Singapore , Singapore
doi: 10.1192/j.eurpsy.2025.1708

Introduction: Obsessive-compulsive disorder (OCD) is characterized by recurrent intrusive distressing thoughts, images, or urges (obsessions), and/or by behavioral acts (compulsions) that the individual feels driven to perform. In patients with severe functional impairment, a combination of selective serotonin reuptake inhibitors (SSRIs) or chlomipramine and cognitive behavioural therapy is recommended. Evidence for use of repetitive transcranial magnetic stimulation (rTMS) as an adjunct in severe, medication-resistant cases of OCD is accumulating.
Objectives: We present a case of severe OCD in a patient who responded poorly to SSRIs, and who was trialed on rTMS, with marked improvement.
Methods: Details of the case were described. Information was gathered based on medical records.
Results: Patient T was a 34-year-old Chinese male, with a drug allergy to clomipramine, who was diagnosed with severe OCD in 2017, when he presented to the Institute of Mental Health for excessive anxiety with checking behaviour. He was maintained on fluoxetine 60mg OM and aripiprazole 10mg OM, from 2017 to 2020. He completed a course of rehabilitation during admission, as well as empowerment and job training programs in the outpatient setting. He still had residual symptoms of excessive checking and would take a long time to complete activities of daily living such as eating or showering. He then defaulted medications and follow up from 2020 onwards. In 2024, he was brought in by his father to the emergency services for an infected foot wound due to poor self-care, as well as loss of weight from only eating one meal a day, due to his excessive checking behaviour. He would take 5 hours to finish a meal and 4 hours a day showering. He had also stopped speaking to anyone for 3 years. In the ward, he was switched to paroxetine 40mg OM as he had urinary incontinence on fluoxetine and weight gain on aripiprazole. However, improvement with paroxetine was minimal and the patient was still taking 2 hours each for showering and meals. The decision was made to give him a trial of rTMS. Drug treatment remained unchanged during the rTMS trial. Prior to rTMS, his Yale-Brown Obsessive-Compulsive Scale (YBCOS) was 30 (severe OCD).
After 30 sessions of rTMS, his obsessions and compulsions were significantly reduced, with a YBCOS of 17. He was able to finish his meals and shower for less than 30 minutes each. He was also more participative in ward activities with other patients, such as playing ping pong. He also showed interest in self-care by asking questions about his infected foot wound and prevention strategies.
Conclusions: In this case, there was a need for early treatment to address the risk of self-neglect posed by the patient's obsessive checking behaviour. rTMS is a safe and efficient treatment for patients suffering from refractory OCD. Further research is needed to optimize rTMS protocols and evaluate the long-term efficacy of rTMS for OCD.

EPV1106

Comorbidity between autism spectrum disorder and obsessive compulsive disorder. A case series

P. Del Sol[1]*, L. Mallol[1], A. Izquierdo[1], R. Fernández[2] and M. García Moreno[1]

[1]Hospital Puerta de Hierro, Madrid and [2]Hospital Infanta Cristina, Parla, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1709

Introduction: Autism spectrum disorder is a complex pathology that can occur very frequently with other disorders. It is known to co-occur with ADHD (attention deficit hyperactivity disorder), anxiety disorders or depression. Comorbidity with obsessive-compulsive disorder (OCD) can be difficult to detect since rigid and obsessive thinking, which in many cases is similar to the obsessions and compulsions of the OCD patient, is part of the core symptomatology of autism spectrum disorder.
Objectives: To present two cases of patients atteded in the Adolescent Hospitalization Unit with Autism Spectrum Disorder comorbid with OCD
Methods: Two clinical cases are presented, with review of literature.
Results: First case
This is a 16-year-old male, diagnosed with autism spectrum disorder at age 4. He begins with intense preoccupation for hygiene, developing cleaning rituals. He begins to develop the idea that his cells are released from his body and that they are sensitive to external stimuli in the same way that he is. He claims that in order for them to be eliminated and "not to suffer" he has to wash them and make flapping movements and avoid their accumulation.
He begins to treat with sertraline up to 200 mg with partial response, adding fluvoxamine 100 mg with important improvement of the symptomatology.
Second case
17-year-old male admitted to the inpatient unit for isolation and cleaning rituals and fear of contamination. The patient had no past

psychiatric history. He had been out of school for 4 months. The patient began to develop a fear of pathogen contamination. He maintained cleaning and checking rituals. He ate only packaged food and spent hours, and slept, in the same corner of the bed.
Medication with sertraline up to 150 mg was started with progressive improvement. During the admission a history of evolutionary development was taken, observing a difficulty in the mentalization of other people's emotions. Very adult and literal speech with difficulty in abstract thinking. He revealed presence of restricted interests throughout his history such as rare languages. Finally, the diagnosis of Autism Spectrum Disorder and comorbid obsessive compulsive disorder was made.
Conclusions: The comorbidity between autism spectrum disorder and OCD occurs between 37%. This comorbidity can make it difficult to perform psychotherapeutic interventions. This work shows on the one hand an already diagnosed autistic patient who develops an OCD, and on the other hand, how the initial diagnosis is an OCD on which an autism spectrum disorder is detected. This highlights the importance of knowing the comorbidity in order to detect both diagnoses.

Instruments and scales for assessing schizo-obsessive disorder: a systematic review

Y. A. Ferrao[1,2], J. V. B. Ferrão[3]*, P. C. Miranda[1,2], A. P. Feier[1,2], G. M. Ferreira[4], R. Massuda[4], D. Fragoso[4] and M. S. Barbosa[1,2]

[1]Psychiatry, UFCSPA; [2]Psychiatry, HMIPV; [3]Medicine, PUCRS, Porto Alegre and [4]Psychiatry, UFPR, Curitiba, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1710

Introduction: Recent evidence suggest the nosological entity called Schizo-Obsessive Disorder (SchizoOCD), similar to Schizoaffective Disorder. Some authors argued that obsessions and delusions would be on a continuum, which justify the difficulty in distinguishing obsessive from delusional thoughts, and compulsions from stereotypical behaviors. In order to assist in the screening, monitoring or treatment of such disorders, instruments as scales and questionnaires may be important tools in psychiatric practice.
Objectives: This systematic review investigated the most frequent instrumentsused to assess SchizoOCD.
Methods: We systematically reviewed articles up to 2015 in English, Portuguese and Spanish at PubMed, Scielo and Embase databases. We included studies with humans, no age limitation, with OCS or diagnosis of OCD and schizophrenia or psychotic symptoms. Systematic review articles, meta-analysis, letters to the editor and case reports were excluded, as well as articles that did not use assessment instruments for the diagnosis of schizophrenia comorbid with OCD. The methodological and clinical data extracted from the articles are described at the results.
Results: A total of 9,833 articles were selected, but 53 were read. Cross-sectional studies were the most frequent (n=39; 73.6%), followed by cohort studies (n=9; 17.0%).The total sample size of Schizo-OCD patients was 2,605 patients (in 44 studies), of which 44.7% (n=1,164) were female. The mean age and the age of onset of the disorders are described in Table 1. Only 23 (44.4%) of the studies described the psychiatric comorbidities (2 (3.8%) studies reported that the patients had no comorbidities). The most frequent comorbidities were Major Depression (n=18; 34%) and Substance Use Disorder (n=9; 17.0%). The used diagnostic instruments or interviews are listed in Table 2. Table 3 describes the scales used to assess the severity of Schizophrenia and/or OCD symptoms. From a psychopathological point of view, only 9 (17.0%) of the articles described psychotic symptoms in more detail. For OCD, 15 (28.3%) of the articles detailed the obsessive-compulsive symptoms.

Table 1 - Mean age and age at onset of the groups studied in the 53 selected articles

	Schizophrenia	SchizoOCD	OCD	Statistics
	Mean (SD)	Mean (SD)	Mean (SD)	Test (p)
Current age[a]	32,13 (8,25)	31,14 (8,82)	22,17 (5,70)	F= 0,69 (0,51)
Age at onset[b]	23,94 (4,19)	22,66 (5,18)	21,63 (4,54)	F= 0,95 (0,39)
	Minimum: 8	Minimum: 7	Minimum:15	
	Maximum: 32	Maximum: 33	Maximum:27	

Legend: a- number of studies: Schizophrenia = 25; SchizoOCD = 26; OCD = 1. b- number of studies: Schizophrenia = 36; SchizoOCD = 20; OCD = 6. SD, Standard Deviation; OCD, Obsessive Compulsive

Conclusions: Few studies in the literature used scales to discriminate psychotic and obsessive-compulsive aspects in patients with the alleged diagnosis of Schizo-OCD. Scales for measuring symptom severity such as PANSS and YBOCS were widely used in the studies, indicating that their application in clinical practice can serve as an aid during treatment management. Specific scales and instruments for Schizo-OCD were not found and we suggest as a future perspective the development of a new tool to assess symptoms and to elucidate possible symptomatic confusions.

Brexpiprazole augmentation in patients with a resistant obsessive compulsive disorder with psychotic features: an observational study in a psychiatric rehabilitation center

F. Franza[1]*, A. Franza[2], F. Pellegrino[2], G. Del Buono[2] and A. Ricca[2]

[1]Psychiatric Rehabilitation Center "Villa dei Pini", Avellino and [2]Neamente Neuroscience Study Center, Avellino - Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1711

Introduction: The relationship between obsessive-compulsive disorder and psychotic disorders has been frequently observed. Subject to diagnostic and therapeutic controversies, this association is a challenge for clinicians. Several scientific studies have observed a frequency of approximately 12% of this association in patients affected by schizophrenia. The efficacy of augmentation of SGAs with antidepressants in treatment-resistant OCD is demonstrated. Several studies have shown the efficacy of some dopamine receptor partial agonists (DRPAs) (aripiprazole and cariprazine) in augmentation with SSRIs in zOCD-psychotic features treatment-resistant. Brexpiprazole is a DRPAs with serotoninergic 5-HT1A agonism and 5-HT2A receptor antagonist.
Objectives: To evaluate the efficacy of brexpiprazole in augmentation with SSRIs in OCD patients with psychotic features resistant to pharmacological treatment.
Methods: Eleven patients (6 females, 5 males; mean total age (42.818 yrs ±12.679)) were recruited into our observational study. Affected by Obsessive Compulsive Disorder with psychotic features (based on the DSM-5-TR criteria). All patients were assessed using the SCID-5-CV. Levels of insight were assigned using DSM-5-TR specifiers. A detailed interview was conducted containing information on the demographic profile of the patients. All patients were administered the following rating scales: BPRS, Y-BOCS, GAF, CGI-S, at baseline (T0), after one month (T1), two months (T2), six months (T3), and one year (T4). All patients were administered bexpiprazole, replacing other SGAs associated with SSRIs (see Table 1).
Results: Table 2 and the graphic show the results obtained with our study. A statistically significant reduction of the mean total score was observed in the BPRS, Y-BOCS scales, an increase in the mean total score with the GAF. An improvement in the mean total score was also observed with the CIG-S. In all the scales used, the ANOVA results indicate that at least two of the repeated measures differed significantly. The preliminary data also indicate adequate safety and effectiveness.

Image 3:

Conclusions: Our small observational study aimed to evaluate the efficacy of brexpiprazole in a group of patients affected by OCD with psychotic features. Despite the small sample analyzed, the results of our study point towards a possible use of brexpiprazole in this group of patients affected by OCD with psychotic features during normal routine clinical practice.

New pharmacological therapies in pure OCD: about a case

C. Garcia Bernal

Psychiatry, Private Medical Center Dra. Cristina Garcia Bernal, Seville, Spain
doi: 10.1192/j.eurpsy.2025.1712

Introduction: Obsessive disorders occur in 2 to 3% of the world's population. They are very often underdiagnosed, causing great discomfort to the person.
Objectives: With this clinical case I would like us to be able to use new therapeutic strategies that, even though they are outside the technical specifications, work and improve the quality of life of patients with obsessive disorder.
Methods: I present the clinical case of a 14-year-old male who consulted for obsessive symptoms a year and a half ago.
The patient reports that he cannot stop thinking throughout the day, any type of absurd thought comes to him and he is not able to stop it, it limits his functionality to the point that a significant academic decline had occurred when previously the minor scored very good grades. He has had angry outbursts at school due to the discomfort his thoughts cause him. I treated with Clomipramine 75 mg and Clonazepam solution as a rescue anxiolytic and appointment in 3 weeks.
Results: The patient progressively improves in the organization of thought and decreases obsessive content, increasing the medication with Clomipramine up to 150 mg at night. After two months, it is the mother who consults because she sees her son very tired, he had gained a lot of weight and was complaining of dry mouth (side effects) and it continues to persist and worsen functionality. Given the patient's lack of complete improvement and the obvious side effects, I decided to first progressively change Clomipramine to Vortioxetine up to 40 mg. Upon evaluation, the patient feels better about the obsessive content and no side effects appear, but cognitive rigidity, inflexibility, and functional and academic decline persist. That is why two months later, I started Cariprazine 1.5 mg and in a few days the patient felt more animated, eager to do things and concentrated better, even so I decided to go up to 3 mg and that is when the patient reported a notable improvement, also reported by his mother and his psychologist. He is currently continuing with this treatment.
Conclusions: Neither Vortioxetine nor Cariprazine has an indication in the technical specifications for obsessive disorders, but there are publications that show that it works without having the side effects of drugs with a dirtier pharmacological profile.

Disclosure of Interest: None Declared

Case report: a rare case of obsessive-compulsive disorder

E. Ilgin[1]*, S. Göktaş[2], Ö. Gülerer[2] and S. T. Tabur[3]

[1]Psychiatry, Marmara University; [2]Psychology, Yeditepe University, Istanbul and [3]Psychology, Hasan Kalyoncu University, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1713

Introduction: Obsessive-compulsive disorder (OCD) is a chronic mental health condition characterized by intrusive thoughts (obsessions) and repetitive behaviors (compulsions), which significantly impair daily functioning and quality of life. While common obsessions often revolve around contamination, symmetry, or safety, rarer forms of OCD can involve highly specific and unusual fears.
Objectives: The aim of this case analysis is to comprehensively examine the possible causes and treatment approaches of obsessive-compulsive disorder, focusing on the investigation of various obsessive conditions that are rarely observed in the literature.
Methods: The patient's history was thoroughly examined, and interviews conducted with the patient's family were also included in the evaluation. Possible causes of the disorder (from a biopsychosocial perspective) and treatment approaches such as psychotherapy and pharmacotherapy were analyzed through a literature review. Additionally, the patient was assessed using the Yale-Brown Obsessive Compulsive Scale (YBOCS), Brown Beliefs Scale, Beck Anxiety Inventory, and Beck Depression Inventory.
Results: The patient, N.C., is a 64-year-old woman whose general appearance is somewhat older than her age, with partially diminished self-care, having insight, divorced, and living with three of her six children. The patient experiences intense anger when any product containing sweets enters her home, including fruits. She feels discomfort even when using or hearing the word "sweet." The patient insists that no family member brings any sweet-containing products into their home, leading to frequent arguments on the subject. She reports high levels of anxiety, difficulties in social relationships, and significant limitations in daily life activities.

Her relatives have also observed and reported these challenges. The patient mentions feeling a sticky sensation on her hands when she sees sweets and experiences a compulsion to wash her hands when this sensation occurs. Her symptoms are consistent with the classical symptoms of obsessive-compulsive disorder, including obsessions (persistent thoughts about sweets and associated anger) and compulsions (the need to wash her hands). The diagnosis was made by Dr. Ece Ilgın.She has been started on fluvoxamine 50 mg/day, which will be titrated. She will return for a follow-up appointment at the clinic in one month.
Conclusions: The symptoms of obsessive-compulsive disorder in patient N.C. include obsessions related to sweets, fruits, a sense of 'stickiness' that cannot be clearly identified, and avoidance obsessions linked to these. These symptoms significantly impact the patient's quality of life and family relationships. It is believed that a combination of psychotherapy and pharmacotherapy will be effective in alleviating the patient's symptoms and improving their quality of life.

Relationship obsessive compulsive disorder: The hidden struggle in romantic relationships

A. Karmous[1], H. Ktari[2]*, H. Ghabi[3], A. Hajri[1], E. Khelifa[1], A. Maamri[1] and H. Zalila[1]

[1]Emergency and outpatient department, Razi hospital, Manouba; [2]Psychiatry department, Tahar Maamouri hospital, Nabeul and [3]Department G, Razi hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1714

Introduction: Obsessive-compulsive disorder (OCD) is a psychiatric disorder that presents a wide variety of clinical features and obsessional themes. A particular form of OCD has received growing attention from researchers and clinicians. Called relationship OCD (ROCD), this form concerns obsessive-compulsive symptoms arising around the romantic relationship and the partner.
Objectives: The aim of this work was to explore ROCD through a case report and a systematic review.
Methods: We report the case of a patient who visited the outpatient department of the Razi hospital (Tunisia) for obsessive thoughts evolving over 11 months. Moreover, a systematic review was conducted. PubMed via Medline, Google Scholar and Semantic Scholar were used as search engines. The keywords used were « Relationship obsessive compulsive disorder » or « ROCD » or « Relationship centered obsessive compulsive symptoms » or « Partner focused obsessive compulsive symptoms ». The publication period of the articles searched was from inception to December 2023. The language of the articles searched was either English or French.
Results: Mr M.A, 25 years old, was in a relationship with a girl since two years. He was repeatedly wondering if he was in the right relationship and if he would be happier with another girl. He often sought reassurance from his friends and visualized photos of his girlfriend to ensure his feelings for her and to reduce these thoughts. The diagnosis of ROCD had been made. Cognitive behavior therapy sessions were carried out with the patient, with a clear decrease in obsessive thoughts and compulsive behaviors of checking and seeking reassurance.
The systematic review performed identified a total of 14 studies that were included in the final analysis. The mean age of patients was 30 years, with extremes of 19 and 84 years. In all the reviewed studies, ROCD symptoms were assessed using the "ROCD Inventory" and the "Partner-Focused Obsessive-Compulsive Inventory". Study results suggest that obsessive symptoms linked to romantic relationships negatively affect the functioning of patients. Several cognitive distortions have been identified such as perfectionism and intolerance of uncertainty. Cognitive-behavioral therapy was the most used therapy in ROCD with a better understanding of one's feelings and an improved decision-making ability.
Conclusions: ROCD is a particular form of OCD that impacts on interpersonal relationships, particularly romantic or marital ones. A better understanding of this pathology by therapists would enable partners to overcome challenges and maintain healthy and fulfilling relationships.

EPV1113

Trait and State Differences in OCD Patients with Comorbid Mood Disorders: A Comparative Analysis of Demographic and Clinical Scales

S. Y. Lee[1]* and C. H. K. Park[1]

[1]Asan medical center, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1715

Introduction: Obsessive-compulsive disorder (OCD) is a chronic condition that frequently co-occurs with mood disorders such as major depressive disorder (MDD) and bipolar disorder (BD), complicating both prognosis and treatment. The presence of MDD or BD in OCD patients is associated with more complex clinical presentations and worse outcomes.
Objectives: Despite the high prevalence of these comorbidities, few studies have thoroughly compared the traits and states of OCD patients with comorbid mood disorders. This study aims to explore the differences in traits and states among OCD patients with comorbid mood disorders, including MDD, bipolar disorder I (BD1), and bipolar disorder II (BD2).
Methods: The study included 114 OCD patients: 21 without mood disorders, 32 with MDD, 47 with BD2, and 14 with BD1. Demographic variables such as family history of psychiatric disorders and history of pharmacological treatment for OCD were analyzed. Participants were evaluated using standardized tools such as the Patient Health Questionnaire-9 (PHQ-9), Generalized Anxiety Disorder-7 (GAD-7), Temperament Evaluation of Memphis, Pisa, Paris, and San Diego Autoquestionnaire (TEMPS-A), Obsessive-Compulsive Inventory (OCI), Depressive Symptom Inventory Suicidality Subscale (DSI-SS). Statistical analyses including one-way analysis of variance (ANOVA) and chi-squared tests were conducted to identify significant differences between groups.
Results: Patients with comorbid bipolar disorder (BD), particularly those with BD1, had a significantly higher prevalence of psychiatric family history (85.7%, $p = .031$). Pharmacological treatment for OCD was less frequent in patients with BD, with the lowest rate in the BD2 group (61.7%, $p = .008$). Compared to patients without mood disorders or those with MDD, OCD patients with BD showed higher scores in several temperament dimensions, including cyclothymic temperament ($p < .001$), depressive temperament ($p = .007$),

hyperthymic temperament (p = .006), anxious temperament (p < .001), and irritable temperament (p < .001). These patients also exhibited more severe depressive symptoms (p < .001), higher anxiety levels (p < .001), and greater suicidality (p = .002). Obsessive-compulsive symptoms, particularly neutralizing behaviors (p = .010), ordering behaviors (p < .001), and hoarding behaviors (p < .001), were more pronounced in the BD groups.
Conclusions: OCD patients with comorbid BD show distinct clinical profiles compared to those with MDD. They have a stronger genetic predisposition to psychiatric disorders and are less likely to receive pharmacological treatment for OCD. These patients also experience more severe depressive symptoms, anxiety, and obsessive-compulsive traits, complicating treatment. The findings highlight the need for comprehensive evaluations and personalized treatment plans for OCD patients with mood disorder comorbidities.

Impact of romantic love on obsessive-compulsive disorder phenotypes

D. Marazziti[1], R. Gurrieri[2], N. Schulz Bizzozzero Crivelli[1]*, M. Gambini[1], A. Arone[1], S. Palermo[1] and L. F. D. C. Fontenelle[3]

[1]Department of Clinical and Experimental Medicine; [2]Department of Surgical-Medical and Molecular Pathology and Critical Care Medicine, University of Pisa, Pisa, Italy and [3]Institute of Psychiatry of Federal University of Rio de Janeiro, Rio de Janeiro, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1716

Introduction: In recent years, multiple observational studies have been conducted to investigate the hypothesis of a correlation between romantic love (RL) and the phenotypic expression of obsessive-compulsive disorder (OCD).
Objectives: Our study aimed to evaluate the impact of RL on the clinical expression of OCD. Attention was specifically focused on investigating the onset of two OCD phenotypes with distinct characteristics, based on whether the subjects were at the onset of a romantic relationship or had experienced a romantic break-up, also considering the possible correlations with different clinical aspects and socio-demographic variables.
Methods: Our sample includes a total of 212 subjects with OCD recruited among outpatients at the University Psychiatric Clinic of Pisa, Italy, and the Federal University of Rio de Janeiro, Brazil. The following instruments were employed for psychometric assessments: the Structured Clinical Interview for DSM-5 (SCID-5), the Yale OCD Natural History Questionnaire, and the Yale-Brown Obsessive-Compulsive Scale (Y-BOCS). The study participants were then divided into two groups (love-precipitated [LP-OCD] and break-up OCD [BU-OCD]) according to the romantic factor that was deemed responsible for the onset of OCD. An appropriate statistical analysis was applied.
Results: The average age of onset of OCD was significantly different between the two groups, which may reflect a vulnerability of the brain's maturational stages in young individuals who are at risk for OCD. A trend towards three types of obsessions and compulsions (aggression, sexual/religious and symmetry, ordering, and rearrangement) in the BU-OCD group emerged, which may reflect some normal features of a romantic relationship. However, total Y-BOCS obsessions and compulsions subscale scores were similar, indicating an overall severe clinical picture.
Conclusions: Despite some limitations, our results suggest that different stages of RL might influence some characteristics of OCD, namely age at onset and some specific dimensions, but would not appear to interfere with the overall severity of the disorder. These results should encourage further research on the topic to learn more about the characteristics of these individuals and to better understand how the most natural experience of humankind, that is love, may represent a vulnerability factor towards the onset and some features of OCD, similarly to other mental disorders, where the evidence is currently strongest.

EPV1117

Blurred Boundaries Between Obsessive and Psychotic Symptoms: A Case Report

F. Mayor Sanabria[1,1]*, C. Regueiro Martín-Albo[1], M. Fernández Fariña[1], E. Expósito Durán[1], M. D. P. Paz Otero[1], J. Sánchez Rodriguez[1] and B. Serván Rendón-Luna[1]

[1]Instituto de Psiquiatría y Salud Mental, Hospital Clínico San Carlos, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1717

Introduction: Obsessive-Compulsive Disorder (OCD) and psychotic disorders are traditionally considered distinct entities; however, there is increasing evidence of a spectrum where these conditions overlap. In some cases, OCD presents with poor insight, leading to obsessive thoughts and behaviors that resemble psychotic features. These "schizo-obsessive" phenomena challenge standard diagnostic categories and suggest a continuum between OCD and psychosis, necessitating a more integrated approach to diagnosis and treatment.
We report the case of a 69-year-old male evaluated in the emergency department for severe obsessive symptoms, including intrusive images and compulsive behaviors, accompanied by low insight and depressive symptoms, such as suicidal ideation. Initial management with selective serotonin reuptake inhibitors (SSRIs) led to only partial improvement, highlighting the complexity of distinguishing obsessive from psychotic symptomatology and supporting the concept of a continuum between OCD and psychosis.
Objectives:
1) To describe the clinical presentation and management of a patient with OCD and psychotic features.
2) To review the evidence regarding the clinical characteristics and management of the schizo-obsessive spectrum.

Methods: A review of the patient's clinical history, psychiatric assessments, and treatment responses was conducted. A literature review was also performed to provide an overview of OCD with low insight and schizo-obsessive phenomena.
Results: The schizo-obsessive spectrum concept suggests an overlap between obsessive-compulsive symptoms and psychotic features, particularly when insight is impaired. In OCD with poor insight, obsessions can lose their typical egodystonic quality and appear more like delusions. This challenges traditional diagnostic boundaries and indicates a continuum between OCD and psychosis, where insight fluctuates and symptoms may shift from obsessive to delusional states. Clinical management is complex;

combining SSRIs with antipsychotics can be effective, particularly in cases with minimal insight. In our case, the introduction of low-dose aripiprazole led to significant improvement, supporting a combined pharmacological strategy addressing both obsessional and psychotic dimensions and aligning with the schizo-obsessive spectrum framework.

Conclusions:

1. This case highlights the difficulty in distinguishing psychotic from obsessive symptoms when insight is poor, emphasizing the need for careful differential diagnosis.
2. The overlap of obsessive and psychotic features in this patient indicates the need for further study of "schizo-obsessive" phenomena.
3. The patient's positive response to combined SSRIs and antipsychotics suggests this approach may be effective for similar cases with overlapping symptoms.

From OCD Traps to Transformative Dialogue: Managing a Case of OCD and Body Dysmorphic Disorder with Dramatised Socratic Dialogue

F. Raffone[1]*, A. Russo[2], A. Capasso[1], F. Mancini[3] and A. M. Saliani[4]

[1]Department of Mental Health, Asl Napoli 1 Centro; [2]Department of Mental Health, Asl Napoli 3 Sud, Naples; [3]Scuole di Psicoterapia Cognitiva APC-AIPC-SPC-SICC and [4]Scuole di Psicoterapia Cognitiva APC-SPC-AIPC-SICC, Rome, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1718

Introduction: Obsessive-compulsive disorder (OCD) and body dysmorphic disorder (BDD) often co-occur, creating complex symptom profiles and requiring multifaceted treatment approaches. OCD can lead to intense self-monitoring and distressing obsessive-compulsive behaviours, while BDD contributes to a distorted self-image, exacerbating feelings of inadequacy and shame. This case study explores the use of a metacognitive approach using Dramatised Socratic Dialogue (DSD) in the treatment of a patient with severe OCD and BDD, focusing on relational challenges, pervasive shame and self-criticism.

Objectives: To evaluate the effectiveness of dramatised Socratic dialogue and exposure with response prevention (E/RP) in the treatment of a complex case of OCD and BDD. Specifically, to address intrusive self-criticism, enhance the therapeutic alliance, and reduce shame-related behaviours.

Methods: A 33-year-old man with a long history of OCD and BDD symptoms, including excessive mirror checking and social avoidance, was assessed using the MMPI-2, PID-5, MADRS, STAY-1 and 2, and Y-BOCS, confirming OCD, BDD, and major depressive disorder. Treatment included establishing a strong therapeutic alliance, psicoeducation, E/RP and DSD targeting persistent self-criticism. After an initial phase, interventions focused on reducing compulsive behaviours and promoting self-acceptance.

Results: Initial E/RP led to symptom improvement but maintained a sense of control that limited full therapeutic progress. DSD successfully reduced self-critical dialogue and addressed shame and self-perceived social unacceptability, although it temporarily disrupted the therapeutic alliance. Subsequent reintegration of E/RP alongside DSD facilitated substantial reductions in OCD and BDD symptoms, with the patient reporting increased mood stability and reduced social avoidance.

Conclusions: This case highlights the benefits of integrating dramatised Socratic dialogue with traditional CBT methods such as E/RP to address OCD and BDD symptoms where shame and self-criticism are significant. DSD proved effective in reframing negative self-talk, breaking cycles of self-criticism and supporting long-term symptom reduction. This approach shows promise for treating complex cases involving intense feelings of inadequacy and shame.

EPV1119

Investigating the efficacy of an online mindfulness-based intervention in a sample of medical students with obsessive-compulsive disorder

J. Rodrigo[1]*, A. Hassoulas[2], E. Forty[2] and P. Palmer[3]

[1]Cardiff University, Cardiff, United Kingdom; [2]School of Medicine and [3]Institute of Psychological Medicine and Clinical Neurosciences, Cardiff University, Cardiff, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1719

Introduction: Obsessive-compulsive disorder (OCD) affects 1-3% of the population and is the fourth most debilitating psychiatric disorder. OCD characterised by persistent obsessions and compulsions in the ICD-11 is more common in students, with rates often exceeding 3-4% in medical students. Effective mental health services and interventions are critical in supporting these students.

Objectives: Creating an online mindfulness-based intervention for Cardiff University medical students to engage with remotely. Evaluating the effectiveness of the intervention in reducing OCD symptoms.

Methods: Medical students at Cardiff University's School of Medicine, including those in intercalation years, were invited to fill out an online survey using Microsoft Forms. This included self-report measures such as the Beck Depression Inventory-II (BDI-II), the State-Trait Anxiety Inventory (STAI), and the Obsessive-Compulsive Inventory-Revised (OCI-R). Recruited participants completed a two-part intervention based on Acceptance and Commitment Therapy (ACT). The course was designed on the Xerte platform and used reflective tasks, interactive elements, and embedded videos. The intervention was developed with MyMedic, the Medical School's mental health service. Participants completed the same online survey and a feedback form post intervention. Responses were analysed for changes in OCI-R scores.

Results: Thirty-two students completed the pre-intervention survey. Six students met the study's inclusion criteria. A significant positive relationship was found between OCI-R scores (minus hoarding) and BDI-II scores (χ^2 (3, N=32) = 10.745, p=0.01) (Figure 1). Three participants revealed reduced OCI-R (minus hoarding), STAI, and BDI-II scores after the intervention (Figure 2). The intervention was rated highly for usefulness and relevance, but neutral for interactivity. The embedded videos were deemed useful, and the module was thought-provoking.

Image 1:

Chi-Square Tests

	Value	df	Asymptotic Significance (2-sided)
Pearson Chi-Square	10.745[a]	3	.013
Likelihood Ratio	10.435	3	.015
Linear-by-Linear Association	.680	1	.410
N of Valid Cases	32		

Figure 1: Chi-square analysis for the relationship between OCI-R (minus hoarding) scores and BDI-II score using SPSS software

Image 2:

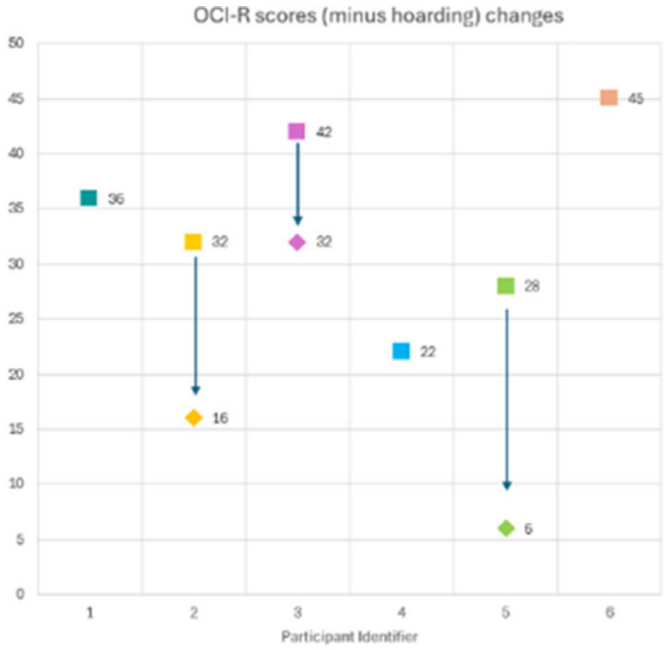

Figure 2: Analysis of participants OCI-R (minus hoarding) score changes

Conclusions: This study found an 18% prevalence of OCD among medical students. The ACT-based skills course which emphasises psychological flexibility and mindfulness resulted in a significant reduction in the OCI-R. ACT could be a useful tool for university support services, potentially complementing or replacing CBT. Integrating such interventions into medical curricula may provide more comprehensive support and reduce wait times for mental health services.

EPV1120

Obsessive-Compulsive Disorder and the Postpartum Period: A Clinical Analysis

A. Rodríguez-Quiroga

Psychiatry, Hospital Universitario Infanta Leonor, Madrid, Spain
doi: 10.1192/j.eurpsy.2025.1720

Introduction: The postpartum period is a crucial stage in women's lives, characterized by significant physical, emotional, and psychological changes. Among the mental complications that can arise during this stage, postpartum Obsessive-Compulsive Disorder (OCD) has gained increasing attention due to its significant impact on the quality of life of mothers and their ability to care for their newborns.
Objectives: This study aims to analyze the prevalence, etiology, clinical manifestations, and therapeutic approaches of OCD in the postpartum period.
Methods: The study reviews existing literature on the prevalence of postpartum OCD, which varies between 2% and 16.9%. It examines symptoms such as intrusive thoughts of harm towards the baby, repetitive checking behaviors, and cleaning compulsions. The study also identifies risk factors including personal or family history of OCD, traumatic experiences, and high-stress levels, as well as the influence of hormonal fluctuations and neurobiological changes on the vulnerability to postpartum OCD. The therapeutic approaches reviewed include pharmacological interventions, primarily with selective serotonin reuptake inhibitors (SSRIs), and psychological therapies, including cognitive-behavioral therapy (CBT) specialized in OCD.
Results: The combination of pharmacological and psychological strategies shows promise in reducing symptoms and improving the overall functioning of patients. Early detection and adequate treatment of postpartum OCD are essential to prevent long-term complications, promoting the well-being of mothers and their families. The study underscores the need for further research and awareness about postpartum OCD to develop more effective mental health policies and specific support programs.
Conclusions: This study underscores the need for further research and increased awareness about postpartum OCD. Developing more effective mental health policies and specific support programs is crucial to address this condition. Enhanced understanding and intervention can significantly improve outcomes for affected mothers and their families.

Disclosure of Interest: A. Rodríguez-Quiroga Grant / Research support from: The conference registration will be funded by Adamed.

A broken heart due to obsessive-compulsive disorder (OCD): a case report of Takotsubo Syndrome in a woman with untreated OCD

E. Serna Crespo[1]*, M. Carrasco Álvarez[1], J. Hidalgo-Lopez[1] and R. De Hita Santillana[2]

[1]Psychiatric Trainee and [2]University Hospital Jose Germain, Leganes, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1721

Introduction: Takotsubo cardiomyopathy, or broken heart syndrome, is a rare condition characterized by a temporary decrease in the left ventricle ejection fraction. Takotsubo was first described in Japan in 1990. 90% of cases occur in women over 67 years of age. Although the clinical presentation is similar to acute myocardial infarction, normal coronary arteries are usually detected upon cardiac catheterization. The etiology is not defined yet, but all the studies conclude that physical or emotional stress generates a release of catecholamines that produces a transient left ventricular apical dysfunction.
Obsessive-compulsive disorder (OCD) is characterized by recurrent intrusive thoughts, images or impulses. These obsessions provoke distress (typically anxiety) and compulsions which can be described as repetitive behavioral or mental acts that the person feels compelled to perform. If they don't perform the compulsions, the anxiety rises.
Objectives: To highlight the importance of treating mental illness to promote health in a multidimensional way.
Methods: We review the currently available literature on Takotsubo cardiomyopathy and its emotional triggers. We also study OCD as a stress factor and the characteristics of this pathology. Finally, we present a case report of a 37-year-old woman, with no previous contact with Mental Health Services. She had developed since the Covid 19 pandemic a severe obsessive-compulsive disorder, which was neither diagnosed nor treated. In the 36th week of pregnancy, after several days without leaving her home due to the limitations of her OCD, she went out into the street, which caused her considerable stress. The next day she suffered from Takotsubo cardiomyopathy or broken heart syndrome, with added analytical signs of preeclampsia, for which a cesarean section was also performed.
Results: In this case, the patient had been suffering from severe obsessive-compulsive symptomatology for approximately 4 years, which had worsened during pregnancy. This caused her a significant level of stress and anxiety, which in the absence of psychiatric treatment, could have endangered her life and that of the baby.
Conclusions: Mental illness tends to have serious medical consequences for patients, that could be prevented with proper treatment of their psychiatric pathology.

EPV1125

Depression or Dementia? The Development of Frontotemporal Dementia in the Shadow of Pseudodementia

M. C. Altınay[1]* and F. Ekici[1]

[1]Psychiatry, Selcuk University, Konya, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1722

Introduction: Pseudodementia presents with symptoms resembling dementia but with cognitive dysfunction improving after depression treatment. Dementia is a progressive, irreversible disorder causing impairment in multiple cognitive domains and daily activities. In the elderly, depressive disorders can manifest as pseudo-forgetfulness due to deterioration of attention functions, while cognitive decline and behavioral changes in dementia may mimic depression. Distinguishing between elderly depression and dementia is challenging because depression often co-occurs with cognitive impairments, and dementia frequently presents with depressive symptoms.
Objectives: This case report aims to highlight the importance of differential diagnosis in cognitive impairments among the elderly by presenting a case where frontotemporal dementia insidiously developed on a background of pseudodementia.
Methods: A 62-year-old woman with a recent history of treatment for depressive symptoms exhibited a gradual decline in planning abilities and behavioral changes over time. Following a non-suicidal jump attempt, she was admitted to the psychiatric ward for diagnostic clarification and treatment. A thorough evaluation of her socio-demographic data, family history, and medical and psychiatric history was conducted.
Results: The patient's initial complaints began after a psychosocial stressor, including headaches, depressed mood, loss of interest, sleep disturbances, attention difficulties, and increasing forgetfulness. Struggling with daily tasks led her to consult neurology, where age-appropriate atrophy was observed. She was prescribed migraine medication and metformin. Referred to psychiatry, she received sertraline with a preliminary diagnosis of depressive disorder but missed follow-up due to limited social support. Over the next five months, she developed reduced planning abilities, behavioral changes, aimless wandering, inappropriate mood shifts, weakness, and significant functional decline. After a non-suicidal jump attempt, she was admitted to psychiatry. Observations revealed persecutory thoughts and agitation. MRI showed pronounced frontal lobe atrophy inconsistent with her age. Diagnosed with frontotemporal dementia, she was discharged on olanzapine 5 mg and donepezil 10 mg.
Conclusions: This case demonstrates how confounding factors in dementia can adversely affect clinical progression, emphasizing the importance of social support and regular follow-up for accurate diagnosis and treatment. In patients with irregular follow-ups and low social support, conditions like dementia can have dramatic and irreversible courses. Therefore, performing differential diagnosis for dementia in elderly patients with depressive symptoms and reassessing dementia etiologies during follow-ups are vital.

Socio-demographic Characteristics and Psychiatric Disorders of Patients Aged 60 and Over Admitted to the Psychiatry Department at Razi Hospital, Tunisia

S. Aouadi[1]*, H. Ghabi[1,2], Y. Rebei[1], M. Karoui[1,2], H. Nefzi[1,2], R. Kammoun[1,2] and F. Ellouze[1,2]

[1]Psychiatry G, Razi Hospital and [2]Faculty of Medecine of Tunis, El Manar university, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1723

Introduction: Psychiatric issues are prevalent among the elderly, and as people age, they often face both medical and psychiatric comorbidities, creating significant challenges. However, there is a notable lack of literature on inpatient studies focused on this demographic.

Objectives: This study aims to assess the socio-demographic profile of patients over the age of 60 admitted to a psychiatric unit at Razi Hospital, Tunisia, while identifying the prevalence of various psychiatric disorders.
Methods: This was a retrospective and descriptive study. It included patients aged 60 and above who were first-time psychiatric admissions at the El Jazzar department of CHU Razi between 2020 and 2024. Data were collected from medical records, covering variables such as gender, age, year of admission, marital status, education level, occupation, socioeconomic status, medical history, prior treatments, diagnoses, admission type, and discharge treatments.
Results: In this study, we reviewed 40 case files. The analysis revealed that the majority of patients were male (80%), with most falling within the 60-70 age range. The majority were married (65%), and educational attainment was typically low, with 60% having a primary education level or below. Retirees accounted for 65% of the sample. Regarding comorbidities, 70% of the patients had both medical and psychiatric histories. The primary reasons for admission included behavioral disorders, delusional syndromes, and depressive disorders. Prior to admission, treatments mainly consisted of mood stabilizers and first- or second-generation antipsychotics. The most frequent mode of admission was hospitalization at the request of a third party (HDT), followed by involuntary hospitalization (HO). During hospitalization, prescribed treatments included antipsychotics (both atypical and typical), benzodiazepines, and antidepressants. No significant adverse drug reactions were reported. Dementia, recurrent depression, and psychotic relapse in the context of schizophrenia were the most common diagnoses.
Conclusions: This study provides valuable insights into the socio-demographic and clinical profile of patients over 60 admitted to psychiatry at Razi Hospital, highlighting key trends in mental health and treatment approaches. The frequent presence of somatic comorbidities emphasizes the need for a multidisciplinary therapeutic approach. These findings underscore the importance of specialized treatment for the complex needs of this elderly population.

Virtual darkness for agitation in dementia: The DARK.DEM randomized controlled trial

L. I. I. Berge[1,2*], T. E. G. Henriksen[3], S. V. Skagen[1], K. Nedreskår[4], V. Casadei[1], A. M. E. Mork[2], M. Patrascu[1], S. E. Fæø[5] and E. Flo-Groeneboom[6]

[1]Department of Global Public Health and Primary Care, University of Bergen, Bergen; [2]NKS Olaviken Gerontopsychiatric Hospital, Askøy; [3]Helse Fonna, Valen Hospital Trust, Valen; [4]Department of Global Public Health and Primary Care, University of Begen; [5]Department of nursing, Vid Specialized University and [6]Department of clinical psychology, University of Bergen, Bergen, Norway
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1724

Introduction: This poster will outline the rationale, objective, methods and preliminary results of the DARK.DEM trial.
Introduction: Behavioral and psychological symptoms of dementia (BPSD) such as agitation, psychosis and depression are prevalent, often treatment resistant and associated with reduced cognition, level of functioning, quality of life and mortality. In dementia, circadian rhythms become less robust, which potentiates BPSD. As such, *chronotheraphy*, i.e., interventions targeting the circadian rhythm, is promising. Bright light therapy can improve sleep and depressive symptoms in residents with dementia in nursing homes (Hjetland GJ, BMC Geriatrics, 2021). Intrinsically photosensitive retinal ganglion cells (*ipRGC)* monitor the perception of day and night and are maximally sensitive to light with short wavelength. This discovery paved the way for virtual darkness therapy, that is, solely exposure to light deprived of blue wavelengths in the evening and night. Virtual darkness is effective in reducing manic symptoms in persons with bipolar disorders (Henriksen TEG, Bipolar Disorders, 2016), however the symptom relieving effect in people with dementia has not been explored.
Objectives: Develop and evaluate virtual darkness therapy to enhance treatment of agitation and other BPSDs in specialized dementia care.
Methods: The DARK.DEM RCT will include patients from September 2024 to December 2027 at NKS Olaviken Gerontopsychatric Hospital, Norway.
Inclusion criteria: dementia related agitation (CMAI ≥45), all etiologies and stages of dementia, age ≥50. Exclusion criteria: use of beta-blockers or melatonin, clinically significant pain (MOBID-2≥3), total blindness. A total of 72 patients will be randomized to treatment as usual or 14 days with add on treatment with blue light depleted environment from 19-08, provided with circadian lightning in secluded units. Primary outcome is 14 day change in CMAI, secondary outcomes include change in NPI-12, CSDD, QoL, ADL, use of psychotropic drugs and restraints, length of hospital stay.
Results: We will present preliminary results on number of participants included, baseline characteristics related to age, sex, type dementia, level of symptoms, intervention effects and feasibility.
Conclusions: The DARK.DEM trial will provide real word evidence for clinicians and stakeholders to determine if virtual darkness theraphy should be implemented for treatment of agitation in people with dementia.

Persecutory Delusion in Parkinson's Disease: At the Crossroad Between Psychosis and Dementia

K. Mahfoudh[1], A. Hakiri[1], H. Khiari[1], A. Jaoua[1], I. Besbes[1*], A. Bouallagui[1], G. Amri[1] and R. Ghachem[1]

[1]Department B, Razi Hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1725

Introduction: Patients with Parkinson disease (PD) may present psychiatric manifestations like delusions and hallucinations which can significantly impact their quality of life. These psychotic symptoms may also occur during neuro-cognitive decline which poses a diagnostic challenge.
Objectives: This case study aims to investigate the clinical overlap between psychosis and cognitive decline in Parkinson's disease, focusing on the diagnostic difficulties in differentiating these psychiatric symptoms.
Methods: We report a single case of a patient admitted to the psychiatric department "B" of Razi Hospital, who exhibited symptoms of both psychosis and cognitive decline. We also conducted a literature review on Pubmed using the following keywords: Parkinson disease, Dementia, Delirium, psychosis.

Results: Mr. T.J, a 64-year-old man with a 10-year history of PD, was treated with levodopa, amantadine, and pramipexole. He developed depression a year ago, managed with fluoxetine. Recently, he was admitted to the psychiatric ward due to severe behavioral disturbances, including hetero-aggressiveness towards his wife.
Psychiatric assessment revealed a delusional syndrome with themes of jealousy and persecution towards his wife, accompanied by a hallucinatory syndrome primarily characterized by auditory hallucinations that appeared 2 years ago.
A neurological examination identified an amnesic syndrome that preceded the onset of delusions, raising concerns about the differential diagnosis between psychosis and dementia in the context of PD with the added consideration of the iatrogenic effects of his Parkinson's treatment.
In collaboration with neurologists, we adjusted the treatment regimen by tapering off amantadine and pramipexole while maintaining levodopa. We introduced 5 mg of olanzapine, which led to a favorable clinical response. After two weeks, Mr. T.J was considered stable enough for discharge. Improvements included a reduction in delusional ideation and a decrease in the frequency and severity of auditory hallucinations.
Conclusions: This case highlights the complexity of managing psychiatric symptoms in Parkinson's disease, particularly the challenge of differentiating between psychosis and dementia. The positive outcome following medication adjustments underscores the importance of a multidisciplinary approach in addressing both motor and psychiatric symptoms in PD patients.

Disclosure of Interest: None Declared

The Journey of Gender Identity in the Elderly: Needs and Challenges

L. M. Carrasqueira[1]*, B. Wildenberg[2], P. Esteves[2], F. Tavares[3], B. Araújo[4], J. Brás[5] and M. Coroa[2]

[1]Psychiatry , ULS Região de Leiria, Leiria; [2]Psychiatry, ULS Coimbra, Coimbra; [3]ULS Algarve- Unidade de Faro, Faro, Portugal; [4]Psychiatry, ULS Algarve- Unidade de Faro, Faro and [5]ULS Coimbra, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1726

Introduction: Gender identity issues in the elderly are often overlooked in psychiatric practice. Older transgender and gender-diverse adults face significant barriers, including social isolation, stigma, and limited access to gender-affirming care. These challenges, coupled with healthcare discrimination and gatekeeping, negatively impact mental health outcomes, often leaving this population underserved in healthcare systems.
Objectives: The aim is to identify the challenges transgender and gender-diverse elderly individuals face in accessing appropriate medical care and to explore how these barriers impact their overall health and well-being. Additionally, the objective is to propose strategies to improve both the mental health and general healthcare outcomes for this vulnerable group, ensuring that their specific needs are addressed within healthcare systems.
Methods: A narrative review of the literature was conducted using PubMed, ResearchGate, and Medline databases. Search included combinations of the terms "gender identity," "geriatic psychiaty " and "gender dysphoria. Studies were selected based on their relevance to understanding the mental health and healthcare needs of elderly transgender and gender-diverse individuals.
Results: The review revealed that elderly individuals with gender identity concerns experience higher levels of depression, anxiety, and social isolation. Historical discrimination and healthcare disparities significantly impact their well-being. Studies indicate that increased risks for dementia, linked to factors such as cardiovascular disease and sexually transmitted infections, further heighten their vulnerability.Moreover, there are significant gaps in gender-affirming care within geriatic services. Healthcare providers often lack the training necessary to address the specific needs of older transgender adults, leading to delays or denials in appropriate care.
Conclusions: This review highlights that transgender and gender-diverse older adults remain a population often overlooked in psychiatric and geriatric care. Recognizing the importance of tailored care for this population is essential, as well as training healthcare providers and implementing gender-affirming treatments to ensure inclusive, equitable care that meets their specific needs.

Delirium in a geriatric patient with Parkinson's disease, management and outcomes: a case report

I. Contreras Pérez[1]*, A. Jurado Arévalo[1], M. P. Vargas Melero[1], I. Caparrós del Moral[1], R. Carrillo Molina[1] and F. Vílchez Español[1]

[1]Psiquiatría, Hospital Neurotraumatológico, Jaén, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1727

Introduction: Up to 40% of patients diagnosed with Parkinson's disease (PD) may experience a psychotic episode during the course of the disease, with antiparkinsonian medications being the main cause. Frequently, aging is associated with a higher risk of comorbid delirium in this population.
Objectives: To analyze the treatment strategy for delirium in a geriatric patient with Parkinson's disease.
Methods: An 88-year-old male patient, diagnosed with Parkinson's disease for 12 years, was admitted to the Acute Psychiatry Hospitalization Unit due to a treatment-resistant confusional state. He presented fluctuating symptoms characterized by verbal and physical hetero-aggressiveness, visual illusions and hallucinations, as well as delusional ideas of harm, control, and mystical-religious content. The patient exhibited significant psychological distress, refused to eat, and had erratic medication adherence.
Results: Following a comprehensive organic assessment and treatment of intercurrent conditions, a readjustment of dopaminergic medication was performed, and quetiapine was introduced (up to 900 mg/day), with a partial response. Subsequently, the doses of quetiapine were reduced, and ziprasidone was introduced, achieving total remission of symptoms with good tolerance (quetiapine 450 mg/day, ziprasidone 80 mg/day, levodopa/carbidopa 150 mg/day).
Conclusions: Following pharmacological recommendations for managing delirium, initial treatment with quetiapine (first-line) was established. Subsequently, clozapine (second-line) was introduced, achieving a better response and cessation of symptoms. This case highlights the complexity of managing delirium in geriatric

patients with PD, considering the patient's age and lack of response to standard therapeutic guidelines. Clozapine, with a more favorable profile regarding motor effects, presents as the preferred option compared to other antipsychotics that may exacerbate parkinsonism.

The role of humor in the psychosomatic health of older adults

B. Eleni[1]*, E. Dragioti[1], N. Zagorianakou[1], A. Nakou[1], C. Tsironis[1], S. Mantzoukas[2] and M. Gouva[1]

[1]Department of Nursing, School of Health Sciences, Research Laboratory Psychology of Patients, Families & Health Professionals and [2]Department of Nursing, School of Health Sciences, Research Laboratory of Integrated Health, Care and Well-being, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1728

Introduction: Humor is widely recognized for its potential to improve psychosomatic health, enhancing both physical and mental well-being.

Objectives: To investigate the correlation between humor styles and psychosomatic health in older adults.

Methods: A cross-sectional study was conducted with 83 older adults (41 females, 42 males), aged 65 to 94 years (mean age: 74.1, SD = 8.1). Participants completed a sociodemographic questionnaire, the 32-item Humor Styles Questionnaire, and the 36-Item Short Form Survey (SF-36). Linear regression analysis was used to examine the relationship between humor styles and psychosomatic health outcomes.

Results: Self-Enhancing Humor. For Aggressive Humor, the mean was 22.7 (SD = 7.95), and for Self-Defeating Humor, 26.3 (SD = 8.70). The mean scores for Physical Health and Mental Health were 277 (SD = 84.5) and 272 (SD = 70.6), respectively. Self-Enhancing Humor had a significant positive effect on Mental Health (B = 3.458, SE = 0.893, $p < 0.001$), RF (B = 0.7659, SE = 0.375, $p = 0.044$), GH (B = 0.7113, SE = 0.234, $p = 0.003$), MH (B = 0.9711, SE = 0.228, $p < 0.001$), and SF (B = 0.7165, SE = 0.329, $p = 0.033$). Additionally, Self-Defeating Humor showed a significant negative effect on RE (B = -1.093, SE = 0.474, $p = 0.024$).

Conclusions: The findings suggest that positive humor styles, particularly Self-Enhancing Humor, are strongly associated with better psychosomatic health in older adults. Incorporating humor-based interventions could be a valuable approach to enhancing psychosomatic health in this population.

Let's Talk About Potentially Modifiable Risk Factors for Dementia

M. B. Fonseca[1]*, A. S. Pires[1], S. Mouta[1], D. Figueiredo[1], M. Pires[1] and I. Soares[1]

[1]Psychiatry and Mental Health, ULS Guarda, Guarda, Portugal

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1729

Introduction: Dementia is a syndrome usually chronic and progressive, in which cognitive deterioration occurs at a rate greater than what is expected due to natural aging. (WHO). Because it has a major impact on functional levels, dementia is a major cause of dependence and loss of autonomy in the elderly population.

As the population ages, the prevalence of dementia disorders is expected to increase over the years. This will lead to serious problems in the healthcare sector and social welfare. As populations age, the prevalence of dementia will increase, with the number of people with dementia worldwide expected to rise to 150 million by 2050. This group of neurocognitive disorders has multiple possible aetiologies, constituting a highly heterogeneous group. However, several studies within this area have been searching for and studying modifiable risk factors, to predict and reduce its incidence.

Objectives: The authors propose a review of the various modifiable risk factors involved in developing dementia syndromes.

Methods: Review of the existing literature about modifiable risk factors for dementia, using the keywords: dementia, modifiable risk factors, prevention. The results were selected taking into account the degree of relevance.

Results: Several studies argue that several modifiable risk factors may be involved in the development of dementia, from early to late life, such as less education, mental illnesses such as depression, hearing, and vision loss, high LDL cholesterol, and social isolation, among others.

Conclusions: Dementia has a significant mortality rate and is responsible for great disability and dependence in older populations. The implementation of global health measures, focusing on prevention and reducing risk factors, could be an important link in reducing the prevalence of dementia in the future.

Emotions and perceptions of elderly patients during the care pathway in healthcare settings

F. Franza[1], A. Franza[2]*, G. Conte[3], L. Roselli[4], B. Solomita[1], M. Minò[5] and A. Vacca[6]

[1]"Villa dei Pini", Psychiatric rehabilitation center; [2]Neamente Neuroscience Association, Avellino; [3]Il Filo di Arianna" – Alzheimer's Disease Center Social Cooperative, Venosa; [4]Healthcare Residence, RASS1 "Villa Caterina", Pescopagano (PZ); [5]Psychiatric Rehabilitation Center "Don Tonino Bello" - Assoc. M.I.T.A.G. - Onlus, Brindisi and [6]Mental Health Department, ASL Taranto, Grottaglie - Manduria, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1730

Introduction: The number of elderly people requiring social and health care support in the last years of life is constantly increasing. The consequence is a significant increase in the number of guests in assisted nursing homes. The elderly patient, collaborating with healthcare professionals, becomes the protagonist of the entire care process. The places and times of care, together with the lived experience and the emotions felt, are just some dimensions of humanization, dignity of care and dignified care. This recognition of the patient experience within the definition of quality of care is associated with better clinical outcomes and patient safety. Patient Reported Experience Measures (PREM) are psychometrically validated questionnaires returned directly by patients and aim to provide a standardized assessment of individual care experiences.

Objectives: Assess the emotionality, dignity, depressive symptoms of the elderly patient without significant psychiatric disorders at the time of admission to a place of care.
Methods: Sixty-seven elderly subjects (28 F, 38 M) were recruited in some elderly residential facilities (total mean age (yrs)(±*SD*): 75.64 ±*5.96*)
Inclusion criteria: age ≥ 65 years; MMSE ≥20; absence of overt diagnosis of psychiatric or neurodegenerative disorders (evaluation with SCID-5-CV). All patients were given a PREM questionnaire at the beginning and during the care pathway. All patients were administered at baseline (T0), after 6 months (T1) and after 1 year (T2) the following evaluation rating scales:

- Mini-Mental State Examination (MMSE) (only T0); Patient Dignity Inventory (PDI); Geriatric Depression Scale (GDS); Global Assessment of Functioning (GAF); Quality Life Index (QLi)

The data were statistically analyzed with the EZAnalyze 3.0 software for the Excel platform.
Results: Tables 1 and 2 show the results obtained with each scale analyzed. On the PDI scale, the ANOVA results indicate that at least two of the repeated measures differed significantly [Mean scores ± *Std. Dev*: (T0) 63.388 ± *22.042*; (T1): 57.313 ±*21.159*; (T2): 49.985 ±*17.418*]. The data obtained with the GDS scale showed no variation during the observational period. Although the differences were not statistically significant, the data indicate that no increases in depressive symptoms were observed. I results obtained with the QLi showed that the ANOVA results indicate that at least two of the repeated measures differed significantly [Mean scores ± *SD:* (T0) 3.358 ± *1.164*; (T1): 6.075 ±*1.222*; (T2): 6.657 ±*1.213].* Similar results were observed with the GAF scale.

Image 1:

Table 1 - EZAnalyze Results Report - Repeated Measures ANOVA (PDI and QLI)

PDI P: 0.000; Eta Squared 0.378

Post Hoc tests	Comparison	T-Value	P - Unadjusted	P - Bonferroni	Eta Squared
PDI T0	PDI T0 and PDI T1	4.435	**0.000**	**0.000**	0.227
	PDI T0 and PDI T2	8.044	**0.000**	**0.000**	0.491
PDI T1	PDI T1 and PDI T2	5.088	**0.000**	**0.000**	0.279

The ANOVA results indicate that at least two of the repeated measures differed significantly

QLi P: 0.000; Eta Squared: 0.735

QLi T0	QLi T0 and T1	13.870	**0.000**	**0.000**	0.742
	QLiT0 and T2	19.538	**0.000**	**0.000**	0.851
QLi T1	QLi T1 and T2	3.116	**0.003**	**0.008**	0.127

The ANOVA results indicate that at least two of the repeated measures differed significantly

Image 2:

Table 2 - EZAnalyze Results Report - Repeated Measures ANOVA (GDS and GAF)

GDS P 0.071 Eta Squared 0.039

The ANOVA results indicate that none of the repeated measures differed significantly

GAF P 0.006 Eta Squared 0.074

Post Hoc tests	Comparison	T-Value	P - Unadjusted	P - Bonferroni	Eta Squared
GAF T0	T0 and T1	2.721	**0.008**	**0.025**	0.100
	T0 and T2	2.593	**0.012**	**0.035**	0.091
GAF T1	T1 and T2	1.460	0.149	0.447	0.031

The ANOVA results indicate that at least two of the repeated measures differed significantly

Conclusions: Intervention programs that allow older residents to express their emotions and observations are not only beneficial for corporate welfare, but also promote a sense of empowerment and involvement. Our small observational study has shown that these programs can significantly improve residents' quality of life and protect against the onset of depressive symptoms.

Disclosure of Interest: None Declared

Lithium-induced neurotoxicity (SILENT Syndrome) in a Schizoaffective patient: A case of prolonged treatment leading to severe neurological complications

E. García[1]*, J. Tortajada[1,2,3] and J. Santilari[1]

[1]Hospital Universitari Institut Pere Mata de Reus; [2]CIBERSAM and [3]Institut d'Investigació Sanitària Pere Virgili, Reus, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1731

Introduction: A 71-year-old female patient with schizoaffective disorder, under psychiatric follow-up and treated with lithium for over 20 years (with successive stable therapeutic blood levels), presented to the emergency department with symptoms of temporospatial disorientation, aphasia, gait disturbances, tremor, and fluctuating encephalopathy. Symptoms have progressively worsened since she was found on the floor of her home one month ago. Subsequent complementary examinations (clinical evaluation, cranial CT scan, and laboratory tests) returned normal results.
Given the clinical picture presented, a differential diagnosis was made including neurocognitive, toxic-metabolic, psychiatric, and pharmacological causes (lithium neurotoxicity). Initially, the treatment was adjusted by reducing the lithium dose (from 600mg to 400 mg/day) and the associated medication was modified (mirtazapine and lormetazepam). Additional investigations or hospital admission were recommended to rule out an underlying pathology.
Objectives: The aim of this study is to explore and discuss the differential diagnosis and symptoms associated with lithium neurotoxicity.
Methods: We conducted a literature review through the PubMed database.
Results: The patient's symptoms worsened, and she was admitted to a long-term care facility. Active psychiatric pathology and cognitive decline were ruled out; renal function, thyroid function, and cranial MRI were normal. However, neurological symptoms and disorientation persisted.
The lithium dose was reduced to 200 mg/day, which led to the onset of manic symptoms. Upon increasing the dose back to 400 mg/day, the patient exhibited decreased consciousness, and serum lithium levels increased to 1.24 mEq/L, despite previously stable levels at this dose. Lithium was discontinued and replaced with valproic acid.
After the medication change, the manic state resolved, and consciousness and disorientation improved. A few months later, the patient remained stable with no other symptoms except gait instability.
Conclusions: Lithium neurotoxicity is a rare but severe complication of chronic lithium treatment, which can occur even at therapeutic levels (Konieczny K et al. Alpha Psychiatry 2024; 25:190-205). It should be suspected in cases of cerebellar ataxia, parkinsonism, disorientation, or cognitive impairment and requires early intervention to prevent irreversible neurological dysfunction (Schneider MA et al. J Neurosci Nurs. 2019; 51:283-286). In this case, symptoms improved following lithium discontinuation, although sequelae persisted months later, suggesting a potential diagnosis of SILENT syndrome.

We encourage clinicians to consider these symptoms and approach lithium dosing more cautiously in patients undergoing long-term treatment who have maintained psychopathological stability over time (Marmol S et al. Cerebellum 2024; 23:1733-1735).

EPV1136

Distribution of tasks between physicians and nurses in delirium management

G. Gübel[1]* and F. Riese[2]

[1]Geriatric psychiatrie, University Hospital of Psychiatry Zurich and [2]Dynamics of Healthy Aging, University of Zurich, Zurich, Switzerland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1732

Introduction: Delirium is a severe neurocognitive condition marked by acute, fluctuating disruptions in attention, awareness, and cognition, leading to significant morbidity and mortality. Despite its impact, there is currently no definitive pharmacological or non-pharmacological treatment for delirium (cf. American Psychiatric Association, 2013). Recognizing and managing delirium early is crucial to prevent long-term consequences. However, there is an international lack of consensus regarding the division of responsibilities in delirium care among physicians and advanced practice nurses (APNs).
Objectives: Distribution of tasks between physicians and nurses in delirium management: „where everyone is responsible, no one is responsible
Methods: An international systematic literature review investigated the task distribution between advanced practice nurses (APNs) and physicians. The review focused on publications retrieved from PubMed and CINAHL databases.
Results: From the initial systematic literature search, 395 articles were identified. Following the PRISMA statement (cf. Page et al., 2021) criteria, 30 articles were selected for analysis. Utilizing MAXQDA® (Release 2022.6) and qualitative content analysis, the literature was examined across categories such as physical examination, delirium screening, ordering pharmacological tests, treatment, psychoeducation on delirium. or procedures, diagnosis, non pharmacological treatment, and
Conclusions: Our systematic review revealed the absence of international guidelines for defining task distribution between physicians and nurses, particularly advanced practice nurses (APNs), in delirium care. We propose that research defining the roles among these experts will create synergies in delirium management which result in better recognition and management of delirium. Future research will test this hypothesis

EPV1137

Letter to a Judge The implementation of the Law 8 / 2021 three years on

M. Hernandez

MAPFRE, Madrid, Spain
doi: 10.1192/j.eurpsy.2025.1733

Introduction: Last scene of all That ends this strange eventful history, Is second childishness and mere oblivion, Sans teeth, sans eyes, sans taste, sans everything. Shakespeare, As you like it, II, vii, 163-166
Objectives: The paper will make reference to the debate generated by the implementation of the Law 8/ 2021 approved three years ago in Spain. The objective was to provide support measures to persons with dementia according to their wishes, beliefs, values and preferences without resorting to legal incapacity. Respect to the person´s wishes is pivotal to the Law and is creating many problems due to the fact that some patients with severe cognitive impairment cannot make a judgement and is not clear what the judge can decide.
From the start, forensic psychiatrists received an increasing number of requests to produce medico-legal reports due to the omission to refer to the protective, medical and personal aspects that such measures involve. Some decisions totally ignore these aspects referring only to the patrimonial ones with no mention of the person`s life trajectory nor to the personal and medical care provided and the medication prescribed.
Methods: In the second section, a case where the medical aspects where not contemplated in the sentence will illustrate the consequences for a patient who was misdiagnosed and mistreated.
Results: An extensive observation following the Tavistock Method will describe the process, including the organizational dynamics.
Conclusions: As Kitwood suggested, working with people suffering from dementia includes confronting organic impairment and the great difficulties there may be in consciously articulating any psychological conflicts, there may also be a breaking down of the individual's lifelong defences that leaves the person exposed and vulnerable to episodes of catastrophic anxiety and rage. Fear of abandonment and inability to bear separateness are characteristic of dementia sufferers, and these persecutory states of mind increase with organic impairment. Caregivers, whether family or staff in residential or nursing homes, have a crucial function in containing those deteriorated aspects of the person they are with.
"Dementia will always have a deeply tragic aspect, both for those who are affected and for those who are close to them. There is, however, a vast difference between a tragedy in which persons are actively involved and morally committed, and blind and hopeless submission to fate" (Kitwood, 1997).

Effects of antioxidants and phosphorylated tau protein on mitochondrial respiration and hydrogen peroxide production

J. Hroudová[1]* and Z. Fišar[1]

[1]Department of Psychiatry, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1734

Introduction: Alzheimer's disease (AD) is a progressive neurodegenerative disease and the most common form of dementia; currently there is no effective causal treatment for AD. The main targets of new drugs for AD are processes related to amyloid beta and tau neurotoxicity, neurotransmission, inflammation, metabolism and bioenergetics, synaptic plasticity, and oxidative stress.

Objectives: The effects of methylene blue, curcumin, ginkgolide B, and melatonin are being tested as antioxidants, tau-aggregation inhibitors, and mitochondrial-targeted therapies. These antioxidants will also be tested as protective agents against tau-induced mitochondrial dysfunction caused by oligomers of phosphorylated tau (P-tau). The aim of our study is to systematically investigate tau-induced mitochondrial dysfunction in isolated brain mitochondria and the protective effects of AD drugs, adjuvants, against mitochondrial dysfunction.
Methods: Isolated pig brain mitochondria were used as an *in vitro* biological model to evaluate the effects of antioxidants. Hydrogen peroxide formation was determined by fluorescence measurements (starting with Amplex Red, horseradish peroxidase). Mitochondrial respiration was measured using high-resolution respirometry. The effects of tested drugs were measured at concentrations in the range 0.1 to 500 µmol/l; the effect of P-tau was measured in the range 3-120 nmol/l.
Results: Methylene blue and curcumin significantly reduced hydrogen peroxide production at high concentrations. The antioxidants were further tested in combination with effect of P-tau oligomers in various states of mitochondrial respiration.
Conclusions: The results of this study will contribute to the connection of today's most accepted hypotheses of AD (amyloid, tau and mitochondrial), to the understanding of intracellular processes associated with the formation and progression of AD. The applied impact of the study will be the introduction of an *in vitro* mitochondrial assay to evaluate the anti-tau effects of new AD drugs, which will allow the selection of agents with high potential for causal treatment of AD.

Acute outpatient ECT for depression: case series of the first clinical pilot in Ireland

S. Inam[1]*, M. Qari[1], H. Roberts[1], T. McMonagle[1], J. Lorey[1], M. McGarry[2], V. McMullan[2] and M. Finnegan[1]
[1]Department of Psychiatry and [2]Department of Anaesthesiology, Tallaght University Hospital, Dublin, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1735

Introduction: ECT is a well-evidenced, cost-effective intervention for treatment-resistant depression. In Ireland acute (twice-weekly) outpatient ECT for depression has not been reported, though common elsewhere. Ireland has among the lowest number of inpatient psychiatry beds per person in Europe. We observed a clinical need for acute outpatient ECT for people who could not access elective inpatient care.
Objectives: We describe the process, interventions, outcomes and stakeholder feedback for four cases of acute outpatient ECT.
Methods: All cases provided written informed consent. A multidisciplinary (psychiatry, anaesthesiology, nursing) protocol for assessment and delivery of acute outpatient ECT was developed and implemented, cases described and feedback from stakeholders sought in an acceptability forum.
Results: Four medically stable patients (ASA Grades 2-3) completed acute outpatient ECT (Table 1), receiving between n=6 and n=12 ECT treatments, attending from home. N=140 inpatient psychiatry bed days were saved, and n=45 community psychiatry reviews were required. No adverse events or medical interventions occurres. Three people had CGI outcome of "very much improved" and one person halted their treatment course when "minimally improved", citing lack of response. Stakeholder feedback in an acceptability forum highlighted the increased resource intensity of twice-weekly community review for outpatient ECT, and the positive outcomes for treatment-resistant depression.
Conclusions: Acute outpatient ECT was safe and effective in this case series and resulted in n=140 psychiatry inpatient bed days being saved. There was an increased need for reviews from the community team during the treatment protocol. Medically stable patients with substantial social support were eligible for this pilot phase, thus a priority for future development must be equity of access to this effective intervention.

Late onset psychosis as an indicator of c9orf72 frontotemporal dementia: a case report

M. Irureta[1]*, I. Loinaz[2] and M. Alonso[1]
[1]Hospital Universitario Donostia, Donostia-San Sebastián and [2]Universidad de Barcelona, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1736

Introduction: Frontotemporal dementia (FTD) is a heterogeneous group of brain disorders associated with progressive frontal and temporal lobe atrophy. The main syndrome, behavioral variant FTD, is characterized by personality and behavior changes such as apathy, disinhibition, loss of empathy, new compulsive behaviors and executive dysfunction (Pressman, 2021). Psychotic symptoms may occur years prior to diagnosis of FTD, which can lead to misdiagnosis of a psychiatric disorder.
Objectives: To highlight late psychosis as an initial indicator of frontotemporal dementia and emphasize the relationship of somatic delusions with the c9orf72 mutation.
Methods: We reported the clinical case of a 64-year-old patient who was admitted in our acute psychiatric unit for late-onset psychosis with predominance of somatic delusions as the first indicator of c9orf72 frontotemporal dementia. Access to the medical history of the patient and non-systematic review of the literature on MEDLINE (Pubmed) was conducted.
Results: A 64-year-old male initially consulted the mental health services for oral stereotyped movements and behavioral changes after dental surgery. After a few months, the patient was concerned because he reported that he had holes in his mouth from which liquid was leaking. He consults numerous dentists and undergoes several surgeries, without success. The belief becomes more intense and delirious, and he develops self-harming ideation that leads him to be urgently admitted to the acute psychiatric unit. During the admission, aggressive behavior of the patient towards the staff was observed. Treatment with antipsychotics, antidepressants and ECT was carried with little improvement. He was admitted to a Medium-Term Unit where the patient deteriorated rapidly becoming

apathetic, uninhibited and mutistic. Finally, after several months, he was diagnosed with C9orf72 frontotemporal dementia. Psychotic symptoms may be the initial manifestation of frontotemporal dementia. There is a hypothesis that somatic delusions are caused by an altered body schema, correlated with a pattern of posterior, subcortical and cerebellar atrophy (Ducharme, 2011).
Conclusions: Late-life psychosis should be investigated as a possible prodrome of a frontotemporal dementia. Physicians should be aware given the psychiatric-like presentation, unaltered imaging exam and delayed appearance of typical symptoms of FTD. An increased prevalence of somatic delusions in FTD patient with C9orf72 expansion has been reported (Downey, 2014).

Brexpiprazole in the treatment of behavioral symptoms of dementia: a case report

A. Izquierdo De La Puente[1]*, P. Del Sol Calderon[1] and R. Fernandez Fernandez[2]

[1]Psiquiatria, Hospital Universitario Puerta de Hierro de Majadahonda and [2]Psiquiatria, Hospital Universitario Infanta Cristina, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1737

Introduction: A case report on the use of Brexpiprazole for the treatment of behavioral disturbance in dementia is presented.
Objectives: A brief review of the benefit of Brexpiprazole treatment in the treatment of dementia is presented in a case report.
Methods: This is an 84-year-old female patient with newly diagnosed multifactorial cognitive impairment. The patient was brought to Mental Health because of the behavioral alteration presented. She reported delusions of harm, theft and a suspicious attitude in relation to moderate cognitive impairment, as well as the recent transfer to a nursing home. In addition, the nursing home had observed that he presented erratic wandering that affected the functioning of the residential environment. In response to this symptomatology, the patient was aggressive and physically heteroagressive towards the caregivers.
The patient, due to the clinical presentation, had been treated with benzodiazepines, which had worsened the episodes of agitation and confusion, interspersed with episodes of somnolence. Therefore, her treatment was modified by adding quetiapine and haloperidol, worsening her psychomotor restlessness and alertness.
Results: When the patient was seen in the psychiatry department, she presented a high level of restlessness that corresponded to akathisia due to the haloperidol, as well as a fluctuating level of alertness that oscillated between wakefulness and somnolence. Despite the overmedication, according to the residency report, the patient maintained episodes of agitation and heteragresivity during wakefulness.
For this reason, it was decided to replace the antipsychotic treatment of quetiapine and haloperidol, progressively with brexpiprazole at 4mg DMD divided in two.
After two weeks of monotherapy with brexpiprazole, the side effects of the previous treatment disappeared, and the patient's daily functioning improved. She remained alert, the suspicious attitude and the delusions of harm disappeared. The episodes of behavioral disturbances had also ceased.
Conclusions: For the treatment of behavioral symptoms in dementia, it is important to have an effective approach to the clinical management without causing adverse effects that can be severe in elderly people. Brexpiprazole is an atypical antipsychotic, being a 5HT1A and D2 partial agonist and a 5HT2A antagonist, and is an appropriate treatment in this age group.

Descriptive Study of Language and Communication Disorders Using a Psychopathological Protocol in a Matched Control Group to a Sample of People with Mild Cognitive Impairment

A. Moreno-Romero[1], A. Arjona-Valladares[2] and N. Jimeno[2]*

[1]University of Valladolid, Valladolid, Spain and [2]Psychiatry, University of Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1738

Introduction: Aging leads to a progressive deterioration at the communicative level. The identification of language impairment in older adults could help to prevent or slow down the development of a possible neurocognitive disorder.
Objectives: To evaluate psychopathological manifestations in language and communication by means of a psychopathological evaluation protocol in a control group of subjects matched by age and sex to a group of people with mild cognitive impairment.
Methods: The sample consists of twenty healthy older adults (75% female, 25% male) with mean age of 84.15 years (SD = 6.81). A descriptive and observational study was carried out. Subjects of both sexes between 70 and 95 years of age, with absence of possible cognitive impairment, were included. The *Mini-Cognitive Examination* was used to assess cognitive performance, the *PRESEEA* interview was used to obtain the speech sample and a psychopathological assessment protocol.
Results: Increasing age is associated with greater intensity of language impairment (R^2 = .02, p = .047). In the MEC-35 total score, the control group shows a significantly higher performance than the patient group (F = 49.11, p < .001). A negative correlation appears between the total score of psychopathological manifestations and the variables 'educational level' (R^2 = .23, p = .029) and 'socioeconomic level' (R^2 = .33, p = .007).
Conclusions: Anomia, perseverations, disintegrated language, concretism and paragrammatism are possible early indicators of cognitive impairment. The elaboration and application of both assessment protocols and speech therapy intervention programs in older adults may improve communication skills.

Health literacy and psychological well-being in community-dwelling older people: data from FelizIDADE project

S. Lima[1]*, S. Martins[1], J. L. Martins[2], R. Carvalho[3] and H. Correia[4]

[1]Innovation in Health and Well-Being Research Unit (iHealth4Well-being), CESPU, Porto; [2]PrestigeHealth; [3]Centro Social de Requião, Vila

Nova de Famalicão, Portugal and [4]Social Work, Centro Social de Requião, Vila Nova de Famalicão, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1739

Introduction: Health literacy (HL) is characterised as the ability to understand health and involves people's knowledge, motivation and skills to access, recognise, evaluate and apply health-related information. It is an important topic in the context of healthcare, with studies suggesting that low levels of HL are predictors of adverse health outcomes. Socioeconomic status, age, race, cognition and level of education are factors that contribute to HL levels, with older age being strongly associated with poor HL. However, the relationship between HL and the psychological well-being of older people has not been explored as much in the literature.
Objectives: To describe HL and psychological well-being levels in community-dwelling older people and to analyse the association between these two constructs.
Methods: The data analysed in this study derives from a longitudinal research project called FelizIDADE, whose main objective was to empower older people to promote health and HL. A sample with older people aged 65 years and over, living in the municipality of Vila Nova de Famalicão, in Portugal was included. All participants were assessed with a comprehensive research protocol, which comprised, amongst others, the European Health Literacy Questionnaire (HLS-EU-Q16) and the Psychological Well-Being Scale (PWBS). For statistical analysis, non-parametric tests were used, since data did not follow a normal distribution.
Results: A sample with 59 community-dwelling older people was considered, with a mean age of 72 years (SD=4.5). The majority was female (59%), married (83%) and 91.5% had the completed primary school. Around 83% lived with their spouse and 88% were retired due to age. Statistically positive correlations were identified between the HLS-EU-Q16, age (rs=0.0274; $p<0.05$) and PWBS (rs=0.336; $p<0.01$). The total of HLS-EU-Q16 also correlated positively with the total of four domains of the PWBS: Autonomy (rs=0.412; $p<0.01$); Personal Growth (rs=0.280; $p<0.05$); Positive relations with others (rs=0.275; $p<0.05$) and Purpose in life (rs= 0.379; $p<0.01$).
Conclusions: It is well known that HL plays a fundamental role in older people and lower levels are related to negative impacts on health. This reinforces the importance of understanding the factors that are associated with poor HL. The present findings provide empirical insights into the association between HL and psychological well-being among older people living in the community. Furthermore, these results emphasise HL as an individual resource in promoting well-being.

Psychiatric symptoms in vascular dementia. A new perspective

C. M. Martín Gozalo[1]*, E. L. Bori[1], P. G. Melero[1], S. P. González[1] and A. G. Ontaneda[2]

[1]Psychiatry and [2]Geriatrics, Hospital Clínico San Carlos, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1740

Introduction: Psychiatric symptoms in vascular dementia occur in up to 95 % of patients. These symptoms can be of a depressive or manic type, among others. For this reason, it is essential to carry out a proper differential diagnosis between vascular dementia and other types of pathology that include psychiatric symptoms.
Objectives:
1) To describe the main psychiatric symptoms that could guide the diagnosis of vascular dementia.
2) To make an appropriate differential diagnosis in order to carry out the most suitable therapeutic approach in each specific case.

Methods: A review of the most recent literature related to psychiatric symptomatology in patients with vascular dementia.
Results: Vascular dementia can present with very diverse psychiatric pathology. Depending on the subcortical area affected, a particular symptomatology will predominate. For this reason, it is of vital importance to carry out a proper differential diagnosis. When the brain area affected is the ventromedial prefrontal cortex, the predominant symptomatology is depressive, with a higher percentage of patients with abulia. If the area most affected is the orbitofrontal cortex, disinhibition will predominate. However, if it is the dorsolateral prefrontal area, it will lead to executive dysfunctions.
On the other hand, it should be noted that psychiatric symptomatology due to vascular damage often has an atypical presentation in patients. For example, if what predominates is depressive symptomatology, what might appear relatively frequently would be late onset anxiety, irritability, or excessive somatic preoccupation. However, sadness or crying would not be as representative. If what predominates is the manifest symptomatology, in this case, with a high probability it would manifest itself in the form of behavioural disinhibition.
Because of these peculiarities, it is essential to make a proper screening between vascular dementia, late onset depression or Alzheimer's disease, as the therapeutic approach to each pathology will be very different, as will be the prognosis.
Conclusions:
- Atypical psychiatric symptomatology may be the key to a diagnosis of vascular dementia.
- A proper differential diagnosis between vascular dementia, late onset depression and Alzheimer's disease is essential.
- There is no clear benefit in the use of ACE inhibitors and NMDA receptor antagonists in cognitive impairment. However, there is evidence of improvement in cognitive function with SSRI antidepressants in patients with and without depression.

Is dependence on activities of daily living an indicator of social isolation among old people living alone in public housing?

S. P. V. Martins[1,2,3]*, J. Guedes[1,4], H. Alves[1,5], M. Videira[1], I. Machado[1,6], S. Melo[1,6] and F. Melo[7]

[1]ISSSP, Porto Institute of Social Work; [2]CESPU, CRL - Cooperativa de Ensino Superior, Politécnico e Universitário - iHealth4Well-being Research Unit; [3]CINTESIS@RISE, Faculty of Medicine, University of Porto; [4]CLISSIS-Centro Lusíada de Investigação em Serviço Social e Intervenção Social; [5]LIAAD-INESC TEC; [6]Institute of Sociology, University of Porto and [7]Domus Social Company-Porto City Council, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1741

Introduction: Social isolation (SI) is defined as the lack of social contact or support. Older adults have a higher risk of social isolation because of the changes in health and social relationships that can occur during ageing. Several studies have shown that SI is independently associated with poorer physical and mental health and worsened quality of life. However, limited evidence is available on SI predictors in old public housing populations.
Objectives: To assess the risk of SI and dependency in Basic and Instrumental Activities of Daily Living (BADL; IADL) in a sample of older people living alone in public housing. To identify predictors of SI, namely whether ADL dependency is one of them.
Methods: As part of the ongoing "Porto Importa-se" project, this study included a sub-sample of older persons aged 70 years and over living alone in public housing communities in Porto City, Portugal. All participants were assessed with a comprehensive multidimensional assessment protocol, which encompassed the Barthel and Lawton Indexes (BADLs and IADLs dependency) and the Lubben Social Network Scale-6 (SI risk). Loneliness was measured with a categorical question. A multiple logistic regression model was performed to identify predictive factors for SI. Odds Ratio (OR) and its 95% Confidence Interval (95%CI) were calculated. A $p<0.05$ was considered statistically significant.
Results: The final sample (n=716) was namely female (84%), with an average age of 80.4 years (SD=6.2). Around 36% presented a risk of SI, and 24% reported feeling lonely almost always to always. About 53% had moderate dependency on IADLs, and 11% dependency on BADLs. The proportion of participants dependent on BADLs and at risk of SI is more than double the proportion of cases considered not to be at risk (17%v.s.8%; $p<0.001$). Similarly, the proportion of cases considered to be severely dependent on IADLs and at risk of SI is about four times higher than the proportion of cases considered not to be at risk (13%v.s.3%; $p<0.001$). Based on the logistic regression model, severe dependence on IADLs (OR=5.16, 95%CI[2.37;11.24], $p<0.001$) and loneliness (OR=2.87, 95%CI[2.02;4.09], $p<0.001$) were significant predictors of the risk of SI. The model has a modest explanatory power (Nagelkerke $R^2=0.126$).
Conclusions: The rate of SI found in this study aligns with the results reported in other studies with similar objectives. The identification of loneliness and dependence in ADL as predictors of SI also complies with previous studies. These results reinforce the importance of monitoring elderly people who find themselves alone and dependent on the fulfilment of their ADLs more closely.

Impact of medical comorbidities on mental disorder pathoplasticity in elderly patients: a case report

F. Mayor Sanabria[1]*, M. Fernández Fariña[1], M. D. P. Paz Otero[1], E. Expósito Durán[1], C. Regueiro Martín-Albo[1], J. V. De Leon Quiroz[2] and M. I. Ramos García[1]

[1]Instituto de Psiquiatría y Salud Mental, Hospital Clínico San Carlos, Madrid and [2]Servicio de Geriatría, Hospital San Pedro de Alcantara, Cáceres, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1742

Introduction: Careful qualitative analysis of medical comorbidities in psychogeriatric patients is frequently overlooked in clinical practice, although these individuals often present with complex clinical pictures where multiple age-related somatic conditions can influence or alter the psycopathological presentation of mental disorders. This interplay can significantly affect both diagnosis and management, complicating the therapeutic approach and influencing prognosis.
We present the case of an 81-year-old male with a history of schizoaffective disorder admitted to our Psychiatry Unit due to an episode of marked motor inhibition and delusions. This case is notable for its complex clinical presentation, requiring a broad differential diagnosis, and serves as a representative example of the challenges in managing psychogeriatric patients with overlapping psychiatric and neurological comorbidities.
Objectives:
1) To describe the clinical particularities of this case, focusing on relevant psychogeriatric comorbidities and related changes in pathoplasticity.
2) To review the available evidence regarding the characteristics and management of comorbid neurological disorders in psychogeriatric patients.

Methods: The patient's clinical history was reviewed, including complementary tests such as brain MRI and PET-CT scans. Additionaly, a literature search was carried out, focusing on psychiatric and neurological comorbidities in elderly patients with a history of psychotic and affective disorders.
Results: The patient's clinical course reveals a significant change in the presentation of symptoms starting at the age of 70. Prior to this age, episodes were characterized mainly by inhibition, mutism, and delusional guilt. However, from the age of 70, there is a notable shift to more complex presentations with both manic and psychotic symptoms, including persecutory delusions, hyperactivity, and religious ideation, alongside periods of mixed affective states with significant affective lability. The development of probable drug-induced parkinsonism, confirmed by a negative DaTSCAN, and neuroimaging findings suggestive of a neurodegenerative process akin to Alzheimer's disease further complicated the clinical picture. Therapeutic interventions included psychopharmacological adjustments and electroconvulsive therapy, resulting in partial stabilization.
Conclusions:
1. Managing psychogeriatric patients requires addressing comorbidities with a flexible, symptom-based approach.
2. Neurodegenerative processes can alter prognosis by increasing relapse risk and changing symptom patterns.
3. A multidisciplinary approach is crucial for optimizing care in complex psychogeriatric cases.

Assessing hair cortisol levels and cognitive function in older palliative care patients: a potential for broader clinical application of a stress biomarker

R. Ribić[1], M. Neuberg[1], T. Košanski[1], I. Herak[1] and T. Meštrović[1]*

[1]Department of Nursing, University North, Varaždin, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1743

Introduction: Older patients in palliative care often experience considerable stress due to physical, emotional and existential factors. Previous research has identified cortisol, a glucocorticoid hormone, as a key biomarker for stress assessment. This pilot study aimed to investigate the potential of hair cortisol as a potentially objective stress biomarker in a specific population (aiming for a broader aplicability), as well as to explore cognitive changes in older palliative patients using the Mini-Mental State Examination (MMSE-2).
Objectives: This study objectives were to (1) assess changes in hair cortisol levels and cognitive function in older palliative care patients over three weeks of hospitalization and (2) evaluate the suitability of hair cortisol as a short-term stress biomarker in this patient group.
Methods: This monocentric pilot study included 19 patients from different palliative care hospital services in Croatia, gathered via a convenience sampling approach with strict inclusion/exclusion criteria. Hair cortisol levels were measured at baseline and after three weeks using an enzyme-linked immunosorbent assay (ELISA). Cognitive function was assessed using the 16-point MMSE-2. Statistical analyses included paired t-tests and linear regression, and significance was set at $p<0.05$.
Results: A statistically significant increase in mean hair cortisol levels was observed after three weeks of hospitalization ($p=0.007$), suggesting heightened stress over time. In contrast, MMSE-2 scores showed no statistically significant change ($p=0.064$), indicating no detectable cognitive decline within the study period. No significant correlations were found between cortisol levels and MMSE-2 scores at either time point, and differences between male and female patients were not statistically significant.
Conclusions: The findings support the potential use of hair cortisol as a biomarker for stress in palliative care settings, especially for tracking the transition from acute to chronic stress. However, MMSE-2 may not be sensitive enough to detect cognitive changes over short time spans in this patient group. Consequently, further research with larger samples is needed to validate hair cortisol as a practical tool for monitoring stress and to explore its clinical implications for improving palliative care outcomes.

EPV1152

Profile of Elderly Patients Hospitalized for the First Time in Psychiatry

D. Mezri[1]*, A. Gharbia[1], S. Hamzaoui[1], U. Ouali[1], A. Aissa[1] and R. Jomli[1]

[1]Avicenne, Razi hospital, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1744

Introduction: Hospitalization in psychiatry often marks a critical point in the management of mental health disorders. For elderly patients, this can be a first-time experience and is often associated with complex psychological, social, or medical factors. Due to the age, psychiatric symptoms may become more pronounced because of comorbidities, cognitive decline and social challenges. Understanding the profile, medical history, presenting complaints, and associated conditions of elderly patients admitted for the first time to psychiatric care is essential to improve the comprehensive care.
Objectives: The objective of this study is to analyze the profile of elderly patients hospitalized for the first time in the psychiatric department, focusing on their medical history, presenting complaints, diagnoses, and comorbidities.
Methods: It's a retrospective study. We reviewed the files of all patients aged over 65 years old who were hospitalized in the Avicenne Psychiatric Department at Razi Hospital between September 2022 and September 2024.
Results: We identified 22 patients with 16 men and 6 women. The average age of our patients was 68 years (ranging from 64 to 80 years). The majority had a secondary school education (47%), came from an urban background (81%) , were retired (54%), with a high socioeconomic status (42%), married (61%), parent of an average of 2 children and with a family history of mental disease (52%). A history of somatic illness was found in 61% of the patients. The reason for hospitalization was behavioral disorder in 73%, suicidal thoughts in 18.2% and refusal to eat in 8.8%. A history of psychiatric consultation without the need for hospitalization was found in 59% of the cases around the age of 51 years. In 18% of the cases, the onset of the disorder was acute, while it was progressive in the rest. Concerning the diagnosis, we observed mental confusion caused by an organic pathology in 9%, a purely neurological cause of the disorder in 14% (dementia in 10% and Parkinson's disease in 4%), a depressive episode in 31%, a manic episode within the context of bipolar disorder in 37%, and schizophrenia in 9%. Comorbidity with paranoid personality disorder was observed in 4 patients, all of them were females. For patients with a psychiatric diagnosis, a neurological comorbidity was found in 31.25% (25% dementia, 6.25% Parkinson's disease).
Conclusions: This study shows that elderly patients in their first psychiatric hospitalization have complex profiles affected by age-related factors and comorbidities. Diagnosis varied from mood to psychotic disorders, often with neurological issues. The frequent history of psychiatric consultations without hospitalization suggests that early intervention could help prevent more severe admissions. Understanding these profiles is crucial for improving care and treatment for elderly patients.

EPV1153

Navigating Polypharmacy in Elderly Psychiatric Patients: A Review of the Literature

R. A. Moreira[1]*, H. J. Gomes[1], E. Maldonado[1], I. Machado[1] and J. M. Justo[1]

[1]Psiquiatria, Unidade Local de Saúde do Nordeste, Bragança, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1745

Introduction: According to the World Health Organization, the global population aged 60 and older is projected to nearly double between 2015 and 2050, increasing from 12% to 22%. This demographic shift presents unique challenges in the management of psychopharmacological treatment in the elderly. Factors such as multimorbidity, atypical presentations of psychiatric disorders, age-related alterations in pharmacokinetics and pharmacodynamics, and the high prevalence of polypharmacy— often defined as the concomitant use of five or more medications—complicate therapeutic approaches in this population.
Objectives: This review synthesizes the current evidence on the prevalence, contributing factors, and consequences of polypharmacy in elderly psychiatric patients.

Methods: A narrative review was conducted using key terms and their combinations, including "polypharmacy", "elderly", "geriatric" and "psychiatry". Relevant studies, case reports, and reviews published from 2000 to 2024 were included.
Results: The prevalence of polypharmacy in the population varies across the literature; however, several well-established risk factors have been identified. These include age 65 years and older, living in a nursing home, comorbidities like diabetes mellitus, cardiovascular disease, metabolic syndrome, and COPD, as well as cognitive impairment. Additionally, prescription-related factors contribute to polypharmacy, such as poor quality of clinical records, automatic prescription renewals, and the involvement of multiple prescribers. The high rate of polypharmacy in older adults is associated with several challenges, including inappropriate medication use, difficulties in adhering to treatment regimens, increased risk of hospitalization, a higher likelihood of adverse effects, functional and cognitive decline, higher healthcare costs, and an increased risk of mortality. Additionally, a recent meta-analysis revealed for the first time that polypharmacy was significantly associated with the incidence of dementia and worsened its prognosis.
Conclusions: Advanced age is a significant risk factor for polypharmacy, often resulting in adverse outcomes such as reduced quality of life, increased morbidity, and higher mortality rates. Identifying and regularly assessing polypharmacy cases, alongside evaluating potentially inappropriate medications, are critical steps. Implementing safe prescribing practices and deprescribing strategies specifically adapted to the needs of elderly patients can effectively reduce risks and improve overall well-being in this vulnerable population.

Echoes of solitude: systematic review and meta-analysis revealing mortality risks in older adults due to loneliness, social isolation, and living alone

A. Nakou[1]*, E. Dragioti[1], N. Zagorianakou[1], F. Tatsis[1], S. Mantzoukas[2] and M. Gouva[1]

[1]Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina, Research Laboratory Psychology of Patients, Families & Health Professionals and [2]Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina, Research Laboratory of Integrated Health, Care and Well-being, Ioannina, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1746

Introduction: Loneliness, social isolation, and living alone are emerging as significant risk factors for mortality, especially in older adults.
Objectives: Loneliness, social isolation, and living alone are recognized as significant risk factors for mortality in older adults. This study aimed to quantify their associations with all-cause and cause-specific mortality, extending the scope of previous research by considering a broader range of social factors.
Methods: A systematic search was conducted in PubMed, APA PsycINFO, and CINAHL databases up to December 31,2023, adhering to PRISMA 2020 and MOOSE guidelines. Inclusion criteria comprised prospective cohort or longitudinal studies examining the relationship between loneliness, social isolation, living alone, and mortality. Quality assessment was performed using the Newcastle-Ottawa Scale. Meta-analyses utilized random-effects models with the Restricted Maximum Likelihood method, while subgroup and meta-regression analyses explored further relationships.
Results: Out of 11,964 studies screened, 86 met the inclusion criteria. Loneliness was associated with a 14% increase in all-cause mortality risk, social isolation with a 35% increase, and living alone with a 21% increase. However, substantial heterogeneity was observed across studies, influenced by various factors including gender, age, geographical region, chronic diseases, and study quality. Meta-regression analysis identified predictors such as longer follow-up periods, female sex, validated social network indices, cognitive function adjustments, and study quality.
Conclusions: Loneliness, social isolation, and living alone significantly increase mortality risk in older adults, emphasizing the urgency of public health interventions targeting these factors to enhance health outcomes among the aging population. However, due to study variations, further research is needed to understand their cumulative effect on mortality risks and inform tailored interventions.

Cognitive impairment in patients with very late onset schizophrenia-like psychosis

V. Pochueva[1]* and I. Kolykhalov[1]

[1]FSBSI Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1747

Introduction: Very late-onset schizophrenia-like psychosis (VLOSLP) is one of the largest group of mental illnesses in late life after dementia and depression. The question of role of cognitive impairment and the risk of dementia development in this group is still open.
Objectives: To determine the relationship between cognitive impairment and clinical features.
Methods: 65 patients (62 woman, 3 man), medium age 72,5 [63,5; 78,5], medium age of onset 69 [62; 76] with schizophrenia (F20), n=23; chronic delusion disorder (F22.81), n=7, organic schizophrenia-like disorder (F06.2), n=7, schizoaffective disorder (F25), n=11, manifesting after 60 years, underwent clinical examination. The assessment was carried out using clinical-psychopathological, psychometric and statistical methods.
Results: Based on clinical and psychopathological features, 3 clinical groups were formed. The group of patients with acute polymorphic symptoms with mental disorganization included 25 patients. The cognitive impairment was the most acute in this group and correlated with psychotic and affective symptoms. It reduced by the 28th day of investigation, but didn't reach the normative ones, which may indicate the presence of persistent cognitive dysfunction associated with the present neurobiological changes and creates particular concern regarding the development of a neurodegenerative process in this group of patients.
The 2nd group included 30 patients with a predominance of paranoid symptoms with an "age" coloring, which, however, wasn't the leading plot. Cognitive impairment was less pronounced compared

to the first group and was stable in nature, was not associated with the degree of reduction of psychotic and affective symptoms. This allows us to consider it as a predictor of the development of psychosis.
The 3rd group included 10 patients and was characterized by the prevalence of affective and delusional symptoms with acute sensory delirium, pseudodementia at the height of the condition. The degree of cognitive decline at the beginning of the study was comparable with patients in the 2nd group. High correlations were established between the degree of reduction of productive and affective symptoms and the improvement of cognitive functions. A complete reduction of existing disorders was noted by the end of treatment, which may indicate a more congenial prognosis.
Conclusions: This study confirms the results of previous studies on presence cognitive impairment in patients with VLOSLP, and in addition demonstrates specific differences in cognitive profiles depending on the clinical variant of VLOSLP.

Exercogs®: Technology Solution Applied in Dementia Prevention

C. Pombo[1], P. Varandas[2], C. Gameiro[1]*, B. Lopes[1], B. Freitas[1], S. Rosado[1], A. Bernardino[3] and H. Cardoso[3]

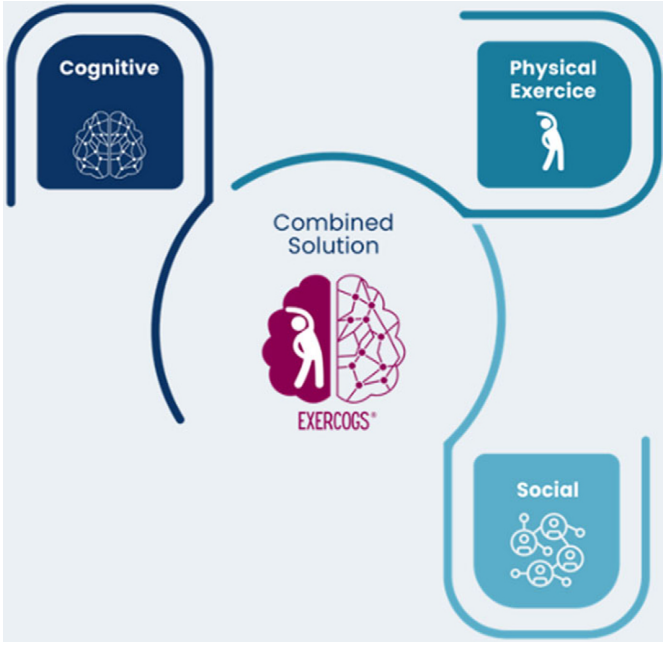
[1]Aging and Dementia; [2]Clinical Management, Sisters Hospitallers and [3]Institute for Systems and Robotics, Instituto Superior Técnico (University of Lisbon), Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1748

Introduction: Recent research highlights the importance of technological solutions in delaying cognitive decline and improving life quality for at-risk individuals, emphasizing the need for innovative, tech-based approaches in dementia prevention (Johnson et al.,2023; Smith et al.,2023). Exercogs® is an innovative tool designed to tackle the global challenge of dementia by addressing modifiable risk factors (Livingston et al.,2020). Developed through a clinic-academia partnership, it integrates physical exercise, cognitive skills, and social interaction into a single activity for dementia prevention programs.
Objectives: This scientific study aims to: 1) Creating and validating 4 Exercogs® (using gamification) for an augmented reality platform; 2) Validating a dementia prevention program that generates health benefits using Exercogs®.
Methods:

1. **Research and Planning:** assessment of seniors' needs; survey of market solutions;
2. **Ideation and Concept Development:** definition of therapeutic objectives; selection of stimulus types; idealization of game scenarios, cognitive, and motor areas;
3. **Design and Prototyping:** programming video games; implementation of gamification techniques;
4. **Testing and Evaluation:** testing the prototypes and interaction mechanics with a group of users; usability testing.;
5. **Scientific Validation:** experimental study with pre and post-test assessment, with a sample of 204 subjects aged ≥ 65 years old.
6. **Maintenance and Improvement:** the solution is being used in pilot studies in different institutions in Portugal for evaluation and continuous improvement.

Results: Exercogs® consists of 4 games that target key areas of healthy and pathological ageing, focusing on cognitive (attention, memory, executive functions), physical (mobility, coordination, balance) and social (general social skills) domains. Each game adapts to users' abilities with different difficulty levels and is designed for group play to enhance social interaction, crucial for mental health. Utilizing gamification and augmented reality for engagement, scientific validation showed significant improvements in cognitive, affective, social, functional domains, and quality of life, with marked statistical significance in all areas assessed.

Image 1:



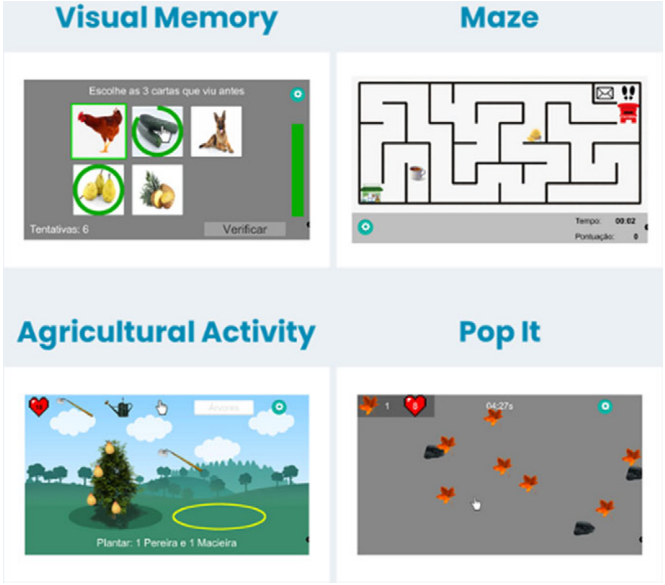


Image 2:

Conclusions: Notable health benefits were observed among users, particularly in cognitive function and quality of life. These findings indicate the potential effectiveness of Exercogs® in dementia prevention programs. The alliance between the clinic and academia is crucial for solving the challenges of longevity and creating technological solutions that respond to new health needs. The use of technologies in health intervention generates high levels of adherence and motivation among older adults, as well as among health professionals. Exercogs® are a promising technological solution that uses gamification with clinical support to prevent dementia!

Meta-analysis of Ginkgo biloba extract EGb 761 in the treatment of mild dementia

M. Riepe[1]* and M. Burkart[2]

[1]Division of Geriatric Psychiatry, Ulm University, Ulm and [2]Global Medical Affairs, Dr. Schwabe Holding SE & Co. KG, Karlsruhe, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1749

Introduction: Even mild forms of dementia have a detrimental effect on memory and activities of daily living, and cause distress to patients and their families. As the disease progresses, the impairment of patients and the burden on their carers increases over time. Thus, there is a need for effective, safe and well-tolerated treatments that can be initiated at the earliest stages.

Objectives: A meta-analysis of pooled patient subgroup data from randomised clinical trials was conducted to assess the treatment effects of Ginkgo biloba extract EGb 761 in patients with mild dementia.

Methods: The studies included in this meta-analysis were selected from a previous systematic review (von Gunten *et al.* World J Biol Psychiatry 2016, 17(8),622-633). They enrolled patients with mild dementia (total score 9-15 on the SKT Short Cognitive Performance Test, SKT) (Lehfeld and Erzigkeit, Int Psychogeriatr 1997, 9(Suppl 1), 115-21) with probable Alzheimer's disease, probable vascular dementia, or possible Alzheimer's disease with cerebrovascular disease, respectively. Outcome measures were cognition, activities of daily living, global clinical assessment and quality of life.

Results: From four eligible trials data of 782 patients with mild dementia were included in the meta-analysis. The analysis demonstrated that treatment with 240 mg EGb 761 daily was significantly superior to placebo in cognition (p=0.04), global assessment (p=0.01), activities of daily living (p=0.01) and quality of life (p=0.02) with medium to large standardised effects. Adverse events were similarly frequent in patients treated with EGb 761 and placebo (p=0.66).

Image:

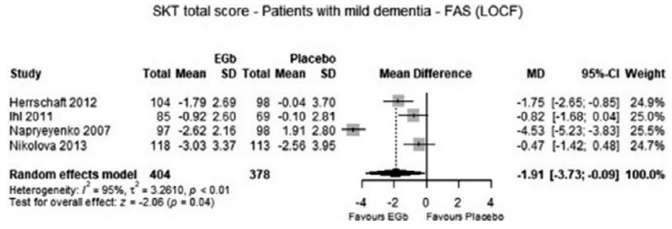

Image 2:

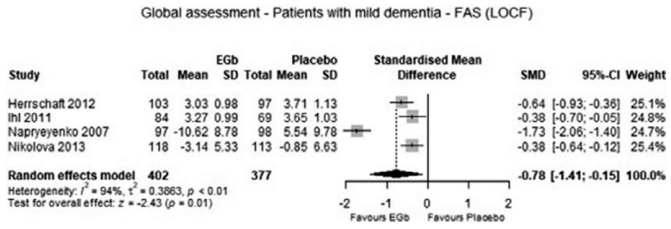

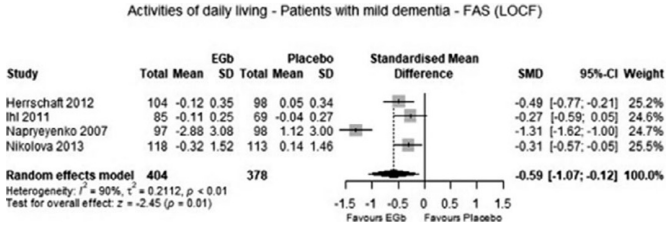

Image 3:

Conclusions: The meta-analysis shows that EGb 761 has beneficial effects on cognition, activities of daily living, global assessment and quality of life in patients with mild dementia.

Efficacy of music therapy in patients with mild cognitive impairment. Systematic review

I. Rodríguez Blanco[1]*, L. M. D.-P. Barros[1], P. S. Aranda[1], C. G. Cerdán[1], M. L. Argudo[1], R. K. G. Bolaños[1], C. M. Cossio[1] and R. M. B. Rey[1]

[1]University Clinical Hospital of Salamanca, Psychiatry, Salamanca, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1750

Introduction: The concept "mild cognitive impairment" (MCI) means a decline in executive functions (such as memory, attention, language or thought) that does not correspond to what is expected for a person's age group. It is estimated that this diagnosis may affect a fifth of the population over 65 years and 50-80% of them will develop dementia. This pathology is related to a loss of autonomy and an increase in dependence. In addition, there are therapeutic limitations, so it is a flagrant health and social problem. In this context of difficulties, various non-pharmacological therapies are emerging with the aim of improving various aspects of this disease, among which we can found music therapy (MT).

Objectives: The aim of this study is to review the most recent findings of the scientific community regarding the validity of MT as an intervention in patients with MCI. Specifically, its efficacy on cognition and its power to stop the progression of dementia are evaluated, as well as its effects on other areas of the patient.

Methods: A systematic review was carried out in the "WOS-Web of Science", "Scopus" and "Psycoinfo" databases following PRISMA guidelines. The keywords were "MT" and "MCI". We included clinical trials, systematic reviews and meta-analyses in english or spanish whose study population had MCI, excluding those published before 2017.
Results: 15 studies were selected, all with high quality evidence designs measured by Scotish Intercollegiate Guidelines Network scale. Among all the types of MT evaluated, various studies agree that Active MT (which includes activities that involve active participation of the patient such as singing or dancing) stands out as one of the best options, showing post-intervention improvements in MMEE scores and, secondarily, in emotional well-being (specially depression and anxiety). Instrumental practice has an important protective effect on cognitive function. On the other hand, MT with movement, in addition to being effective on cognition (it increases activity in prefrontal cortex), also causes an improvement in physical conditions. However, musical reminiscence (which consists of listening to music with an emotional component for patients with simultaneus display of images to favor memories), although it shows postive effects in several articles, these are not statistically significant. Finally, multimodal therapy (which is a combination of training and cognitive stimulations based on reminiscence and MT) did not show statistically significant changes in either mood or executive functions.
Conclusions: MT is a valid intervention to improve cognitive function, some neuropsychiatric symptoms and the quality of life of patients with MCI. If we also take into account its economic accessibility, the organizational simplicity and null adverse effects, it is easily concluded to be one of the most attractive therapeutic options for treating MCI today.

EPV1163

Cognitive impairment or delusional disorder? A case report

B. Rodríguez Rodríguez[1], N. Navarro Barriga[1], C. Rodríguez Valbuena[1]*, M. Fernández Lozano[1], J. C. Fiorini Talavera[1], G. Guerra Valera[1], A. Aparicio Parras[1], P. Marínez Gimeno[1], M. A. Andreo Vidal[1], M. Calvo Valcárcel[1], M. P. Pando Fernández[1], G. Lorenzo Chapatte[1], M. Ríos Vaquero[1], A. Monllor Lazarraga[1], L. Rojas Vázquez[1], F. J. González Zapatero[1], L. Del Canto Martínez[1] and M. B. Arribas Simón[1]

[1]Psiquiatría, Hospital clínico universitario de Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1751

Introduction: Delusions and hallucinations can appear in various psychiatric and neurological pathologies. When these psychotic symptoms are of late onset, in geriatric age, it may be necessary to make a differential diagnosis between dementia or other psychiatric disorders.
Objectives: To describe the differential diagnosis between dementia and delusional disorder.
Methods: Review of the scientific literature based on a relevant clinical case.
Results: 70-year-old woman who lives with her husband. She has two independent daughters. History of a depressive episode in her youth related to her husband's gambling addiction. She attended the emergency department due to behavioural alteration at home with verbal heteroaggressiveness towards her sister and several neighbours. At the hospital she was approachable, with some psychomotor restlessness, reporting that a neighbour wanted to harm her and spoke of her, making delirious interpretations of harm and referring to visual hallucinations in the form of animals in the courtyard of her house. A brain CAT scan was performed, with normal results.
Her family reports that for about a year she has been saying incoherent things on occasions and behaving strangely. It was decided to admit her to the acute care unit.
Conclusions: During hospitalisation she didn't present behavioural alterations. Treatment with risperidone was introduced with adequate tolerance and response, with distancing of the delusional ideation of harm. MOCA test was performed: 23/30 (suggestive of cognitive impairment), so PET-CT was requested with results not suggestive of neurodegenerative disease and neurodiagnostic tests (SCIP-S and BCSE); the results indicate heterogeneous cognitive performance, and no global cognitive impairment could be observed at the present time and a repeat assessment was recommended in one year's time. Due to the results of the tests and the decrease in positive symptomatology with antipsychotic treatment, a diagnosis of delusional disorder was made upon discharge.

Complex Visual Hallucinations in Charles Bonnet Syndrome: Diagnostic and Treatment Challenges in a Case with Psychotic Features

A. Romero Teruel[1]*, A. Vives Luengo[1] and B. Franco Lovaco[1]

[1]Psychiatry, Hospital Dr. Rodríguez Lafora, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1752

Introduction: A 64-year-old male with diabetes-related blindness was admitted with anxiety, low mood, and passive suicidal ideation. Despite no psychiatric history, he experienced visual hallucinations, which he recognized as "optical illusions." A CT scan ruled out organic causes, and retinal detachment with irreversible vision loss was confirmed. Diagnosed with Charles Bonnet Syndrome (CBS), he developed delusional interpretations and auditory hallucinations. Initially treated with Venlafaxine 150 mg/day, his psychotic symptoms persisted until Risperidone was increased to 6 mg/day, which resolved the hallucinations. Lithium was then added, allowing a reduction in Risperidone without relapse.
Objectives: This review, based on a case study, focuses on the challenges of treating Charles Bonnet Syndrome (CBS), early diagnosis, and the lack of clear diagnostic criteria. It explores the connection between CBS and visual loss, the emergence of psychotic symptoms, and the role of antipsychotics in managing them.
Methods: Literature was reviewed using the following keywords: (Charles Bonnet syndrome) AND (visual hallucinations OR hallucinations) AND (treatment OR management OR therapy OR pharmacotherapy). Databases such as PubMed were used to gather relevant studies.
Results: There are several challenges in diagnosing and treating CBS. Underdiagnosis is common, leading to misdiagnoses such psychosis (Voit et al., 2021; Stojanov, 2016). Non-pharmacological

approaches, including improving vision aids, have shown effectiveness in reducing hallucinations (Yacoub & Ferrucci, 2011; Pang, 2016).However, pharmacological treatments, including antipsychotics and SSRIs, have shown inconsistent results (Voit et al., 2021; Rojas & Gurnani, 2023). Differentiating CBS from psychiatric disorders is crucial, as patients typically retain awareness of the unreal nature of their hallucinations (Stojanov, 2016). Emerging research on CBS neurobiology suggests potential for future targeted therapies (Weil & Lees, 2021; Collerton et al., 2023).
Conclusions: Charles Bonnet Syndrome (CBS) is frequently underdiagnosed due to limited awareness and patient underreporting. Non-pharmacological approaches, such as improving vision and social support, help alleviate symptoms, though no standardized pharmacological treatments exist. This case underscores the importance of distinguishing CBS from psychiatric disorders, especially when psychotic features are present. A multidisciplinary approach, involving ophthalmologists, psychiatrists, and neurologists, is essential for effective management, as seen in this case. Early diagnosis and ongoing research are crucial for developing more targeted treatments for CBS.

Neuropsychiatric Disorders and Psychosis Induced by Chronic Toluene Exposure: Case Review and Antipsychotic Treatment Approaches

A. Romero Teruel[1]*, A. Vives Luengo[1], P. Vazquez Giraldo[2], B. Franco Lovaco[1] and G. Vega[3]

[1]Psychiatry, Hospital Dr. Rodríguez Lafora; [2]Psychiatry, Hospital Universitario de La Paz and [3]Subdirección General de Humanización de la Asistencia Sanitaria, Consejería de sanidad, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1753

Introduction: This case of a 79-year-old patient with inferred past exposure to toluene and persistent paranoid delusions illustrates the potential neuropsychiatric consequences of solvent exposure. The patient's work as a car painter (1990-1992) aligns with literature highlighting the neurotoxic effects of organic solvents. Despite no direct evidence of exposure, treatment with Zuclopentixol 200 mg Depot every two weeks led to symptom improvement, reflecting findings on toluene-related neuropsychiatric disorders such as psychosis.
Objectives:
- Present a potential case of toluene-induced psychosis.
- Review the etiopathogenesis and treatment.
- Assess evidence linking chronic solvent exposure with neuropsychiatric disorders.

Methods: A literature search using PubMed databases was conducted with keywords: (toluene OR xylene OR volatile organic compounds OR organic solvents) AND (psychosis OR schizophrenia OR mental disorders). Case series and observational studies were reviewed. No randomized clinical trials on antipsychotic treatment for toluene-induced psychosis were found.
Limitations: The patient's exposure to toluene was inferred based on work history, without direct evidence such as biomarkers or occupational assessments. As most studies are case series, results must be interpreted with caution. There is a lack of randomized controlled trials exploring antipsychotic treatments in solvent-induced psychosis.
Results: Chronic exposure to toluene is associated with cognitive impairment, memory deficits, personality changes, and psychosis. Neuroimaging often reveals white matter alterations and cerebral atrophy in chronic users. Rare cases of irreversible schizophreniform psychosis have been documented. Treatment with atypical antipsychotics like risperidone shows variable efficacy, but outcomes differ between patients. In this case, Zuclopentixol 200 mg Depot every two weeks led to significant symptom reduction.
Conclusions: Chronic toluene exposure can result in severe neuropsychiatric disorders, including psychosis, as demonstrated by this 79-year-old patient. Neuroimaging showed cerebral atrophy and white matter changes in long-term exposure cases. Treatment with Zuclopentixol effectively reduced symptoms, despite the limited literature, which is mostly based on case series. Randomized clinical trials are needed to develop standardized treatment protocols. Additionally, occupational safety measures are critical to preventing adverse effects from solvent exposure.

Disclosure of Interest: None Declared

EPV1166

Auditory Charles Bonnet Syndrome in a Geriatric Patient with Hearing Loss and Depressive History: A Case Report and Multidisciplinary Approach

A. Romero Teruel[1]*, A. Vives-Luengo[1], M. Aledo-Serrano[2] and B. Franco-Lovaco[1]

[1]Department of Psychiatry, Hospital Dr. Rodríguez Lafora and [2]Department of Neurology, Hospital Universitario La Paz, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1754

Introduction: We present the case of an 88-year-old woman with severe hearing loss and a history of hypertension, non-valvular atrial fibrillation (AF), hypothyroidism, and depressive episodes, admitted following a medication overdose in a context of depressive ideation. The patient reported auditory hallucinations, hearing the voice of her deceased mother; however, she did not exhibit delusional interpretations regarding these experiences, suggesting auditory Charles Bonnet syndrome. This rare phenomenon is primarily described in older patients without psychotic disorder and requires an interdisciplinary approach for appropriate management.
Objectives: To describe the clinical progression of a probable case of auditory Charles Bonnet syndrome and analyze the importance of a multidisciplinary approach, particularly in coordination with neurology, to achieve optimal diagnosis and treatment in a geriatric context.
Methods: The case was addressed through a detailed psychiatric evaluation focused on psychopathological assessment and structured interviews to evaluate affective, cognitive, and behavioral symptoms. Neuropsychological assessment included the Phototest and Clock Drawing Test to rule out advanced cognitive impairment, as well as a cranial CT scan, which showed no significant abnormalities. The neurology consultation evaluated cognitive status, hearing loss, and its impact on the patient's psychological state, while also ruling out other neurological disorders.
Results: The patient showed favorable progress during admission, with mood stabilization and reduced anxiety. She exhibited

long-standing depressive symptoms, including feelings of guilt and burden on her family. She acknowledged hearing her mother's voice calling her and was able to critically assess the unreal nature of these hallucinations. The neurology consultation confirmed significant hearing loss, which contributed to her isolation and, possibly, to the development of auditory hallucinations (due to the lack of sensory input). No signs of advanced cognitive impairment were found.
Conclusions: This case highlights the importance of a multidisciplinary approach in managing elderly patients with unusual hallucinatory phenomena. Once psychotic symptoms were ruled out by psychiatry, the neurology consultation was essential to exclude cognitive impairment and contextualize the auditory hallucinations in relation to the patient's hearing loss and emotional burden. The integrated intervention with her family facilitated a more comprehensive approach, including family support and psychoeducation, adjustments in psychopharmacological treatment, and recommendations to improve quality of life (including emphasizing the use of hearing aids) and social support; demonstrating the effectiveness of collaboration between psychiatry and neurology.

Disclosure of Interest: None Declared

EPV1167

Outcome and cognitive assessment of subjects over 65 years old admitted to the psychiatric ward

F. Catalano[1], A. Di Lisi[1], M. Beghi[2], F. Cappella[1], M. Benassi[3], R. Raggini[2] and R. P. Sant'Angelo[2]*

[1]Psychiatry, University of Bologna, Bologna; [2]Mental Health Department, Ausl Romagna and [3]Psychology, University of Bologna, Cesena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1755

Introduction: The psychogeriatric wards are managed by a specialized multidisciplinary team and are designed to provide a safe, comfortable, and therapeutically appropriate environment for patients with psychiatric issues, where, due to advanced age, pre-existing medical conditions, polypharmacy, cognitive impairments, and fragile physical conditions often coexist.
The elderly population, which is admitted in psychiatric ward in the absence of psychogeriatric wards, appears to be rather heterogeneous and in continuous grow. There are few studies in the literature that investigate the outcomes of hospitalization for these often fragile and vulnerable individuals in environments specific for the intensive management of acute psychopathological conditions.
Objectives: This retrospective observational study aims to evaluate the effectiveness of clinical interventions in patients aged over 65 who are hospitalized in acute phases in the psychiatric ward at the Bufalini Hospital in Cesena.
Methods: At the beginning and end of hospitalization, psychopathological symptoms were measured using the Brief Psychiatric Rating Scale (BPRS). Social and relational functioning was evaluated with the Health of the Nation Outcome Scales (HoNOS), while global cognitive performance was assessed through the Mini-Mental State Examination (MMSE) and the Clock Drawing Test (CDT).
Results: The sample included 166 patients (91 F), with an average age of 71.2 years (SD 5.7). Among these, 128 (77.1%) completed tests. Patients were hospitalized for Bipolar Disorder (46), Psychotic symptoms (16), Major Depression (58), and Dementia (8).
From the general linear model for repeated measures, it emerged that the treatment administered during hospitalization led to a significant improvement in outcomes regardless of the admission diagnosis, for psychopathological symptoms, for socio-relational functioning, and for general cognitive functionality (MMSE and marginally p<0,05 CDT). There were no statistically significant differences related to diagnostic category, age, or gender.
Conclusions: The present study provided important insights regarding the effectiveness of clinical interventions applied to patients over 65. The relevance of these results is particularly pronounced considering the increasing heterogeneity of the elderly population with psychiatric issues and the complexity of the treatments needed to address coexisting conditions and polypharmacy. Further studies are needed to monitor clinical outcomes in the field of psychogeriatrics to further improve the quality of care, while also exploring the challenges related to the early differential diagnosis between psychiatric and dementia-related disorders, in order to ensure increasingly effective and personalized care.

Disclosure of Interest: None Declared

EPV1168

Late Depression and Senescence-Associated Secretory Phenotype (SASP)

A. Sidenkova

Psychiatry, Ural State Medical University, Ekaterinburg, Russian Federation
doi: 10.1192/j.eurpsy.2025.1756

Introduction: Neurobiological mechanisms of late depression include abnormal regulation and interaction of multiple biological processes, as well as abnormalities of brain structures and organs.
Objectives: literature analysis
Methods: general scientific method
Results: The results of the study show that the SASP index as an integral indicator of changes in proteins associated with the cellular aging secretory phenotype is significantly higher in patients with late depression. A high SASP index correlates with older age and age-related diseases. A high SASP index correlates with low cognitive function (low executive function, information processing speed), and high gray matter atrophy. According to the authors, this indicates a connection between late depression and the molecular picture caused by structural and phenotypes of brain aging. Postmortem studies of patients with late depression revealed a coincidence of abnormal gene expression with genes whose expression is regulated by age. Proteomic studies show that late-onset depression associated with cognitive impairment is associated with abnormal regulation of biological pathways related to immune inflammation control, proteostasis, cellular communication and signaling, and oxidative stress. These biological pathways were downregulated during aging, suggesting that depression is associated with lifelong biological abnormalities, limitations with aging. Studies have shown that some of the biomarkers associated with inflammation, growth factors, and cell surface proteins are abnormally regulated in late-onset depression (e.g., elevated sTNFR2 levels) or are associated with certain clinical characteristics such as cognitive impairment (e.g., angiogenin, IGFBP-6). The biological effects of SASP proteins are mediated by p53, p38MAPK, and NFκB

signaling pathways. The SASP index correlates with poor executive function and information processing speed. Patients with late-onset depression associated with cognitive decline have been shown to have profound neurobiological abnormalities and significantly reduced BDNF levels, which is consistent with an enhanced molecular profile of aging. SASP proteins can be produced and secreted by senescent glial cells and activate neuronal intracellular cascades associated with nutrition, metabolic control, cell growth, and apoptosis.
Conclusions: Key to understanding the neurobiology of late-onset depression is how it interacts with brain and systemic biological changes associated with aging.

Disclosure of Interest: None Declared

EPV1169

Prevalence of sarcopenia in elderly psychiatric inpatients of central Slovenia - study protocol

A. Stojkovska[1]* and P. Rus Prelog[1,2]

[1]University Psychiatric Clinic and [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1757

Introduction: Sarcopenia is a syndrome described as generalized and progressive loss of muscle mass, strength and function, leading to an increased risk of falls, fractures, disability and mortality. Recent studies have shown that sarcopenia is more common in patients with long-standing psychiatric illnesses compared to the general population, particularly in those with depression and dementia. There have also been reports of higher prevalence in patients with schizophrenia and bipolar disorder.
Objectives: Our study aims to determine the prevalence of sarcopenia and the factors associated with the syndrome among the geriatric psychiatric population diagnosed with Alzheimer's disease, depression, bipolar disorder, or schizophrenia in the central Slovenian region.
Methods: A single-centre cross-sectional study will be conducted over 3 months at the Department of Geriatric Psychiatry of the University Psychiatric Clinic Ljubljana. Admitted patients aged 65 years or older with a diagnosis of Alzheimer's, depression, bipolar disorder, or schizophrenia will be eligible (50 patients per each diagnosis). The SARC-F (Strength, Assistance with walking, Rising from a chair, Climbing stairs, and Falls) and the MSRA (Mini Sarcopenia Risk Assessment) questionnaires will be used as screening tools to identify sarcopenic patients. Additionally, calf circumference and handgrip strength will be measured. The patients' cognitive functioning will be assessed using the Mini-Mental State Evaluation (MMSE).
Results: We expect to detect higher rates of sarcopenia among inpatients with mental illness. Subgroups will be analyzed according to different demographic and disease parameters.
Conclusions: This study is the first to evaluate sarcopenia among elderly Slovenian inpatients with a mental health illness. We believe that sarcopenia is an important yet underdiagnosed parameter of functional health in the elderly struggling with a chronic mental health illness and should be regularly screened for. Further research is required to identify sarcopenia in this vulnerable population, especially at an early stage, to counteract the progression of the disease.

EPV1170

Using a reflective practice group to facilitate the professional development of care staff in a dementia care setting

L. L. Tan[1]* and H. K. Wong[1]

[1]Psychological Medicine, Changi General Hospital, Singapore, Singapore
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1758

Introduction: Research has shown that staff working in clinical environments caring for frail, elderly or dying patients often must deal with high levels of emotional distress and psychological pain. Psychological defences are necessary and are part of our normal coping mechanism to deal with grief and losses but if they are not understood and recognized, may impact on staff and organizations in unhelpful and destructive ways. In resilient caregiving organizations, emotions are respected and attending to these emotions allow staff to create relationships which will help them cope with their work better.
Objectives: Through interprofessional education with a reflective group, it was hoped that the improved understanding of emotions and experiences of staff and patients could directly influence clinical practice.
Methods: Participants were invited to monthly meetings of 60 minutes for 12 months. A psychodynamic perspective addressed the unconscious processes in clinical encounters. Participants were encouraged to describe how they felt and the meanings of their behaviour rather than just focusing on what happened. Group size was capped at 12 with 2 psychodynamically-oriented facilitators. Semi-structured interviews were conducted and a qualitative approach with content analysis of the transcribed interviews was adopted.
Results: Interdisciplinary staff included nurses, psychologists, social workers, junior and senior clinicians. Our findings showed that staff in dementia care encountered significant levels of emotional distress. The major themes emerged included:
1. Universality of emotions
2. Psychologically safe space
3. Enhancement of reflective capacity
4. Sense-making in the clinical environment

Conclusions: The experiential group discussions allowed staff to better understand and recognize their vulnerability by providing a safe space for directed catharsis. The enhancement of reflective capacity through mirroring and universality in groups allowed members to create relationships which helped them cope with their work better. Through critical inquiry and dialogue, there was better awareness of the social, cultural, economic and political forces at work as staff were encouraged to think and respond honestly to day to day clinical and organizational pressures.

doi: 10.1192/j.eurpsy.2025.1759

Introduction: Previous research suggests that individuals with lower socioeconomic status are frequently exposed to more health risks and emotionally stressful conditions compared to those with higher status. There is a clear link between income and poor quality of life, with disadvantaged older adults lacking key resources. This study explores the relationship between the economic profile of older individuals and their psychosomatic health within the Greek population. It continues a previous investigation on the impact of socioeconomic status on health, offering a deeper understanding of long-term effects.

Objectives: This study investigates how socioeconomic status affects the physical and mental health of older adults in Greece, focusing on income levels' influence on health quality and disparities in health outcomes.

Methods: This cross-sectional study was conducted among 516 Greek participants (214 men, 302 women, average age 73.47 ± 7.72). The participants' average monthly income was €796.72 ± 621.82 (p=0.002). Psychosomatic health was evaluated using the Other As Shamer Scale (OAS), Experience of Shame Scale (ESS), and Cardiac Anxiety Questionnaire (CAQ). A one-way MANOVA analyzed the impact of income on health quality, focusing on both physical and mental health using the 36-Item Short Form Health Survey (SF-36).

Results: Our findings revealed that individuals with a monthly income above €1,500 reported significantly higher quality of life scores. In contrast, those with lower economic profiles exhibited increased levels of shame (measured by OAS and ESS), anxiety about their heart health (measured by CAQ), and a tendency to somatize stress. The analysis indicated that for every additional €100 of monthly income, physical health quality increased by 4.4 points on the SF-36 Physical Health Scale, and mental health quality improved by 2.9 points on the SF-36 Mental Health Scale. These results underscore the statistically significant impact of monthly income on overall physical and mental health scores.

Conclusions: The study highlights a strong link between lower economic status and poorer physical and mental health among older Greek adults. Addressing these effects requires political and societal efforts, with mental health policies that focus on economically vulnerable populations to mitigate the health impacts of low income and improve overall well-being.

AI in Personalized Learning for Older Adults and Intergenerational Engagement: A Systematic Review

E. Tsiloni[1]*, E. Dragioti[2], M. Gouva[2], S. P. Vassilopoulos[1] and M. Mentis[1]

[1]Department of Educational Sciences and Social Work, University of Patras, Patra and [2]Department of Nursing, University of Ioannina, Ioannina, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1760

Introduction: Artificial Intelligence (AI) is increasingly recognized as a powerful tool for customizing learning experiences, fundamentally transforming traditional teaching methods.

Objectives: This systematic review aims to evaluate and synthesize current research on AI learning tools and their role in enhancing educational experiences for older adults, as well as in promoting intergenerational learning and engagement.

Methods: Following PRISMA guidelines, a comprehensive review of both quantitative and qualitative data was conducted. Electronic databases such as PubMed, Scopus, and ERIC were searched up to October 20, 2024. The reference lists of included studies and relevant review articles were also thoroughly examined. The quality of the eligible studies was assessed using the Mixed Methods Appraisal Tool (MMAT).

Results: Nine studies met the inclusion criteria. Findings indicate that personalized education for older adults can be delivered through various approaches, including interactive, user-friendly learning environments, training via virtual conversation agents and digital assistants, and automatic adjustments of pace and content to meet user needs (Figure 1). These approaches also facilitate and promote intergenerational learning (Figure 2).

Image:

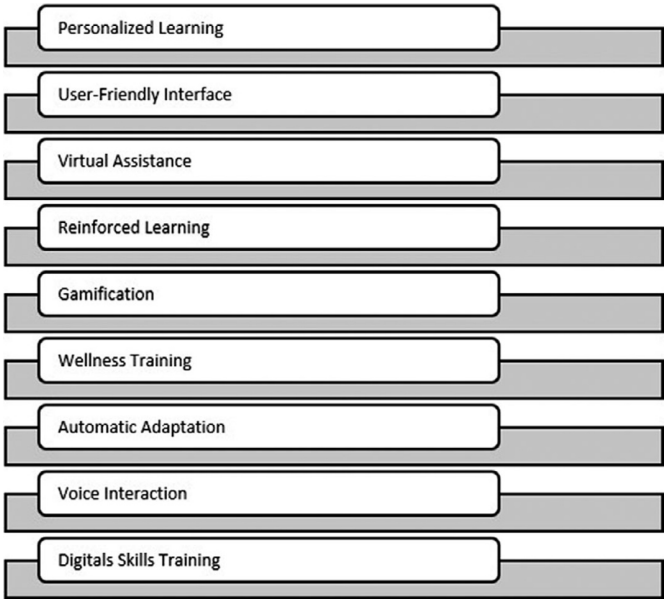

Image 2:

Conclusions: Personalized education through artificial intelligence can significantly enhance older adults' quality of life by promoting autonomy, expanding knowledge, supporting psychosocial well-being, and fostering intergenerational connections.

The Mediating Role of Loneliness in the Association Between Oral Health and Mental Health in Older Adults

C. Tsironis[1]*, M. Mantzoukas[2], A. Nakou[1], E. Bartzou[1], E. Dragioti[1] and M. Gouva[1]

[1]Research Laboratory Psychology of Patients Families and Health Professionals and [2]Nursing, University of Ioannina, Ioannina, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1761

Introduction: Loneliness is widely recognized as a significant risk factor for psychosomatic issues in older adults, potentially impacting various aspects of health, including oral health.
Objectives: This study aims to investigate the relationship between loneliness and oral health in older adults.
Methods: This cross-sectional study was conducted with a sample of 84 older adults (41 females and 42 males), aged between 65 and 94 years (mean age: 74.1 years, SD = 8.1). Participants completed a sociodemographic questionnaire, the 12-item Geriatric Oral Health Assessment Index (GOHAI), and the Emotional and Social Loneliness Scale. Multivariate analysis was used to assess the impact of loneliness on oral health outcomes.
Results: The analysis revealed that emotional and social loneliness had a significant negative impact on oral health. Furthermore, the overall loneliness score was strongly associated with poorer oral health quality, independent of marital status or the presence of children. In other words, the relationship between loneliness and oral health was not moderated by these demographic factors.
Conclusions: As loneliness increases in older adults, their susceptibility to poor oral health rises, which can have significant implications for their psychological well-being. This study underscores the need to consider oral health as an integral component of overall well-being, particularly in the context of mental health in older populations.

Differential diagnosis of restlessness in a middle-aged woman from akathisia to frontotemporal dementia: A Case Presentation

S. Turkan[1]*, R. S. İlhan[1] and M. C. Saka[1]

[1]Psychiatry, Ankara University, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1762

Introduction: Frontotemporal dementia (FTD) is the second most common cause of early-onset dementia and is clinically characterised by progressive behavioural changes, executive dysfunction and language difficulties. FTD is often confused with Alzheimer's disease and other psychiatric disorders. Clinical features of FTD include personality changes, agitation, loss of inhibition, apathy, social withdrawal and impulsivity. In some cases, the disease is accompanied by mood or psychotic symptoms, resulting in the diagnosis of an additional psychiatric disorder. (Gliebus G. (2014). *SAGE open medical case reports*,*2*, 2050313X13519977.). This article presents the case of a middle-aged woman who was diagnosed with an anxiety spectrum disorder before developing and being diagnosed with FTD.
Objectives: A 57-years-old right handed female with previous history of anxiety disorder admitted to psychiatry clinic with restlessness, decreased sleep, and complain of constant non-purpose walking. Physical examination revealed bradymimia and grabellar reflex. Additionally in her psychiatric evaluation she had short-term memory impairment, disinhibition and verbal perseverations. She had been given multiple combinations of medications by outpatient providers and her restlessness only increased. At the time of admission she was taking mirtazapine,olanzapine and clonazepam. The initial impression was that she had akathisia, and her medications were tapered. She was then started on propanolol and lorazepam. After several days her symptoms had not changed.
Methods: In routine biochemical and hematological tests, electroencephalogram (EEG) were within normal limits. 18F-FDG PET/MRI revealed hypometabolism in the bilateral temporal-frontoparietal region, more pronounced in the frontal region which is consistent with FTD.
Results: Trazodone was started to control behavioural symptoms and the dose was gradually increased to 150 mg/day. The dose of

propranolol was increased to 80 mg/day, and lorazepam was tapered and discontinued. During the follow up with this treatment, there was an improvement in her restlessness and anxiety symptoms, but her memory problems were persistent.
Conclusions: Frontotemporal dementia may overlap and be confused with other psychiatric disorders. Therefore, a comprehensive history, physical and neurological examination are required to differentiate each clinical entity (Khan I, De Jesus O. (2023).Frontotemporal Lobe Dementia. In: StatPearls). Additionally, the use of functional neuroimaging, such as 18F-FDG PET/MRI, enables the different distribution of pathology in dementing disorders to be highlighted, as can be seen in our case. This case report highlights the importance of re-evaluating patients with psychiatric diseases, especially when symptoms are resistant to treatment.

Lyme neuroborreliosis presenting as rapidly progressive dementia - a case report

S. Verhnjak

University Psychiatric Clinic Ljubljana, Ljubljana, Slovenia
doi: 10.1192/j.eurpsy.2025.1763

Introduction: Lyme borreliosis is one of the most common vector diseases transmitted by tick bites; it is caused by Borrelia burgdorferi. Mostly it manifests on the skin, in the nervous system or joints. It involves the nervous system in 10-15% of cases, of which 2-4 % affect the central nervous system. The most common manifestation is encephalitis, which has a diverse clinical picture.
Objectives: We aim to describe a rare case and discuss the diagnostic challenges of a rapidly progressive disease.
Methods: A detailed description of the patient based on our interview and clinical findings, including blood work, imaging, microbiological testing, lumbar puncture, and treatment.
Results: A 67-year old female patient came to the psychiatric emergency room in March 2024, because of persistent anxiety and unexplained somatic disorders, including weight loss, tremor and unstable gait, which began a few months ago. She had some somatic diagnostic procedures done, with no abnormal findings. 2 weeks before being admitted she was sent to the emergency neurological unit because of fatigue and tremor. They excluded focal neurological signs and concluded that she had an adjustment disorder and suggested psychiatric treatment. In March 2024 she was admitted to the geriatric psychiatry ward, where at first our main differential diagnosis was pseudodementia. In the next few days her condition worsened. She appeared psychotic, with ideas of persecution and reference. On the psychological exam she had moderate cognitive decline with a focus on impaired attention, memory and executive systems, misinterpretations of past and current events, misidentifications of people and possible complex visual hallucinations. At that time we suspected she might have prolonged delirium. Because of an uncommon clinical picture, we pursued further diagnostics. The lumbar puncture showed cerebral spinal fluid (CSF) pleocytosis, which confirmed the diagnosis of encephalitis. Blood tested for multiple infectious causes was positive for Lyme borreliosis. The brain CT scan showed an inflammatory or infiltrative process in both cerebral hemispheres. We then transferred her to the infectious disease clinic where she had a brain MRI with contrast and her CSF was tested for Borrelia and other possible causes. On the MRI they suspected she had rhombencephalitis with leptomeningitis. After the diagnosis of neuroborreliosis was confirmed, she received a 4-week parenteral treatment with ceftriaxone. Two months after completing the treatment she has fully recovered.
Conclusions: When faced with a patient with rapidly progressive dementia a wider range of possible diagnoses has to be considered. We have to be aware of the importance of recognising the cause of the disease sooner, as the patient may have a treatable condition.

Older LGBTQIA+ adults: Analyzing shame and double stigmatization

S. von Humboldt

William James Center for Research, ISPA – Instituto Universitário, Lisbon, Portugal
doi: 10.1192/j.eurpsy.2025.1764

Introduction: Discriminatory and abusive behaviors may strongly affect older LGBTQIA+ (lesbian, gay, bisexual, transgender, queer or questioning, intersex, asexual, and more) adults, and poorer health is linked to discriminating practices. Shame is associated with ageism and sexual orientation-based discrimination and may be a significant impediment to aging well by undermining older adults' sense of agency, health, and well-being. However, little is still known about older LGBTQIA+ adults who encounter double stigmatization.
Objectives: This study aims to explore the dimensions of shame and double stigmatization of older LGBTQIA+ adults.
Methods: The significant psychological challenges and relevant themes experienced by older LGBTQIA+ adults, as related to shame and double stigmatization, were illustrated by semi-structured interviews with 329 older adults in a qualitative study through content analysis.
Results: The results highlight four themes of shame and double stigmatization among older LGBTQIA+ adults, encompassing (1) ageism (86.5%), (2) sexual orientation-based discrimination (81.1%), (3) stereotyping (76.8%), and (4) social exclusion (72.3%).
Conclusions: The study reveals the profound negative effects of shame and double stigmatization on older LGBTQIA+ adults, emphasizing the need for inclusive policies and interventions to address multiple forms of discrimination and promote equitable treatment in aging populations.
Keywords: Shame; Ageism; double stigmatization; LGBTQIA+; multiple discrimination; older adults.

Pets, intimacy, and mental health: A study with older couples

S. von Humboldt[1]*, S. Silva[2] and I. Leal[1]

[1]William James Center for Research and [2]ISPA – Instituto Universitário, Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1765

Introduction: Pet companionship plays a pivotal role in the lives of older couples, significantly influencing their intimate relationships, by fostering deeper connections and enhancing mental well-being.
Objectives: This study has two aims: (1) to explore the impact of pet companionship on the intimacy of older couples; and (2) to examine its influence on their mental health.
Methods: This study included 223 older couples aged between 65 and 94 years. To explore the multifaceted role of pets in their relationship, content analysis was conducted on all interviews.
Results: Their experiences shed light on the significance of this bond for promoting healthy and fulfilling intimate relationships, with the following themes: (1) contributing to emotional well-being (87.3%), (2) improving mental health in later life (83.1%), (3) fostering a deep relationship between couples (78.7%), (4) facilitating the formation of new emotional connections with others (72.1%), and (5) boosting physical and sensory functions (67.2%).
Conclusions: The findings emphasize the diverse advantages of pet companionship among older adults. These include enhancing emotional well-being, bolstering mental health, fostering interpersonal bonds, and improving physical capacities. These insights underscore the potential for integrating pet interventions into comprehensive strategies aimed at promoting the overall quality of life for older individuals.
Keywords: Pet companionship; intimate relationships; mental health; older couples; well-being.

EPV1178

When care turns to harm: Unveiling abusive behaviors of older towards their caregivers

S. von Humboldt[1]*, N. Ilyas[2] and I. Leal[1]

[1]William James Center for Research, ISPA – Instituto Universitário, Lisbon, Portugal and [2]Center for Clinical Psychology, University of the Punjab, Lahore, Pakistan
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1766

Introduction: Violent, abusive, and harmful behavior enacted by older adults upon their caregivers represents a distressing and frequently disregarded facet within the domain of caregiving.
Objectives: This qualitative study aims to 1) explore family caregivers' experiences of violent, abusive, and harmful behavior by the older person and 2) explore how violent, abusive, and harmful behavior by the older person affects family caregivers' mental health.
Methods: This qualitative study encompassed 307 participants, with a diverse age range spanning from 65 to 87 years. All the interviews went through the process of content analysis.
Results: For the first objective, findings indicated six emerging themes: Persistent and intense verbal abuse (79.1%); Subjugation and manipulation by older adults (72.5%); Unexpected illicit activities initiated by older adults (62.1%); Financial exploitation by older adults (39.8%); Physical abuse (31.5.%); and Sexual abuse (30.7%). The second objective highlighted four themes: High levels of anxiety and depression (87.9%), Intense rage (79.4%), Feelings of moral isolation (77.4%), and Intense explosions (63.6%). Brazilian participants mainly experienced persistent and intense verbal abuse (64.1%). Moreover, higher levels of depression and anxiety were mainly verbalized by English participants (81.8%).
Conclusions: These findings underscore the significant toll that older individuals' violent, abusive, and harmful behavior can have on the mental well-being of family caregivers. This study sheds light on the complex experiences faced by family caregivers and emphasizes the urgent need for targeted interventions to foster healthier caregiving environments.
Keywords: Carers; family caregivers; mental health; older adults; violent, abusive and harmful behavior.

EPV1179

Discrimination and Elder Abuse Toward Elderly LGBT Individuals:A Systematic Review

P. Yılmaz[1]*, C. H. Ayhan[1], H. Akbulut[1] and Ö. Sukut[2]

[1]Sağlık Bilimleri Fakültesi, Van Yüzüncü Yıl Üniversitesi, Van and [2]Sağlık Bilimleri Fakültesi, İstanbul Üniversitesi, istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1767

Introduction: Despite increasing social acceptance over the past two decades, lesbian, gay, bisexual, and transgender (LGBT) individuals continue to face unequal treatment in society (Institute of Medicine, 2011; Caceres et al., 2020). Elderly LGBT adults include the population of sexual and gender minorities over the age of 50 (Choi et al., 2016).They continue their lives under the shadow of negative societal stereotypes and assumptions about their physical and mental health, sexuality, sexual lives, and ability to contribute to society, as well as their family and societal values. When individuals find themselves at the intersection of being elderly and LGBT, they encounter a combined situation that leads to an increased risk of discrimination, social exclusion, and violence. Over time, this can lead to high levels of depression, anxiety, loneliness, and other mental health issues. When they are not accepted by social circles, it often results in social isolation and loneliness. (Geneva, 2023)
Objectives: The aim of this study is to examine the challenges faced by elderly LGBT individuals by addressing issues of discrimination and elder abuse. By evaluating the extent to which current services meet the needs of these individuals, it aims to propose solutions from the perspective of social equality and human rights.
Methods: The study was conducted between December 2024 and February 2025 using the keywords "elderly," "elderly LGBT individuals," and "LGBT discrimination" "elder abuse" in databases (PubMed, Scopus, Springer, etc.). These databases have been preferred because they contain a significant amount of evidence-based literature in the field of psychology. Studies conducted between 2000 and 2024, with full texts accessible and written in Turkish and English, have been included in the study
Results: As of November 2024, 28 national and international research articles related to the subject have been reached. The literature review is ongoing. When the literature review is completed, all the study results will be presented together.
Conclusions: The human rights violations, discrimination, social exclusion, and risk of violence faced by elderly LGBT individuals are not only individual but also societal issues.Developing policies that are sensitive to the needs of elderly LGBT individuals in social services, healthcare services, and the legal system is an important step toward improving their physical, mental, and social health.

Awareness-raising activities need to be expanded to reduce stigma and discrimination against elderly LGBT individuals in society. Additionally, establishing LGBT-friendly elderly care centers and strengthening social support networks are crucial to preventing social isolation.In conclusion, achieving a more inclusive, equal, and fair society is only possible by respecting the rights of every individual.

Psychological burden, feelings of loneliness and life satisfaction in old age

C. Peglidi[1], E. Fradelos[1], F. Malli[1] and A. Zartaloudi[2]*

[1]University of Thessaly, Larissa and [2]University of West Attica, Athens, Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1768

Introduction: As the world population continues to age, understanding the psychological well-being of older people is becoming increasingly vital. Among the various aspects affecting their quality of life, psychological distress, feelings of loneliness and life satisfaction stand out as key dimensions to explore. With age, individuals face a multitude of physical, social and emotional changes that can significantly affect their overall well-being. Consequently, examining the complex relationship between these factors provides valuable insights for promoting healthy ageing and improving the overall quality of life of older people. Psychological distress, often resulting from a range of factors such as chronic health conditions, cognitive decline and social isolation, can manifest itself in various forms, such as anxiety, depression and stress.
Objectives: To investigate the correlation between psychological burden (depression, anxiety, and stress), feeling of loneliness and satisfaction with life among elderly.
Methods: The sample consisted of 148 elderly people over 65 years old. The research instruments used were a) the Depression Anxiety Stress Scale-21, b) the Life Satisfaction Index, c) The UCLA Loneliness Scale, and d) the Athens Insomnia Scale (AIS).
Results: There is a statistically significant association between engagement in domestic activities and a reduction in depressive symptoms. The frequency of children's visits and the presence of social support networks significantly influence psychological burden. Those who received infrequent or no visits from their children exhibited higher levels of depression. Loneliness was affected by family interactions, and life satisfaction was influenced by gender and education. Participants who had people in their immediate environment helping them with daily needs reported reduced depressive symptoms. Finally, the study revealed statistically significant differences in reported life satisfaction based on participants' gender and educational level.
Conclusions: These findings emphasize the need for personalized interventions that acknowledge the complex interplay of these factors in shaping the mental health of older adults.

Capgras syndrome in an elderly patient with severe organic comorbidities and aggression: a case report

N. Zigic[1]* and N. Aljukic[1]

Department of Psychiatry, University Clinical Center, Tuzla, Bosnia and Herzegovina

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1769

Introduction: Caprags syndrome is a rare syndrome characterized by a false belief that an identical duplicate has replaced someone significant to the patient. It is widely regarded as the most prevalent of the delusional misidentification syndromes and appears in psychiatric and non-psychiatric cases, including organic disorders.
Objectives: To present a case report of 84 years old male patient with severe organic comorbidities who developed Capgras syndrome.
Methods: Psychiatric interview
Results: An 84-year-old male patient came to the first psychiatric examination accompanied by his son, due to the suspicion and hostility he has been showing towards his wife for the past month. A few days before the examination, patient became extremely aggressive in the evening hours, he accused his wife that she was not his wife, that another person had been framed instead of her, he demanded that she show him her identity card and threatened to report her to the police. The wife locked herself in the bathroom in fear, but the patient broke down the door. Neighbors called the police, who then restrained him. The patient calmed down after that, but wife went to live with her son. During the examination, patient was completely calm and cooperative, with a neat appearance, oriented, his thought process was normal, conversation was conducted adequately in the desired direction. When asked about thought content he dissimulated it by stating that he was angry because his wife often hangs out with other women and doesn't pay enough attention to him. He denied the presence of hallucinations. Affect was stable, cognitive capacities seemed appropriate for his age. Patient has been treated for several organic comorbidities, including prostate cancer, which was removed a few years ago, but due to problems with urination after surgery he wears a permanent catheter. He was diagnosed with atrial fibrillation and diabetes. He had a heart attcak a year ago, when a stent was implanted, while a bypass was implanted 12 years ago. Laboratory findings indicate elevated glucose and HbA1c values while other parameters are within reference values. He takes all prescribed medicine alone and on time. I diagnose Capgras syndrome and did psychoeducation. Patient showed an interest in taking medication and a desire for his wife to come back to live with him. Low doses of typical antipsychotic was prescribed, which led to cessation of psychomotor restlessness and harmonization of sleep rhythms. Further neuroradiological diagnostics and regular internist follow-up were recommended.
Conclusions: Previous studies showed the link between Capgras syndrome and aggression, which this case report confirms. Probable basis for emergence of this form of delusional disorder is this patient in not dementia, but rather the consequence of serious organic comorbidities. Further diagnostic processing is in progress.

Insomnia and psychological distress in lung cancer

M. Abdelkefi[1]*, I. Gassara[1], R. Jbir[1], S. Omri[1], B. Abderrahmane[2], R. Khemakhem[2], R. Feki[1], N. Smaoui[1], J. Ben Thabet[1], M. Maalej[1], M. Maalej[1], S. Kammoun[2], N. Charfi[1] and L. Zouari[1]

[1]Psychiatry C department and [2]Department of pneumology, Hedi Chaker university hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1770

Introduction: The high symptom burden of lung cancer, coupled with the emotional strain of diagnosis and treatment, often leads to disrupted sleep patterns and heightened levels of anxiety and depression.
Objectives: The aim of this study was to assess the prevalence and severity of insomnia in patients with primary bronchopulmonary cancers, and to explore its relationship with anxiety and depression.
Methods: This was a cross-sectional, descriptive and analytical study conducted among patients followed up for bronchopulmonary cancer at the palliative care unit in the pneumology and allergology department of the Hedi Chaker University Hospital in Sfax. The questionnaire used included patients' sociodemographic characteristics, clinical and treatment data. Sleep disturbance was assessed using the insomnia severity index (ISI) and psychological distress using the Hospital Anxiety and Depression Scale (HADS).
Results: A total of 49 patients participated, with a mean age of 61,8 years, the majority being male (85,7%). The disease duration was less than one year in 61,2% of cases, and 59,2% of patients had stage IV lung cancer, with tumor progression observed in 32,7%.
Mild to moderate insomnia affected 49% of the patients.
The mean anxiety score was 7,08 (SD = 3,6), with a prevalence of anxiety observed in 4,1% of patients. The mean depression score was 6,92 (SD = 3,4), and 34,7% of patients exhibited signs of depression.
A significant association was found between insomnia and depression (p=0,005), but no significant relationship was observed between insomnia and anxiety (p=0,14).
Conclusions: The relationship between sleep disturbance and psychological distress highlights the need for comprehensive management that addresses both physical symptoms and mental health in this population. Early identification and intervention for insomnia and depression in lung cancer patients may enhance their overall well-being and quality of life.

Disclosure of Interest: None Declared

Assessment of quality of life in lung cancer patients undergoing chemotherapy

M. Abdelkefi[1]*, I. Gassara[1], R. Jbir[1], R. Feki[1], B. Abderrahmane[2], R. Khemakhem[2], N. Charfi[1], N. Smaoui[1], S. Omri[1], J. Ben Thabet[1], M. Maalej[1], S. Kammoun[2], M. Maalej[1] and L. Zouari[1]

[1]Psychiatry C department and [2]Department of pneumology, Hedi Chaker university hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1771

Introduction: Lung cancer remains one of the leading causes of cancer-related morbidity and mortality worldwide. Despite being a crucial treatment, chemotherapy often brings a range of side effects that can significantly impact the overall quality of life of the patients.
Objectives: To evaluate the quality of life (QoL) in lung cancer patients undergoing chemotherapy.
Methods: The sample consisted of 49 lung cancer patients undergoing chemotherapy at the Pneumology and Allergology Department of the Hedi Chaker University Hospital in Sfax. The questionnaire used included patients' sociodemographic characteristics, cancer and treatment data, and the European Organization for Research and Treatment of Cancer Core Quality of Life Questionnaire 30-item version (EORTC QLQ-C30).
Results: The mean age of the patients surveyed was 61,8 years, with a male predominance (85,7%). The most frequently reported functional signs of lung cancer were dyspnea (36,7%), cough (34,7%) and chest pain (20,4%). Disease duration was less than 1 year in 61,2% of the cases, and 59,2% were classified as stage IV. Tumor progression occurred in 32,7% of cases. Of the patients, 20,4% were on a single chemotherapy agent, while 79.6% were on a combination regimen.
According to QLQ-C30, the mean global QoL score was 61,24 ± 24,5 for the entire sample. Physical functioning and role functioning were the most affected on the functional scale, while fatigue and appetite loss were the most frequent symptoms.
Conclusions: The findings indicate that lung cancer patients undergoing chemotherapy experience significant challenges to their quality of life, particularly in physical functioning and symptom management. These results highlight the critical need for integrating routine QoL assessments into clinical practice to better address patients' needs and improve supportive care.

Disclosure of Interest: None Declared

Delusional parasitosis secondary to vascular pathology in an oncological patient: case study

M. Garza[1], A. Alcorta[1]*, C. Martinez[1], A. Cantú[1] and S. Reyes[2]

[1]Psicooncología, Medicina de Enlace y Cuidados Paliativos and [2]Psychiatry, Hospital Universitario Dr José Eleuterio González, Monterrey, Mexico
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1772

Introduction: Delusional parasitosis is a psychotic disorder where individuals firmly believe they are infested with parasites despite no medical evidence. It can be primary or secondary, the latter being a symptom of other medical conditions like neurological diseases. Effective management requires collaboration between psychiatry and other specialties.
Objectives: The evaluation of each patient with an interdisciplinary team increases adherence to treatment in patients with cancer and psychiatric illness.
Methods: Clinical history, complementary studies, and review of the literature on the case of a 66-year-old woman subjected to multiple dermatological treatments due to a sensation of body infestation. History of type 2 diabetes and diabetic neuropathy since 2021. In 2022, she was diagnosed with stage IIIA luminal B

breast cancer and treated with surgery, chemotherapy, and radiotherapy. She is currently on adjuvant treatment with Anastrozole. The oncologist referred her due to the presence of psychotic symptoms. The General Health Questionnaire (GHQ-28), Functional Assessment of Cancer Therapy—General (FACT-G), and Positive and Negative Syndrome Scale (PANSS) were applied.
Results: The patient presents with a psychotic disorder secondary to vascular pathology, manifested by delusions of infestation and sudden-onset hypodermic tactile hallucinations. Test results show a GHQ-28 score of 10/84, FACT score of 24/108, and PANSS score of 49 points. Although denying affective symptoms, anxiety, or cognitive impairment, neurological findings indicate decreased brain parenchyma, suggesting small vessel disease. Treatment includes Risperidone 1 mg once daily, along with therapeutic interventions such as psychoeducation and continued multidisciplinary monitoring by neurology for comprehensive disease management.
Conclusions: Evaluating psychotic symptoms requires assessing organic and non-organic factors. Neuroimaging aids diagnosing delusional parasitosis, improving treatment through interdisciplinary collaboration.

Somatic Genetic Predictive Testing for Therapeutic Decision-making in Women at Early Stage of Breast Cancer: What is The Role of Geneticists in Psychological Support?

N. Bouayed Abdelmoula[1]* and B. Abdelmoula[1]

[1]Genomics of Signalopathies at the Service of Precision Medicine LR23ES07, Medical University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1773

Introduction: Somatic genomic variation testing has become an integral part of breast cancer management. Genetic tests based on gene expression profiles in cancer cells (biopsy or surgical specimen) are used for diagnostic, prognostic and theranostic purposes, helping to make therapeutic decisions: selection of adjuvant therapy, prediction of therapeutic responses and of breast cancer recurrence, in patients with early-stage breast cancer. The currently used gene expression assays including MammaPrint, Oncotype DX, Prosigna, etc..
Objectives: The aim of this study was to collect, through a recent review of the literature, the guidelines concerning psychological support before and after predictive genomic exploration in order to situate the role of the geneticist in this mental care.
Methods: We conducted a comprehensive review of the scientific literature with the following keywords: genomic predictive diagnosis, breast cancer and mental health. Through the papers emerging from this research, we assessed guidelines concerning mental health care and genetic counselling.
Results: There is not any guidelines or frameworks concerning the psycho-management of the new predictive genomic tests of breast cancer. Our review show that psychological support is systematically offered in oncology (psycho-oncology) and that the American Society of Clinical Oncology (ASCO) has established guidelines for the management of anxiety and depression in adult survivors of cancer. Moreover, the most recent ASCO guidelines recommend the use of each genomic assay according to the level of evidence available for specific clinical conditions, in breast cancer. There are few papers dealing with genetic counselling and psychological support during the oncotype Dx and MammaPrint tests that are the incorporated into in everyday practice and recommended in clinical guidelines for women with node-negative, hormone-receptor-positive breast cancer. While, in pre-test genetic counselling is well established in breast cancer genetic predisposition, the frameworks in predictive tests and their emotional and psychological impact during prescription, testing and discussion of results as well as the therapeutic choices, are not clear until now.
Conclusions: Genetic counseling includes both informative and educational aspects, as well as advice on personal decisions that may affect the rest of the patient's life. During next-generation predictive testing, the objectives would also be to provide the patient with the ability to gain a sense of control by reducing uncertainty, to determine her own level of risk of recurrence and her therapeutic chances and to receive psychological support during the shared therapeutic decision. Thus, the role of the genetic counsellors must be an essential key in the recent era of mainstreaming of genomic sequencing.

Resilience among male laryngeal cancer patients treated with total laryngectomy

L. S. Chaibi[1,1]*, A. Amri[2], O. Feki[2], M. Cheour[3], S. Hallit[4] and F. Fekih-Romdhane[3]

[1]Department of Psychiatry, Razi Hospital, Mannouba; [2]Head and Neck Carcinologic Surgery, Salah Azaiez Institute, Tunis; [3]Department of Psychiatry, University of Mannouba, Mannouba, Tunisia and [4]School of Medicine and Medical Sciences, Holy Spirit University of Kaslik, Jounieh, Lebanon
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1774

Introduction: Laryngeal cancer patients who undergo total laryngectomy (TL) face significant physical, emotional, and psychological challenges. This group of patients often struggle with feelings of social isolation, depression, and anxiety, as the surgery alters both their appearance and daily interactions. Despite these difficulties, patients can experience remarkable resilience in adapting to life post-surgery, with important individual differences though. Understanding factors associated with resilience among laryngeal cancer patients who had TL is crucial for improving mental health interventions and enhancing rehabilitation efforts.
Objectives: The objective of this study was to examine the resilience of patients who had TL for laryngeal cancer and identify the associated factors.
Methods: We carried-out a descriptive cross-sectional study including 30 patients treated for laryngeal cancer with TL in the Head and Neck Carcinologic Surgery Department at Salah Azaiez Institute.The operations took place during the period 2019-2022. All patients completed the Arabic versions of the Brief Resilience Scale (BRS) and the Arabic Multidimensional Scale of Perceived Social Support (MSPSS).
Results: The study involved 30 male participants with a mean age of 62 years (±10 years).The mean BRS score was 17.6 ± 3.6. Patients from urban areas had lower BRS scores (P=0.005). Additionally, a

higher level of education, particularly secondary or higher, was associated with lower BRS scores (P=0.001). Similarly, a higher socio-economic status correlated with lower BRS scores (P=0.02). Furthermore, greater resilience was significantly associated with higher perceived social support (P=0.001).
Conclusions: This study reveals that patients who have undergone total laryngectomy may experience varying levels of resilience based on socio-demographic factors and perceived social support. Higher social support is linked to greater resilience, emphasizing the need for robust support systems to aid in recovery. Further research is needed to refine support strategies for these patients.

Exploring psychological distress in Tunisian patients with laryngeal cancer after total laryngectomy

L. S. Chaibi[1,1]*, A. Amri[2], O. Feki[2], M. Cheour[3], S. Hallit[4] and F. Fekih-Romdhane[3]

[1]Department of Psychiatry, Razi Hospital, Mannouba; [2]Head and Neck Carcinologic Surgery, Salah Azaiez Institute, Tunis; [3]Department of Psychiatry, University of Mannouba, Mannouba, Tunisia and [4]School of Medicine and Medical Sciences, Holy Spirit University of Kaslik, Jounieh, Lebanon
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1775

Introduction: Approximately 450,000 new cases of head and neck cancers are diagnosed annually worldwide, with laryngeal cancer representing a significant proportion. In Tunisia, these cancers account for approximately 7.3% of all cancers diagnosed. Among those receiving surgical treatment, total laryngectomy is performed in nearly 50% of cases. Total laryngectomy (TL) is regarded as one of the most emotionally challenging surgical procedures due to its profound psychological and functional impacts.
Objectives: This study aimed to investigate psychological distress (i.e. depression, anxiety, and stress) in Tunisian patients who had TL for laryngeal cancer.
Methods: A descriptive cross-sectional study was conducted among 30 patients treated with TL in the Head and Neck Carcinologic Surgery Department at Salah Azaiez Institute.The operations took place during the period 2019-2022.Socio-demographic and clinical data were gathered. All patients completed the Arabic version of Depression, Anxiety and Stress scale (DASS-21).
Results: The study involved 30 male participants with a mean age of 62 years (±10 years). All patients were married and tobacco users, and 53% lived in urban areas. Regarding the Tumor, Node and Metastasis (TNM) staging: 63% were classified as T3, 83% as N0, and 100% as M0. The therapeutic modalities include primary total laryngectomy (TL) followed by radiotherapy, an organ preservation protocol (OPP) followed by TL, partial laryngectomy (PL) followed by TL, and primary TL followed by both radiotherapy and chemotherapy.A total of 67%, 100% and 3% patients had moderate to severe levels of depression, anxiety, and stress respectively.In addition, our study found that a higher level of education was significantly associated with lower levels of depression and anxiety (P=0.001 and P= 0.012, respectively). Urban living was linked to reduced anxiety (P=0.05). Stage N1 was associated with higher depression levels (P=0.013). Finally, previous conservative treatments, such as partial laryngectomy or organ preservation protocol were associated with higher depression scores (P=0.001).
Conclusions: Our findings showed high levels of psychological distress in patients with laryngeal cancer after total laryngectomy. Some factors correlated to distress in this group have been identified, enabling the identification of at-risk groups and effective prevention approaches.

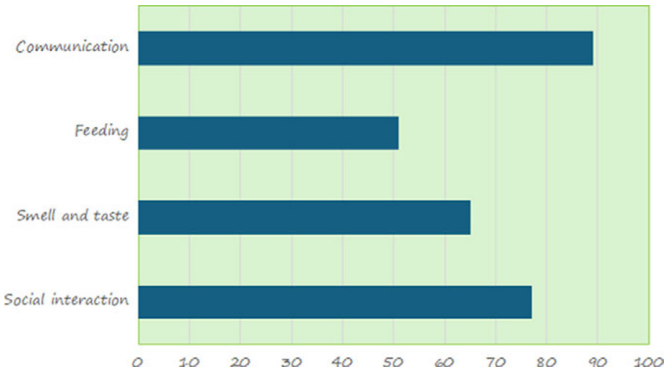
EPV1190

How do patients with laryngeal cancer perceive their quality of life following total laryngectomy? Insights from a Tunisian cross-sectional study

L. S. Chaibi[1]*, A. Amri[2], S. Hallit[3], M. Cheour[4], O. Feki[2] and F. Fekih-Romdhane[4]



[1]Department of Psychiatry, Razi Hospital, Mannouba; [2]Head and Neck Carcinologic Surgery, Salah Azaiez Institute, Tunis, Tunisia; [3]School of Medicine and Medical Sciences, Holy Spirit University of Kaslik, Jounieh, Lebanon and [4]Department of Psychiatry, University Tunis El Manar, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1776

Introduction: Quality of life is a subjective evaluation that individuals make of the various aspects of their lives in relation to their health. Head and neck cancers and their surgical treatments, such as total laryngectomy (TL), change some of the most basic and important vital functions and can affect patients' lives in many ways. The patient's altered appearance, loss of their normally used voice, difficulty swallowing, and certain complications from this kind of surgery, all contribute to impaired quality of life by imposing daily limitations. Despite these considerable impacts, there is no or only very limited research addressing the quality of life of patients post- TL, highlighting the need for further exploration into this critical aspect of patient care.
Objectives: The purpose of this study was to assess self-perceived quality of life in Tunisian male patients who underwent TL for laryngeal cancer.
Methods: A descriptive cross-sectional study was conducted in the Head and Neck Carcinologic Surgery Department at Salah Azaiez Institute. Socio-demographic and clinical data were gathered. All patients completed the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Head and Neck Module (EORTC QLQ-H&N35), Depression, Anxiety and Stress scale, and Voice Handicap Index.
Results: The study involved 30 male participants with a mean age of 62 years (±10 years). The mean EORTC QLQ-H&N35 total score was 60 ± 9.8. The areas of EORTC QLQ- H&N35 score most affected are shown in Figure 1.
Our results indicated that younger patients (P=0.002) and those from rural areas (P=0.04) tended to report better quality of life scores. Additionally, higher socioeconomic status was linked to a reduced quality of life (P=0.006). Patients who were classified as (N +) according to the Tumor, node and metastasis (TNM) staging, showed significantly better quality of life (P=0.004).A higher quality of life was significantly correlated with primary TL (P=0.004), while a lower quality of life was significantly associated with TL

followed by radio-chemotherapy (P=0.005).Depression, anxiety, and stress were significantly correlated with poorer quality of life (P=0.002, P=0.001, P=0.001, respectively). Finally, lower quality of life scores were strongly associated with the Voice Handicap Index score (P=0.0001).

Figure 1. Distribution of patients according to their EORTC QLQ-H&N35 scores.

Image 1:

Conclusions: In conclusion, patients who underwent TL for laryngeal cancer seem to exhibit an impaired quality of life, with factors like age, socioeconomic status, treatment type, voice handicap and psychological distress likely playing an important role. These findings underscore the need for comprehensive post-surgical care aiming at improving quality of life for people affected by this condition.

The Role of Stigma, Illness Acceptance, and Social Support in Mental Health Care Service Utilization Among Cancer Patients in Hungary

R. Chowdhry[1]*, A. Kegye[1], E. Földesi[1], V. K. Bognár[1], G. Purebl[1] and D. Őri[1]

[1]Institute of Behavioral Sciences, Semmelweis University, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1777

Introduction: An understanding of cancer from a psychological perspective is being increasingly prioritized in research and clinical care. Psychiatric disorders have been demonstrated to affect at least 35% and up to 55% of cancer patients throughout their trajectory. Further, cancer treatment adherence and health behaviors have been shown to have a marked decrease due to a series of mental health contributors. Therefore, comprehensive collaborative care interventions incorporating psychological care into oncological care has shown increased promise in reducing the burden of such comorbid diseases and promoting positive health outcomes. Social contexts, support, internal beliefs, and social perceptions significantly influence patients' tendencies to utilize mental health services. An understanding of the psychosocial factors that influence mental health care utilization among cancer patients may promote greater utilization, evidence-based interventions, and consequently better health outcomes.

Objectives: We aim to assess perceived stigma towards disease, perceived social support, and acceptance of the illness as related to rates of utilization among cancer patients undergoing treatment.

Methods: We will measure the perceived stigma of the disease via the Hungarian version of the Stigma Scale for Chronic Illnesses (SSCI-8). The perceived social support will be measured by the Hungarian version of the Multidimensional Scale of Perceived Social Support (MSPSS) and the acceptance of illness will be measured via the Acceptance of Illness Scale (AIS) and Mini-Mental Adjustment to Cancer (Mini-MAC) to assess coping reactions to cancer. These surveys will be administered to 150 cancer patients at Semmelweis University in Budapest, Hungary and data collection will take place from November 2024 until February 2025.

Results: This research is currently ongoing, and we will be able to present study results based on a sample of 150 individuals, demonstrating how perceived social support, perceived stigma of the disease, and illness acceptance relate to rates of the utilization of mental healthcare services such as psychotherapy and psychotropic medications, specifically among cancer patients in Hungary.

Conclusions: An in-depth understanding of the social and psychological factors that influence positive health behaviors in the form of mental healthcare service utilization may inform the development of more tailored evidence-based collaborative care interventions.

Impact of Chronic Pain on Anxiety, Depression, and Daily Life Activities Among Breast Cancer Survivors in Tunisia

A. Hadj Salah[1,1]*, M. Chaouat[2], A. Haouala[1], A. krir[2], S. Zaied[2], F. zaafrane[1], A. mhalla[1] and B. amamou[1]

[1]psychiatry and [2]oncology, Fattouma Bourguiba Hospital, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1778

Introduction: Chronic pain is a prevalent issue among breast cancer survivors, often causing significant distress, disability, and interference with daily activities. Affecting around 18% of the global population, chronic pain is the leading cause of years lived with disability. Among breast cancer survivors, it has become a key focus due to its high prevalence and impact on quality of life.

Objectives: To assess the prevalence and characteristics of chronic pain in breast cancer survivors and examine its correlation with anxiety, depression, and interference with daily life activities.

Methods: This is a cross-sectional descriptive and analytic study conducted on 100 women treated for breast cancer at the medical oncology department of Fattouma Bourguiba University Hospital. The study spanned eight months (June 2021–February 2022). Pain characteristics were assessed, and anxiety and depression levels were measured using the Hospital Anxiety and Depression Scale (HADS). Pain-related catastrophic thinking was evaluated with the Pain Catastrophizing Scale (PCS), and family functionality was measured using the Family APGAR score.

Results: The study involved 100 breast cancer survivors, with a mean age of 53.6 ± 10.1 years.

Our entire population confirmed having chronic pain for more than 3 months, most of them (53%) had it from 2 to 5 years
The median duration of chronic pain was 3 years [IQR: 2-5], with the most common pain locations being the breast area (72%) and upper limb (27%). Pain intensity was predominantly mild (62%), followed by moderate (34%), and severe (4%).
Chronic pain significantly interfered with daily activities, especially in patients with moderate to high pain intensity ($p < 0.001$), affecting both affective and activity clusters. The mean Pain Catastrophizing Scale score was 7.79 ± 5.25, indicating mild catastrophic thinking, which was most likely due to the low pain intensity experienced by the majority.
Anxiety levels were significantly correlated with higher pain intensity ($p = 0.013$), whereas depression, though elevated in patients with more severe pain, did not demonstrate a statistically significant association ($p = 0.135$).
The majority of participants were from highly functional families, with 88% reporting strong family support
Despite the prevalence of chronic pain, fatigue was not significantly related to pain intensity.
Conclusions: Chronic pain in breast cancer survivors significantly interferes with daily activities, particularly among those with moderate to high pain intensity. Anxiety is notably more prevalent in patients experiencing more severe pain. These findings underline the importance of comprehensive pain management strategies and psychological support for breast cancer survivors.

Long-term impacts of prostate cancer treatments on sexual function and psychological well-being: A comprehensive narrative review

R. Arif[1], H. Hami[2], S. Sennani[2], S. Irnat[2]*, A. Mokhtari[2], S. Jaouhar[3], A. Soulaymani[2], J. Bouzid[1] and F. Hadrya[1]

[1]University Hassan First of Settat, Higher Institute of Health Sciences, Health Sciences and Technologies Laboratory, Settat; [2]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra and [3]Higher Institute of Nursing and Technical Health Professions, Fez, Meknes Annex, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1779

Introduction: Sexual dysfunction, which is frequently observed in cancer patients, especially those undergoing prostate cancer treatments, has significant implications for both psychological well-being and intimate relationships. This review consolidates the current understanding of treatment impacts on this patient group.
Objectives: This study examines the prevalence and psychological impact of sexual dysfunction among prostate cancer survivors following treatment.
Methods: A narrative review was conducted, analyzing data from six observational studies involving 7,146 participants and one meta-analysis published between 2015 and 2024. These studies focused on elucidating the relationship between sexual dysfunction and psychological well-being post-treatment using databases such as Scopus, PubMed, and Web of Science.
Results: All main prostate cancer treatments (surgery, radiotherapy, and hormonal therapy) are associated with substantial risks of sexual and erectile dysfunction, as well as depressive symptoms. Notably, radical prostatectomy significantly reduces sexual function, with about one-third of patients experiencing depressive symptoms post-surgery. Additionally, within a year of undergoing radical prostatectomy, approximately 90% of patients experience moderate to severe erectile dysfunction. The associated depressive symptoms largely stem from diminished sexual activity and dissatisfaction stemming from disrupted sexual normalcy. Antiandrogen therapies also progressively worsen sexual function, impacting perceived masculinity and contributing to psychological distress. Notably, older men generally adapt to these changes more adeptly than younger men.
Conclusions: Persistent erectile dysfunction is a major, detrimental side effect for prostate cancer survivors, profoundly impacting their quality of life. Enhanced education for patients and their partners about potential sexual side effects, along with improved awareness and preparedness strategies, are essential to alleviate the psychological burdens stemming from post-treatment sexual dysfunctions.

EPV1195

Psychodynamic-oriented Psychoeducation for Early-Stage Breast Cancer Patients: Effects on Clinical and Psychological Outcomes

S. Jang[1]*, K. Kim[2], H.-D. Rim[2] and J. Woo[2]

[1]Psychiatry, Daugu Catholic University and [2]Psychiatry, Kyungpook National University, Daegu, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1780

Introduction: Breast cancer is one of the most common cancers in women. Depression and anxiety affect not only health behaviors and treatment adherence but also cancer recurrence. Several studies have demonstrated that psychosocial interventions improve both mood symptoms and survival in breast cancer patients.
Objectives: Psychodynamics plays a significant role in psychological distress and maladaptive behaviors. Therefore, psychoeducation focusing on patient dynamics can offer more individualized and tailored intervention. This study investigated the impact of psychodynamic-oriented psychoeducation for early-stage breast cancer patients on both psychological distress and disease trajectory, compared to those receiving standard cancer treatment only.
Methods: Psychodynamic-oriented psychoeducation aims to provide guidance on managing psychological distress during cancer treatment, based on clinical and psychodynamic assessments of patients. A trained psychiatrist delivered this 60-minute intervention at least once within one-week post-mastectomy. The study included early-stage breast cancer patients (AJCC stages 0-IIIA) who underwent mastectomy at Kyungpook National University Hospital (KNUH) and Kyungpook National University Chilgok Hospital (KNUCH) between 2008 and 2015, excluding those with prior cancer history. Participants were divided into two groups: control (standard treatment) and treatment (standard treatment plus psychodynamic-oriented psychoeducation). Outcomes measured included breast cancer recurrence, disease-free survival, and psychological assessments using the Hospital Anxiety and Depression Scale (HADS) and Experiences in Close Relationships-Modified 36 (ECR-M36) at baseline and

12 months post-intervention in the treatment group. Propensity score matching was used to control for recurrence-related factors.

Results: The median follow-up was 72.6 months. Recurrence rates were comparable between control and treatment groups (control vs. treatment: 9.0% vs. 8.3%, p=0.763). In a subanalysis of recurrent cases, the treatment group showed longer disease-free survival (51.3 vs. 32.5 months, p=0.038). (Table 1 and Figure 1) HADS scores showed no significant difference at 12 months, while ECR-M36 showed significant decreases in total and anxiety subscale scores at 12 months (p<0.05). (Table 2)

Image:

	total participants (N=554)		P=0.721	recurrent participants (N=48)		P=0.038
	Mean (month)	SE		Mean (month)	SE	
Treatment	139.4	2.5		51.3	7.7	
Control	117.9	1.8		32.5	4.7	

SE=standard error.

Image 2:

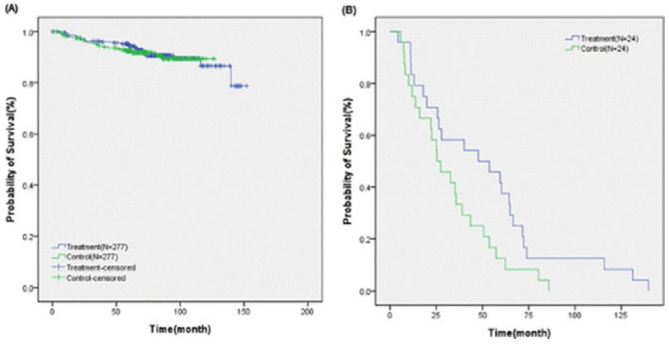

Image 3:

	Pre		Post		Mean difference	t	P value
	mean	SD	mean	SD			
ECR-total	127.4	18.1	109.6	25.1	17.8	2.48*	0.031
ECR-Anxiety	60.5	14.1	50.5	14.7	10.0	3.13*	0.010
ECR-Avoidance	66.9	10.4	59.1	12.7	7.8	1.67	0.123

ECR=the Modified Experiences in Close Relationships; SD=standard deviation. *p<0.05.

Conclusions: This study, unique in integrating psychodynamic principles into psychoeducation, showed improvements in attachment-related anxiety and longer disease-free survival, specifically among recurrent cases, suggesting the potential benefits of this approach for certain breast cancer patients. Further research is needed to identify which patients might benefit most from this intervention.

EPV1196

Attitudes toward death as a predictor of affective spectrum disorders in oncopsychology: a cross-cultural comparison

K. Kholmuradova

Psychology, MSU, Tashkent, Uzbekistan

doi: 10.1192/j.eurpsy.2025.1781

Introduction: Affective spectrum disorders remain an underestimated problem in the field of oncopsychology, affecting not only the immune response and progression of some cancers in cancer patients (Smulevich, 2001; Reiche, Nunes, Morimoto, 2004; Schulz-Kindermann, 2021), but also performance and the provision of quality medical support by oncology staff (Mern, 2017; Klimenko, 2023). One of the possible factors contributing to depressive states and emotional burnout, we believe the peculiarities of attitudes toward death, which may have cross-cultural differences.

Objectives: The main hypothesis of the study was the assumption that the nature of the attitude to death may be associated with both the level of depression in cancer patients and the severity of emotional burnout in medical workers of oncological institutions. We also assumed that this relationship may have cross-cultural differences due to differences in worldview attitudes (primarily related to the dominant type of religiosity), as well as due to organizational peculiarities of medical care in different countries.

Methods: The study included 240 participants: 50 cancer patients from Russia and Germany (M_{age} = 55.3; SD = 8.6; 32 women and 18 men), and 190 medical specialists employed in oncologic institutions in Uzbekistan and Germany (M_{age}= 37.1; SD = 9.6; 73 women and 117 men).

The study was based on a survey design using three questionnaires adapted in two languages (Russian and German): Beck's Depression Inventory (Tarabrina, 1992; Hautzinger, Keller, Kühner, 2009), The Maslach Burnout Inventory (Vodopyanova, Starchenkova, 2001; Burisch, 2010), and Death Attitude Profile-Revised (Chistopolskaya, Mitina, Enikolopov, 2017; Jansen, Schulz-Quach, Eisenbeck, 2019). In addition, the study used questionnaires to collect data on the following characteristics of respondents.

Results: It was revealed that the attitude towards death was found to be correlated both with the level of depression in cancer patients and with the syndrome of emotional burnout in workers of oncological institutions, namely: fear of death accompanies an increased level of affective disorders, while neutral acceptance - a lower level or none. Along with this, other variables were also identified that found a relationship with the development of affective spectrum disorders. Cross-cultural differences were also found regarding medical personnel: specialists employed in Uzbekistan showed a lower level of mental well-being, in contrast to personnel in Germany. When it comes to cancer patients, no culture-specific differences were found.

Conclusions: According to the results of the study, it can be stated that the attitude to death can be not only a predictor of affective spectrum disorders (depression in cancer patients and emotional burnout in medical professionals), but also a resource in preventing these disorders. Neutral acceptance of death may be one of them.

EPV1197

Day to day work as a psychiatrist in the psycho-oncology department

J. Knific[1]*, A. C. Skufca Smdrel[1] and S. Kocijančič Azzaoui[1]

[1]Psycho-oncology, Institute of Oncology, ljubljana, Slovenia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1782

Introduction: Liaison psychiatry mostly deals with consultations that are required in different department of somatic hospitals. The patients range from surgery to dermatology and the consultations vary depending on the department. As far as we know, in Europe, there is no psycho-oncology department with a psychiatrist on board full-time. In Ljubljana, Slovenia, this has been the case since 1984, with a short break for a few years, but an addition again in the last three years. Working as a psychiatrist in a very specific and demanding environment at oncology has its; challenges, as well as integrating the work with a team of clinical psychologists.
Objectives: We wanted to analyse how many and what kind of patients are referred to the psycho-oncology department, either to a psychiatrist or a clinical psychologist.
Methods: We gathered the data from referrals; How many patients were checked in an office or in a hospital setting, how many of these were first referrals. We also compared the checkups by a psychiatrist or by a clinical psychologist. Out of these, we looked at the oncological diagnosis and if they were referred by an oncologist. Out of our first referrals checked which diagnosis was most prevalent.
Results: In the year 2023 the statistical data of the psycho-oncology department was gathered by the psychiatrist and clinical psychologist. Number of referrals for a psychiatrist was 895 and for a clinical psychologist was 1511. The psychiatrist performed 215 first referrals, so 24% out of all checkups. The psychologist did 325 first referrals, which is 21% out of all check-ups. For the psychologist and the psychiatrist the most common adjoining cancer diagnosis with a referral was breast cancer, making up 47% in the psychiatrist case and 44% in the psychologist case of all of the first checkups. Most common indication for a referral to a psychologist was mental distress, while for a psychiatrist was depression. Interestingly both the psychologist and psychiatrist would afterwards diagnose their patients most often with the diagnosis of adjustment disorder.
Conclusions: The data showed interesting differences and similarities between referrals to a psychologist and a psychiatrist. It is important to note, that the distinction of referrals to psychiatrist or clinical psychologist at the psychooncology department is rather new. It should be mentioned, that the distinction is also that there is only one psychiatrist compared to three psychologists. The data will continue to be gathered as to ascertain the adaptation of the entire oncology clinic to a better accessibility of a consultation psychiatrist.

EPV1198

A case report of the two big C's; Cancer or catatonia?

S. Kocijancic Azzaoui[1]*, J. Knific[1] and A. Andlovic[2]

[1]Psycho-oncology and [2]Neuro-oncology, Institute of Oncology, Ljubljana, Slovenia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1783

Introduction: Catatonia is a severe neuropsychiatric condition with distinct motor, behavioural, and affective abnormalities that can manifest suddenly and dramatically. While it is commonly associated with psychiatric disorders, catatonia can also emerge in the context of various medical conditions, including malignancies.
Objectives: This report details the case of a 68-year-old female with lymphoma who developed sudden-onset catatonia, highlighting the complexities of diagnosing and managing this rare complication.
Methods: The patient presented with symptoms of unresponsiveness and aphasia, acutely in the department just a few hours after the nurses reported, she had been confused during the night shift and had visual hallucinations. First the neurologist was consulted. Neurological examination revealed unresponsiveness to verbal or pain stimuli, flaccid muscle tonus, no plantar response, normal reflexes, staring gaze, blinking and resistance to open eyelids. Corneal and oculocephalic reflex including cardiorespiratory functions were normal. Due to the acute nature of the symptoms and history of iatrogenic subdural hygroma a trial with anticonvulsant was performed, with no improvement. CT scan, MRI scan and EEG were unremarkable. Results of the lumbar puncture ruled out any inflammation, infection or lymphoma infiltration.
Results: Since the clinical findings did not correlate with test results, the neurologist consulted the psychiatrist. The patient was promptly treated with lorazepam 2 mg intramuscularly, which is the first-line treatment for catatonia. Within 2 hours of initiating treatment, there was a noticeable improvement in her responsiveness. Over the next 24 hours, she regained the ability to speak and follow commands. The decision was made to continue lorazepam 2 x 1 mg per day plus 2 x 1 mg if needed. After three days the consultation psychiatrist came to do a checkup and found the patient talking slowly and quietly, with some anxiety symptoms, but no apparent mood disorder or delusions or hallucinations. The patient was prescribed antidepressants and continued lorazepam treatment. The psychiatrist tried to decrease the lorazepam dose before the patient discharge, which resulted in worsening of her mental state. Lorazepam dose was again raised to the previous effective dose. She was discharged with sertraline 50 mg and lorazepam 2 x 1 mg. The patient had a checkup a month after being discharged. At the checkup she presented not only without any signs of catatonia, but in complete remission of any mood or anxiety or psychosis symptoms. At that point, the lorazepam dose was reduced, with the intention of keeping only the antidepressant therapy.
Conclusions: Catatonia is a rare and serious complication for patients with lymphoma, and recognizing it constitute a challenge as demonstated by this case. However the lorazepam challenge test still remains a great diagnostic treatment.

Predicting marital adjustment in cancer patients: The impact of attachment styles, disease type, and stage on marital duration

M. Firoozi[1], M. Sharifi[2] and C. A. Lewis[3]*

[1]Psychology, University of Tehran, Tehran; [2]Psychology, Islamic Azad University, Bandar Gaz Branch, Bandar Gaz, Iran, Islamic Republic Of and [3]Psychology, Leeds Trinity University, Leeds, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1784

Introduction: This study examined the interplay between marital relationships and individual adjustment to cancer, considering the influence of attachment styles and marital duration under high-stress conditions.
Objectives: This research aims to elucidate how these factors modulate the marital quality and the psychological well-being of individuals and their partners.
Methods: A total of 312 participants, comprising 223 cancer patients and 89 partners, completed the Golombok-Rust Inventory of Marital State and the Adult Attachment Inventory. Linear mixed-effects models were used to analyze the relationships between marital adjustment, attachment styles, and marital duration.
Results: The findings indicated that females diagnosed with cancer reported significantly poorer marital adjustment compared to their male counterparts (both $p < .05$). Notably, secure attachment was significantly positively associated with better marital adjustment ($\beta = .18$, $p = .016$), while ambivalent attachment was significantly negatively associated with worse marital adjustment ($\beta = -.11$, $p = .029$). These patterns persisted across both patients and their partners, with no significant differences based on sex. Additionally, the impact of attachment styles on marital adjustment did not vary significantly with marital duration (all $p > .05$).
Conclusions: These results underscore the complexity of the marital dynamics among couples confronting cancer. The data reveal that secure attachment enhances marital stability, whereas ambivalent attachment detracts from it, irrespective of the sex of the respondent or marital duration. This study adds to the body of literature by highlighting the nuanced ways in which attachment styles influence marital dynamics under the strain of cancer. The implications for clinical interventions emphasize the importance of fostering secure attachment behaviors in couples therapy, particularly in contexts involving significant health challenges.

Effectiveness of Spirituality-centered Cognitive Therapy and Contextual Transdiagnostic Approach on marital mutuality, dissociative experiences, and cancer-related fatigue in women after mastectomy

M. Firoozi[1], M. Sharifi[2], O. Esmati[3], Z. Kiek[3] and C. A. Lewis[4]*

[1]Psychology, University of Tehran, Tehran; [2]Psychology, Islamic Azad University, Bandargaz Branch, Bandargaz; [3]Psychology, Islamic Azad University, Azadshahr Branch, Azadshahr, Iran, Islamic Republic Of and [4]Psychology, Leeds Trinity University, Leeds, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1785

Introduction: Breast cancer remains the most frequently diagnosed cancer and a leading cause of cancer-related deaths in women worldwide. Post-mastectomy, women often experience heightened emotional distress, diminished quality of life, and interpersonal challenges.
Objectives: This study seeks to evaluate the comparative effectiveness of Spirituality-Centered Cognitive Therapy (SCT) and the Contextual Transdiagnostic Approach (CTA) on marital mutuality, dissociative experiences, and cancer-related fatigue in women after mastectomy.
Methods: In this randomized controlled trial, 132 women, selected based on inclusion criteria from an initial pool of 167, were randomly assigned to two intervention groups: SCT (n=66) and CTA (n=66). Each group underwent eight 60-minute therapeutic sessions over four weeks, held twice weekly from August to September 2022. Standardized questionnaires assessing marital mutuality, dissociative experiences, and cancer-related fatigue were administered pre- and post-intervention. Multivariate analysis of variance (MANOVA) with repeated measures was employed for data analysis using SPSS-24.
Results: CTA demonstrated superior effectiveness in reducing dissociative experiences compared to SCT. Conversely, reductions in cancer-related fatigue were more pronounced in the SCT group. Improvements in marital mutuality were comparable between the two therapeutic approaches.
Conclusions: Both SCT and CTA proved effective in enhancing psychological and relational well-being in women post-mastectomy. However, SCT more effectively alleviated cancer-related fatigue, while CTA showed greater efficacy in addressing dissociative experiences. These findings highlight the potential of integrating tailored therapeutic approaches to improve quality of life for breast cancer survivors.

Predicting emotional disturbance in breast cancer patients: The role of self-empowerment skills, interpersonal relationships, and demographic factors

M. Firoozi[1], M. Sharifi[2] and C. A. Lewis[3]*

[1]Psychology, University of Tehran, Tehran; [2]Psychology, Islamic Azad University, Bandargaz Branch, Bandargaz, Iran, Islamic Republic Of and [3]Psychology, Leeds Trinity University, Leeds, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1786

Introduction: Breast cancer represents a significant health concern among Iranian women, notably impacting their mental health. This has spurred considerable interest within health psychology, given breast cancer's profound effects on both physical and psychological well-being.
Objectives: This study aimed to explore the predictability of emotional disturbances through psychological, socio-cognitive variables, and to quantify their relative impacts among breast cancer patients.
Methods: Employing a descriptive and exploratory approach, this research involved 736 breast cancer patients aged 19 to 80 from Shahada Tajrish Hospital, Tehran during the first eight months of 2017. Participants were selected and screened based on specific inclusion and exclusion criteria. Measures included the Self-Empowerment Skills Scale, the Quality of Interpersonal Interactions Scale, and the Emotional Disturbance Scale. An emotion management therapy program was offered to motivate patient participation.
Results: Analysis revealed significant associations between emotional disturbance and factors such as self-empowerment skills, quality of interpersonal interactions, and various demographic variables including age, education level, employment status, household headship, and gender. Notably, interpersonal quality and self-empowerment skills emerged as the most influential predictors.

Conclusions: The findings underscore the critical roles of interpersonal relationships, self-empowerment skills, and demographic characteristics in influencing the emotional well-being of breast cancer patients. It is recommended that psychologists emphasize these factors when assessing and promoting the mental health of this population.

Mortality Communication and Expected Grief for Caregivers of Cancer Patients

E. ORHAN[1]*, C. H. AYHAN[1], F. TANHAN[2] and M. C. AKTAŞ[1]

[1]Department of Psychiatric Nursing, Van Yuzuncu Yil University Faculty of Health Sciences and [2]Guidance and Psychological Counseling, Van Yuzuncu Yil University , Van, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1787

Introduction: Cancer is a disease with a high mortality rate and requires care. The identification of cancer with death may cause patients and caregivers not to talk about illness and death. However, communication is one of the most important elements of this disease process. In addition to the inability to talk, the increased responsibilities of caregivers cause physical, economic, social and psychological burdens on caregivers. This can lead to high levels of stress, mental fatigue and depression in caregivers. Poor communication between patients and caregivers is an important factor related to depressive symptoms in caregivers during the caregiving process. Open communication between caregivers and the patient is a factor that can positively affect the disease process. With this study, it can be found that being open communication can reduce depression, anxiety and stress levels in caregivers and support studies to reduce the burden of care of caregivers. Thus, it can be ensured that patients and their caregivers experience the disease process more positively and spend it more positively.
Objectives: Existing measures of mortality communication may not capture much of the nuance in that cancer caregiver report to be particularly upsetting, so we thought it would be important to examine reliability and validity of the Caregiver's Communication with the Patient about Illness and Death (CCID) Scale for measuring the extent to which caregivers of cancer patients discuss illness and death with the patientin Turkey.
Methods: The methodological study will be conducted to establish the validity and reliability of the Caregiver's Communication with the Patient about Illness and Death (CCID) Scaleto Turkish Culture and to determine the level of mortality communication, expected grief, care burden and mental health problems among cancer caregiver in Eastern Turkey. The sample of the study will consist of cancer caregivers and who agree to participate in the study. The data will be subjected to appropriate methods for statistical analysis and will be used to understand the relationships between mortality communication and grief, depression, anxiety, stress and caregiver burden at caregivers of cancer patients.
Results: Data extraction is still on going in detailed style by principal authors. Description of studies and the key findings will be presented.
Conclusions: It is predicted that not discussing illness and death causes an increase in depression, anxiety and stress levels in caregivers. In this study, it is aimed to evaluate depression, anxiety and stress in caregivers of cancer patients who will be evaluated with the scale and to evaluate their relationship with care burden.

Adverse psychiatric effects of lorlatinib: a case report and review of the literature

I. Ortín[1]* and L. Nocete[2]

[1]Virgen Macarena University Hospital, Seville and [2]La Paz University Hospital, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1788

Introduction: Lung cancer is one of the most frequent forms of cancer worldwide. Its prevalence has increased substantially the last decades. About 85% of all cases are non-small-cell lung cancer, which can be further divided in other subtypes. The use of targeted therapies and immune check-point inhibitors in the last years has improved survival, such is the case of tyrosin-kinasa inhibitors as lorlatinib. This molecule can reduce neoplastic growth when ALK rearrangement is present.
Objectives: To review the literature about psychiatric adverse effects of lorlatinib.
Methods: A narrative review of the evidence was performed. The search was focused on described psychiatric adverse effects in patients with lung cancer who have received lorlatinib as antineoplastic agent.
Results: We report the case of a 54-year-old man with lung adenocarcinoma stage IV ALK+ diagnosed in 2024. Suprarenal metastases were found. He started antineoplastic treatment with lorlatinib as first line agent during hospitalization, with a dose of 100mg per day. Three months later, the patient experienced anxiety and impulse phobias of aggressive content which led to an intense psychological distress and behavioural repercussion (avoidance, overcompensation). He consulted because of these symptoms and the dose of lorlatinib was reduced to 75mg per day by his oncologist. By the time he was evaluated in Psychiatry Service, the symptoms had improved but remained present. Low doses of aripiprazole were prescribed as symptomatic treatment (2,5mg per day) with great results manifested one week later.
Conclusions: Most common adverse effects of tyrosin-kinasa inhibitors are fatigue, gastrointestinal symptoms, skin reactions or edema, among others. Although neuropsychiatric adverse effects are infrequent, they can occur and induce significative impairment and emotional distress. It's important to recognize these other symptoms, especially on new drugs, and know how to approach them properly.

Substance use in cancer patients – an undervalued and harmful association

A. L. Ramos[1,2]*, J. T. Coelho[1] and H. Salgado[1,2]

[1]São João Local Health Unit and [2]Faculty of Medicine of University of Porto, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1789

Introduction: Substance use and substance use disorders are widespread among cancer patients, throughout the complex course of the disease. Besides the fact that the use of some substances predisposes individuals to cancer, substance use can also develop after a cancer diagnosis. The latter becomes more concerning by the significant use of opioids in the context of cancer pain management. In addition, individuals with cancer may use substances in an attempt to cope with psychological distress or poorly controlled physical symptoms – "chemical coping".
Objectives: In this work, we intend to do a review on the prevalence and impact of substance abuse in oncological population.
Methods: Our research will focus on papers of the last 10 year, indexed in Pubmed. We will summarize the most relevant data for clinical practice.
Results: The use of substances in cancer patients is extremely heterogeneous. Not all of the situations constitute a Substance Use Disorder categorized in the diagnostic manuals used in psychiatry. Nevertheless, substance abuse always represents a causal agent in the deterioration of clinical and functional state of cancer patients.
According to studies, cancer patient care services do not assess patients substance abuse patterns or risk in an assertive and systematic manner. Moreover, there are no specific guidelines for the approach and treatment of cancer patients with addictive disorders. Some authors also emphasize that the stigma associated with patients with substance dependences can difficult their access to health care and delay the diagnosis of neoplastic diseases or prevent them from undergoing treatment, which is often prolonged.
Conclusions: As a conclusion, we highlight that further studies are needed in this population, with more attention to the interaction between substance use and worse clinical progression. Furthermore, we remind the increasingly need for multidisciplinary teams to approach these patients - from oncology to psychiatry. There should be a greater investment in training these teams, as it can significantly improve the treatment and prognosis of these patients.

Psychological Support in Palliative Care: Findings from a Retrospective Single Centre Cross-Sectional Study in Slovenia

A. Rojs[1]*, L. Ternar[1], R. Globevnik[1], M. Horvat[2] and A. Žist[2]

[1]Maribor University Medical Centre, Maribor, Slovenia and [2]Department of Oncology, Maribor University Medical Centre, Maribor, Slovenia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1790

Introduction: Common psychiatric disorders in oncological patients include depression, anxiety, delirium, sexual dysfunctions, adjustment and sleep disorders, affecting 30%–40% of those diagnosed. The incidence is even higher in advanced cancer stages. Despite the profound impact on quality of life, these issues are often underdiagnosed and undertreated. While effective management includes both pharmacological and nonpharmacological interventions, psychologists are rarely involved in palliative care, as doctors tend to focus primarily on physical symptoms overlooking the emotional and existential suffering these patients endure.
Objectives: The aim of this study was to determine the frequency of clinical psychologist involvement in the care of palliative cancer patients.
Methods: We performed a single centre cross-sectional study of patients with metastatic or locally advanced, inoperable cancer who were hospitalized at the University Clinical Centre Maribor every first Wednesday of October between 2017 and 2023. Patient records were retrieved from the hospital's electronic medical database. Data extraction included demographic information, clinical details, and whether a clinical psychologist was consulted by the treating physician. We also aimed to identify the reasons for consultation when applicable.
Results: Out of the 600 patients, 342 (57.0%) were male, and 258 (43.0%) were female. Their ages ranged from 30 to 95 years, with a mean age of 67.9 ± 11.1 years and a median age of 68 years. Only 1.3% (8 patients) had a clinical psychologist involved in their care through a doctor-initiated consultation while most (592 patients or 98.7%) did not. Anxiety-related concerns were the most common reasons for consulting a psychologist, with 4 patients addressing these issues: 1 patient expressed a fear of dying, another feared the pain, a third had concerns about potential side effects of therapy, especially infertility, and the fourth presented general anxiety. Additionally, 1 patient expressed suicidal ideations. Unfortunately, the reason for consulting was not available for 3 patients.
Conclusions: Our study shows the underutilization of clinical psychologists in the care of palliative cancer patients, with only a small part receiving psychological support despite the known prevalence of psychiatric disorders in this population. Given the comorbidity of depression, anxiety and other psychiatric disorders among these patients, integrating mental health professionals into palliative care teams is crucial for enhancing their overall quality of life and emotional well-being.

Module Development: Psychological-Based Prehabilitation for Breast Cancer Patients and their Family Caregivers

H. S. Saw[1]* and Y. Y. Chen[1]

[1]Department of Psychological Medicine, Faculty of Medicine and Health Sciences, University of Malaysia, Kota Samarahan, Malaysia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1791

Introduction: Cancer prehabilitation has emerged as a pivotal strategy for the augmentation of patients' comprehensive well-being, encompassing physical, psychological, and functional aspects while improving their quality of life. The profound impact of breast cancer on patients and their family caregivers emphasizes the critical need for interventions addressing their holistic well-being.
Objectives: In this portion of the study, researchers intend to develop two psychological-based prehabilitation modules within a larger investigation targeting to address the quality of life as well as relationship quality among breast cancer patients and their family caregivers. The deliberate involvement of the family caregiver proposed here is based on the belief that the well-being of an individual is interconnected with his/her community.

Methods: Guided by the Allostatic Model and Systems Theory, these modules are tailored to mitigate the negative effects associated with breast cancer with a systemic perspective in mind. Leveraging on Sidek's Module Development Model, the first module (PreCARE) targets breast cancer patients, while the second (PreCARE Plus) extends its focus to patients and their family caregivers. The content validity of these modules is rigorously assessed through consultation with six experts across mental health, oncology, rehabilitation, and radiology disciplines. The study aims to look at the aspects of content validity of the developed modules through the content validity index (CVI).
Results: The CVI for both PreCARE and PreCARE Plus modules were high (above 0.83) with values of 0.92 and 0.93 respectively. The findings also yielded high S-CVI for both modules with values of 0.98 (PreCARE) and 0.96 (PreCARE Plus).
Conclusions: These crafted psychological-based prehabilitation modules proposed to revolutionize oncological care in Malaysia by empowering healthcare professionals in the oncology setting to enhance the psychological and physical well-being of breast cancer patients and their family caregivers. Their potential impact underscores the importance of integrating systemic-inspired interventions into comprehensive cancer care paradigms.

Quality of life after total laryngectomy: a retrospective study

N. Sghaier[1]*, R. Ben Soussia[2], W. Zaier[2], W. Bouali[2], F. Youzbechi[2], H. Ben Garouia[1] and L. Zarrouk[2]

[1]Psychiatry Departement, Ibn Jazzar Hospital, Kairouan and [2]Psychiatry Departement, Tahar Sfar Hospital, Mahdia, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1792

Introduction: Total laryngectomy, as a major surgical intervention, leads to significant changes both physically and psychologically. The observed alterations include communication difficulties, adjustments to new breathing methods, and often a lengthy and complex rehabilitation process. These changes can deeply impact social interactions, autonomy, and the emotional well-being of the individuals affected.
Objectives: To assess quality of life in patients who have undergone total laryngectomy, and to investigate the factors associated with its impairment.
Methods: This was a cross-sectional descriptive study with an analytical aim conducted over a period of 6 months, from December 2021 to June 2022, involving patients followed for laryngeal cancer who had undergone total laryngectomy at the Oto-rhinolaryngology department of Tahar Sfar Mahdia Hospital. Quality of life was assessed using the SF-36 in its validated Arabic version. Referring to Lean's threshold value, it is accepted that a mean score < 66.7 indicates an impairment in quality of life.
Results: A total of 40 patients participated in the study. The mean age was 62±9 years, and the population was 100% male. Quality of life assessment revealed that 87% of patients had scores below 66.7, attesting to impaired quality of life. A study of the mean scores per dimension on the SF36 revealed the following rates of impairment, in descending order: 100% for physical pain (D3), 97% for psychological health (D8), 95% for life and relationships with others (D6), 87% for vitality (D5) and limitations due to psychological state (D7), 72% for perceived health (D4), 55% for physical activity (D1) and 22% for limitations due to physical state (D2). In univariate analysis, rural origin (p=0.015), low socio-economic level (p=0.023), the existence of discomfort with eating (p=0.002), the existence of pain (p=0.008) and long hospital stay (p=0.056) were associated with impaired quality of life in our study population.
Conclusions: It is crucial to recognize and address these challenges holistically. Multidisciplinary approaches, including voice rehabilitation, psychological support, and social assistance, play an essential role in improving the quality of life for total laryngectomy patients.

Disclosure of Interest: None Declared

EPV1211

Anxiety and depression in patients undergoing total laryngectomy

N. Sghaier[1]*, W. Zaier[2], R. Ben Soussia[2], W. Bouali[2], F. Youzbechi[2], S. Ben Hadj Said[2] and L. Zarrouk[2]

[1]Psychiatry Departement, Ibn Jazzar Hospital, Kairouan and [2]Psychiatry Departement, Tahar Sfar Hospital, Mahdia, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1793

Introduction: Total laryngectomy is a major surgical procedure involving the complete removal of the larynx, often necessary to treat severe conditions such as laryngeal cancer. Although this operation is often life-saving, it leads to significant and often disabling consequences that impact mental health, including increased levels of anxiety and depression.
Objectives: Determine the prevalence of anxiety and depression among a group of patients who have undergone total laryngectomy and to investigate the factors associated with their occurrence.
Methods: This is a descriptive cross-sectional study with an analytical aim conducted over a period of 6 months from December 2021 to June 2022, involving patients followed for laryngeal cancer who had undergone total laryngectomy at the Otolaryngology department of Hospital Tahar Sfar Mahdia. Anxiety and depression were assessed using the Hamilton Anxiety Rating Scale and the Beck Depression Inventory , respectively.
Results: A total of 40 patients participated in the study. The average age was 62±9 years, with a population consisting of 100% males. A score greater than 20 indicating the presence of anxiety symptoms was noted in 50% of patients. Depression was noted in 78% of patients, with moderate intensity in 42% and severe in 25% of cases. We found that shorter postoperative follow-up was associated with greater anxiety symptoms (p=0.005). However, other factors such as diabetes and impact on social life could be related to anxiety, though no statistically significant associations were found. Regarding depressive symptoms, only the presence of postoperative complications was statistically related to moderate or severe depressive symptoms (p=0.004) in our study. Other factors such as radiotherapy and impact on work might be related to depressive symptoms, although no statistically significant associations were found.

Conclusions: Total laryngectomy has undeniable repercussions on the mental health of patients. Medical and social support is essential to help them better cope with this disability.

Disclosure of Interest: None Declared

EPV1212

Psycho-oncology: Mental Illness and Psychopharmacology in Breast Cancer

S. M. Sousa[1]*, D. Areias[1], R. Dionísio[1], C. Portela[1], F. Leitão[1] and N. Oliveira[1]

[1]Psychiatry, Unidade Local de Saúde de Santo António, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1794

Introduction: Patients with breast cancer have a higher incidence of psychiatric symptoms and mental illness compared to those without a cancer history. Breast cancer survivors often experience increased depression, anxiety, neurocognitive and sexual dysfunction, sleep disorders, stress-related conditions, and other psychiatric issues. Psychopharmacological intervention plays a key role in managing both comorbid mental illness and cancer-related symptoms caused by the disease or its treatment. However, there is limited scientific evidence regarding the specificities of psychotropic drug prescriptions in patients undergoing antineoplastic therapy.
Objectives: Considering the specificities of this population (greater physical fragility, polypharmacy) and the limited scientific evidence on the subject, the aim of this work is to review the literature on the use of psychotropic drugs—antidepressants, anxiolytics, antipsychotics, mood stabilizers, and psychostimulants—in the treatment of psychiatric symptoms and cancer-related symptoms in this patient population, with a particular emphasis on psychopharmacological-antineoplastic drug interactions.
Methods: A non-systematic literature review using PubMed as the database.
Results: In patients undergoing tamoxifen treatment, the use of psychotropic drugs that have inhibitory properties on cytochrome P450 (CYP2D6), the enzyme responsible for its metabolism into its active form (endoxifen) should be avoided. This specificity limits the use of strong inhibitors of this enzyme, such as some selective serotonin reuptake inhibitors—fluoxetine, paroxetine, and fluvoxamine. In the use of antipsychotics, the preference for drugs less associated with hyperprolactinemia should be considered when managing these patients. Commonly used mood stabilizers, such as lithium and valproic acid, do not interact with the most commonly used antineoplastic drugs in breast cancer, and are frequently used in this population safely, requiring the same monitoring as in the general population.
Conclusions: The need for pharmacological management of psychiatric symptoms or illnesses in the breast cancer population is a reality for which there is still little information in the available scientific literature. It is crucial that the use of psychotropic drugs is carefully monitored due to the potential pharmacological interactions with antineoplastic treatments, which may alter the efficacy or increase the toxicity of the drugs. For this reason, the present review is important and can enrich clinical practice. Collaboration between psychiatrists and oncologists is essential to optimize treatment and improve the quality of life for these patients.

EPV1214

The Big Five Personality Factors Among Cybercrime Victims in Jordan in Light of Some Variables

S. F. Abu Dayeh[1]*, A. Khawaldeh[2] and B. Shawqfeh[3]

[1]psychiatry; [2]psychology, moh and [3]psychology, jordan university, amman, Jordan
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1795

Introduction: This study aimed to identify the big five personality factors among cybercrime victims in Jordan and to investigate the differences in the level of the big five personality factors due to the type of crime, gender, age, and educational level. The descriptive analytical approach was used. The study sample consisted of (515) cybercrime victims in Jordan. To achieve the aims of the study, the five major factor scale was used, and its reliability and validity were checked.
Objectives: Study Objectives:

1. ersonality traits of cybercrime victims in Jordan.
2. The differences in the Big Five personality traits of cybercrime victims based on the type of cybercrime.
3. whether Big Five personality traits among cybercrime victims varied significantly with regard to gender, age, and educational status of respondents.

Methods: Study Tool: The Big Five Personality Traits Scale
This study used The Big Five Personality Traits Scale (Costa & McCrae, 1992) . In its original configuration, the scale consisted of 60 items or questions.
Item Characteristics of the Assessments Scale: 1.Internal Construct Validity. Internal consistency was checked using Cronbach's alpha. The Cronbach's alpha reliability coefficient was 0.701to 0.818, which was above 0.70; therefore, it is acceptable. Scoring of the scale: A 5-point Likert scale was employed .The second question was approached with One-way ANOVA. The third question was addressed via MANOVA.
Results: The results show that the level of extraversion and openness factors came at a high level, while the conscientiousness, agreeableness, and neuroticism factors came at a moderate level. Also, the results found that there were no differences due to the type of crime in the neuroticism factor and there were differences in the factors (extraversion in favor of device hacking crime, openness in favor of unwanted sexual crime, conscientiousness, and agreeableness in favor of identity theft crime). Also, the results show that there are differences in the factors (neuroticism, extraversion, and openness) due to gender in favor of females, and due to age in the factors (neuroticism, acceptability, and conscientiousness) in favor of less than 30 years, and the level of education in the openness factor in favor of a secondary class or less, while in the acceptability

factor in favor of a bachelor, while in the scientific factor in favor of postgraduate students.
Conclusions: Actions should be taken against cybercrimes, which include:
- More education about cybercrimes and how to use internet in a safe way.
- Supervision of people who are still not efficient in using technology and close supervision of the way that teenagers are using high technology devices.
- Trainings should be done to start protecting people from such crimes.

Work-Related Burnout Among Physicians at Sultan Qaboos University Hospital: Prevalence and Risk Factors

M. M. Albattashi[1]*, H. Mirza[2] and S. A. Albusaidi[3]
[1]psychiatry residency program, Oman Medical Specialty Board; [2]Department of behavioral medicine and [3]Department of medicine, Sultan Qaboos University Hospital, Muscat, Oman
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1796

Introduction: Burnout is a work-related syndrome characterized by emotional exhaustion, depersonalization, and a reduced sense of personal accomplishment. It is particularly prevalent among physicians and it is associated with various personal and occupational risk factors. This study aims to assess the prevalence of burnout and its predictors among physicians across different specialties at Sultan Qaboos University Hospital (SQUH).
Objectives: to assess the prevalence of burnout and its predictors among physicians across different specialties at Sultan Qaboos University Hospital (SQUH).
Methods: A cross-sectional study was conducted from October 2023 to January 2024 involving Omani and non-Omani physicians from all specialties at SQUH, Muscat, Oman. Data were collected via an electronic and paper-based survey that included the Oldenburg Burnout Inventory and a sociodemographic questionnaire. Stepwise regression analysis was used to identify independent predictors of burnout.
Results: A total of 353 physicians participated, yielding a response rate of 79%. The prevalence of burnout was 56.7% (n = 200). The majority of respondents were male 56.4%, with 88.4% being married and 66.3% having one to four children. Of the participants, 45% were consultants or senior consultants, and 70% had been practicing for over ten years. Independent predictors of burnout included male gender [OR 1.62 (1.01-2.59), p = 0.007], older age [OR 1.12 (0.66-1.89), p = 0.02], less than 6 hours of sleep per night [OR 2.57 (1.62-4.10), p < 0.001], administrative responsibilities [OR 2.75 (1.41-5.34), p = 0.015], and involvement in research activities [OR 3.75 (1.77-7.95), p = 0.036].
Conclusions: The high prevalence of burnout among physicians at SQUH highlights the need for targeted interventions to mitigate burnout and its associated negative impacts. Addressing the identified risk factors is essential for promoting physician well-being and optimizing healthcare delivery.

Acute confusional state vs psychological and behavioral symptoms of dementia. About a case

A. Alcantara Gutierrez[1]*, L. Soldado Rodríguez[1], M. Martos Castello[1,1], I. Contreras Perez[1], A. Jurado Arévalo[1] and E. Perdiguero Sempere[1]
[1]Psichiatry, Hospital Universitario de Jaen, Jaen, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1797

Introduction: Acute confusional state is usually the main diagnosis we encounter in hospitalized older adults. Its incidence increases in parallel with age. Often underdiagnosed. The main characteristics are alteration in the level of consciousness and/or attention, cognitive impairment (disorientation or reduction in memory), relatively rapid onset and fluctuations. As clinical manifestations there is usually disorganization of thought, perceptual disorders, hyper or hypoactivity, alteration of sleep rhythm and alteration of mood.
Behavioral and psychological symptoms of dementia (BPSD) describes a heterogeneous group of behavioral or mood disturbances, such as agitation, anxiety, depression, psychosis, or sleep disorders. They are universal and are present in dementia of any etiology and can be observed in any phase of the disease. They are considered multifactorial and are characterized by a recurrent or sporadic course.
68-year-old female patient who went to the hospital due to the presentation of symptoms that had been going on for 3 months (memory lapses, insomnia and irritability) that had intensified in recent days, leading to the appearance of visual hallucinations, episodes of disconnection from the environment, their language becomes impoverished and a disintegrated and incoherent speech appears with difficulty in naming.
Objectives: Propose differential diagnosis between confusional syndrome and psychological and behavioral symptoms of dementia.
Methods: Analytical: elevation of acute phase reactants.
Cranial CT: no findings that justify the diagnostic suspicion.
Neurology: despite the sudden onset of the symptoms, they rule out performing LP, given the unremarkable nature of the rest of the complementary tests.
It was decided to admit him to mental health to study the condition. The evolution is characterized by a fluctuating picture while the acute phase reactants begin to gradually increase, D-Dimer: 5500 and an ECG with an S1Q3T3 pattern. CT angiography is requested (ruling out PET)
Finally, after evaluation by neurology in which new analysis is requested along with urine and culture (+ for C.Glabrata) due to fever peak, lumbar puncture and cranial MRI (small acute ischemic lesions). Finally, it was decided to admit him to neurology with targeted treatment, resulting in resolution of the condition.
Results: Confusional syndrome with a subacute course of etiology under study.
Conclusions: BPSD of dementia are multifactorial and include different neurobiological factors, as well as environmental, social and psychological factors. They generally have a recurrent or sporadic character and can appear in all phases of any type of dementia, although they do not usually occur acutely. Therefore, it is important not to lose sight of carrying out complementary tests and a multidisciplinary approach, given that psychopathology of acute-subacute onset should not make us forget to rule out an acute confusional state.

Profile of patients in the psychiatric Convalescence Unit at Husa

E. D. Alvarez[1]*, A. M. M. Sanchez[1], P. A. Olivera[1], M. L. Argudo[1], N. M. C. Espada[1], R. D. A. Gómez[1], J. I. D. L. I. Larrad[1], C. I. F. Velasco[1] and A. Z. Gomez[1]

[1]CAUSA, Salamanca, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1798

Introduction: The Convalescence Unit provides semi-open inpatient care during the subacute phases of psychiatric illness, with the goal of restructuring and reorganizing the personality after a crisis or relapse.
Objectives: The main objective is to observe the profile of patients admitted to the Convalescence Unit who could benefit from this type of resource.
Methods: A retrospective, observational study was conducted by collecting and analyzing data in 2019, which 61 patients were admitted in this resource. The profile of patients during the year 2019 was analyzed.
Results: Of a total of 61 patients, 47 were referred from the Brief Hospitalization Unit (UHB), 11 from the Mental Health Team (ESM), and 3 from other facilities. By gender, there were 38 women and 23 men. The average age was 44.16 years. Regarding the type of admission, 29 were voluntary and 32 involuntary. Seventeen patients had been readmitted from previous years. The diagnoses were: 10 patients with bipolar disorder, 14 with schizophrenia, 6 with substance-induced psychosis, 2 with schizoaffective disorder, 10 with anxiety-depressive syndrome, 5 with dysthymia, 2 with obsessive-compulsive disorder, 7 with delusional disorder, and 6 with personality disorders. Of these patients, 58 received therapeutic discharge, 1 voluntary discharge, and 2 were transferred to other facilities. Regarding marital status, 43 were single, 7 married, 4 widowed, and 7 divorced. The average length of stay was 48.56 days.
Conclusions: As for the profile of patients admitted to the Convalescence Unit, it is not possible to determine a statistically significant pattern. However, we observed that most are women with severe mental health disorders. Notably, the majority are single, suggesting less family support, and a high percentage are admitted involuntarily, often from the UHB, to extend their stay for the management of subacute conditions in a more controlled environment. This helps ensure adherence to treatment, which is both difficult and crucial for a favorable outcome in these patients.

EPV1219

Much More Beyond Motor Symptoms – The Social Symptoms of Parkinson's Disease

M. Andrade[1]* and M. Magalhães[1]

[1]Hospital Júlio de Matos - Unidade Local de Saúde São José, Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1799

Introduction: Parkinson's disease (PD) is the second most common neuropsychiatric disorder, affecting approximately 6.1 million people worldwide. Its incidence has increased over the last two decades, with a higher rate observed in industrialized countries, suggesting that pollution and social isolation may contribute. Some studies even identify loneliness as an independent risk factor. PD is characterized by a slow progression of disability, often lasting decades, with significant impact on both individuals and caregivers. In addition to its hallmark motor symptoms (rigidity, bradykinesia, and tremor), neuropsychiatric symptoms are now better understood, and some researchers have also identified social symptoms.
Objectives: Our aim is to describe the social symptoms of PD and assess the impact of these symptoms on patients' quality of life.
Methods: A narrative literature review was conducted through bibliographic research in the PubMed and Google Scholar databases, using the terms "Parkinson's disease," "social symptoms," and "social impact."
Results: The so-called social symptoms arise from various changes that occur in PD, affecting both the verbal and non-verbal components of communication. "Facial masking" results from facial muscle bradykinesia, leading to a diminished ability to produce facial expressions. Research has shown that individuals with PD have a reduced capacity to modulate emotional expressions, which are crucial for eliciting empathy and facilitating social interactions. Additionally, patients demonstrate difficulties in recognizing emotions, possibly due to a dysfunctional theory of mind (Embodied Simulation Theory). Reduced prosody leads to monotonous, emotionless speech, which contributes to negative self-perception and a feeling of impaired communication abilities. Furthermore, in more advanced stages of PD, there appears to be a deficit in interpreting prosody.
These factors contribute to stigma, dehumanization, and social isolation among PD patients, with significant consequences for their quality of life, which has been demonstrated in several studies.
Conclusions: Social symptoms, though often overlooked, are prevalent in PD and substantially reduce patients' quality of life. It is crucial to further investigate these symptoms and develop interventions to mitigate their impact.

Antidepressant Discontinuation Syndrome in Patients on SSRIs During Viral Infections: A Study of Prevalence and Mechanisms

M. S. Artemieva[1]*, I. E. Danilin[1], A. T. M. Mkrtchyan[1] and L. D. Osiia[1]

[1]Psychiatry and medical psychology, RUDN University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1800

Introduction: This study examines the frequency and underlying mechanisms of antidepressant discontinuation syndrome (ADS) in patients receiving SSRI therapy who subsequently experience viral infections such as influenza or COVID-19. Clinical observations suggest that viral infections may diminish the efficacy of SSRIs, potentially triggering ADS even without changes in dosage.

Objectives: To assess the prevalence of ADS symptoms among patients undergoing SSRI treatment during viral infections and to explore potential biological mechanisms behind this interaction.
Methods: A sample of 84 individuals was recruited from a large Russian-language forum for users of antidepressants. Data on ADS symptoms onset and exacerbation during viral infections were collected using a survey based on the DESS scale. Inclusion criteria for ADS were the new appearance or worsening of withdrawal symptoms specifically during the viral illness.
Results: A significant portion of the cohort reported ADS symptoms. Key findings included dizziness (62%), increased anxiety (40%), mood instability (57%), sleep disturbances (65%), and memory impairment (40%). Notably, brain zaps were observed in 63% of patients, identifying this symptom as distinct to ADS rather than typical viral symptomatology.
Conclusions: The study indicates a high prevalence of ADS symptoms in patients continuing SSRI therapy during viral infections, likely influenced by neuroinflammatory responses and cytokine release, along with tryptophan depletion driven by interferon activity. These insights underscore the importance of vigilance and potentially adapting SSRI management strategies during periods of viral illness to mitigate ADS effects.

Prevalence of migraine among medical students at the University of Science and Technology, Omdurman, Sudan- A cross-sectional study

M. A. M. Baraka[1]*, M. M. A. Adam[1], T. A. K. T. Al-Jabali[1], A. A. M. Bakheit[1], A. I. A. B. Abdulrhman[1], M. H. O. Ali[1], A. A. S. Ahmed[1], A. M. S. Hassan[1], A. B. A. Hag ali[1] and F. O. I. Ahmed[1]

[1]Faculty of medicine, University of Science and Technology, Omdurman, Sudan
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1801

Introduction: Migraine is one of the leading neurological causes of disability worldwide with a significant impact on all aspects of life, despite the high prevalence and debilitating effects migraine remains underestimated in Sudan. This study aims to measure the prevalence of migraine among medical students at a Sudanese University.
Objectives: This study aims to measure the prevalence of migraine among medical students from the University of Science and Technology Faculty of Medicine, Omdurman, Sudan.
Methods: This descriptive cross-sectional study was carried out between June and August 2024 involving 283 medical students enrolled in the University of Science and Technology, data was collected online and ID-Migraine was used to screen for migraine and R programming language for statistical computation and graphics was used to analyze the data.
Results: The prevalence of migraine was 41% and females were more affected than males. The most reported trigger factor was irregular sleep 84%, with rest being the most used method for relief 43% and the majority of migraine-positive students 46% mentioned their academic performance was moderately affected.
Conclusions: This study found a high prevalence of migraine among medical students enrolled in the University of Science and Technology, with female students being more affected and significant impact on academic performance.

Preliminary data on medication response to Suicide Crisis Syndrome

A. Bassi De Toni[1]*, E. Wheeler[2], R. El Hayek[2], B. D. Park[2], M. Pompili[3] and I. Galynker[2]

[1]Psychiatry Residency Training Program, Faculty of Medicine and Psychology, Sapienza University of Rome, Roma, Italy; [2]Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York City , United States and [3]Department of Neurosciences, Mental Health and Sensory Organs, Faculty of Medicine and Psychology, Sant'Andrea Hospital, Sapienza University of Rome, Rome, Italy, Roma, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1802

Introduction: Suicide Crisis Syndrome (SCS) is an acute suicidal state characterized by feelings of entrapment, affective disturbances, loss of cognitive control, hyperarousal, and social withdrawal. It has been demonstrated that SCS predicted suicidal behavior post discharge and that could help identifying high risk patients (Galynker I. Oxford University Press 2023; Yaseen ZS *et al.* Suicide Life Threat Behav Aug 2019;49(4):1124-1135). Until today, there is no valid consensus on which medication class is more effective in reducing the acute symptoms of SCS, which often accompany suicidal patients.
Objectives: The present study aims to evaluate medication response to SCS along hospitalization into a psychiatric unit and to determine if certain drug classes can alleviate SCS symptoms.
Methods: The sample consisted of 133 participants, aged 18 to 85, recruited across four Mount Sinai Health System hospitals in New York City, USA and admitted to the psychiatric units for suicidal behavior in the past week. Patients were assessed at intake and discharge with the Suicide Crisis Syndrome -Checklist (SCS-C) to evaluate the presence of SCS symptoms. Administered medication were divided into 5 classes: antipsychotics, antidepressants, mood stabilizers, benzodiazepines and opioids.
Results: Looking at administered medications, descriptive analysis showed an overall decrease in mean SCS-C scores from intake to discharge with antipsychotics and opioids being associated with greater SCS symptoms reduction throughout hospitalization. On the other hand, participants taking antidepressants, mood stabilizers or benzodiazepines did not show different SCS-C results than participants who were not administered these medications.
Conclusions: Our results are preliminary and to gain a clearer perspective a larger sample size would be needed. Nonetheless, antipsychotics drugs given their broad psychopharmacological properties might be able to address the difficult and heterogeneous symptomatology of suicidal patients, especially loss of cognitive control aspect of the SCS. Given that opioids are used to treat emotional pain, they may be an effective treatment for symptoms of SCS as well. These results highlight the need for further studies and randomized clinical trials to adequately assess the effectiveness and safety of these medications in treating SCS.

Association between Sick Days and Psychological Problems Among Teachers in Canada

A. Belinda[1]*, Y. O. Wei[1], R. D. L. D. Dias[2], A. Orimalade[1], P. B.-M. Brett-MacLean[1] and V. I. O. Agyapong[1,2]

[1]University of Alberta, Edmonton and [2]Dalhousie University, Halifax, Canada
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1803

Introduction: Increased sick leave among educators can detrimentally impact students' productivity, and academic achievement. It remains unknown whether the number of sick days taken by educators in the preceding school year correlates with the prevalence or severity of psychological problems among educators in the subsequent school year.
Objectives: This study aimed to examine the number of self-reported sick days taken by educators in three Canadian provinces during the 2021/2022 academic year and its association with measures of stress, burnout, low resilience, depression, and anxiety during the 2022/2023 school year.
Methods: Data was collected from educators in three Canadian provinces, Alberta, Nova Scotia, and Newfoundland and Labrador, from September 1, 2022, to August 30, 2023. The Maslach Burnout Inventory-Educator Survey (MBI-ES), the Brief Resilience Scale (BRS), and the Perceived Stress Scale were used to assess burnout, resilience, and stress, respectively. Likely Generalized Anxiety Disorder (GAD) and likely Major Depressive Disorder (MDD) were assessed using the Generalized Anxiety Disorder-7 and Patient Health Questionnaire-9 scales, respectively. Statistical analysis was conducted using SPSS version 28.
Results: 763 subscribers completed all the demographic, professional questions, and clinical scales, giving a response rate of 39.91%. Of these, there were 94 (12.3%) males and 669 (87.7%) females. Educators who reported taking 11 or more sick days in the previous academic year were at least three times more likely to exhibit high stress, emotional exhaustion, likely GAD, low resilience, and likely MDD than educators with no sick days during the preceding year. Similarly, educators with 11 or more sick days had significantly higher mean scores on the GAD-7 scale, the PHQ-9 scale, the PSS-10, the MBI Emotional Exhaustion subscale, and the MBI Depersonalization subscale than those with zero sick days.
Conclusions: This study demonstrates a significant association between sick days and the prevalence and severity of high stress, low resilience, burnout, anxiety, and depression among educators. Short-term sick leave can escalate into long-term absences without adequate support for teachers. Governments and policymakers in the education sector must foster a supportive environment that enables teachers to thrive and effectively perform their professional role without taking prolonged sick days, which can undermine student learning and achievement.

Workplace Psychiatric Disorders: Analysis of Socio-Professional Risk Factors and Fitness Outcomes among Tunisian workers

G. Ben Rejeb[1]*, N. Kammoun[1,2], S. Ernez[1], S. Haj Ali[1] and S. Fehri[1]

[1]Tunisian Occcupational Safety and Health Institute and doc.name]} >[2]University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1804

Introduction: Psychiatric disorders in the workplace represent a major challenge for occupational medicine, affecting workers' health and their professional capacity.
Objectives: The study aims to analyze the socio-professional characteristics, risk factors, clinical evolution, and work fitness of patients with psychiatric disorders in the workplace.
Methods: A retrospective analytical study was conducted on 62 medical files from the Institute of Health and Safety at Work (ISST) in Tunisia, covering the period 2023-2024. Sociodemographic, professional, medical data, and fitness decisions were extracted. Descriptive statistical analyses were performed to identify significant correlations.
Results: The study included 62 cases. The average age was 44 years. The sex ratio was 0.8.
The most represented sectors were industry (29%), healthcare (24%), and education (11%). Depressive syndrome was the most frequent diagnosis (55%), followed by anxiety disorders (29%) and bipolar disorder (10%). Psychosis was found in 6% of cases.
A significant correlation between the industrial sector and the prevalence of depressive syndrome was found ($p<0.01$).
The predominant occupational risk factors included stress (51.6%), shift work (22.6%), and exposure to chemicals (16.1%). A positive correlation was observed between exposure to chemicals and the onset of anxiety disorders ($p=0.03$).
Analysis of fitness decisions showed that 41.9% of cases were deemed fit with accommodations, 29% temporarily unfit, 19.4% fit without restriction, and 9.7% permanently unfit.
Conclusions: This study highlights the high prevalence of psychiatric disorders in the workplace and their significant impact on work fitness. The results underscore the importance of implementing targeted prevention strategies to preserve workers' mental health and maintain their professional fitness.

EPV1226

Epidemiological Characteristics and Occupational Impact of Organic Solvent-Induced Psychosyndromes

G. Ben Rejeb[1]*, N. Kammoun[1,2], S. Ernez[1], S. Haj Ali[1] and S. Fehri[1]

[1]Tunisian Occcupational Safety and Health Institute and [2]University Tunis El Manar, Faculty of medicine of Tunis, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1805

Introduction: Organic solvent-induced psychosyndromes (OSP) constitute a major occupational health concern, particularly in industrial sectors involving frequent use of chemical products. This

neurotoxic disorder can have significant consequences on workers' health and their ability to maintain professional activity.
Objectives: This study aims to analyze the epidemiological, clinical, and occupational characteristics of organic solvent-induced psychosyndromes diagnosed in the workplace, as well as to evaluate their impact on work fitness.
Methods: A retrospective study was conducted based on medical records collected at the Institute of Occupational Health and Safety (ISST) in Tunisia during a period of 5 years from 2019 until 2024. Socio-professional data, risk factors, diagnoses, progression, and fitness decisions were analyzed with a focus on OSP cases. The severity of the psychosyndrome was assessed using the Raleigh classification and the WHO criteria.
Results: The study identified 11 cases of organic solvent-induced psychosyndromes. The average age of patients was 41 years. The gender distribution showed 6 women and 5 men.
The professional sectors were distributed as follows: chemical industry (n=4), textile industry (n=3), electronics (n=2), and other sectors (n=2).
The main solvents involved were xylene (n=7), toluene (n=6), hexane (n=5), and cyclohexane (n=4), with multiple exposures in 8 cases. The average duration of occupational exposure before diagnosis was 14 years ranging from 5 to 30 years. An ineffectiveness of protective measures was found in 6 patients.
The most frequently reported symptoms included memory disorders (n=9), attention disorders (n=8), and mood disorders (n=7).
The most common type of psychosyndrome was type 2B (n=8).
Regarding work fitness, nine cases required removal from solvent exposure, including six through job transfer and three through workplace accommodation. Two cases were declared unfit for their current position.
Conclusions: This study highlights the impact of organic solvent-induced psychosyndromes on workers' health and emphasizes the need for better protective measures, early screening, and regular medical monitoring.

EPV1229

Accommodations for Autistic Young Adults in Employment Processes: Experiences in Chile

J. Madrid Lira[1,2], M. Ulloa Velascos[1,2] and M. S. Burrone[1]*

[1]Instituto de Ciencias de la Salud and [2]Psychology Bachelor's Degree, Escuela de Ciencias Sociales, Universidad de O'Higgins, Rancagua, Chile
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1806

Introduction: Access to employment is a significant challenge in adulthood, particularly for autistic individuals. Accommodations, both in the workplace and during selection processes, are essential to support the inclusion of this population in the labor market. Given the dynamic nature of support needs, understanding the specific characteristics and needs of autistic individuals is necessary to provide reasonable adjustments. However, this process becomes more complex when individuals do not disclose their autism diagnosis, hindering organizations' ability to identify and address their needs.
Objectives: To identify accommodations that support the employment of autistic young adults in Chile.
Methods: Semi-structured interviews were conducted with 12 autistic young adults with job interview experience in Chile. Participants, residing across five regions, were selected through theoretical sampling. Data were analyzed using content analysis in alignment with the principles of Grounded Theory by Glaser and Strauss. Ethical approval was obtained from the Universidad de O'Higgins Ethics Committee, and all participants provided informed consent.
Results: While accommodations are deemed necessary by autistic individuals, they are seldom requested due to concerns that such requests may imply reduced competence, potentially lowering employment prospects. Participants in this study highlighted key dimensions essential for support, including procedural adjustments (advance preparation, privacy, and flexibility), interpersonal approaches (empathy and respect for diversity), and sensory accommodations (specific sensory considerations and clear, literal communication). Additionally, virtual interview formats were viewed positively, as they facilitate the fulfillment of certain sensory needs.
Conclusions: This study reveals a tendency among autistic individuals not to request accommodations during job-seeking processes, despite recognizing their necessity. Promoting professional practices based on updated, inclusive knowledge is essential for developing employment processes that effectively support autistic individuals.

Pro-Environmental Behaviour: Psychometric assessment and relationship with psychological variables in a Portuguese community sample

C. Cabaços[1,2]*, A. Macedo[1,2], M. J. Soares[1], A. I. Araújo[1,2], A. S. Grave[1] and A. T. Pereira[1,2]

[1]Institute of Psychological Medicine, Faculty of Medicine and [2]Coimbra Institute for Biomedical Imaging and Translational Research, University of Coimbra, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1807

Introduction: Climate change is one of the main global challenges of the 21st century due to its consequences for the environment, the economy and health. Given that human behaviour exists at the forefront of many of the environmental issues we face, it is crucial to effectively measure pro-environmental behaviours (PEB). Stanley et al. (2021) proposed the PEB Scale (PEBS), a bifactorial measure including eight items asking about personal behaviours and eight collective actions that revealed good psychometric properties. To the best of our knowledge, there is no instrument that validly assesses these parameters in the general Portuguese population.
Objectives: To analyze the psychometric properties of the Portuguese version of PEBS and to explore its relationship with individual factors.
Methods: A community sample of 599 Portuguese adults (64.6% women; mean age=34.40±16.18) answered to the Portuguese preliminary version of PEBS and to the validated instruments: Climate Change Distress and Impairment Scale/CC-DIS, Big3 Perfectionism Scale–Short version/BTPS-SF, HEXACO-60 and Toronto and Coimbra Prosocial Behaviour Questionnaire/ProBeQ. SPSS 29 and AMOS-29 were used for Exploratory Factor Analysis (EFA; with a

subsample of n=291) and Confirmatory Factor Analysis (CFA; n=308), respectively.
Results: EFA revealed a 3-factor solution with an explained variance of 60.52% confirmed by parallel analysis. With CFA, fit indices were found to be acceptable for first and second-order models (X^2/df=4,0741; CFI =.8638; TLI=.8382; GFI=.8515; RMSEA= .0887, p<.001). Cronbach's alphas were of .871 for the total scale (16 items), .857 for F1 (Collective actions/CA; 5 items), .832 for F2 (Personal behaviours/PB; 8 items) and .736 for F3 (Political actions/PA; 3 items). PEBS correlated with CC-DIS (r=.48 with total PEBS, r=.42 with CA and PB and r=.21 with PA, p<.01), ProBeQ (r=.24 with total PEBS, r=.12 with CA, r=.37 with PB and r=-.14 with PA, p<.01), Narcissistic Perfectionism (r=.08, p<.05 with CA and r=.20, p<.01 with PA), Honesty-Humility (r=-.15, p<.01 with PA), Emotionality (r=-.12, p<.01 with PB and r=.09, p<.05 with PA), Extraversion (r=.09, p<.05 with CA and r=.12, p<.01 with PA), Agreeableness (r=.11 with total PEBS, r=.12 with CA and r=.14 with PA, p<.01) and Conscientiousness (r=.09, p<.05 with total PEBS). When the correlated variables were inserted as predictors in linear multiple regression models where CA, PB and PA were dependent variables, they explained 19.8% (R^2=.198), 24.6% (R^2=.246) and 14.9% (R^2=.149) of their variance, respectively (all p<.001).
Conclusions: PEBS shows adequate psychometric properties, therefore, it can be used to measure PEB in the Portuguese population, namely, to analyze the efficacy of pro-climate interventions and campaigns. These initiatives should take into consideration the role of individual factors (such as personality traits) in PEB.

Disclosure of Interest: None Declared

EPV1231

Climate Change Beliefs and Attitudes Measure: a preliminary psychometric study in a Portuguese community sample

C. Cabaços[1,2]*, A. T. Pereira[1,2], M. Carneiro[1], M. J. Soares[1], A. I. Araújo[1,2] and A. Macedo[1,2]

[1]Institute of Psychological Medicine, Faculty of Medicine and [2]Coimbra Institute for Biomedical Imaging and Translational Research, University of Coimbra, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1808

Introduction: Climate change beliefs influence people's behaviours such as the adoption of pro-environmental actions, therefore it is crucial to effectively measure them. We developed a short measure (Climate Change Beliefs and Attitudes Measure/CC-BAM), comprising 4 items whose content was adapted from previous studies, namely Loram et al. (2019)'s 8 item climate change denial measure. To the best of our knowledge, there is no instrument that validly assesses these beliefs in the general Portuguese population.
Objectives: To analyse the psychometric properties of the preliminary Portuguese version of the CC-BAM.
Methods: Item content validity was guaranteed by 7 experts. 599 Portuguese adults (mean age=34.40±16.18) answered to the Portuguese preliminary version of CC-BAM (4 items) and to the validated instruments: Climate Change Distress and Impairment Scale/CC-DIS and Pro-environmental behaviour scale/PEBS. Item 1 ("Do you believe in climate change?") had three possible options of answer: a) "No", b) "Yes, I believe they are a natural phenomenon" or c) "Yes, I believe they are caused by human activity". Items 2 ("How convinced are you of your previous answer?") and 3 ("Do you think climate change is a serious problem?") were answered on a Likert scale from 0 ("Not much") to 4 ("Very much"). Item 4 ("How often do you think about climate change?") was answered on a Likert scale from 0 ("Never") to 4 ("All the time"). SPSS 29 was used to perform Exploratory Factor Analysis/EFA, descriptive statistics and inferential analysis.
Results: EFA revealed a 1-factor solution with an explained variance of 55.90% confirmed by parallel analysis. Cronbach's alpha was of .704 (lower if any item excluded) and all items had a corrected item-total correlation >.20. All items correlated with each other (from r=.27 to r=.59) and with the total score (from r=.63 to r=.85, all p<.01). CC-BAM correlated with CC-DIS (r=.51) and PEBS (r=.49, both p<.01). Women had significantly higher mean scores in all items and total CC-BAM. Age correlated with CC-BAM total score (r=.12) and with item 4 (r=.35, all p<.01). 86.5% of participants (n=518) answered to item 1 with option c) (group 1); 12.5% (n=75) answered b) (group 2) and 1% (n=6) responded a) (group 3). Kruskal-Wallis test revealed that those 3 groups significantly differed in mean/median scores of items 2, 3 and 4 and of CC-DIS and PEBS.
Conclusions: The preliminary version of CC-BAM shows adequate psychometric properties, however more studies are needed. Although caution must be taken in the interpretation of this preliminary results, this study provides a novel, internally consistent and short (easily implementable) measure of climate change beliefs.

Manic Episode or Dissociative Episode? The Importance of Differential Diagnosis in Maniform Symptomatology: A Case Report

S. Castelao-Almodovar[1]*, A. Arce de la Riva[2], R. Albillos Perez[2], A. Pérez Balaguer[1] and E. Gil Benito[1]

[1]Centro de Salud Mental El Escorial, El Escorial and [2]H. U. Puerta de Hierro, Majadahonda, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1809

Introduction: Dissociative episodes are characterized by disruptions in consciousness, identity, or perception of reality and can be confused with other psychiatric disorders, such as manic episodes. This case describes a patient with both manic-like and dissociative symptoms, highlighting the need for a precise differential diagnosis. The case emphasizes how prolonged stress and psychosocial factors triggered a dissociative crisis, which improved significantly with anxiolytic and antidepressant treatment, a key factor in clarifying the diagnosis.
Objectives: To describe a case of dissociative episode with manic-like symptoms, emphasizing the importance of differential diagnosis and appropriate treatment.
Methods: We present the case of a 43-year-old woman who was admitted to the emergency department following an acute dissociative episode. The patient arrived with a behavioral disturbance that had begun abruptly a few days earlier. She reported experiencing feelings of clairvoyance, mystical thoughts, and the sensation of receiving "alphanumeric codes," interpreting gestures and everyday objects as messages with special meaning. During this episode,

she exhibited behavioral disorganization, prolonged insomnia, euphoria, and a sense of hyperactivity, with impulses to compulsively reorganize her surroundings. These symptoms escalated until the patient, recognizing she could not control the situation, alerted her husband, who decided to take her to the emergency department due to the severity of her condition.
Results: Disorganized behavior, with accelerated and delusional speech and megalomaniacal thoughts were present. Complementary tests were performed, ruling out organic causes. After administering midazolam for imaging procedures and initiating a fixed regimen of Lorazepam, the symptoms improved markedly, allowing for a more accurate assessment. The episode was interpreted as dissociative, with identified triggers including work-related stress, her relationship with her daughter, and the recent death of a friend. Pharmacological treatment with anxiolytics and antidepressants proved effective, leading to significant improvement in the following weeks, with resolution of delusions and insomnia.
Conclusions: This case highlights the importance of differential diagnosis between a dissociative episode and a manic episode, given the shared symptoms such as megalomaniacal delusions, insomnia, and euphoria. The rapid response to anxiolytic and antidepressant treatment suggests that the episode was more related to a stress-induced dissociative disorder rather than a bipolar affective disorder that would have required mood stabilizer treatment. This therapeutic approach resulted in a complete remission of symptoms, demonstrating the importance of a treatment plan tailored to the patient's specific needs.

Delayed diagnosis of Visual Snow Syndrome due to misdiagnosis as conversion disorder : a rare case report

L. S. Chaibi[1,1]*, S. Hallit[2], S. Majoul[3], M. Cheour[4], S. Ellini[4], M. Bouchendira[1] and F. Fekih-Romdhane[4]

[1]Department of Psychiatry, Razi Hospital, Mannouba, Tunisia; [2]School of Medicine and Medical Sciences, Holy Spirit University of Kaslik, Jounieh, Lebanon; [3]Department of Neurology, Razi Hospital and [4]Department of Psychiatry, University Tunis El Manar, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1810

Introduction: Visual snow syndrome (VSS) is a rare condition that presents as a form continuous visual disturbance that occupies the entire visual field, described as tiny flickering dots. Although VSS might be expressed in patients with migraine as visual aura, persistent VSS has been accepted as a distinct clinical entity. Symptoms of VSS commonly emerge in late adolescence and early adulthood, but it can affect people of any age. In the literature,a few cases of childhood VSS have been reported.The peculiarity of this condition is that it remains rare and challenging to diagnose.
Objectives: Here, we report an uncommon case of VSS in a Tunisian female adolescent aged 17 years, that has been misdiagnosed for years as Conversion Disorder/Functional Neurological Disorder.
Methods: A clinical history, neurological assessment and visual tests were performed, leading to the diagnosis VSS in a misdiagnosed 17-year-old Tunisian female.
Results: A nine-year-old girl with no prior medical history started experiencing symptoms of vision of white lines in a net and abnormal image persistence throughout her entire visual field. The patient initially consulted an ophthalmologist, then a neurologist. The patient's visual field testing, retinal imaging, and eye examination were all within the normal range. Electroencephalography, cerebrospinal fluid analysis, and brain MRI revealed nothing unusual. The psychogenic origin was initially considered, and the patient was referred to a psychiatrist. The diagnosis of functional neurological disorder was established. The patient underwent cognitive behavioral therapy with no improvement.Over the next years, the patient consulted several psychiatrists, but her visual symptoms did not improve. Gradually, her symptoms worsened, with a significant impact on her academic performance. New symptoms such as entopic phenomena appeared, with floaters, sparkling dots, and luminous flashes associated with palinopsia and photophobia. A tinnitus was also associated. At the age of 17, and given the therapeutic impasse, her treating psychiatrist concluded that she needed to be referred back to neurology and ophthalmology. She had to undergo all the complementary tests again, which once more came back without abnormalities. The neurologist retained the diagnosis of VSS. The patient was put on anti-epileptic and migraine medications, which were ineffective. Food supplements were also prescribed to reduce stress. The patient underwent psychotherapy with partial recovery. Being correctly diagnosed helped her better cope with her symptoms. Her academic results substantially improved.
Conclusions: Despite its rarity, VSS should be taken into consideration in any patient whose vision has been continuously pixelated. More research is required to pinpoint the actual cause of this condition. Beyond its difficult diagnosis, the pathogenesis is uncertain, which the treatment plan problematic as well.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1811

Introduction: Workplace violence, particularly in the healthcare sector, is on the rise and severely affects the quality of life and performance of healthcare workers. The psychological repercussions of such violence are particularly concerning, making it imperative to develop appropriate prevention strategies.
Objectives: To evaluate the prevalence of assaults against healthcare staff at the Farhat Hached University Hospital in Sousse over a 20-year period, describing the characteristics of the victims, the circumstances of the assaults, and the psychological impacts observed.
Methods: This retrospective descriptive study, covering the years 2004 to 2023, analyzes workplace injury reports related to violence at the Farhat Hached University Hospital. The sample includes healthcare workers who were victims of reported assaults, with data

collected on a synoptic sheet detailing sociodemographic aspects, the circumstances of the assaults, and their consequences.
Results: Out of a total of 5695 workplace accidents, 110 were recorded as assaults, representing a prevalence of 1.9%. The victims had an average age of 46.8 ± 6.72 years, with a strong female predominance (69.1%). The most affected professions were nurses (50%) and workers (25.5%), with the most impacted departments being maternity (15.5%), emergency (13.6%), and psychiatry (11.8%). The majority of assaults (68.2%) occurred in the morning, and the perpetrators were primarily patients themselves (38.2%) or their relatives (33.6%).
Regarding the psychological aspects of the assaults, 42.7% of incidents involved psychological violence, such as verbal abuse, intimidation, or threats. The psychological consequences were significant: 26.4% of the victims developed disorders such as post-traumatic stress disorder (PTSD) and sleep disturbances.
Conclusions: The high prevalence of assaults and their psychological repercussions highlight the urgent need to strengthen preventive measures. Specific training on conflict management and psychological support strategies should be implemented to improve the safety and well-being of healthcare staff.

Occupational Fitness Assessments in Healthcare Workers with Psychiatric Disorder

C. Sridi[1,2]*, F. Chelly[1,2], A. Fki[1,2], N. Belhaj[1,2] and S. Ksibi[1]

[1]Occupational Medicine Department, Sahloul University Hospital and [2]Occupational Medicine Department, Faculty of Medicine of Sousse, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1812

Introduction: Healthcare professionals are exposed to numerous stressors in their work environment, which can lead to psychiatric disorders.
Objectives: To describe the profile of healthcare professionals who requested a fitness-for-duty evaluation due to a psychiatric disorder and to identify the recommended workplace adaptations.
Methods: A retrospective study was conducted in the University Hospital Sahloul of Sousse (Tunisia) over a three-year period (2022-2024). Data from healthcare staff who consulted for fitness-for-duty evaluations related to psychiatric conditions were collected, including age, work experience, job position, psychiatric diagnosis, and fitness-for-duty decisions.
Results: The study included 13 healthcare professionals comprising 6 senior technicians, 6 nurses, and 1 worker. The average age was 45 ± 3.2 years, with an average seniority of 11 ± 2.8 years. The most common psychiatric conditions were anxiety-depressive syndrome (10 cases), post-traumatic stress disorder (2 cases), and obsessive-compulsive disorder (1 case). All patients were on antidepressants and/or anxiolytics at the time of consultation. The fitness-for-duty decisions included recommendations for avoiding night shifts and exposure to stressful situations.
Conclusions: Psychiatric disorders among healthcare workers present significant challenges for occupational health services. Workplace adaptations, such as avoiding night shifts and stressful environments, may be necessary to facilitate a return to or continuation of work.

Development and validation of the Psychological Response Scale (PRS)

S. Choi[1]*, H. Shin[1] and S. Park[1]

[1]Duksung Women's University, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1813

Introduction: People experience psychological changes during adaptation process to stress; a person is angry to others or the environment but later he falls in depression. Although there are so many scales for measuring stress, they only measure the severity of stress or evaluate single emotions. None of them can track the psychological changes during the adaptation to stress.
Objectives: The purpose of this study is to develop a comprehensive scale that can measure various psychological symptoms occurring in stressful situations. Specifically, the goal is to create a tool that can track an individual's adaptation to stress over time through repeated measurements. Furthermore, the objective is to accurately understand the individual's current state and stress adaptation patterns, enabling appropriate interventions at each stage.
Methods: We established constructs and subscales based on the Kubler-Ross stages which defines general psychological change to five phase: denial, anger, bargaining, depression, acceptance. To assess the clarity and validity of the preliminary items developed, content validity was evaluated by 12 clinical psychologists and face validity was assessed with 32 adults.
Results: A total of 107 initial items were developed based on literature analysis and discussions. After the content validation and face validation, items with a CVI below .83 were either revised or removed. This process resulted in a final set of 88 items: denial (18 items), anger(17 items), bargaining(19 items), depression (17 items), and acceptance(17 items). The item content validity index (I-CVI) ranged from 0.833 to 1 and the scale content validity index (S-CVI/Ave) for denial, anger, bargaining, depression and acceptance was 0.91, 0.97, 0.96, 0.98 and 0.99 respectively. In addition, exploratory and confirmatory factor analyses indicated a good level of model fit, and the internal reliability of each subscale was also found to be satisfactory.
Conclusions: This results indicate that the PRS is highly valid, and that it can be utilized as an effective measure of the person's current state. PRS can help the clinicians to understand how the patients percept the stressful situation and their stress adaptation pattern.

EPV1238

Psychological aspects of nurses' attitudes towards death

A. M. Cybulska[1]*, K. Rachubińska[1], D. Schneider-Matyka[1], I. Czeryna[2] and E. Grochans[1]

[1]Department of Nursing, Pomeranian Medical University in Szczecin and [2]Independent Public Provincial Hospital in Szczecin, Szczecin, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1814

Introduction: Attitude towards death is an individual's psychological reaction to death, which includes basic components, such as thinking about death, fear of death, and defence mechanisms. Due

to the nature of their work, nurses often accompany patients at the end of life and choose different ways to cope with this difficult situation.
Objectives: The aim of this study was to analyze the psychological aspects of nurses' attitudes towards the death of a patient, and to determine the variables that influence their choice of strategies to deal with this difficult situation.
Methods: This survey-based study was performed using the author questionnare, and standardized research tools, namely *the Polish adaptation of* the Death Attitude Profile Revised (DAP-R-PL), and the Mini-COPE inventory.
Results: The study involved 315 subjects with a license to practice nursing, 85.7% of whom were women. The age of the respondents ranged from 21 to 70 years, and was on average 40.5 years (SD = 10.7). The nurses' dominant attitudes towards death were neutral acceptance (5.40 ± 0.97 points) and escape acceptance (5.09±1.01 points). Age, sex, work experience, and having a specialty credential influenced the attitudes towards death according to the DAP-R-Pl. The predominant stress coping strategies among the nurses according to the Mini-COPE were: self-distraction (1.98 ± 0.75 points), active coping (1.88 ± 0.69 points), planning (1.87 ± 0.77 points), and acceptance (1.84 ± 0.62 points). Factors that had an impact on the choice of stress coping strategies according to the Mini-COPE were: sex, place of residence, marital status, education, having a specialty credential, work experience, and place of work. Based on the collected data, statistically significant correlations were also found between the nurses' attitudes towards death according to the DAP-R-PL and stress coping strategies according to the Mini-COPE.
Conclusions: The nurses showed different attitudes towards the death of a patient, the most common of which were neutral acceptance and escape acceptance. Age, sex, marital status, and place of residence had a significant impact on the nurses's attitudes towards the patient's death. Contact with dying patients evokes many negative emotions in nurses, such as sadness, compassion, helplessness, regret, and a sense of injustice. Therefore, it is important to provide them with psychological support when not coping with the death of a patient. Due to the strong emotional reaction associated with the death of a patient, nurses choose coping strategies, such as: self-distraction, active coping, planning, and acceptance. Both sociodemographic and work-related variables influence the choice of coping strategies for the patient's death.

Long-term diagnostic stability, predictors of diagnostic change, and time until diagnostic change of first-episode psychosis: a 21-year follow-up study

D. P. Donner[1]*, L. Janda[1], E. Garcia de Jalon[1,2], L. Moreno-Izco[2,3], A. M. Sanchez-Torres[2,3], M. J. Cuesta[2,3] and V. Peralta[1,2]

[1]Mental Health Department, Servicio Navarro de Salud; [2]Department of Psychiatry, Instituto de Investigacion Sanitaria de Navarra (IdiSNA) and [3]Department of Psychiatry, Hospital Universitario de Navarra, Pamplona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1815

Introduction: Although diagnostic instability in first-episode psychosis (FEP) is of major concern, little is known about its determinants.
Objectives: To examine the long-term diagnostic stability of FEP diagnoses, the baseline predictors of diagnostic change to schizophrenia and the timing of diagnostic change.
Methods: This was a longitudinal and naturalistic study of 243 subjects with FEP who were assessed at baseline and reassessed after a mean follow-up of 21 years. The diagnostic stability of DSM-5 psychotic disorders was examined using prospective and retrospective consistencies, logistic regression was used to establish the predictors of diagnostic change to schizophrenia, and survival analysis was used to compare time to diagnostic change across diagnostic categories.
Results: The overall diagnostic stability was 47.7%. Schizophrenia and bipolar disorder were the most stable diagnoses, with other categories having low stability. Predictors of diagnostic change to schizophrenia included a family history of schizophrenia, obstetric complications, developmental delay, childhood adversity, poor premorbid functioning in several domains, long duration of untreated continuous psychosis, spontaneous dyskinesia, lack of psychosocial stressors, and poor early treatment response (Table 1). There were no significant differences between specific diagnoses regarding time to diagnostic change. At 10-year follow-up, around 80% of the diagnoses had changed.
Table 1. Main baseline predictors of diagnostic change to schizophrenia over the follow-up (univariate logistic regression)

	No diagnostic change (n=124) †	Diagnostic change (n=47) †	OR (95% CI)	p
Family history of schizophrenia spectrum disorders	16 (12.9)	16 (34.0)	3.48 (1.56 – 7.75)	**0.002**
Obstetric complications, any definite	9 (7.3)	12 (25.5)	4.38 (1.70 – 11.2)	**0.002**
Developmental delay at year 3, any	30 (24.2)	30 (63.8)	5.52 (2.68 – 11.3)	**<0.001**
Childhood adversity score, high (< 77)	39 (31.5)	24 (55.1)	2.27 (1.14 – 4.51)	**0.019**
Premorbid adjustment score, poor (≥ 4)	30 (24.2)	23 (48.9)	3.00 (1.48 – 7.07)	**0.002**
Acute psychosocial stressors, any	62 (50.0)	11 (23.4)	0.30 (0.14 – 0.65)	**0.002**
Duration of untreated continous psychosis, long (≥ 1 month)	34 (27.4)	26 (55.3)	3.27 (1.63 – 6.58)	**0.001**
Spontaneous dyskinesia, Schooler & Kane criteria	2 (1.9)	9 (24.3)	17.0 (3.48 – 83.3)	**<0.001**
CGI-EI at index discharge, marked improvement	100 (80.6)	28 (59.6)	0.35 (0.17 – 0.73)	**0.005**

† Data are number (and percentages) of the stated features
CGI-EI = Clinical global impression-Efficacy Index

Conclusions: FEP diagnoses other than schizophrenia or bipolar disorder should be considered as provisional. Considering baseline and background predictors of diagnostic change to schizophrenia may help to enhance diagnostic accuracy and guide therapeutic interventions.

Affective peculiarities in patients with drug-resistant epilepsy

G. Carausu[1] and N. Doten[2,3,4]*

[1]Department of Mental Health, Medical Psychology and Psychotherapy, State University of Medicine and Pharmacy, Chisinau; [2]National Centre of Epileptology, Institute of Emergency Medicine, Chișinău; [3]State University of Moldova and [4]Laboratory of Neurobiology and Medical Genetics, USMF Nicolae Testemitanu, Chisinau, Moldova, Republic of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1816

Introduction: According to WHO data, currently more than 50 million people suffer from epilepsy, about 30% of these people are diagnosed with drug-resistant epilepsy. Drug-resistant epilepsy involves multiple psychological problems such as cognitive impairment, emotional and behavioural disorders, which contribute to a reduced quality of life.
Objectives: The aim of our study was a comparative analysis of the affective peculiarities of patients with drug-resistant epilepsy and patients with well-controlled epilepsy.
Methods: The research took place during 2020-2023 within the National Centre of Epileptology, Chisinau, Republic of Moldova. The study was conducted on a group of 102 subjects with epilepsy (aged 18-62 years), including 62 subjects with drug-resistant epilepsy and 40 subjects with well-controlled epilepsy. We applied the Beck Depression Inventory (BDI) and Hamilton Anxiety Rating Scale (HAM-A). Statistical methods used are analysis of frequencies and percentage values, comparison of means by descriptive statistics, determination of Pearson correlation coefficients, difference of means by independent T-test.
Results: According to the research results, depression is present in 43% of subjects, of which 23% in subjects with well-controlled epilepsy and 56% in those with drug-resistant epilepsy. Anxiety is present in 44 % subjects with epilepsy, of which 53% are subjects with drug-resistant epilepsy and only 33% with drug-controlled epilepsy. Statistical results reveal significant differences in the manifestation of depression (t=3.50 and p=0.001) and anxiety (t=3.09 and p=0.003) in subjects with drug-resistant epilepsy compared to those with well-controlled epilepsy. At the same time, no significant gender differences were found, but we find that women with drug-resistant epilepsy are 3.3 times more depressed and 2.6 times more anxious compared to women with well-controlled epilepsy. Divorced, non-employed, secondary technical education subjects with epilepsy of unknown aetiology are most affected by depression and anxiety, while subjects with higher education and those employed are more protected from suffering from anxiety and depression. As the disease progresses over time and the number of epileptic seizures increases, so does the level of depression and anxiety.
Conclusions: Patients with drug-resistant epilepsy have significantly higher values for the depression and anxiety, compared to subjects with well-controlled epilepsy. Depression and anxiety were found in more than half of the drug-resistant subjects and twice less in subjects with well-controlled epilepsy.

Exploring the relationship of cognitive style with psychosocial factors in Kosovo youth

S. Mustafa[1,2], N. Fanaj[2,3]* and E. Krasniqi[2,4]

[1]AAB College, Prishtina; [2]PMSH, Prizren; [3]Alma Mater Europae Campus College Rezonanca and [4]UBT College, Prishtina, Kosovo
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1817

Introduction: Recently it was highlighted that individuals not only vary in their beliefs but also in the manner of their thinking, and this diversity can significantly predict various crucial psychological outcomes.
Objectives: This research addresses the underexplored relationship between cognitive styles and psychosocial factors like hope, subjective well-being, coping and social support, specifically in Kosovo. These variables have not been investigated in Kosovo before, making this study the first of its kind.
Methods: Its cross-sectional study. The sample consisted of 490 students aged 15 to 23 (Mage=19.06; SD=4.17). Participants completed the instruments below: Adult Hope Scale ; Brief COPE Scale ; Oslo 3-item Social Support Scale; WHO-5 Well-Being Index ; Rosenberg Self-Esteem Scale and Cognitive Reflection Test . Data processing was done with SPSS 27.0 and Microsoft Excel 2019.
Results: Significant negative correlations were observed between Cognitive Reflection Test scores and gender ($r = -.197$, $p < 0.00$), Adult Hope Scale score ($r = -.173$, $p < 0.00$), WHO-5 Well-being Index ($r = -.098$, $p < 0.04$) and Emotion–Focused Coping ($r = -.125$, $p < 0.01$). However, no significant correlations were found with Social Support, Problem-Focused-Coping, or Dysfunctional Coping (all $p > 0.05$). The correlational analysis, suggested that individuals with higher analytical thinking tendencies are more likely to be male, have lower levels of hope, employ less emotion-focused coping strategies and reported lower subjective well-being.
Conclusions: The study emphasized that psychosocial factors are intricate, influenced by diverse elements. While cognitive abilities, as measured by the Cognitive Reflection Test, played a role in some aspects of these factors, they didn't fully explain their complexity. Therefore, the research suggests that further investigation is needed to grasp the underlying mechanisms and implications of these correlations in a Kosovo context.

EPV1245

Diabetes Distress in patients of Type 2 Diabetes Mellitus at a Teaching Hospital in Pakistan

M. Fatima[1,2]

[1]Academic Department of Psychiatry and Behavioral Sciences, King Edward Medical University Lahore, Lahore, Pakistan and [2]Psychiatry, Dublin North Mental Health Service, Dublin, Ireland
doi: 10.1192/j.eurpsy.2025.1818

Introduction: Diabetes management in lower-middle-income countries is becoming more challenging with an ever-increasing prevalence. It encompasses emotional distress, regimen, physician-

related & interpersonal distress. Diabetes Distress is associated with poor psychosocial well-being & self-management, depression, medication non-adherence, poor glycemic control, & diabetic complications. There is a shortage of literature on diabetes distress, in terms of original studies from Pakistan.
Objectives: To assess the prevalence of Diabetes Distress and its associated factors in Type 2 Diabetes Mellitus (T2DM) patients attending a teaching hospital.
Methods: This cross-sectional study was conducted at the Endocrinology clinic, Mayo Hospital Lahore Pakistan from November 2023 to May 2024. 254.
Type 2 Diabetes Mellitus patients, 30-80 years old, diagnosed according to American Diabetes Association diagnostic criteria at least 6 months before data collection were included. Those who had any terminal illness, substance dependence, active psychosis, or couldn't understand & speak Urdu were excluded. Diabetes Distress Scale-17 (DDS-17) was used for data collection. It has four dimensions & 17 items, each rated on a 6-point Likert scale. SPSS 26 IBM Corp was used for data analysis. Quantitative variables were presented as Mean (SD) & qualitative as f(%). The association of diabetes distress with various factors was elicited using the Chi-square test of independence at $\alpha \leq 0.05$.
Results: The mean age of the respondents was 53.62 ± 8.55 & duration of illness 8.86 ± 6.7. Mean DDS-17 scores were 2.732 ± 1.036 SD, equivalent to moderate level distress. Emotional Burden & Regimen-related distress had comparatively higher scores than Physician-related & interpersonal distress. 40.9% had high & 33.5% had moderate level distress. Only 25.6% of participants had little to no diabetes distress. There was no statistically significant relationship between diabetes distress severity & age, employment, marital status, & urban or rural living. There was a statistically significant relationship of diabetes distress severity with gender (p=0.001), education (p=0.05), socioeconomic status (p=0.01), & illness duration (p=0.05). Female gender, lack of education, and low & middle socioeconomic status had considerable association with greater severity of diabetes distress. Participants with < 1-year duration of diabetes distress had a higher proportion reporting little to no diabetes distress.
Conclusions: This study concludes that a considerable proportion had moderate to high level distress: emotional burden and regimen-related distress being of the utmost significance. The concerted efforts from all stakeholders will ensure early and timely screening of Diabetes Distress to avoid adverse psychosocial and patient outcomes. Integrating mental health with diabetes care in Pakistan could be the first step towards improving patient outcomes.

Serotonin reuptake inhibitors improve muscle stem cell function and muscle regeneration in male mice: antidepressant effects beyond the brain

M. Fefeu[1,2*], M. Blatzer[2], A. Kneppers[3], D. Briand[2], P. Rocheteau[2], A. Haroche[4], D. Hardy[2], M. Juchet Martin[2], A. Danckaert[2], F. Coudoré[5], A. Tutakhail[5], C. Huchet[6], A. Lafoux[6], R. Mounier[3], O. Mir[7], R. Gaillard[2,4] and F. Chrétien[2,4]

[1]Child and Adolescent Psychiatry Department and the Child Brain Institute, Hôpital Robert Debré, AP-HP; [2]Institut Pasteur, Paris; [3]Institut NeuroMyoGène, Lyon; [4]Hôpital Sainte Anne, GHU Paris Psychiatrie Neurosciences, Paris; [5]Université Paris Saclay, Chatenay-Malabry; [6]Université Nantes, Nantes and [7]Gustave Roussy, Villejuif, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1819

Introduction: Fluoxetine, the first selective serotonin reuptake inhibitor, is the world's most prescribed antidepressant. Several mechanisms of action underpin the effect of this antidepressant, such as enhancing serotonin (5-HT) neurotransmission, increasing hippocampal neurogenesis, neuronal survival and cerebral angiogenesis. The effects of fluoxetine on stem cell behaviour and tissue regeneration beyond the central nervous system have been little studied to date.
Objectives: We investigated whether fluoxetine (FLX) might have broader peripheral regenerative properties using a recognized regenerative medicine paradigm such as the animal model of ad integrum muscle regeneration.
Methods: To investigate the impact of fluoxetine (FLX) on muscle at steady state, FLX was delivered *per os* at 18 mg/kg daily for six weeks to uninjured wild-type and specific transgenic mice. To investigate FLX´s regenerative capacity on skeletal muscles, we delivered FLX for six weeks and then performed notexin-induced injuries (phospholipase that induces a severe muscle necrosis) of the *tibialis anterior* muscle in wild-type and specific transgenic mice. Muscle force, muscle stem cells number, dividing muscle stem cells, differentiating muscle stem cells number, vessels number and muscle fiber parameters were specifically assessed.
Results: After prolonged administration (6 weeks) of fluoxetine to male mice, we showed that prolonged FLX treatment increased the number of muscle stem cells and muscle angiogenesis in mice. FLX also improved skeletal muscle regeneration after single and multiple injuries induced by intramuscular notexin injection. The acceleration of muscle regeneration induced by FLX resulted from a triple action marked by an increase in the muscle stem cell pool, an increase in vessel density and a reduction in fibrotic lesions and inflammation. *In vitro*, we showed that the proliferative effects of FLX on immortalized myoblasts were dependent on 5-HT and 5-HT1B receptor activation. *In vivo*, mice lacking peripheral 5-HT treated with FLX did not show positive effects during muscle regeneration. Moreover, pharmacological, and genetic inactivation of the 5-HT1B receptor in muscle stem cells also abolished the FLX-induced improvement in muscle regeneration.
Conclusions: We show that FLX promotes a harmonious muscle regeneration underpinned by a combined action on myogenesis, angiogenesis and inflammation. These results highlight the serotonergic identity of skeletal muscle and point to a promising therapeutic strategy for endogenous muscle diseases. Beyond muscle and brain, this work opens new perspectives of investigation both on the role of serotonin and the 5-HT1B receptor in other types of stem cells and on the therapeutic potential of antidepressants in regenerative medicine.

Characterization of University Hazing in 74 Brazilian Medical Schools and the Development and Validation of the University Hazing Self-Report Scale (UNI-Hazing)

L. Fernandes Berto[1]*, R. Furlan Damiano[2], G. Lucchetti[3], E. Constantino Miguel[2], H. Vallada[2], L. F. Dilalla[4], A. Lamas Granero Lucchetti[3], E. J. Allan[5], D. Kerschner[5], J. Piasseschi de Bernardin Gonçalves[2] and B. Besteti Fernandes Damiano[2]

[1]University of São Paulo, São Paulo, Brazil; [2]Department of Psychiatry, University of São Paulo, São Paulo; [3]Federal University of Juiz de Fora, Juiz de Fora, Brazil; [4]Southern Illinois University, Illinois and [5]University of Maine, Orono, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1820

Introduction: University hazing is a common practice that impacts students' mental health and well-being, especially in medical schools. Despite its common occurrence, there is a lack of reliable tools to assess hazing experiences and perceptions among students.
Objectives: This study aimed to evaluate hazing experiences, attitudes, and impacts and to develop and validate the University Hazing Self-Report Scale (UNI-Hazing) among Brazilian medical students.
Methods: This was a cross-sectional study conducted among Brazilian medical students. The UNI-Hazing scale was developed as a four-part questionnaire designed to assess personal experiences with hazing, students' opinions, and its perceived impact on their well-being. Participants also completed a sociodemographic questionnaire and established scales including the Johns Hopkins Learning Environment Scale (JHLES), the Medical Student Stress Factor Scale (MSSF), the Generalized Anxiety Disorder 7-item (GAD-7), and the Patient Health Questionnaire-9 (PHQ-9). We conducted exploratory factor analysis to uncover latent factors and assessed internal consistency, test-retest reliability, and convergent validity.
Results: 1,017 medical students from 74 universities across Brazil participated in the study. While the majority of students did not report being victims or witnesses of hazing, certain hazing behaviors, such as body painting and forced solicitation for money, were relatively common. Hazing incidents most frequently occurred at parties, followed by sports associations and fraternities, with fewer on-campus incidents. Students largely held negative views on hazing. Factor analysis revealed three subscales within UNI-Hazing: "Social Pressure and Institutional Responsibility", "Emotional Harm and Ethical Concerns" and "Physical Hazing and Power Dynamics". The scale demonstrated strong internal consistency (Cronbach's alpha: 0.93, 95% CI: 0.92–0.93) and test-retest reliability (Pearson correlation coefficients: 0.44–0.84). Correlations with the external scales supported the scale's validity, showing positive correlations with MSSF, GAD-7, and PHQ-9, reflecting the psychological impacts of hazing, and negative correlations with JHLES, indicating that as hazing experiences increase, positive life experiences may decrease.
Conclusions: The UNI-Hazing scale is a reliable and valid measure for assessing hazing experiences and perceptions among medical students in Brazil. The findings highlight the need for universities to implement anti-hazing policies and support systems for students impacted by hazing practices.

Sport and Exercise Therapy in the Treatment of Mental Illness -Let's get moving !

K. Friedrich[1]*, C. A. Penkov[1], J. Krieger[1], V. Rößner-Ruff[1], M. Wendt[2] and M. Ziegenbein[1]

[1]Forschung & Entwicklung and [2]Sporttherapie, Wahrendorff Klinikum, Sehnde, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1821

Introduction: As a complementary or stand-alone treatment, sport and exercise therapy (SET) can have a therapeutic effect on the symptoms of mental illness as well as having a therapeutic or preventive effect on physical comorbidities. Therefore, treatment guidelines recommend the integration of exercise therapy as a complementary approach in a multimodal treatment. In a clinical inpatient setting SET are supervised by specialised professionals and conducted in an individual or group setting. Low level of participation in SET during treatment points to the need for research into influencing factors. One study suggests, that SET during mental health treatment increases the likelihood of meeting the physical activity recommendations.
Objectives: The purpose of the study is to investigate the extent to which SET can increase patients' levels of physical activity during inpatient treatment and, in particular, promote a physically active lifestyle after inpatient treatment, thereby supporting long-term stabilisation. In order to gain further insight into the factors that influence participation in SET during treatment, this study analyses both intrapersonal and interindividual factors.
Methods: Patients (age ≥ 18 years, all genders) in partial- or full-time inpatient treatment at a psychotherapeutic and psychosomatic specialist clinic in Lower Saxony, Germany are examined by online self-report questionnaire. It's a longitudinal study design with 3 time points (start of treatment, end of treatment, 12 weeks after the end of treatment). Patients participate in SET as part of their treatment. Physical activity in minutes per week and the therapeutic alliance between exercise therapists and patients are measured. In addition, self-efficacy expectations, sport- and exercise-related self-concordance and the subjectively perceived effectiveness of SET are assessed as further factors influencing physical activity.
Results: The results of the inferential-static data analysis will be reported.
Conclusions: Based on the results, possible implications for the focus of SET and the role of exercise therapists are discussed. Conclusions based on motivational aspects of maintaining a physically active lifestyle after the end of treatment are considered.

The challenge of therapeutic adherence in patients with first-episode psychosis: The rise of pharmacogenetics

C. García Cerdán[1,2]*, P. Salas Aranda[1,2], C. Martín Gómez[1,2,3], C. Lorenzo Romo[1,2], M. C. Turrión Gómez[2], M. Isidoro García[4,5] and J. Pérez[1,2,3]

[1]Psychiatry, Salamanca University Healthcare Complex; [2]Unit of Psychiatry and Neuroscience, Institute Of Biomedical Research of Salamanca (IBSAL); [3]Medicine, University of Salamanca; [4]Biochemistry and Clinical Analysis, Salamanca University Healthcare Complex and [5]Pharmacogenetics and Precision Medicine Unit, Institute Of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1822

Introduction: During the last decades, clinical practice for patients with first-episode psychosis has shifted to early intervention programmes that aim to accelerate access to treatment and also ensure adherence to antipsychotic (AP) medication. However, recent pragmatic, randomised controlled trials still report very high discontinuation rates of the initially prescribed AP treatment due to lack of efficacy, side effects, or other reasons. The CLinical Utility of early intervention including the 5-Step Precision Medicine (5SPM) Method in first-episode Psychosis (CLUMP) Project is a translational research initiative focused on improving adherence to antipsychotic medications and therapeutic outcomes in first-episode psychosis patients using pharmacogenetics. We present a preliminary descriptive analysis of this project based on a retrospective cohort.

Objectives:

- To establish discontinuation rates of the first antipsychotic treatment administered to patients with a first-episode psychosis before the implementation of the CLUMP project.
- To describe reasons for such discontinuations.

Methods: We conducted an observational study on a consecutive, retrospective cohort of 49 patients who experienced a first-episode psychosis in Salamanca, Spain, before the implementation of CLUMP, in order to subsequently determine the impact this project might have on AP treatment discontinuations. We reviewed their clinical records to collect variables such as sex, age, first prescribed antipsychotic medication, and any discontinuation within the first year post-treatment initiation, recording reasons for discontinuation or treatment changes, such as lack of efficacy, non-adherence, side effects, or others.

Results: Of the 49 patients included in the analysis, 7 were excluded due to inaccessible information, leaving a final sample of 42 (26 males). Age ranged between 16 and 48 years, with a mean age of 25.9 (9.2). 38 patients (90.47%) discontinued treatment within one year, with similar rates in men (92.3%) and women (87.5%) (See Figure 1). 16 reported side effects as the main reason for discontinuation, 1 lack of efficacy, 9 lack of adherence, and 12 other reasons (Figure 2). Among the 16 who discontinued due to side effects (Figure 3), 3 experienced extrapyramidal symptoms, 3 drowsiness, 3 sexual dysfunction, 2 hyperprolactinemia/galactorrhea, 1 metabolic syndrome, 1 excessive salivation, and 3 did not specify the symptom.

Image:

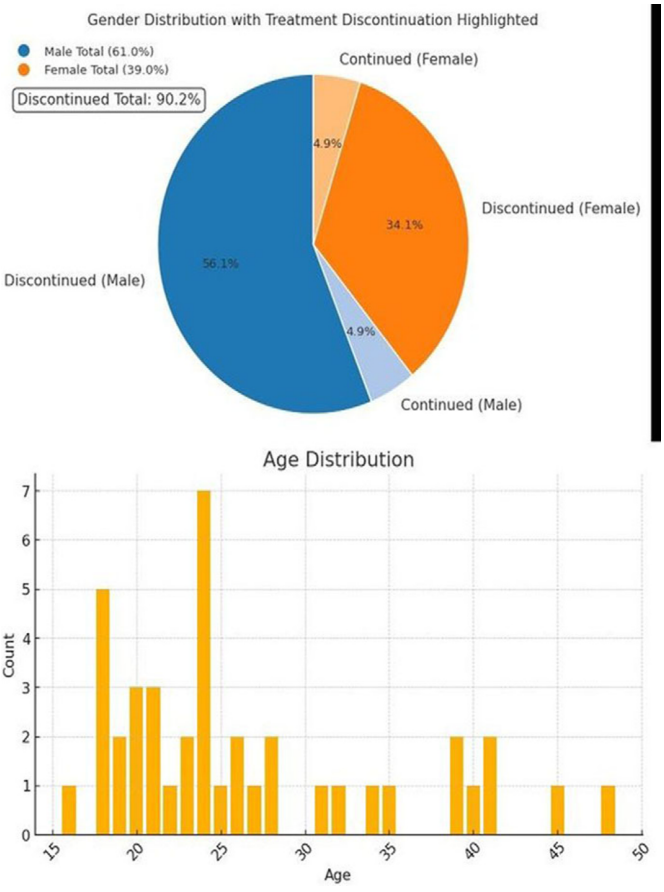

Image 2:

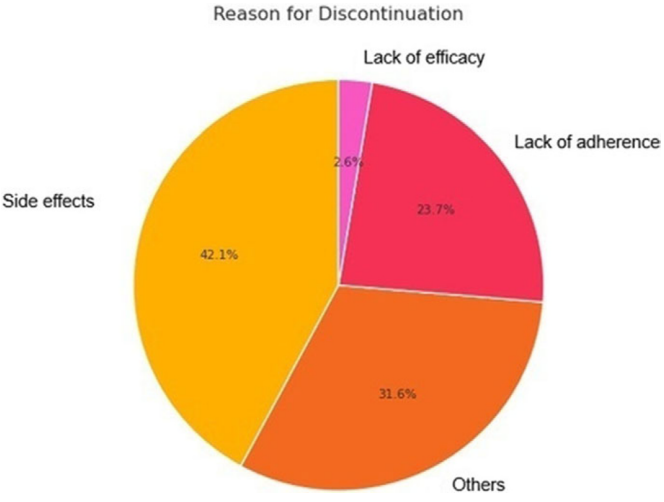

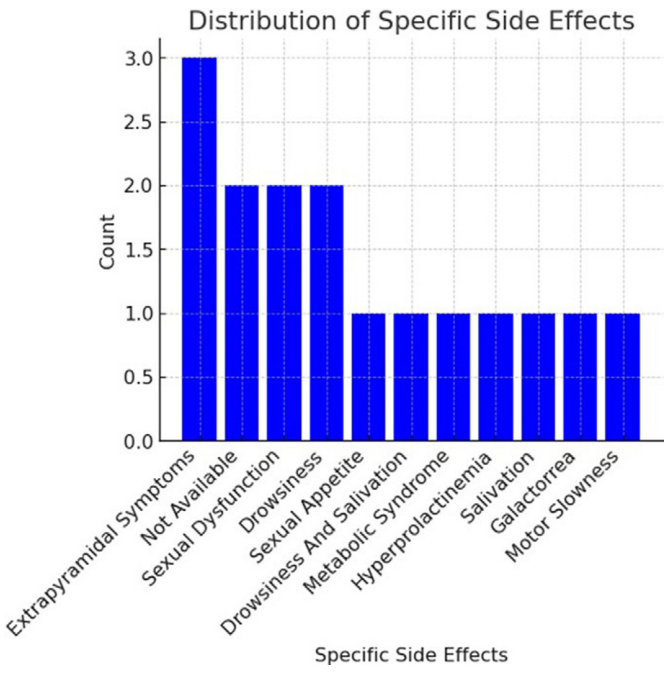

Image 3:

Conclusions: Most patients in our sample discontinued antipsychotic treatment within the first year post-treatment initiation, mainly due to side effects. These data indicate the need to restructure clinical care for patients with first-episode psychosis to ensure adherence to AP and reduce trial-error approaches to treatment choice from start. The CLUMP project proposes an individualised strategy, based on pharmacogenetics, to improve therapeutic adherence and outcomes in patients with FEP.

ADAPTATEA Program: Humanizing Healthcare for ASD Patients in Their Referral Hospital

L. Garcia Murillo[1]*, A. Cañuelo Marquez[1], A. Pascual[1], J. Sanchez Cerezo[1], R. Paricio[1], A. Guzman[1], M. Morales[1] and I. Palanca[1]

[1]Psiquiatría, Hospital Universitario Puerta de Hierro, Majadahonda, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1823

Introduction: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder with increasing prevalence (1 in 36 children, CDC 2023), associated with difficulties in social interaction and repetitive behaviors. These characteristics make it challenging for individuals with ASD to access quality healthcare. Additionally, people with ASD experience a higher number of underlying and intercurrent comorbidities compared to neurotypical individuals. In Spain, we have a public healthcare system intended to provide universal health coverage for all citizens. In 2009, the AMITEA program was created in central Madrid to address healthcare needs for 6,000,000 people (Parellada et al., Eur Psychiatry 2013; 28(2):102-109). However, despite this, patients in our hospital, located in Majadahonda on the outskirts of Madrid, continued to face difficulties accessing healthcare. Main challenges include leaving familiar surroundings and healthcare professionals, long waiting times, difficulties understanding the public healthcare system, and lack of coordination between services. We realized that, even with the program, our patients were still not receiving adequate care.

Objectives:

- To create an integrated program in our hospital that addresses the most common health issues for individuals with ASD.
- To provide ASD patients with healthcare attention as similar as possible to that of neurotypical patients within their referral hospital.

Methods: Given the difficulties our patients faced, professionals from Child Psychiatry, Neuropediatrics, Neurophysiology, and the Pediatric ER formed a network in 2018 to improve healthcare for ASD patients in our hospital. Child Psychiatry acted as a link between services. We held group meetings with department leaders to develop the program in each service. Neurophysiology was the first to fully implement it (Mayoral-Fernandez et al., Metas Enferm 2022; 25(5):70-8).

Results: Thanks to our efforts and support from hospital management, a part-time nurse joined the program in October 2023. With her help, we adapted medical procedures using Alternative Communication systems, trained and advised staff, adjusted hospital spaces, and maintained continuous coordination with professionals and families, humanizing care at our hospital.

By January 2024, our network included 17 services and over 50 professionals. With group support, each service developed its own level of adaptation. Professional satisfaction increased, and specialist coordination improved.

Conclusions: Adaptations like those implemented through ADAPTATEA improve the healthcare experience for ASD individuals at their referral hospitals, highlighting the need for more programs of this kind.

Factors Affecting Psychological Resilience in First Responders and Rescue Team Members

M. G. Goksu[1]*, N. S. Soral[1] and Z. Sofuoglu[2]

[1]Izmir Demokrasi Üniversitesi, Izmir, Türkiye and [2]Public Health, Izmir Demokrasi Üniversitesi, Izmir, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1824

Introduction: Disasters, including natural catastrophes, accidents, and man-made events, impose significant challenges on communities and individuals. First responders, such as rescue teams, firefighters, and prehospital emergency medical services personnel, play a crucial role in mitigating these impacts. Beyond their physical capabilities, these individuals must possess high levels of psychological resilience to perform effectively under extreme and stressful conditions. Understanding the factors that influence this resilience is essential for improving their performance and well-being. This systematic review aims to identify and examine the factors that affect psychological resilience among first responders and rescue team members during disasters and emergencies. The goal is to provide

a comprehensive understanding of how resilience can be supported and enhanced in these critical professionals.
Objectives: To identify the key factors that influence psychological resilience in first responders and rescue team members during disaster response. To evaluate current research on resilience building interventions and their effectiveness in enhancing psychological resilience in these professionals. To highlight gaps in the existing literature and suggest directions for future research on supporting psychological resilience in first responders.
Methods: A thorough literature search was conducted across several databases, including Web of Science, Scopus, Cochrane, PubMed, Medline, and Embase, focusing on articles published between 2019 and 2023. The search terms used were (emergency OR disaster) AND (psychological resilience) AND (rescue workers OR first responders OR firefighters OR ambulance personnel AND prehospital emergency medical services). Articles were selected based on inclusion and exclusion criteria, and only full-text articles published in English or Turkish were considered. Qualitative synthesis was used to analyze the data and draw insights.
Results: The review reveals several critical factors affecting psychological resilience, including stress management techniques, emotional regulation strategies, social support systems, and training programs. It also identifies areas where existing research is lacking, particularly regarding specific interventions designed to bolster resilience in high-stress environments.
Conclusions: Enhancing psychological resilience in first responders is crucial for both their individual well-being and the effectiveness of disaster response efforts. This review provides valuable insights into the factors that contribute to resilience and highlights the need for targeted interventions and support systems. By addressing these factors and promoting resilience, it is possible to improve both the performance of first responders and their capacity to cope with the demands of disaster situations.
Keywords: Psychological resilience, first responders, rescue workers, mental health.

Innovation in Suicidology: Artificial Intelligence-Based Risk Assessment

N. M. Szeifert[1,2], X. Gonda[3,4]* and C. Kerepesi[5]

[1]Department of Sports Medicine, Semmelweis University; [2]Doctoral School of Psychology, ELTE Eotvos Lorand University; [3]Department of Psychiatry and Psychotherapy; [4]NAP3.0-SE Neuropsychopharmacology Research Group, Hungarian Brain Research Program, Semmelweis University and [5]Institute for Computer Science and Control (SZTAKI), Hungarian Research Network (HUN-REN), Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1825

Introduction: The use of artificial intelligence (AI) in suicide risk assessment is gaining prominence as AI algorithms are capable of processing and analyzing large volumes of data quickly. Suicide risk assessments are traditionally carried out by psychiatrists and clinical psychologists following established protocols, but AI systems can provide valuable support in this area, particularly in prevention and faster detection. Based on the collected data, AI algorithms can create predictive models that identify individuals at the highest risk. These models can take into account previous mental health disorders, suicide attempts, and other social or economic factors.
Objectives: The aim of our study was to test a suicide prediction model using an XGBoost machine learning tool.
Methods: We included 357 individuals, out of which 146 were psychiatric patients with a history of suicide attempts in their anamnesis, 154 were psychiatric patients without a history of suicide attempts, and 57 individuals formed the sine morbo control group. Initially, 71 individuals (test dataset) were randomly selected from the total 357, and the remaining sample (training dataset) was used to train the XGBoost machine learning tool. This training process involved optimizing and selecting the best parameters. Afterward, the final model was tested on the reserved test dataset consisting of 71 individuals.
Results: During the machine learning process, we were able to very accurately predict who had a history of suicide attempts and who did not, with a high performance indicated by a ROC AUC score of 0.96. This demonstrates the model's excellent ability to distinguish between individuals with and without suicide attempts based on the data used.
Conclusions: AI systems can complement traditional methods in suicide prevention, but they cannot replace human expertise. It is also important to pay attention to ethical issues, such as data protection and the reliability of these systems. AI can be a powerful tool in predicting suicide risk if properly integrated into mental health services.

Perinatal Psychopathology and Bonding: Implications for Maternal-Infant Attachment and Infant Development

C. M. Grego[1]*, C. Araújo[1] and A. Tarelho[1]

[1]Psychiatry and Mental Health Department, Local Health Unit of Aveiro, Aveiro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1826

Introduction: Perinatal psychopathology, encompassing a spectrum of psychiatric disorders such as perinatal depression, generalized anxiety disorder, post-stress traumatic disorder (PTSD), bipolar disorder, and postpartum psychosis, has been increasingly recognized for its potential to disrupt early mother-infant interactions. These disruptions may have profound consequences on the formation of secure attachment, which is crucial for healthy infant neurodevelopment. Attachment theory posits that early relational experiences shape the foundation of emotional regulation and social functioning, making it essential to understand how maternal psychopathology influences this critical developmental period.
Objectives: This study aims to explore the impact of perinatal psychopathology on the development of attachment between mothers and their infants. Specifically, it seeks to identify how various mental health disorders affect maternal sensitivity and responsiveness, and how these alterations contribute to insecure or disorganized attachment styles in children.
Methods: A comprehensive review of the literature was conducted by searching major medical databases (e.g. PubMed and Google Scholar), giving preference to studies published between 2000 and 2024. Articles were selected based on relevance to perinatal

psychopathology and attachment theory. This narrative review includes both quantitative and qualitative studies, clinical trials, and observational research that examine how maternal mental health conditions during pregnancy and the postpartum period affect attachment processes. Key themes and findings were extracted to provide a holistic view of the current state of knowledge on this subject.

Results: The findings align with existing research on the impact of maternal mental health on early attachment, reinforcing the role of maternal sensitivity as a mediator between psychopathology and attachment security. Psychiatric conditions impair the mother's ability to engage in synchronous interactions with her infant, disrupting the child's ability to develop a secure base. Moreover, the presence of comorbid psychiatric conditions and chronicity of symptoms were identified as risk factors for more severe attachment disruptions. Pharmacological treatment and psychotherapy were shown to mitigate these effects, highlighting the need for integrated perinatal mental health services.

Conclusions: Perinatal depression, PTSD, and psychosis significantly compromise maternal-infant attachment, increasing the risk of insecure or disorganized attachment styles. Timely psychiatric interventions can enhance maternal mental health and promote healthier attachment outcomes. This review underscores the importance of integrating maternal mental health treatment into perinatal care to prevent long-term developmental issues in children and foster secure attachment relationships.

Applied Improvisation to Improve Mental Health Training

J. D. Fekete[1]*, M. Hainselin[2], K. Eklicsné Lepenye[1], P. L. Kanizsai[3] and M. Jouin[2]

[1]Department of Languages for Biomedical Purposes and Communication, University of Pécs, School of Medicine, Pécs, Hungary; [2]Université de Picardie Jules Verne, Amiens, France and [3]Department of Emergency Medicine, University of Pécs, School of Medicine, Pécs, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1827

Introduction: Medical improvisation, or HPTI (Health Professional Training Improv), enhances critical skills in healthcare professionals. These skills include communication, empathy, time pressure management, and creative problem-solving. Our presentation aims to showcase a practical application of HPTI, demonstrating its relevance and effectiveness in mental health training.

Objectives: In this presentation, we will demonstrate our training method, including a short session with exercises adapted to healthcare professions. The session is divided into four parts. Each part is designed to maximize engagement and learning, with debriefing sessions to clarify teaching objectives and foster reflective practice.

Methods: Warm-Up Exercises: Physical and vocal exercises to optimize communication and awareness. Improvisation Techniques: Exercises focused on mastering emotions and various forms of communication, allowing participants to explore their strengths and limitations. Medical Scenario Applications: Short clinical scenarios to emphasize the cognitive and affective dimensions of empathy. Review of Existing Workshops and Research: Presentation of current workshops and research to encourage further exploration and application in training. Each part includes a debriefing session to clarify teaching objectives, develop a reflective approach, and identify areas for improvement.

For our ongoing comparative study we have implemented the following questionnaires for our training participants: IUS (uncertainty intolerance scale) and Acceptance and Action Questionnaire-II (AAQII). A total of 50 students participated in our research in both countries.

Results: Hungarian training participants included medical school students in Hungary and fourth-year speech therapy students in France and included professional scenarios based on stress and emotion management, interdisciplinary collaboration and collaboration with the patient, and communication, with debriefing on their performance. The data is currently being collected.

Conclusions: Applied improvisation through HPTI offers a valuable approach to improving mental health training. By enhancing communication, empathy, and problem-solving skills, healthcare professionals can provide better patient care and navigate their roles more effectively. Our presentation demonstrates these techniques and encourages their integration into regular training programs.

Observational study of referrals to mental health from primary care

A. Izquierdo De La Puente[1]*, R. Fernandez Fernandez[2], P. Del Sol Calderon[1] and M. García Moreno[1]

[1]Psiquiatria, Hospital Universitario Puerta de Hierro de Majadahonda and [2]Psiquiatria, Hospital Universitario Infanta Cristina, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1828

Introduction: Following the COVID pandemic, there has been an increase in mental health consultations in recent years, often referred to as a 'fourth wave'. However, what has been observed in mental health centres is that these consultations are not so much about serious mental disorders, but rather occasional disorders due to social and work-related factors.

Objectives: The aim of this study is to analyse the data collected from referrals to psychology in a mental health centre.

Methods: Referrals to psychology from primary care at the Majadahonda Mental Health Centre were analysed for the period from October 2022 to April 2024 in a specific weekly consultation for the psychology waiting list.

The data collected are the diagnoses of these patients, whether or not they attend the assessment consultation and whether or not they are discharged after the first consultation.

Results: A total of 115 patients were seen between October 2022 and April 2024. These patients were all notified of the appointment one week in advance.

Of the total number of patients who attended, 29 consulted for depressive-anxiety-adaptive disorder, 22 were referred for work-related reasons (burn out), 12 for marital problems, 7 for parenting problems, 12 had no clinical reason for referral to Mental Health and 25 did not attend the consultation.

Those who were discharged at the first consultation were 33.

Conclusions: Given the scarce resources and long waiting lists, it is important at all levels of patient care not only to adjust expectations with regard to specialised care, but also to promote an appropriate setting. In this way it will be possible to run an efficient mental health care system.

Efficacy of lisafentamine treatment in adult patients with comorbid ASD and ADHD: case series

A. Izquierdo De La Puente[1]*, S. T. Romero[2], P. Del Sol Calderon[1], R. Fernandez Fernandez[3], E. Antolin Murillo[2] and P. Martinez Marin[2]

[1]Psiquiatria; [2]Psicología, Hospital Universitario Puerta de HIerro de Majadahonda and [3]Psiquiatria, Hospital Universitario Infanta Cristina, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1829

Introduction: A case series of patients diagnosed with comorbid ASD and ADHD in adulthood is presented.
Objectives: To make a comparison between the situation and social difficulties before and after specific ADHD treatment, in order to reinforce that it is not only a treatment for academic functioning, but also helps social interaction and therefore general functioning.
Methods: Four clinical cases are presented, three females and one male, with a mean age of 45 years. All of them were diagnosed with ASD and comorbid ADHD, with a predominance of impulsive component, in 2023.
All of them, prior to the diagnosis of ASD, were diagnosed with GAD, social phobia or even avoidant personality disorder. For these diagnoses, from a very early age, they received different SSRIs and benzodiazepines with little response.
Results: In the consultation, after taking a complete clinical history, and fundamentally a biographical history, the examination was complemented with ADOS and CPT.
Due to the results obtained in CPT, it was decided to start treatment with lisafentamine between 50 and 70mg DMD.
CPT was performed again, obtaining better results in all cases, with a decrease in impulsivity and attention, mainly. At a subjective level, patients reported a substantial improvement, especially at a social level, which favoured their functioning in basic activities of daily living.
Conclusions: In adults, a correct diagnosis is important given that many of them present symptoms compatible with one or more neurodevelopmental disorders not diagnosed in childhood. Likewise, treatment in accordance with these disorders improves functionality and avoids polypharmacy and side effects of unnecessary treatments.

The Role of Stress and Trauma in the Onset of Mood Disorders

D. Jelaga[1]*, B. Mihaela[1] and O. Valentin[1]

[1]Department of Mental Health, Medical Psychology, and Psychotherapy, Nicolae Testemiţanu State University of Medicine and Pharmacy of the Republic of Moldova, Chişinău, Moldova, Republic of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1830

Introduction: Stressful experiences and traumatic events are major contributors to the development of mood disorders, which affect about 8% of the global population. The interaction between stress, trauma, and mood disorders is multifaceted, involving neurobiological, psychological, and social factors. This study aims to analyze the prevalence, gender differences, and neurophysiological changes linked to these conditions, highlighting the importance of timely interventions for prevention and treatment.
Objectives: To investigate how chronic stress and trauma contribute to the development of mood disorders, examine the impact of resilience factors, and explore the associated neurochemical and structural brain changes.
Methods: A review of literature was performed using psychiatric textbooks, clinical guidelines, and databases such as PubMed/MEDLINE, NCBI, PsycINFO, and Google Scholar. The analysis focused on studies published between 2016 and 2023, with search terms including “chronic stress”, “traum”, “mood disorders” and “resilience”.
Results: An analysis of 30 studies revealed that 65% of individuals exposed to prolonged stress experience mood disorders. Trauma survivors have increased risk of developing depression, women 35% more likely to suffer from depression than men. In contrast, men show a 25% higher incidence of developing bipolar disorder following trauma. Resilience factors such as family support and psychological counseling can reduce the risk of mood disorders by 20%. Additionally, 35% of patients with mood disorders exhibit comorbidities such as PTSD or substance use disorders. Neurochemical changes include a 50% reduction in dopamine levels, while 40% of individuals show hippocampal atrophy linked to chronic stress.
Conclusions: Chronic stress and trauma are key factors in the onset of mood disorders, with distinct gender differences and significant neurobiological changes. Early intervention, focusing on resilience enhancement and psychosocial support, can reduce the long-term effects of stress and trauma, improving mental health outcomes.

An Analysis of Employment for Persons with Intellectual and Mental Disabilities in Japanese Labor Transition Support Offices

Y. KATAYAMA[1]*, A. NAKAO[2], A. SASAKI[3], Y. KADOSHITA[4], F. TOMITA[5] and A. OZAWA[6]

[1]NAGANO UNIVERSITY, Nagano; [2]Decentwork-lab; [3]J.F.Oberlin University, Tokyo; [4]KYOTO UNIVERSITY OF EDUCATION, Kyoto; [5]SAITAMA PREFECTUAL UNIVERSITY, Saitama and [6]University of Tsukuba, Tokyo, Japan
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1831

Introduction: In Japan, the Comprehensive Support for Persons with Disabilities Act, which unifies the three disabilities of physical, intellectual, and mental health, came into effect in 2006, and labor

transition support offices were institutionalized. The labor transition support business office is a business in the welfare sector that places persons with disabilities in general companies for a period of two years.

- In addition, Japan has the Law for Employment Promotion of Persons with Disabilities in the labor field, which imposes an employment rate for persons with disabilities on companies.
- As of April 2024, the employment rate of persons with disabilities in companies is 2.5%.

Objectives: In order to achieve employment for as many people with disabilities as possible, we analyzed two groups of people with and without workplace retention made by disability at labor transition support offices. This is a secondary data analysis of a national survey conducted in 2022.

Methods: The survey instrument included basic attributes of respondents and establishments, as well as the number of people who found employment in general companies in FY 2019 and their workplace retention status, whether or not employment assistance was provided to people with employment difficulties, and the state of practice of approaches to employment assistance. All statistical analyses were conducted using SPSS. Ethical review was conducted with the approval of the Ethical Review Committee of Nagano University (2021-006).

Results: The types of disabilities of the establishments (n=1321) indicated 19 establishments with physical disabilities, 286 establishments with intellectual disabilities, 250 establishments with mental disabilities, 52 establishments with developmental disabilities, 495 establishments with no specific disability, and others.

In this analysis, from the above-mentioned establishments with intellectual disabilities (n286) and establishments with mental disabilities (n250), we divided them into two groups: those with intellectual disabilities (n181) and those with mental disabilities (n181) that discharged employed persons in FY2019.

It was found that the labor transition support offices that were placing people in employment with mental disabilities as their primary disability were accepting those with fewer weeks of use of the offices and with more difficulties in employment.

Conclusions: It became clear that even though the legal system unifies the three disabilities, the approach differs depending on the characteristics of the disability. Furthermore, it was also found that there are some offices that are able to place users in employment even if they have difficulties in finding employment. This suggests that there is a possibility that labor transition support offices, which are unable to produce job seekers, will be able to produce job seekers in the future.

Predictors of assertive behaviors in Tunisian medical students

M. K. Khamassi[1,2*], B. N. Saguem[1,2] and J. Nakhli[1,2]

[1]Department of psychiatry, Farhat hached hospital and [2]Research Laboratory LR12ES04, University of Sousse, Faculty of medicine of Sousse, Sousse, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1832

Introduction: Some individuals might be more prone to acquire assertive behaviors earlier in their lifespan than others. Nevertheless, assertiveness can be learnt, and studies suggest that developing them would be beneficial in various fields, including healthcare and medical studies.

Objectives: This study was conducted to assess medical students' level of assertiveness, and to characterize the factors that might influence it.

Methods: A cross-sectional study was conducted, targeting a representative sample of undergraduate medical students. In total, 91 medical students agreed to participate in an online questionnaire survey. They completed a sociodemographic questionnaire as well as the French validated versions of Rathus Assertiveness Scale (RAS), Depression, Anxiety and Stress Scale, Rosenberg Self-Esteem Scale, General Self-Efficacy.

Results: The response rate was 31.1%. Results showed that 53.8% of participants were considered nonassertive. Assertiveness training was requested by fifty-six students (61.5%). Moderate to extremely severe levels of depression, anxiety and stress were reported by 61.5%, 69.2% and 43.9% of participants respectively. Medical students who practiced individual sport or played music showed significantly lower RAS scores, indicating a higher level of assertiveness (p= .022 and p = .003 respectively). Rosenberg self-esteem scores and general self-efficacy scores were strongly correlated with assertiveness. Depression, anxiety and stress scores were strongly and positively correlated with assertiveness scores. Hierarchical regression analysis revealed that playing music, Self-esteem and self-efficacy were independent predictive variables of assertiveness with beta values of -.219, -.247, and -.209, respectively, explaining 44% of the model.

Conclusions: Assertive communication can provide medical students with an opportunity to become more effective in dealing with those around them, fostering better relationships, and promoting mental well-being. Reinforcing music and individual sports activities may serve as valuable preventive and interventional strategies to improve assertiveness in medical students.

Management of psychiatric disorders in the armed forces: exemptions and changing specialty

N. Khaterchi[1], S. Kamoun[1], H. Ziedi[1] and A. Amri[1*]

[1]Occupational medicine, Military occupational health center, Tunis, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1833

Introduction: Military personnel, faced with stressful and often extreme situations, can develop psychiatric disorders which require specific management to maintain both their well-being and the operational effectiveness of units. These disorders pose significant challenges for the assessment of their fitness for military service.

Objectives: To study the impact of psychiatric pathologies on fitness for military service.

Methods: This was a retrospective study of a descriptive nature, from January 1, 2023 to August 30, 2024, which was conducted among military personnel referred to the occupational pathology consultation at the Military Center for Occupational Medicine and Professional Safety in Tunis to assess their fitness for duty due to psychiatric disorders.

Results: During the study period, 42 patients were included, with a mean age of 38 ± 10 years, all male. The study population was divided into non-commissioned officers (45.2%), unlisted men (40.5%) and officers (14.3%), 44.5% of whom belonged to the army, 19.4% to the navy, 11.1% to the air force and 25% to the joint services. The ranks most affected by psychiatric pathologies were the first-class soldier at 21.4%, the master corporal and the warrant officer at 16.7% each. The most common specialties were infantry and transport at 28.6% and 11.9% respectively. The most common work positions were administrative officer (19.1%) and infantryman (9.5%). The predominant pathologies were anxiety-depressive syndrome in 31% of cases, depression in 26.2%, anxiety disorder in 14.3% and post-traumatic stress disorder in 11.9%. Eighty-one percent were exempted from carrying weapons, 57.1% from guard duty and 2.4% from field trips, with an average exemption duration of 5 months. All requests for exemption were accepted, of which 22% led to a reform file, 14% to psychiatric care, and 5% to a notice of fitness for military service. A change of specialty was indicated in six cases, all of them to an administrative position.
Conclusions: Psychiatric disorders strongly affect fitness for military service, leading to exemptions and changes of specialty. Enhanced psychological care and rigorous follow-up are essential to preserve the operational effectiveness and well-being of military personnel.

EPV1265

Psychiatric disorders and military convalescence: Prevalence, duration of inactivity and operational impact

N. Khaterchi[1], S. Kamoun[1], H. Ziedi[1] and A. Amri[1]*

[1]Occupational Medicine, Military Occupational health center, tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1834

Introduction: Military personnel are exposed to intense stress and potentially traumatic environments, making them particularly vulnerable to psychiatric disorders. These pathologies can lead to prolonged periods of convalescence, affecting not only the health of individuals, but also the operational readiness of the armed forces.
Objectives: To identify the most common psychiatric causes of convalescence in military personnel and assess their impact on the operational readiness of the armed forces.
Methods: This was a retrospective study of a descriptive nature, from January 1, 2023 to August 30, 2024, which focused on military personnel who presented a request for convalescence to the occupational pathology consultation at the Military Center for Occupational Medicine and Professional Safety in Tunis.
Results: During the study period, 275 patients were included in the sample, with a mean age of 40.83 ± 9.93 years and a sex ratio of 2.77. Their average length of service was 15.62 ± 11.87 years. Depression was the most frequent psychiatric pathology, accounting for 70.9% of convalescence causes, followed by anxiety disorder at 8.7%. The most affected category was non-commissioned officers, accounting for 54.7% of cases. The ranks most affected were warrant officer in 12% of cases, chief sergeant in 11.6% of cases and head warrant officer in 10.9% of cases. Military healthcare and administration were the most represented specialties, in 17.5% and 14.2% of cases respectively. The most common workstations were nurses (15.6% of cases), administrative officers (12.4%) and infantrymen (6.2%). The average length of convalescence was 74.78 ± 88.77 days. Convalescence lasting more than 180 days accounted for 10.3% of cases.
Conclusions: Our study shows that psychiatric pathologies have a significant impact on operational readiness. The often prolonged periods of convalescence highlight the importance of implementing effective prevention and management strategies to mitigate the impact of psychiatric disorders within the armed forces.

A case report of lithium-induced bradycardia and syncope

M. E. KILINC[1]*, E. MUTLU[1] and B. DEMIR[1]

[1]Department of Psychiatry, Hacettepe University, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1835

Introduction: Lithium is a mood stabilizer, causing various dose related adverse effects. Cardiac adverse effects are seen more frequently in patients with previous cardiac diseases, overdoses, and chronic use.
Objectives: We report the case of a woman treated with lithium who developed bradycardia and syncope, which are rare adverse effects of lithium.
Methods: A 39-year-old woman was hospitalized due to suicidal ideation during a psychotic depressive episode. She had a previous supraventricular tachycardia episode requiring ablation but was asymptomatic for a long time. On admission, she was using sertraline 100 mg/day and olanzapine 10 mg/day. Lithium was initiated at 600 mg/day due to previous suicide attempts and being in the fourth depressive episode. On the second day of lithium therapy, the patient had a syncope lasting a minute. Electrocardiogram (ECG) showed sinus bradycardia at 46 bpm and 417 msec of QTc. She was normotensive. Her serum electrolytes, myocardial enzymes, thyroid hormones, and thyroid-stimulating hormone levels were within normal limits. Lithium was stopped. The following ECG showed sinus rhythm at 65 bpm. Cardiology consultation resulted in no contraindication to lithium therapy. Lithium was reinitiated with 300 mg, no syncope or bradycardia was observed, and the patient was discharged after 9 days. Lithium concentration was 0.66 mEq/L. The Naranjo Advers Drug Reaction Scale was scored as 5, indicating a probable relationship between syncope, bradycardia, and lithum. She is still using lithium 300 mg/day for four months with no adverse-effects.
Results: At both therapeutic and toxic lithium levels, ECG changes such as T-wave inversions, sinus bradycardia, sinoatrial blocks, PR prolongation, QTc prolongation, and ventricular tachyarrhythmias can be observed. Lithium cardiac adverse effects have been shown to increase with age and duration of treatment and can be seen in both therapeutic and toxic concentrations. Our case is unique, occurring in a relatively young patient in the early phase of lithium treatment.
Conclusions: Other causes of bradycardia should be eliminated by performing a workup that includes calcium level, thyroid function, and cardiac workup, and checking medication interactions. Lithium-induced bradycardia is reversible upon discontinuation

of lithium, but irreversible sinus node may occur when long-term lithium therapy is required. As lithium is an indispensible option for such patients with severe recurrent depression, lithium may be rechallenged with a lower dose and close followup of the ECG despite previous episodes of bradycardia and syncope.

Risk Factors for Psychosis in the Migrant Population in Morocco

N. Kissa[1]*, N. Ait Bensaid[1], A. Korchi[1], F. Laboudi[1] and A. ouanass[1]

[1]University Psychiatric Hospital Arrazi, salé, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1836

Introduction: Immigration has been pivotal in shaping societies, especially post-war, but is associated with a 2 to 3 times higher risk of psychotic disorders for migrants compared to natives [5]. Psychotic disorders, affecting about 0.7% of the population, often involve chronic symptoms with high morbidity and mortality [1][3]. This increased risk in migrants highlights public health issues, particularly due to limited access to care [6][7]. Studies suggest that reducing specific ethnic risk factors could lower psychosis rates by 22% [8].
Objectives: To identify risk factors and explanatory hypotheses for the development and symptomatic reactivation of psychoses in immigrant patients who were hospitalized at the Arrazi Psychiatric Hospital in Salé.
Methods: This is a retrospective, descriptive, and analytical study. Data will be collected from the medical records of immigrant patients hospitalized for psychotic disorders at the Arrazi Psychiatric Hospital in Salé using a data extraction form. This form will include socio-demographic data, primary reason for migration, migration-related stress, social and professional situation, and access to mental health care.
Results: Approximately 60% of immigrant patients hospitalized for psychotic disorders reported migration-related stress as a significant contributing factor. Around 45% experienced social isolation upon arrival, and 50% faced difficulties accessing mental health services. Additionally, 30% of these patients reported unemployment or precarious job situations, and nearly 40% cited family separation as a source of emotional strain, potentially exacerbating their symptoms.
Conclusions: Psychosis in immigrants is often influenced by specific stress factors related to the migration experience, such as social isolation, economic insecurity, and limited access to mental health care. These elements increase the psychological vulnerability of migrants and can trigger or exacerbate psychotic disorders. Tailored support and policy measures are essential to mitigate these risks. These observations highlight the need for in-depth research to better understand and manage the risk factors for psychosis in this population.

Assessing Teacher Burnout in Elementary Education: A Study in Southwestern Greece

P. Kallianezos[1], E. Ntouka[2], M. Bakola[1], A. K. Sakaretsanou[1], K. S. Kitsou[1]*, C. Petropoulos[3], S. Antonopoulou[4] and E. Jelastopulu[1]

[1]Department of Public Health, University of Patras, Medical School; [2]Postgraduate program of Education Management; [3]Department of Mathematics and [4]Department of Management Science & Technology, University of Patras, Patras, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1837

Introduction: Occupational burnout in education is a major problem, especially among elementary school teachers (ESTs) who have the dual task of imparting knowledge and nurturing children's emotional intelligence. Research in recent years focuses on understanding, preventing and addressing teachers' burnout.
Objectives: We aimed to evaluate professional burnout levels among ESTs and identify associated factors.
Methods: We conducted a cross-sectional study among ESTs in southwestern Greece from September to December 2022. Participants answered to a self-administered questionnaire that included the Maslach's Burnout Inventory Educator Survey (MBI-ES), socio-demographic, and other characteristics.
Results: A total of 126 ESTs (63.5% kindergarten, 36.5% elementary school) participated in the study, 81% were female, 39.7% were 31-40 years old, and 51 (40.5%) had 11-20 years of work experience. The majority (63.5%) had a permanent job, mainly as a preschool teacher. Teachers experienced moderate to high levels of job burnout, as indicated by measures of emotional exhaustion (mean 30.03), depersonalization (mean 9.45), and feelings of low personal achievement (mean 46.42). Male teachers had higher levels of emotional exhaustion (50% vs. 46.1%) and female teachers had significantly higher rates of low personal accomplishment (80.4% vs. 66.7%). More experienced teachers showed higher emotional exhaustion (11-12 years: 58.8% vs. 6-10 years: 44.4%). Finally, kindergarten teachers were more likely to report low levels of personal accomplishment compared to other teachers (84% vs. 68.6%).
Conclusions: Elementary school teachers experience moderate to high levels of job burnout, which is influenced by factors such as gender, years of service, employment status, and phase of teaching. These findings can serve as a basis for prevention strategies and interventions to reduce the effects of burnout in elementary school teachers.

EPV1271

Evaluating Cold, Hot, and Social Cognition in Hospitalized Patients

N. Laherran Cantera[1]*, R. Palacios-Garran[1] and G. Lahera Forteza[2]

[1]Psychiatry, Jerez University Hospital, Jerez and [2]Psychiatry, Principe de Asturias University Hospital, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1838

Introduction: Cognitive difficulties in people with psychosis are present at the time of the first episode, even from periods of high risk to early stages of psychosis, their nature and severity seem

similar to those observed in patients with a more chronic evolution, since it seems to be an impairment that in most people remains stable, although there is a group of people that worsens. Therefore, these deficits cannot be fully explained by treatments, hospitalizations, or chronicity, and appear more as an intrinsic characteristic of the disease. The course of their trajectory through the progression of the disease remains uncertain.

Objectives: This study aimed to evaluate changes in cold, hot, and social cognition during acute psychotic episodes in hospitalized patients, to better understand their relationship with psychotic symptomatology.

Methods: A prospective longitudinal study was conducted with 10 patients (age range: 18-65) admitted to the psychiatric acute unit at Jerez de la Frontera Hospital, diagnosed with schizophrenia, schizoaffective disorder, or other psychotic disorders. Cognitive assessments included SCIP (cold cognition), Hinting Task (social cognition), and OSCARS (hot cognition), alongside psychiatric evaluations using PANSS, BPRS, and GAF scales. Statistical analysis was performed to identify correlations between cognitive domains and psychotic symptoms.

Results: Analysis of the 10 selected patients reveals that the levels of impairment in cold, warm, and social cognitive functions vary significantly. The mean obtained for the SCIP-S scale total (64.60) suggests a moderate impairment in cold cognition, which aligns with previous research indicating that this type of impairment is an intrinsic feature of psychotic disorders, regardless of the time course of the illness.The mean on the Hinting task (14.00) and OSCAR total score (52.60) reflect impairment in social and warm cognition, respectively. Regarding the PANSS scale, scores indicate a predominance of positive psychotic symptoms, with a mean of 31.50 on PANSS-P, suggesting a high degree of active symptomatology.

These results are congruent with the hypothesis that alterations in warm cognition could precede and perhaps influence the exacerbation of these psychotic symptoms, as has been suggested in previous studies.

Conclusions: This study provides preliminary evidence of the complex relationship between cold, warm, and social cognitive functions in patients with acute-phase psychotic disorder. The findings suggest that although these functions are impaired in psychosis, their interrelationship is not as strong as might be expected, underscoring the need for differentiated interventions that address each cognitive domain specifically.

EPV1273

Work Climate and nurses' mental health: an observational study in an acute hospital ward

C. Laranjeira[1,2*], M. Dixe[1,2] and A. Querido[1,2]

[1]School of Health Sciences and [2]ciTechCare, Polytechnic Institute of Leiria, Leiria, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1839

Introduction: Since the COVID-19 pandemic, the attention to mental health at work has increased. According to recent WHO reports, 12 billion working days are lost every year to depression and anxiety. The working conditions, particularly the organizational climate, can impact nurses' well-being and mental health. Specifically, in Portuguese nurses, little is known about the relationship between work climate and mental health.

Objectives: To characterize the nurses' lifestyle and mental health and correlate the organizational climate to nurses' mental health.

Methods: A cross-sectional correlational study was conducted in a Medical-surgical ward in a Portuguese acute hospital. A convenience sample was recruited, excluding the nurses with long-term sick leave. An e-survey was sent to the nurses by the head nurse via institutional emails after the approval of the Ethics Committee. The nurses were asked to fill in sociodemographic, professional, anthropometric and lifestyle inquiry, Mental Health Inventory (MHI– 5) and Work Climate Questionnaire (WCQ). Data was analyzed using SPSS 29.0.

Results: 46 Portuguese nurses participated in the study. Most women (87%), aged between 26 and 64 years, have worked for 18 years (±8.4). Most nurses consider BMI median=25.6 (±5.4), 75% exercise regularly, 93% are non-smokers, and 67% consume alcohol occasionally. Most nurses rated their sleep as poor quality. Nurses considered they have good health (43.5%) in general and evidenced reasonable mental health (MHI Mean=19.8± 3.9). Male nurses experienced higher mental well-being than females. As for the level of organizational climate, it was found that, on average, scores are close to 4 (neither agree nor disagree). There was a positive correlation between organizational climate and nurses' mental health.

Conclusions: This study evidenced a neutral perception of confidence and experience of autonomy of nurses working in an acute hospital in Portugal. There is a need to deepen the knowledge of the level of autonomy experienced by nurses in their work in larger samples and different contexts. The results indicate the need to study this correlation in different settings to explore its effect and impact on nurses' mental health and patient quality of care.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1840

Introduction: In recent years, the concept of Self/Other distinction (SOD),the ability to differentiate one's own body, actions and

mental states from those of others,has recieved increasing interest. Studies that have explored SOD in psychiatric or neurodevelopmental disorders generally used static images or movies that progressively morph from one's own face to another's. However, these paradigms may be insufficient for SOD assessment given the centrality of embodiment in the pathophysiology of these disorders. The new Alter Ego double mirror paradigm was developped to specifically explore SOD under greater ecological conditions.This innovative device allows the progressive morphing of one's own face to that of another between two subjects physically facing each other on either side of the device.

Objectives: Two pilot studies were conducted to investigate self-recognition and self/other distinction respectively in adolescents with Anorexia nervosa (AN) and Autism Spectrum Disorder (ASD) compared with matched healthy controls through a self/other face identification task using the "Alter Ego" TM double mirror system.

Methods: Participants had to watch a double mirror in which their own face was gradually morphed into the face of an unfamiliar other (self-to-other) or vice versa (other-to-self), requiring them to indicate at which point they judged the morph to look more like their own face than the other's face.Two judgment criteria were used: 1) M1: Threshold at which the subject starts recognizing his own face during the other-to-self morphing sequence 2) M2: Threshold at which the subject starts recognizing the other's face during the self-to-other morphing sequence. For participants with AN, in a second part, SOD was reassessed during five different sensorimotor tasks aimed at increasing body self-consciousness.

Results: Compared to controls, participants with ASD and AN showed an earlier self recognition in the other-to-self direction and a delayed other recognition in the self-to-other direction. Moreover, contrasting with controls, in ASD and AN participants, the critical threshold for switching between self and other varied with the direction of morphing. Finally, when participants with AN were seated with a backrest and footrest reinforcing the median axis of their body, the self-recognition threshold (M1) increased significantly approaching that of controls.

Conclusions: The preliminary results of these studies uncovered novel findings showing first behavioral evidence of impaired self/other distinction in individuals with ASD and AN through an embodied face-recognition paradigm. These results confirm the interest of the Alter Ego double mirror paradigm for the study of alterations in self-consciousness and Self/Other Distinction as a transosographic dimension common to various neurodevelopmental or psychiatric disorders.

General practitioner hospitalists in psychiatry – may we help you?

K. Mårtenson[1]*, M. Kojoukhova[1], E. Hallvar-Halonen[1], T. Talaslahti[1], M. Honkasalo[1], L. Rehnberg-Laiho[1] and S. Eskelinen[1]

[1]Psychiatry, University of Helsinki and Helsinki University Hospital, Helsinki, Finland

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1841

Introduction: Patients admitted to psychiatric services present with several acute and long-term somatic health problems. Psychiatrists have limited time and expertise to manage those conditions. Nevertheless, general practitioner (GP) hospitalists rarely exist in psychiatric facilities.

Objectives: To examine the effects of a novel hospitalist service we describe performance of GP hospitalists.

Methods: HUS Helsinki University Hospital Psychiatry has 12 hospital campuses (550 beds in total) and over 30 outpatient clinics in Southern Finland. During February-May 2024 the organization had three part-time GP hospitalists covering 11 acute adult psychiatric wards (307 beds), six forensic psychiatric wards (120 beds), and two out-patient clinics. Hospitalist assessments at hospital wards and outpatient clinics included structured health checks and consultations from psychiatrists and registered nurses. The hospitalists collected characteristics from consecutive assessments by filling in an online survey. Somatic health conditions assessed in consultations, and those needing attention in health checks were coded according to ICD-10 classification.

Results: The hospitalists provided 245 assessments: 223 consultations and 22 health checks. The majority (n=146,60%) of the assessments lasted for 30-90 minutes, one third (n=82,33%) lasted less than 30 minutes, while some (n=17,7%) took over 90 minutes. Of the assessments 49% (n=120) were hospitalist's appointments, 12% (n=29) were provided by a phone call, 1% (n=3) were video appointments and 38% (n=93) were solved based on patient records. The most common conditions in the consultations were endocrine and cardiovascular related (Image 1). The hospitalists estimated that eight referrals to emergency departments and 22 to somatic specialists were avoided with the help of the consultations. In turn, hospitalists themselves referred 18 patients to somatic specialists. In the health checks the hospitalists identified 56 somatic conditions needing attention: cardiovascular, endocrine, gastrointestinal, dermatological and vision related problems were the most prevalent (Image 2).

Image 1:

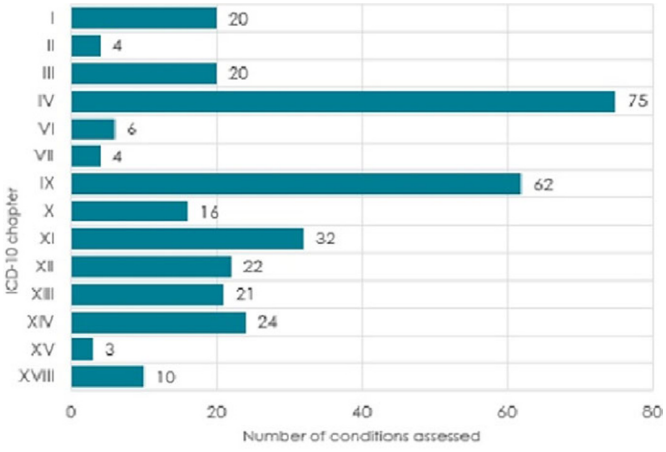

Image 1. Conditions assessed in consultations according to ICD-10 classification.

Image 2:

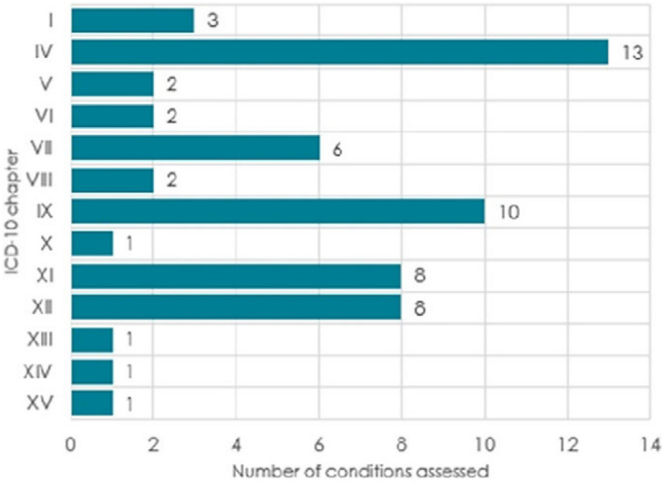

Image 2. Conditions assessed in health checks according to ICD-10 classification.

Conclusions: The variety and amount of untreated chronic common diseases and specific somatic conditions related to psychiatric diseases/medications was substantial, and even for the GP hospitalists, time-consuming to handle. Cardiometabolic problems were the most prevalent of health concerns. GP hospitalists are one of the real-world solutions in improving the overall health of patients with severe mental illnesses, and in alleviating the heavy workload of treating psychiatrists.

EPV1277

Validity Evidence Based on the Content of the MAPS-B Cognitive Assessment Instrument

J. Martini[1]*, M. B. Martins[1], M. R. Zibetti[2], J. J. Schneider[1] and C. M. Trentini[1]

[1]Assessment and Measurement in Psychology, Federal University of Rio Grande do Sul, Porto Alegre and [2]Psychopathological States and Psychotherapeutic Approaches, University of Vale do Rio dos Sinos, São Leopoldo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1842

Introduction: The MAPS-B is part of a project focused on the construction of instruments for cognitive assessment in the Brazilian population. Comprising eight subtests, MAPS-B aims to enhance understanding of cognitive functioning in individuals over 50 years old. The subtests assess autopsychic and allopsychic orientation, perception, naming, memory, praxis, visual and auditory focused attention, working memory, automatic language, inhibition, and semantic memory. Validity evidence is essential to ensure the safe use of new instruments in psychological assessments. Content-based validity evidence reflects the degree to which the instrument aligns with and adequately measures the construct of interest. Such evidence can be derived from expert judgment.

Objectives: To investigate the content-based validity evidence of the MAPS-B.

Methods: The analysis involved four judges with expertise in neuropsychological assessment, who completed a questionnaire on MAPS-B's subtests. The judges assessed the adequacy and clarity of the instructions and the relevance of each subtest for measuring the proposed construct, using a Likert scale (0 to 4). Space was also provided for comments and suggestions. Responses were analyzed using the Content Validity Index (CVI), calculated individually (CVI-I) and globally (CVI-T) for the instrument. A CVI score above 1 was considered acceptable (Yusoff, Education in Medicine Journal Int 2019; 51). Additionally, items with suggestions from the judges were qualitatively reviewed.

Results: Expert analysis indicated total agreement across all subtests, with individual and total CVI scores of 1, demonstrating adequacy in terms of relevance, clarity, and overall suitability. However, qualitative adjustments were suggested for two subtests assessing orientation and perception. Following analysis and consensus among the authors, modifications were made as shown in **Table 1**.

Table 1

Original Item	Post-Judge Analysis Adjustment
"What part of the day is it?"	A note was added to the manual, allowing assessors to clarify the question by adding, 'What part of the day are we in? Morning, afternoon, or evening?'"
"What is your address?"	A note was added to the manual specifying that correct answers may include just the street name and house number.
"Mentally assemble it and name it."	Rephrased to "Can you mentally assemble the figure and name it?"

Conclusions: This study provides content validity evidence for the MAPS-B, showing that its subtests adequately represent the constructs being assessed. All items achieved satisfactory CVI scores in line with literature recommendations (CVI > 1), indicating agreement on item relevance and suitability. The qualitative suggestions from experts contributed to refining the MAPS-B. Although the current results are satisfactory for the instrument's proposed use, future studies are needed to gather further validity evidence and investigate the instrument's reliability.

Disclosure of Interest: None Declared

EPV1278

Study of Correlations between Cognitive Performance, Age, and Education in the MAPS-T Screening Test

M. B. Martins[1]*, J. Martini[1], M. R. Zibetti[2], J. J. Schneider[1] and C. M. Trentini[1]

[1]Assessment and Measurement in Psychology, Federal University of Rio Grande do Sul, Porto Alegre and [2]Psychopathological States and Psychotherapeutic Approaches, University of Vale do Rio dos Sinos, São Leopoldo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1843

Introduction: The MAPS-T is a screening instrument currently under development in Brazil, designed for patients over 50 years of

age and administered in a computerized format, either online or with assistance. Its purpose is to assess memory binding abilities, which involve integrating complex elements into unified representations, crucial for both short- and long-term memory. Conjunctive binding in short-term memory is responsible for the temporary retention of associations or combinations of features, such as color and shape. Screening instruments like the MAPS-T aim to be low-cost, quick, and non-invasive tools that provide indicators of potential clinical conditions.

Objectives: To investigate the relationship between performance on memory tasks involving binding and the variables age and educational level.

Methods: A total of 33 individuals aged between 50 and 78 years (M=62.09; SD=6.67) with 6 to 35 years of education (M=19.88; SD=5.63) were evaluated. Participants with reported neurological/psychiatric conditions or uncorrected sensory impairments were excluded. Data collection was conducted on a computer by a trained administrator in sessions lasting 15 minutes. The memory binding task required the recognition of a nameable figure and the color and geometric shape surrounding it. Data were analyzed using Spearman's correlation.

Results: Spearman's correlation coefficients indicated that age did not show a significant correlation with total recognition, binding score, or dichotomous score ($p > 0.05$), suggesting that this variable does not have a relevant association with performance in these scores. In contrast, education demonstrated a moderate and significant correlation with total recognition, binding score, and dichotomous score ($p < 0.05$), suggesting that more years of education are associated with better performance in these areas.

Descriptive Statistics

	N	Minimum	Maximum	Mean	Std. Deviation
age	33	50,00	78,00	62,0909	6,67254
education_level_years	33	6	35	19,88	5,628
Valid N (listwise)	32				

		Age	education_level_years
MAPS-T - total_recognition_phase_2	Correlation Coefficient	,194	,431*
	Sig. (2-tailed)	,280	,012
	N	33	33
MAPS-T - binding_score	Correlation Coefficient	,198	,383*
	Sig. (2-tailed)	,268	,028
	N	33	33
MAPS-T - dichotomous_score	Correlation Coefficient	,181	,406*
	Sig. (2-tailed)	,313	,019
	N	33	33

Conclusions: Education showed a positive and consistent association with performance across all test measures (total recognition, binding score, and dichotomous score). Age, in turn, did not show a significant correlation with these variables, indicating that, in this sample, education is a more important factor than age in explaining performance on the MAPS-T scores, particularly in the binding stage.

Disclosure of Interest: None Declared

Self-protective behaviours to protect against coronavirus-19 infection and their association with Perceived Infectability, Germ Aversion and Fear of COVID-19 among South African learners

S. Mashegoane[1]*, J. O. August[2], V. Baloyi[3], L. D. M. Lebeloane[4], M. Makhubela[1] and K. P. Moalusi[5]

[1]Psychology, University of Limpopo, Polokwane; [2]Psychology, Nelson Mandeal University, Qheberha; [3]Psychology, University of Venda, Thohoyandou; [4]Further Teacher Education and [5]Industrial and Organisational Psychology, University of South Africa, Tshwane, South Africa

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1844

Introduction: COVID-19 wreaked havoc across the world killing millions along its path. All attempts were made to lower and eventually control the death toll from the pandemic. The "trace, test and treat" approach had its limits since the latter were not developed fast enough. Vaccines were seen as the best hope to protect individuals from the coronavirus and COVID-19. Thus, vaccination was encouraged and promoted widely. Aside from vaccines, interventions emphasised non-pharmaceutical self-protective behaviours to protect against coronavirus infection. Subsequently, there were various levels of compliance and observance of self-protection within nations. Yet studies have not attempted to explore the research implications of compliance patterns.

Objectives: The present study's aim was to (i) identify latent classes of individuals' varying levels of compliance with COVID-19 self-protective behaviours; and (ii) explore the capacity of the latent classes to separate individuals according to their levels of Perceived Infectability, Germ Aversion and Fear of COVID-19.

Methods: Data for the current study was extracted from a cross-district COVID-19 study conducted among *high school level learners (N = 1609; girls = 59%; rural areas = 43%) in South Africa*. Latent classes were derived based on the scores obtained by learners on a self-developed index of non-pharmaceutical self-protective behaviours. Three classes were identified, and they were compared against their obtained Perceived Infectability, Germ Aversion and Fear of COVID-19 scores.

Results: Scores of all three knowledge groups did not differ on Perceived Infectability ($p > .05$), but the highest scorers, the "knowledgeable group", scored higher than the "moderately knowledgeable group" and the "relatively low knowledge group" on Germ Aversion and Fear of COVID-19. The scores of the "moderately knowledgeable group" and the "relatively low knowledge group" did not differ on the Fear of COVID-19.

Conclusions: The study supports an approach where learners are classified according to their knowledge of COVID-19 self-protective behaviours, and their motivation for self-protection established according to the classification.

EPV1281

Psychotic symptoms during puerperium. Regarding a clinical case

C. Mateo Garcia[1]*, Á. Blanco Niño[1], C. Pérez Puente[1] and I. Esteban Hernández[1]

[1]Hospital Virgen del Puerto, Plasencia, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1845

Introduction: The puerperium, or postpartum period, begins immediately after childbirth and is typically considered to last for six to eight weeks. During this time, there is an increased risk of psychiatric pathology, particularly psychotic and affective disorders, due to various factors such as the heightened stress of caring for a newborn and hormonal changes.
Objectives: To analyze the different diagnostic options for a patient presenting with acute psychotic symptoms during the postpartum period, including those not recognized by the DSM-V.
Methods: Presentation of a patient's case and a review of the existing literature concerning the possible diagnoses that were considered.
Results: We present the case of a 31-year-old female with a history of allergy to beta-lactam antibiotics as her only significant medical history, and a personal psychiatric history of anorexia nervosa (currently resolved) and bipolar disorder. The bipolar disorder had been treated with valproic acid and olanzapine since 2015, medications she discontinued upon learning of her pregnancy. She gave birth to a baby boy four days before seeking care in the emergency department. On the same morning of the consultation, her baby was diagnosed with a renoureteral malformation and prescribed amoxicillin treatment. The patient presented to the emergency department with very acute psychotic symptoms that had started that same day, notably a very disorganized speech and delusional ideas of harm, expressing the belief that her family was poisoning her with the prescribed amoxicillin. During her admission to the acute psychiatry ward, her condition evolved rapidly and very favorably, in around 48 hours and she was treated with olanzapine. Several diagnostic possibilities were considered, including postpartum psychosis, brief psychotic episode, manic episode, or even an organic cause. The rapid onset and therapeutic response ruled out the diagnosis of a manic episode. No organic cause was found to explain the symptoms. It also did not meet the temporal criteria required for a postpartum psychosis. Finally, the diagnosis was brief psychotic episode, triggered by an acute stressor.
Conclusions: When managing a patient in the postpartum period, it is crucial to have a comprehensive understanding of the various diagnostic possibilities, including those not covered by the DSM-V or those that may have a somatic cause, in order to provide appropriate and holistic care.

The role of self-esteem in mental health: a comparative study on its association with anxiety, depression and stress in support-seeking and general populations from Croatia

T. Meštrović[1]*, J. Mašek[1], R. Ribić[1] and M. Neuberg[1]

[1]Department of Nursing, University North, Varaždin, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1846

Introduction: Mental health is essential for overall well-being and resilience in facing life's challenges. Self-esteem, a crucial mental health determinant, affects how individuals perceive and manage stress, and may be linked to worse health outcomes when conditions like anxiety and depression are concerned. Consequently, understanding the role of self-esteem in mental health is essential for developing effective preventive strategies and interventions.
Objectives: In this study we aimed to investigate the relationship between self-esteem levels and anxiety, depression and stress, with a hypothesis that the presence of the aforementioned mental health challenges is significantly correlated with lower levels of self-esteem. We sought to explore the potential impact of self-esteem as both a risk factor and a target for interventions in mental health care.
Methods: A cross-sectional study design was employed, involving 100 participants based in the Republic of Croatia and divided equally into two groups: support-seeking individuals or patients from the daily clinical setting and a control group with no psychiatric treatment history. Participants completed the Rosenberg Self-Esteem Scale (RSE) and the Depression Anxiety Stress Scale (DASS-21). The self-esteem scores classified individuals into low, average or high self-esteem categories. Statistical analyses, including chi-square tests and Mann-Whitney U tests, assessed differences in DASS-21 scores between groups, with adjustments for sociodemographic factors.
Results: Psychiatric patients showed significantly lower self-esteem (mean = 20.84, SD = 7.161) than the control group (mean = 29.84, SD = 7.709). Additionally, psychiatric patients experienced higher levels of anxiety (mean = 12.60, SD = 5.237), depression (mean = 12.04, SD = 5.595) and stress (mean = 14.06, SD = 4.433) when compared to the control group, which exhibited mild anxiety (mean = 5.14, SD = 5.018), low depression (mean = 4.90, SD = 5.296) and minimal stress levels (mean = 6.96, SD = 4.973). Statistical analysis revealed a statistically significant association between low self-esteem and support-seeking or patient status ($p = 0.001$). Additionally, low self-esteem was associated with more severe mental health symptoms across all categories ($p < 0.05$).
Conclusions: This study emphasizes the interconnectedness between self-esteem and mental health, demonstrating that lower self-esteem is associated with higher anxiety, depression and stress levels. Therefore, integrating self-esteem enhancement into therapeutic settings may be an effective strategy for mitigating mental health risks, providing a proactive approach to psychological care and prevention.

Schizophrenia versus Traumatic Brain Injury: A Diagnostic Challenge

N. Monteiro[1]*, M. Abrantes[1] and S. Morais[1,2]

[1]Centro de Responsabilidade Integrada de Psiquiatria, Centro Hospitalar e Universitário de Coimbra (CHUC) and [2]Faculdade de Medicina, Universidade de Coimbra, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1847

Introduction: Traumatic brain injury (TBI) is a rare, yet possible cause of psychosis (Fujii D *et al.* Psychiatr Clin North Am. 2014; 37(1):113-24), with one of the main challenges being distinguishing between Psychosis secondary to traumatic brain injury (PSTBI) and schizophrenia (SZ).
Objectives: To discuss the diagnostic challenges in patients with psychosis and history of TBI.
Methods: In addition to describing a case report of a male with psychotic symptoms presenting after a severe traumatic brain injury, research was undertaken in PubMed and other databases using the keywords "traumatic brain injury", "psychosis" and "schizophrenia".
Results: Our patient is a 36 year-old male who suffered a severe TBI at age 22, with consequent frontal and temporal encephalomalacia. Initially he presented with persecutory delusions, delusional perceptions associated with colors, social isolation and decline in academic performance, which were attributed to Post-Concussion Syndrome. However, these symptoms would remain for years to come, leading to the new diagnosis of SZ, at age 25. This way, he started intramuscular antipsychotic medication, which reduced psychotic symptoms and improved his academic performance. This amelioration, at age 30, led to the belief in another diagnosis: Brief Psychotic Episode (after brain trauma). Consequently a reduction in antipsychotic dosage was tried but a resurgence of psychotic symptoms was observed at age 33, which led to the reintroduction of antipsychotic medication, and the reconsideration of the diagnosis of SZ. When we examined him, at age 36, he presented similar symptoms to those observed after the brain injury, intensified by years without antipsychotics. We also found that he had regular use of cannabinoids since age 16 and that his brother was diagnosed with Schizoaffective disorder.

Image:

Image 2:

Conclusions: PSTBI usually occurs after a TBI with frontal and temporal lesions, and psychotic symptoms like persecutory delusions, with the frontal lesions being a possible explanation for the decline in cognitive function by causing deficits in attention, executive functions and memory (Fujii D *et al.* Journal of Neuropsychiatry Clinics in Neuroscience 2002;14:130-140). SZ can similarly explain many of the findings presented, like psychotic symptoms, social isolation and decline in cognitive function due to negative symptoms, specially considering the use of cannabinoids and genetic vulnerability present in this patient and the fact that TBI is also a risk factor for the development of SZ. This case highlights the difficulty in the differential diagnosis between PSTBI and SZ, given that it presents aspects that can point in both directions.

First Episode Psychosis: A Neurodevelopmental Crossroads

N. Monteiro[1]*, M. Vasconcelos[1], R. Resende[1], S. Morais[1,2] and D. Mota[1,2]

[1]Centro de Responsabilidade Integrada de Psiquiatria, Centro Hospitalar e Universitário de Coimbra (CHUC) and [2]Faculdade de Medicina, Universidade de Coimbra, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1848

Introduction: Autism spectrum disorder (ASD) and schizophrenia (SZ) are neurodevelopmental disorders that, although unfolding in

different ways, can present with overlapping symptoms, both negative symptoms like deficits in social–emotional reciprocity and engagement (Trevisan *et al.* Front.Psych; 2020;11:548), and positive symptoms like delusions and hallucinations (Ribolsi *et al.* Front Psychiatry; 2022;13:768586).
Objectives: To discuss the diagnostic challenges between ASD and SZ in patients presenting with both positive and negative symptoms.
Methods: In addition to describing a case report of a man with negative symptoms and presumptive psychotic symptoms, research was undertaken in PubMed and other databases using the keywords "autism spectrum disorder", "schizophrenia" and "multiple sclerosis".
Results: A 26 year-old man was involuntarily admitted to the in-patient unit due to persecutory delusions, irritability, social isolation and cognitive symptoms. He had also been recently diagnosed with Multiple Sclerosis (MS). These symptoms had begun 5 years prior, intensifying over time, leading to the hypothesis of First Episode Psychosis, with a probable recent escalation secondary to the flairing up of MS. Through a detailed clinical history, we discovered that, in fact, the patient exhibited conduct changes since early adolescence: restricted and repetitive behavior, social isolation, reduced tolerance to opposition, cognitive rigidity, circumscribed interests and puerile contact. This lead to the development of great hostility towards his family members, whenever his wants weren't met (most of them mismatched with reality), resulting in isolation from the family and the sending of aggressive messages and emails, even though his parents always tried to provide the patient with everything he wanted, explaining the assumption of persecutory delusions. Intramuscular risperidone and clozapine were initiated for irritability and cognitive symptoms, respectively, with minimal improvement in both, mainting however every other symptom described.
Conclusions: Despite the current distinction between ASD and SZ, they still share many similarities, increasing the difficulty of determining an exact diagnosis. We present a case with negative and cognitive symptoms, that can fit in both conditions, and positive symptoms that fit in SZ. It's possible to understand that the delusions may not be primary, but secondary to social interpretation bias, common in ASD patients, and that part of the cognitive symptoms can be due to MS. The suboptimal response to antipsychotics also makes us lean more to the presence of ASD with temporary psychotic symptoms instead of a primary psychotic disorder.

EPV1285

Diagnostic delays in schizophrenia with catatonic symptoms mimicking conversive disorder

J. L. P. Fernandes[1], N. Monteiro[1]*, S. Morais[1,2] and J. F. A. Brás[1,2]

[1]Centro de Responsabilidade Integrado de Psiquiatria, Unidade Local de Saúde de Coimbra and [2]Faculdade de Medicina, Universidade de Coimbra, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1849

Introduction: Notwithstanding the drastic reduction in the prevalence of catatonic symptoms in schizophrenia with the development of anti-psychotic treatment regimens since the 1950's, a subgroup of patients still presents mostly such symptoms, associated with worse long-term prognosis.
Objectives: Discuss the challenges surrounding the diagnosis and clinical management of patients with schizophrenia with catatonic symptoms.
Methods: In addition to describing a case report of a male with catatonic symptoms mimicking conversive disorder, research was undertaken in PubMed and other databases using the keywords "conversive disorder, "catatonia" and "schizophrenia".
Results: A 29-year-old male patient, a former Geology BA student followed by Psychiatry in our hospital for conversive symptoms – namely mutism and sudden episodes of motor paralysis with no changes in the neurological examination or imaging exams - and admitted twice for that reason in the prior 6 months, was brought to the ED by police after an attempted self-injury with a knife. The family reported for the past week sleep-wake inversion, social isolation, compulsive smoking, refusal to eat any homemade food, soliloquies, staring at the walls for no reason and, in the last 3 days, post its with messages such as "I sinned" or "I disappointed God". In the ER, the patient engaged in mutism, with negativism in his posture. Considering the high suicide risk and the presence of psychotic symptoms, including persecutory, poisoning and mystical delusions as well as likely auditive-verbal hallucinatory activity, he was admitted again, this time in involuntary regime. To exclude secondary causes, both blood samples and imaging techniques (first head CT and later MRI) were ordered. The bloodwork revealed increased levels of CK without any other significant findings, and imaging techniques also had negative results. In the psychiatric ward, the patient engaged in selective mutism towards the medical team, likely in a context of persecutory delusions. Due to the prominence of negative symptoms and lack of adhesion to treatment, we choose to treat with intramuscular paliperidone and sertraline, 50 mg. With this treatment, the patient started feeding himself again, resumed a daily routine and ceased his mutism. Yet, he remained highly defensive psychopathologically, with very poor speech content and severe affective blunting. He was discharged with the diagnosis of schizophrenia and has been followed in outpatient visitations, remaining clinically stable.
Conclusions: Catatonic schizophrenia in its first presentation can be confused with conversive disorder, given the fact both may share movement disorders, in psychotic patients who collaborate very little with psychiatrists, requiring a careful combination of anamnesis, mental state examination and gathering of information with family members or others close to the patient.

EPV1286

On the issue of psychopathological analysis of a work of fiction using the example of Dostoevsky's "The Double"

S. V. Motov[1] and V. V. Motov[2]*

[1]Department of Slavic Languages & Literatures, University of Illinois Urbana-Champaign, Urbana, IL, United States and [2]Psychiatry, Social House "Stupino" (The Institution for Chronic Mental Patients with Disability) of The Department of Labor and Social Protection of the Population of the City of Moscow, Stupino, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1850

Introduction: Vladimir Chizh, who replaced Emil Kraepelin in the Department of Psychiatry at the University of Dorpat in 1891, counted no fewer than 30 characters with psychoneurological

disorders in Dostoevsky's works, beginning with the main character of "The Double," written in 1846.
Objectives: Try to answer the following questions: (1) Should a psychopathological analysis of a literary work include elements of the author's psychobiography, psychopathological components of the author's language, and can such work be carried out by one psychiatrist without the participation of a literary scholar? (2) What goals should such an analysis pursue? (3) Should the accuracy of the author's description of the mental disorders present in the characters of his work be considered as a criterion for assessing the author's artistic skill and the significance of the work as a literary and cultural phenomenon?
Methods: Taking Dostoevsky's "The Double" as a starting point, the authors analyzed professional literature on the topic and conducted their own psychopathological and literary analysis of this literary work.
Results: (1) psychopathological analysis without the participation of a literary scholar is always incomplete, since everything we learn about the hero of the work we learn through the language of the work. (2) the assessment of the quality of a work of art by a psychiatrist from the point of view of the accuracy of the description of psychopathological symptoms in a particular character leads to the fact that the ideal work of art becomes a well-written case history.
Conclusions: It is hardly correct to give a precise psychiatric categorization to persons whose behavior in a work of art is depicted as pathological. The author's depiction of his hero's pathological experiences has goals other than psychiatric ones and is conditioned by the general concept of the work.

EPV1287

The Insane in Chains: Literary Image of Russian Fiction and Historical Truth of the First Half of the 19th Century

S. V. Motov[1] and V. V. Motov[2]*

[1]Department of Slavic Languages & Literatures, University of Illinois Urbana-Champaign, Urbana, IL, United States and [2]Psychiatry, Social House "Stupino" (The Institution for Chronic Mental Patients with Disability) of The Department of Labor and Social Protection of the Population of the City of Moscow, Stupino, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1851

Introduction: A compatriot who is declared insane and ends up chained in a mental institution is a new and unexpected character that appeared in Russian fiction during its heyday in the first half of the 19th century. The theme of "madness" followed by "chaining" is repeated in the influential works of Alexander Pushkin, Alexander Griboyedov, Alexander Voeikov and other outstanding writers of this period.
Objectives: Find out: (1) How historically accurate was this persistent artistic image — was it merely a literary convention or a true reflection of the status quo? (2) Was the shackling of patients "the standard of care" in psychiatric institutions in Russia and Europe in the late 18th and first half of the 19th centuries?
Methods: A historiographical and comparative analysis was conducted, which allowed us to compare historical evidence and manuals on mental illness published in Europe in the period 1782-1845, as well as Russian professional literature on the history of psychiatry in Russia.
Results: The artistic image of the "madman on a chain" largely corresponded to reality; moreover, in a number of cases, the horror of reality exceeded the artistic image.
Conclusions: By bringing the image of the patient in chains to the forefront, Russian fiction attracted public attention to the topic, which was one of the factors that contributed to the opening of a significant number of new psychiatric hospitals in Russia in the second half of the 19th century, with a more humane attitude towards psychiatric patients.

WRITTEN INFO KEEPS YOU ON TRACK! - Importance of written communication/information in therapeutic adherence

S. Mouta[1]*, M. Fonseca[1], A. Pires[1], M. Pires[1] and D. Figueiredo[1]

[1]Psychiatry and Mental Health Department, Unidade Local de Saúde da Guarda, Guarda, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1852

Introduction: Therapeutic adherence is defined by the World Health Organization as the degree to which the patient's behavior corresponds to the recommendations agreed with the healthcare professional. Adequate adherence to pharmacological treatment is essential to achieve therapeutic objectives, but non-adherence rates are high, ranging between 10% and 92%.
Objectives: To highlight the role of written communication/information provided to the patient in the adherence to treatment.
Methods: Non-systematic literature review.
Results: Non-adherence limits therapeutic benefits, compromises the effectiveness of medications and increases the demand for healthcare, representing a major obstacle to the provision of care. One of the factors that contribute to non-adherence is the failure in communication between healthcare professionals and patients, especially with regard to providing clear information about medications.
Since patient educational interventions seem important and effective in improving medication adherence, it is pertinent to adopt more effective ways of communicating and adequately informing patients about the main aspects of the prescribed drugs. Such process can be assisted by written information leaflets.
In this context, studies have revealed that patients appreciate written information to help make decisions about whether or not to take a medication, manage medication intake and interpret symptoms. The benefits and side effects of drugs are generally important information for patients, especially if presented in a legible way, with understandable text, without large volume and without small font size used.
Written instructions can be a useful complement to information transmitted verbally by serving to increase the likelihood that important information can be presented, understood, accepted and remembered by the patient - studies show that patients who received written information better understood their medication, precautions, use instructions, associated side effects, and were more satisfied with the information received, which could contribute to greater therapeutic adherence.

Conclusions: There seems to be a consensus in the bibliography that written information should not replace verbal information. The latter remains a priority, but must be closely associated to written information so that, in combination, its beneficial effects can be enhanced.

Disclosure of Interest: None Declared

EPV1289

Bibliographic Review of Smith-Magenis Syndrome and its Psychopharmacological Management with Lithium: About a case

M. Navarro Bardon[1]* and K. M. Rodríguez[1]
[1]Psychiatry, SERGAS, Vigo, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1853

Introduction: Smith-Magenis Syndrome (SMS) is a neurogenetic disorder caused by deletions on chromosome 17p11.2 or mutations in the **RAI1** gene. It is characterized by **intellectual disability**, **behavioral disturbances** like **aggression**, **impulsivity**, **self-injury**, and **sleep disruptions**. A hallmark feature of SMS is **inverted melatonin production**, leading to **daytime sleepiness** and **nighttime insomnia**, which exacerbate behaviors. Traditional treatments, such as **antipsychotics** and **SSRIs**, often show limited effectiveness and can cause side effects, including **metabolic syndrome**, **sedation**, and **extrapyramidal symptoms**.
Lithium has emerged as a promising alternative to manage **treatment-resistant behaviors** in SMS. Known for its **mood-stabilizing** properties in **bipolar disorder**, lithium modulates **dopamine** and **serotonin**, reduces **aggression**, and promotes **neuronal plasticity**. However, lithium requires **close monitoring** due to the risks of **nephrotoxicity**, **thyroid dysfunction**, and its **narrow therapeutic index**.
Objectives: This study explores **lithium's role** in managing **severe behavioral disturbances** in SMS, especially in patients unresponsive to conventional treatments. The objectives are: (1) to review the **literature** on lithium's efficacy and safety in SMS and similar neurodevelopmental disorders, and (2) to present a **clinical case** of a 25-year-old SMS patient treated successfully with lithium after antipsychotics and SSRIs failed.
Methods: A **literature review** was conducted using **PubMed** and **Web of Science**, focusing on articles published between 2013 and 2023 on lithium in SMS and related disorders. Additionally, the **clinical case** of a 25-year-old male with SMS, exhibiting **aggression** and **self-injury**, was documented. After other treatments failed, lithium was introduced with regular monitoring of **serum levels**, **renal**, and **thyroid function** throughout six months.
Results: Literature supports lithium's **efficacy** in reducing **aggression** and **impulsivity** in SMS. Lithium modulates **dopaminergic** and **serotonergic systems**, stabilizing mood and reducing disruptive behaviors. In the clinical case, the patient improved within two weeks of lithium therapy. Over six months, **aggression** and **self-injury** diminished significantly, with no adverse effects and stable **renal** and **thyroid function**.
Conclusions: Lithium is an effective option for SMS patients with **treatment-resistant behavioral disturbances**, particularly **aggression** and **self-injury**. It offers a valuable alternative to antipsychotics and SSRIs, enhancing **emotional stability** and **quality of life**. However, careful **monitoring** is required to prevent toxicity. Further research is needed to confirm lithium's long-term safety and efficacy in SMS.

EPV1290

The Hidden Burden of Undiagnosed ADHD among Medical Students in Pakistan: A Cross-Sectional Survey of Self-Reported Symptoms

Z. U. Nisa[1]
[1]Psychiatry, Liaquat National Hospital, Karachi, Pakistan
doi: 10.1192/j.eurpsy.2025.1854

Introduction: Attention-deficit/ hyperactivity disorder (ADHA) is recognized as a major public health issue, characterized as a persistent neurodevelopmental disorder that presents challenges in various aspects of life, often continuing into adulthood and frequently going undiagnosed.
Objectives: This study aimed to explore the prevalence, types, participants knowledge and perceptions and demographic determinants of undiagnosed adult ADHD among undergraduate medical students in Pakistan.
Methods: This study conducted from July 2023 to December 2023. A nationwide cross-sectional study enrolled 342 undergraduate medical students who met the selection criteria. Data was collected through an online self-administered survey of three main parts, utilizing the WHO 18 questions Adult ADHD Self-Report Scale, Version 1.1 (ASRS-v1.1), to assess adult ADHD symptoms. Data analysis was carried out using SPSS (version 26.0).
Results: Out of 342 participants, 119 medical students, or 34.8%, were found to have adult ADHD. The most prevalent presentation was inattentive dominance, observed in 86 students (72.3%), followed by mixed dominance in 20 students (16.8%), and hyperactive dominance in 13 students (10.9%). There was a statistically significant ($p < 0.05$) association between individuals screening positive for adult ADHD and the presence of co-occurring psychological disorders (e.g., anxiety, depression) and a family history of psychiatric disorders (e.g., ADHD, generalized anxiety disorder, bipolar disorder). Additionally, these individuals believed that adults with adult ADHD could lead a normal life despite their condition. The type of ADHD was significantly associated with the use of medications for psychological disorders, with a notably higher usage among hyperactive dominants (5, 71.4%), and a significantly higher family history of GAD among mixed dominants (2, 10.0%).
Conclusions: This study uncovers a significant prevalence of undiagnosed adult ADHD and an inattentive dominance among medical students in Pakistan, highlighting the need for enhanced awareness and screening. These findings underscore the critical necessity for the implementation of ADHD screening programs.

EPV1294

From Mood Swings to Psychosis: Exploring the Psychiatric Side Effects of Corticosteroids

A. Pedro Costa[1]*, M. Mousinho[1], A. Matos Pires[1], G. Simões[2], A. I. Gomes[2] and A. R. Coelho[3]

[1]Departamento de Saúde Mental, Unidade de Saúde do Baixo Alentejo, Beja; [2]Departamento de Psiquiatria e Saúde Mental, Unidade Local de Saúde da Região de Aveiro, Aveiro and [3]Serviço de Oncologia Médica, Instituto Português de Oncologia de Coimbra Francisco Gentil, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1855

Introduction: Corticosteroids are integral in treating various medical conditions across multiple specialties. However, they are known to induce psychiatric adverse effects, ranging from subtle mood changes and memory deficits to psychosis.
Objectives: This review aims to explore the current literature on these effects, identifying risk factors and strategies for early intervention.
Methods: A non-systematized literature review was carried out on PubMed and Google Scholar. The following words were searched: ("corticosteroids" OR "steroids" OR "glucocorticoids") AND ("psychiatry symptoms" OR "psychosis" OR "mood" OR "memory").
Results: Despite being recognized for their strong anti-inflammatory and immune-suppressing effects across various medical conditions, corticosteroid therapies frequently come with neuropsychiatric complications, the understanding of which is still limited. Although symptoms usually emerge within 3 to 4 days after starting corticosteroid treatment, they can manifest at any point, even after the therapy has been completed or stopped. Dosage is a significant risk factor, with high doses increasing the likelihood of psychosis. Depression is more prevalent among women. Additional risk factors include past psychiatric history, compromised blood-brain barrier, and hypoalbuminemia. However, some instances show beneficial outcomes, such as alleviation of depressive symptoms without triggering mania and improvements in cognitive function.
Conclusions: Early diagnosis and awareness are crucial in managing corticosteroid-induced psychiatric symptoms. Initial steps should involve tapering or discontinuing corticosteroids, supplemented by psychotropic medications if necessary.

Disclosure of Interest: None Declared

EPV1295

Prevalence of body dysmorphic disorder in the aesthetic medicine practice: a systematic review

I. M. M. Peso Navarro[1]*, C. M. Cossio[1], C. G. Cerdan[1], M. L. Argudo[1], N. M. C. Espada[1], A. G. Mota[2] and R. G. Juanes[3]

[1]Psychiatry, Hospital Clínico Universitario de Salamanca, Salamanca; [2]Psychiatry, Hospital Clínico San Carlos, Madrid and [3]Psychiatry, Hospital Universitario de Son Espases, Mallorca, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1856

Introduction: Body dysmorphic disorder (BDD) consists of preoccupation with one or more perceived defects or flaws in physical appearance that are not observable or appear slight to others, and which cause a great social deterioration. Its prevalence in aesthetic medicine is around 10 percent, and it is higher in women.
Objectives: The overall objective of this systematic review is to gather integrated evidence to ascertain the prevalence of body dysmorphic disorder in an aesthetic medicine practice and its association with satisfaction with the results of the derived interventions.
Methods: An initial search of ScienceDirect, PubMed, PsycInfo, Cochrane, and CINAHL was conducted. In addition, scientific journal publications, book articles and clinical guidelines were used. The search terms were: "body image", "eating disorder", and "aesthetic medicine". The search included results from January 2000 to January 2023, in Spanish and English.
Results: The total number of participants in all studies was 3004. 42.86% of the studies were conducted between 2000 and 2009, while the rest were conducted from 2010 onwards. It has been observed that most patients with BDD seek non-psychiatric treatment for their perceived appearance defects. The result after an aesthetic intervention is that in most patients with BDD there is no improvement in the concern for the perceived body image defect, and they present greater dissatisfaction. A high number of patients with BDD are being overlooked in aesthetic medicine practice who should receive a combined medical and psychological intervention.
Conclusions: It is necessary to create protocols for an early diagnosis of body dysmorphic disorder in the aesthetic medicine practice which include a comprehensive approach.

Disclosure of Interest: None Declared

EPV1296

Advances in Catatonia: Diagnostic Breakthroughs, Neuroimaging Insights, and Emerging Treatments

M. Peyioti[1]*, P. Argitis[2], A. Karampas[3], M. Demetriou[2], V. Anagnostopoulou[2] and Z. Chaviaras[2]

[1]University General Hospital of Alexandroupolis, Alexandroupolis; [2]Psychiatric Clinic, General Hospital of Corfu, Corfu and [3]Psychiatric Clinic, University General Hospital of Ioannina, Ioannina, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1857

Introduction: Catatonia is a neuropsychiatric syndrome characterized by motor, behavioral, and autonomic disturbances, frequently associated with psychiatric disorders such as schizophrenia and mood disorders, but also manifesting in medical conditions like autoimmune encephalitis and epilepsy. Despite its prevalence, catatonia remains underdiagnosed and undertreated. Recent advances in neuroimaging, diagnostic frameworks, and therapeutic interventions have enhanced our understanding of the syndrome, contributing to improved clinical outcomes.
Objectives: This abstract synthesizes recent developments in the diagnosis and treatment of catatonia based on research conducted from 2020 to 2024.
Methods: A systematic review of the literature published between 2020 and 2024 was performed using databases such as PubMed and Google Scholar. The search strategy included the terms "catatonia," "diagnosis," "treatment," and "neuroimaging." Relevant studies, case reports, and reviews focusing on diagnostic innovations, neuroimaging techniques, and therapeutic advances were included.
Results: Advances in neuroimaging, particularly functional MRI, have revealed abnormalities in the frontoparietal cortex, basal ganglia, and cerebellum, offering insights into the neurobiological mechanisms underlying catatonia. Resting-state fMRI studies have demonstrated altered functional connectivity in these regions, facilitating differentiation between catatonia and other movement disorders. Diagnostic tools such as the Bush-Francis Catatonia Rating Scale (BFCRS) remain integral to clinical assessment.

Benzodiazepines, particularly lorazepam, continue to be the first-line treatment, while electroconvulsive therapy (ECT) is employed in treatment-resistant cases, especially in malignant catatonia marked by autonomic dysregulation. Emerging treatments, including NMDA receptor antagonists like memantine, have shown potential in refractory cases. Special considerations are required for populations with autism spectrum disorder (ASD) and neurodevelopmental conditions, where catatonia presents uniquely.
Conclusions: Recent findings underscore the importance of early diagnosis and timely intervention in catatonia. Advances in neuroimaging and novel therapeutic options have enhanced the management of this complex condition, opening new directions for research and clinical practice.

EPV1297

The experience of Stigma on Recovery Among Parents with Serious Mental Illness: A Systematic Review

M. G. Pijnenborg[1]*, E. sportel[2], I. Hasson-Ohayon[3], I. Bogers[2] and C. Prins[2]

[1]university of Groningen, Groningen; [2]GGZ Drenthe, Assen, Netherlands and [3]bar-ilan university, tel aviv, Israel
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1858

Introduction: The parental role is often central to the recovery process. For the 70% of people with Serious Mental Illnesses (SMI) who are or will become parents, the parental role is often central to their recovery process. Although a growing number of studies focuses on recovery in parents with SMI, little is known about the experienced influence of stigma on recovery within this specific group.
Objectives: This systematic review aims to provide a deeper understanding of the interaction between various types of stigma, the parental role, and the recovery process in parents with SMI.
Methods: A systematic search was conducted in four online databases and the reference lists of included articles. Primary research studies of any design that included stigma- and recovery-related experiences among parents with SMI were included. Stigma-related experiences were categorized into six distinct types. The findings of included studies were inductively coded. Reflexive Thematic Analysis (RTA) was applied for the data-analysis.
Results: A total of 25 studies were included, all of which identified various types of stigma related to the parental role. The data analysis of the interaction between the parental role, stigma, and recovery resulted in the conceptualization of six themes: (1) Loneliness and isolation; (2) Struggling with parental identity; (3) Protecting the children; (4) Not having the same rights and chances; (5) Lost in the system and (6) Overcoming stigma.
Conclusions: Parents with SMI experience stigmatization of their condition as well as stigmatization of their parental role. Stigmatization of the parental role can have a profound impact on their recovery process, since it limits or even restricts parents from fulfilling their parental role. In order to protect their parental role and family life, parents are hesitant to disclose their SMI and ask for help. As a result, parents and their families are hindered in receiving the needed (psychiatric) support. Since the parental role is central to the recovery process for parents with SMI, it is crucial for Mental Health professionals to pay specific attention to the stigma- and recovery-related factors associated with this role.

Communicating Bad News in Emergency Health Care: clinicians needs and perceptions - a comparative study between Portuguese and Brazilian samples

C. Pires-Lima[1,2]*, F. Bittencourt-Romeiro[3], S. Morgado-Pereira[4] and M. Figueiredo-Braga[1,5]

[1]Neurosciences and Mental Health Department; [2]CINTESIS – Center for Health Technology and Services Research, Faculty of Medicine, University of Porto, Porto, Portugal; [3]Faculdade de Tecnologia, SENAI, Porto Alegre - Rio Grande do Sul, Brazil; [4]IVAR – Research Institute for Volcanology and Risk Assessment, University of the Azores, Ponta Delgada, Azores and [5]i3S – Institute for Research and Innovation in Health, University of Porto, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1859

Introduction: Communicating bad news is a common occurrence in the healthcare sector, especially in emergency services. However, it is also recognized as one of the most stressful, uncomfortable and difficult moments. Clinicians may appear cold, exhibiting depersonalized communication, or feel detached and overwhelmed due to a lack of training in communicating bad news. Therefore, it is crucial to develop their skills in communicating bad news to improve their proficiency in these challenging situations.
Objectives: The purpose of this study is to comprehend the specific needs of clinicians when delivering bad news to emergency patients, and to identify effective strategies for tailoring educational programs to the demands of emergency healthcare. Additionally, the study aims to identify differences and similarities across two geographic and cultural settings.
Methods: A group of emergency health professionals working in Portugal and Brazil were invited to participate in the study. We will collected sociodemographic data and performed a professional characterization. Participants will describe their experience and training in delivering bad news in emergency settings and preferences regarding methods and design of communication skills training. The evaluation included clinicians self-evaluate their knowledge, skills, and application of seven relevant skills (adapted from Breaking Bad News, Servotte et al 2019).
Results: We expect clinicians from emergency health units in Portugal and Brazil to identify specific strategies applied when delivering bad news, and how theoretical knowledge and previous training imbed their sense of capability. Sociodemographic and professional characteristics are probable factors influencing clinicians' self-perception of communicating bad news to emergency patients and families.
Conclusions: Breaking bad news can be challenging for clinicians due to the complexity of communication and the emotional intensity involved. This highlights the need for tailored training programs that are culturally adapted and focused on clinicians' needs and preferences. Albeit speaking the same language differences in the healthcare setting (Portugal vs. Brazil) must be considered when designing educational interventions.

Communicating Bad News in Emergency Health Care: Challenges and Best Practices – A Literature Review

C. Pires-Lima[1,2*] and M. Figueiredo-Braga[1,3]

[1]Neurosciences and Mental Health Department; [2]CINTESIS – Center for Health Technology and Services Research, Faculty of Medicine, University of Porto and [3]i3S – Institute for Research and Innovation in Health, University of Porto, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1860

Introduction: Communicating bad news (CBN) in emergency medicine is a crucial and challenging aspect of clinical care. Emergency Health Care (EHC) operates in high-pressure, time-sensitive environments, where life-altering information must be communicated rapidly, leaving little time for careful preparation or consideration. The emotional, ethical, and psychological complexities of CBN in such settings necessitate effective communication strategies to mitigate the distress of patients, families, and healthcare providers. This literature review aimed to examine the key challenges and best practices associated with delivering bad news in emergency medicine.
Objectives: This review aims to synthesize the literature with the main objectives of 1. identifying the challenges faced by emergency medical professionals in delivering bad news and 2. collect the best practices, general guidelines, specific protocols and communication models used in emergency settings.
Methods: A systematic review of the literature was conducted, focusing on peer-reviewed articles published between 2000 and 2023, using the keywords "comunicating bad news," "emergency health care," "communication in emergencies," and "best practices for CBN.". Articles were screened for relevance and rigor, and key findings were synthesized thematically.
Results: The literature highlights several challenges: time constraints in EHC, lack of formal communication training, and emotional toll on both providers and recipients of the news. Emergency physicians often struggle to deliver bad news in a compassionate yet efficient manner, especially in the context of sudden or unexpected death. The best practices identified include the use of structured communication frameworks, such as the SPIKES protocol, which helps guide healthcare providers through the process. Multidisciplinary support, including involving social workers and counselors, was also emphasized as essential to alleviating the burden on both the physician and the patient. Furthermore, studies have revealed that when formal DBN training is implemented during residency, physician confidence and patient satisfaction improve significantly.
Conclusions: The review underscores the complexity of delivering bad news in emergency medicine. Incorporating structured communication protocols and formal training into medical education and emergency department practices is essential for improving patient outcomes and physician well-being. Future research should focus on evaluating the effectiveness of tailored CBN protocols and programs as well as interdisciplinary collaboration.

Clinicians' Training Needs and Perceptions in Communicating Bad News in Emergency Health Care: A comparative study across rural and urban Health Care Units

C. Pires-Lima[1,2*], S. Morgado-Pereira[3] and M. Figueiredo-Braga[1,4]

[1]Neurosciences and Mental Health Department; [2]CINTESIS – Center for Health Technology and Services Research, Faculty of Medicine, University of Porto, Porto; [3]IVAR – Research Institute for Volcanology and Risk Assessment, University of the Azores, Ponta Delgada, Azores and [4]i3S – Institute for Research and Innovation in Health, University of Porto, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1861

Introduction: Communicating bad news is common in the health care sector, especially in emergency services. The importance of formal training in giving bad news in health care and the differences in the services provided by health care units in urban and rural contexts are well-documented in the literature. However, opportunities for clinicians to develop bad news communication skills provided by the distinct contexts of the health care unit in which they are included have rarely been studied. We assume that the communication of bad news is part of the service provided in emergency departments. Therefore, it can vary across rural and urban health care units.
Objectives: This comparative cross-sectional study aims to test whether the location of the health care unit (rural vs. urban) has a significant impact on the communication of bad news by clinicians in emergency services.
Methods: Data will be collected through an online questionnaire based on the literature in two purposive samples of emergency health care professionals in rural and urban contexts. Qualitative and quantitative methods will be applied to analyze data regarding work features, situational context, experience, perceived knowledge and skills in providing bad news, and training needs and preferences.
Results: Rural health care units serve populations with more health disparities and poorer outcomes than non-rural, and classically have shortage of emergency medicine trained physicians. In urban areas health units have larger and more differentiated teams. The results will be discussed in the light of the literature on discrepancies between rural and urban health care units, describing professional characteristics and experience in delivering bad news of the study participants. We expect to identify specific contextual factors associated with geographic location, institutional settings, and health professionals' training in delivering bad news in emergency medicine.
Conclusions: The results of this study can aid to differentiate bad news communication trainers and health care unit managers in rural and urban areas (a) justifying the implementation of training programs, (b) adapting training programs to the audience, and (c) improving institutional facilities, practices, and policies to support adequate communication of bad news in emergency settings.

Association of Imposter Syndrome and psychological well-being in the doctoral process - how they are influenced by experiences of discrimination, social support and belonging

J. Pokrandt[1]*, P. J. Buspavanich[1,2], M. Berger[1], G. Stadler[1] and J. B. Smith[1]

[1]Charité Universitätsmedizin Berlin and [2]Brandenburg Medical School Theodor Fontane, Berlin, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1862

Introduction: Individuals who develop an Imposter Syndrome do not attribute objective successes to their own abilities and competences, but rather believe that they are not intelligent enough, and are sometimes convinced that they have deceived others. It is known that the Imposter Syndromehas various effects on health. In particular, it affects the mental health of the individuals affected. Although it is known that the manifestation of the Imposter Syndrome is higher in marginalized groups in academic fields. Whether the intersectionality of the relevant diversity domains and personal resources such as social support and belonging have an influence on the extent of the imposter phenomenon has not yet been investigated.
Objectives: The aim of the study was to determine the association between imposter syndrome to the psychological well-being of supervisors and doctoral students in the doctoral process considering the mediating influence of experiences of discrimination, social support and belonging.
Methods: A six-month program was developed to accompany the promotion process. A total of seven groups were conducted from April 2024 to May 2025. At the beginning of the programme, baseline data was collected using The WHO-5 Well Being Questionnaire, the Sense of Belonging Questionnaire, the F-Sozu-6 Questionnaire, the Diversity minimal item set and the Clance Imposter Phenomenon Scale.
Results: Preliminary data show that the Imposter syndrome is widespread among supervisors and doctoral students. Individuals who perceive themselves as belonging to multiple diversity domains tend to exhibit diminished psychological well-being, particularly when considering the intersectionality of these domains.
Conclusions: The findings of this study indicate that the Imposter syndrome should be addressed in an accompanying doctoral program with a focus on gender- and diversity aspects. Diversity domains, social support and sense of belonging should be considered more frequently in the development of academic career interventions.

EPV1302

Mental Illness in the Bible (Old and New Testament)

N. Ramalho[1]*, T. Rocha[1], J. F. Cunha[1], J. C. Moura[1], J. Leal[1], D. Seabra[1], I. Lopes[1], G. Santos[1] and M. Rosa[1]

[1]Psychiatric and Mental Health Department, ULSAR, Barreiro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1863

Introduction: The Bible offers various insights into human struggles, including what can be interpreted today as mental illness. Although ancient texts do not explicitly refer to mental health using modern terminology, there are many accounts of emotional distress, depression, anxiety, and other psychological challenges. Throughout Scripture, several figures are portrayed grappling with deep sorrow, fear, and mental turmoil. These narratives provide spiritual reflections on suffering, healing, and divine intervention, shedding light on how biblical teachings have historically addressed human fragility.
Objectives: To raises questions about how we can relate ancient wisdom to contemporary mental health issues, offering opportunities for spiritual growth, empathy, and care in our own lives.
Methods: A non-systematic review of the published literature was conducted using the Google Scholar database with the search terms “Bible” and “mental illness.” Articles were selected based on their relevance, and further information was obtained through direct consultation of biblical texts.
Results: The prophet Elijah exhibits signs of reactive depression, triggered by stress after confronting the prophets of Baal and receiving a death threat from Jezebel (1 Kings 18:20-40). His symptoms—loss of appetite, isolation, low self-esteem, and hopelessness—are well-documented (1 Kings 19:3). God’s response (1 Kings 19:11-14) provides an example of care for depression, with affection, understanding, and patience.
James 5:15-18 references Elijah to highlight that depression can affect Christians, suggesting that illness, whether physical or spiritual, requires dialogue and support. James emphasizes God’s forgiveness, even if illness stems from sin, viewing depression as an organic condition in line with the holistic Jewish understanding. He advocates for confession and prayer as therapeutic (James 5:16), stressing that mercy triumphs over judgment.
Psalm 6:6-7 captures the deep despair of depression, showing the importance of seeking God amid mental anguish, which is often invisible to others.
Conclusions: The accounts of figures like Elijah and the reflections in Psalms demonstrate that conditions resembling modern definitions of depression and anxiety have long been acknowledged, albeit through the lens of ancient cultural and religious contexts. The compassionate care that God extends to Elijah, coupled with the guidance found in the New Testament, particularly in the book of James, underscores the importance of community and support in addressing mental health challenges.
By examining these stories, we gain a broader understanding of how faith communities have interpreted and coped with the complexities of mental illness - in light of their relationship with God.
These accounts present a holistic biblical view of depression, underscoring the need for empathy, spiritual care, and community support in mental health.

Palinacusia: Regarding a peculiar clinical case

R. Ramallo Castillo[1]*, M. Pérez Sosa[1], M. Vázquez Delgado[1], C. Sánchez Martínez[1] and J. M. Duro Garrido[1]

[1]Clinical Management Unit of Mental Health, Virgen Macarena University Hospital, Seville, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1864

Introduction: A 44-year-old woman with a history of migraine, ulcerative colitis, obesity, and hypertension. She experienced a depressive episode that resolved completely in 2013. Hospitalized

in 2020 and 2021 for psychotic symptoms (auditory pseudohallucinations) resistant to treatment, requiring bilateral ECT (LOW05, dose titration up to 45% - 227 mC-) and initiation of clozapine. In October 2021, she was enrolled in a monthly ECT maintenance program, maintaining a period of euthymia without psychotic symptoms until September 2022. At that point, she began to present anxiety secondary to auditory perseveration: after an auditory stimulus, the patient verbalizes an echo of that sound outside her head, which lasts for hours or even days.
Objectives: Perform a differential diagnosis between schizoaffective disorder (given the persistence of psychotic symptoms despite euthymia) and palinacusia. Additionally, monitor the patient's progress and address the described psychopathology according to current scientific evidence.
Methods: Systematic review of the existing literature on the etiology, pathophysiology, and therapeutic approach to palinacusia. Clinical follow-up of the patient's progression.
Results: Various complementary tests are performed: normal blood tests (complete blood count, biochemistry, serologies, autoimmune markers, thyroid function). Clozapine levels: 315 ng/ml; norclozapine 189 ng/ml; ratio 1.6 (all within normal range). EEG: overload of slow activity over bilateral temporal regions. No postictal activity. MRI: slight cortico-subtemporal atrophic changes with a temporal predominance. No mesial sclerosis foci observed. Since October 2023, different antiepileptic drugs have been trialed (topiramate, eslicarbazepine, and valproic acid). Additionally, the patient continues in a monthly maintenance ECT program (bilateral, LOW05, reaching a dose of 90%). As a result, the patient shows slow progress, with no remission of the described symptoms, although there is a temporary reduction in intensity (February 2024).
Conclusions: The term "palinacusia" was described by Jacobs in 1971 as auditory perseveration (following a trigger and with neutral content). It is associated with various etiologies, primarily convulsive phenomena, and it remains debated whether it is ictal or postictal. The temporal lobe's GTS is typically affected. To date, it has been described in 43 patients, and only in two patients with psychosis. The case described began after treatment with ECT, which raises the possibility of its pathophysiological involvement (difficulty in postictal suppression capacity). Currently, after discontinuing ECT treatment in March 2024 due to the possibility that it was exacerbating the palinacusia, and after trialing the aforementioned antiepileptic drugs, no remission of symptoms has been achieved.

Study of Formal Thought disorder symptoms in adults with Level 1 Autism Spectrum Disorder: Correlations between TALD, ADOS-2, and other neuropsychological dimensions

C. Ricci[1]*, F. Iannotta[1], A. Catino[1], M. S. Vescio[1], W. Del Monaco[1], C. Ceparano[1], A. de Bartolomeis[1] and F. Iasevoli[1]

[1]Section of Psychiatry, Department of Neuroscience, University of "Federico II", Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1865

Introduction: While several studies have investigated language disorders in individuals with Autism Spectrum Disorder (ASD), few have specifically examined formal thought disorder (FTD) symptoms, particularly in adults.
Objectives: This study aims to assess FTD symptoms in adults with Level 1 ASD using the Thought and Language Disorder (TALD) scale and to analyze correlations between TALD scores and other neuropsychological dimensions.
Methods: The study included 23 adults with Level 1 ASD (16 males, 7 females). Inclusion criteria were: a diagnosis of Level 1 ASD and age between 18 and 50 years. Exclusion criteria included: presence of major psychiatric comorbidities, intellectual disability, and neurological disorders that could impair language abilities. A comprehensive evaulation was conducted using TIB, HAMD, PANSS, STAI-Y1 and Y2, TASIT (Parts 1, 2, and 3), Ekman Facial Expression Test, TAS-20, ADOS-2, RAADS, AQ, and EQ. Language and thought disorders were evaluated using the TALD scale. Statistical analyses were performed using SPSS software to examine correlations between TALD scores and other neuropsychological dimensions.
Results: The study population had a mean age of 27.6 ± 8.22 years, comprising 16 men and 7 women. Total TALD scores showed no significant correlation with educational level ($r = -0.028$, $p = 0.914$). Results revealed a significant correlation between the total TALD score and the total TASIT-2 score ($r = -0.679$, $p = 0.011$). Additionally, the "manneristic speech" item correlated with paradoxical sarcasm on TASIT-2 ($r = -0.620$, $p = 0.024$) and with lie recognition on TASIT-3 ($r = -0.633$, $p = 0.02$). The total ADOS-2 score showed a strong correlation with the total TALD score ($r = 0.607$, $p = 0.028$) and with specific linguistic features, including verbigeration ($r = 0.725$, $p = 0.005$), pressured speech ($r = 0.648$, $p = 0.017$), clanging ($r = 0.725$, $p = 0.005$), echolalia ($r = 0.725$, $p = 0.005$), and concretism ($r = 0.738$, $p = 0.004$). Furthermore, TALD was predictive of higher ADOS-2 scores ($\beta = 0.607$, $t = 2.53$, $r = 0.607$, $p = 0.028$, $R^2 = 0.368$).
Conclusions: Our findings highlight specific FTD symptoms in adults with Level 1 ASD. The TALD scale proved to be a valuable tool, showing significant correlations with other neuropsychological domains. TALD scale also demonstrated a reliable predictive ability for higher ADOS-2 scores and distinct linguistic characteristics associated with ASD. TALD scale is proposed as a useful tool in clinical evaluations, providing additional insights beyond traditional diagnostic tools and showing independence from educational level.

Disclosure of Interest: None Declared

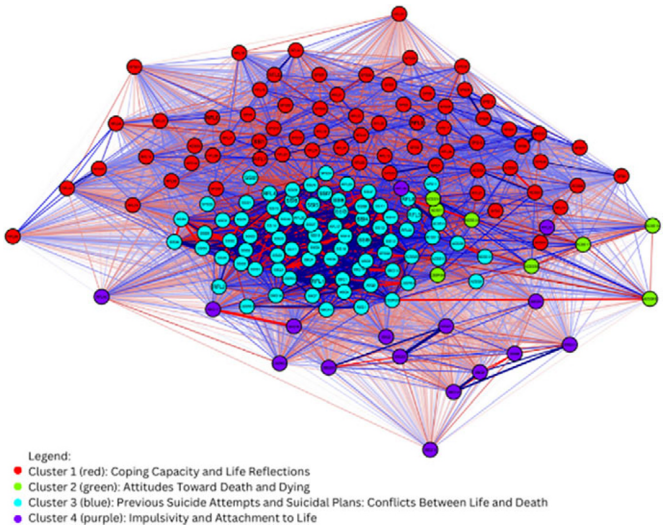
Depicting Self-Report Instruments Assessing Self-Injurious Thoughts and Behaviors (STBs) in Adults: An Umbrella Review with Network Analysis

L. L. D. Figueiredo[1], G. P. Roncete[2]*, B. B. F. Damiano[1], L. Beiram[1], M. Auler[3] and R. F. Damiano[1]

[1]Departamento e Instituto de Psiquiatria, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo HCFMUSP; [2]Faculdade de Medicina da Universidade de São Paulo FMUSP and [3]Faculdade do Hospital Israelita Albert Einstein, São Paulo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1866

Introduction: Self-report instruments assessing self-injurious thoughts and behaviors (STBs) are widely used, but their effectiveness and predictive validity vary.
Objectives: This study aimed to synthesize findings from previous reviews and identify self-report instruments assessing suicidal thoughts and behaviors (STBs) in adults, followed by a network analysis to explore psychometric properties and inter-item relationships.
Methods: Systematic searches were conducted in MEDLINE/PubMed, EMBASE, and the Cochrane Database of Systematic Reviews, covering inception to July 2023, using terms like "suicide risk," "self-report instruments," and "psychometrics." From 318 publications, 22 manuscripts were selected, including reviews, guidelines, and book chapters on STB instruments. Data were extracted under PRISMA guidelines, focusing on scale characteristics, predictive validity, item composition, and psychometric performance. Seven frequently cited scales (SPS, SSI, RFL, ASQ, SBQ-R, ACSS, and C-SSRS) were analyzed using Harmony, which uses NLP via Sentence-BERT to evaluate semantic similarity among items. A correlation matrix based on cosine similarity measured inter-item relationships, forming an undirected weighted graph analyzed with the Louvain community detection algorithm. Centrality measures (strength, betweenness, closeness) and questionnaire-based aggregation enabled scale comparisons. Additionally, Exploratory Graph Analysis (EGA) with the GLASSO model and Walktrap algorithm, assessed by the Total Entropy Fit Index (TEFI), explored network dimensionality and community structures.
Results: Thirty-four scales were identified, with 35% having 1-10 items and 29% having 11-20 items. ASIQ and ASQ displayed high predictive validity (sensitivity: 96% and 96.9%, respectively). The Beck Scale for Suicide Ideation (SSI) had the highest strength centrality (68.1) and eigenvector centrality (0.871), while the CSSRS had the highest betweenness centrality (488.0). Four clusters were identified (Image 1) with a modularity score of 0.0838, indicating moderate cluster separation. The EGA (Image 2) confirmed a multidimensional structure, with an edge density of 0.667 and the Walktrap algorithm identified two main communities focused on cognitive and behavioral/protective aspects. The TEFI score of -3.778 indicated a multidimensional network structure.

Image:



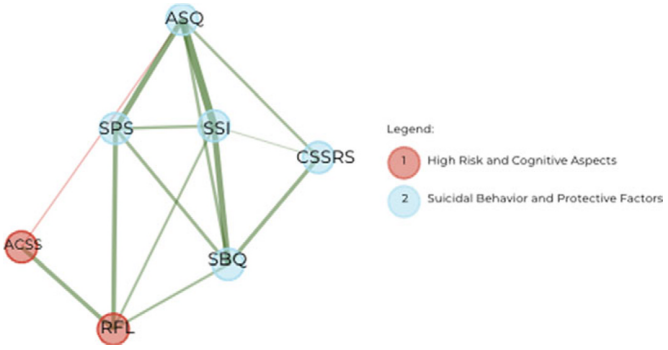


Image 2:

Conclusions: The findings underscore the need for multidimensional approaches to STB assessment. Key tools like the SSI and CSSRS are central, with future research recommended to enhance predictive validity and enable cross-cultural adaptation. To advance psychometric evaluation, future work will include a systematic review and meta-analysis following the COSMIN (COnsensus-based Standards for the selection of health Measurement INstruments) protocol to assess these scales' psychometric properties in depth.

Disclosure of Interest: None Declared

EPV1307

Quality of Life, Depression, Anxiety, and Stress in Humanities Students and People living with HIV in Russia during the COVID-19 Second Wave

V. I. Rozhdestvenskiy[1]*, V. V. Titova[1], I. A. Gorkovaya[1], Y. S. Aleksandrovich[1] and D. O. Ivanov[1]

[1]Department of Psychosomatics and Psychotherapy, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1867

Introduction: During the pandemic of a new coronavirus infection in Russia, the number of patients with diagnosed depressive and anxiety disorders increased. Studies have shown a sharp increase in the number of respondents who recorded stress as a non-specific reaction to a sudden change in environmental conditions. Quality of life, encompassing physical, psychological, and social well-being, often correlates with individuals' emotional and mental states.
Objectives: The study aimed to examine the associations between quality of life and emotional states — specifically, depression, anxiety, and stress — in humanities students and people living with HIV.
Methods: Data were collected from January to July 2021 through a Google form. The sample comprised 35 humanities students from Russian universities and 59 HIV-positive patients. The WHOQOL-BREF assessed quality of life, while the DASS-21 measured levels of depression, anxiety, and stress. Both questionnaires have been adapted for Russian respondents.
Results: We found that in the student group, depression was related to physical and psychological well-being (r_s = -0.491, $p < 0.01$), self-image (r_s = -0.552, $p < 0.05$) and microsocial support (r_s = -0.550, $p < 0.05$), and anxiety with physical and psychological well-being (r_s = -0.356, $p < 0.05$) and microsocial support (r_s = -0.353, $p < 0.05$). In the patient group, physical and psychological well-being was associated with depression (r_s = -0.309, $p < 0.05$) and anxiety (r_s = -0.269, $p < 0.05$); self-perception was associated with depression (r_s = -0.490, $p < 0.01$), anxiety (r_s = -0.311, $p < 0.05$) and stress (r_s = -0.361, $p < 0.05$); microsocial support — with depression (r_s = -0.381, $p < 0.01$), anxiety (r_s = -0.260, $p < 0.05$) and stress (r_s = -0.322, $p < 0.05$); social well-being — with depression (r_s = -0.360, $p < 0.01$), anxiety (r_s = -0.426, $p < 0.01$) and stress (r_s = -0.334, $p < 0.05$).
Conclusions: The study revealed distinct patterns in the relationship between life quality and emotional states across groups during the COVID-19 second wave in the Russian Federation. Among students, life quality, especially physical and psychological well-being, was associated with depression and anxiety but was notably independent of stress. Social well-being (including material security, health environment, leisure, and access to medical care) remained stable and unlinked to their emotional state. Among people living with HIV, almost all life quality domains correlated with depression, anxiety, and stress. This group displayed heightened vulnerability to emotional distress, affecting their self-perception, social interactions, and sense of security, thus underscoring the pandemic's amplified impact on this group's mental health.

Disclosure of Interest: None Declared

EPV1308

Level of Asthenia and Life Quality among Students during the COVID-19 Second Wave in the Russian Federation

V. I. Rozhdestvenskiy[1]*, V. V. Titova[1], I. A. Gorkovaya[1], Y. S. Aleksandrovich[1] and D. O. Ivanov[1]

[1]Department of Psychosomatics and Psychotherapy, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1868

Introduction: The COVID-19 pandemic significantly impacted the population in Russia, particularly students, who were forced to radically restructure their daily lives rhythm due to the introduction of distance learning, more homework, increasing the share of self-education. These factors could provoke the emergence of a particular psychopathological syndrome — asthenia, which is characterised by general and mental weakness, increased exhaustion, irritability, decreased productivity of cognitive processes, decreased motivation, sleep disorders and other psychosomatic disorders. These symptoms, in turn, could be associated with changes in the student's quality of life.
Objectives: The study aimed to assess the level of asthenia among students in humanities programs and to examine the relationship between asthenia indicators and quality of life.
Methods: Data collection was conducted from January to April 2021 through a specially developed Google form. Thirty-five students at the universities of the Russian Federation took part in the study. We used MFI-20 to assess the level of asthenia, and WHOQOL-BREF to study the life quality. Both questionnaires were adapted for Russian-speaking respondents.
Results: We found that 31% of respondents had symptoms of general asthenia, 29% had symptoms of decreased activity, 26% had symptoms of decreased motivation, 71% had symptoms of physical asthenia, and 26% had symptoms of mental asthenia. No statistically significant correlations were found between asthenia manifestations and life quality indicators. However, significant direct correlations were obtained between all quality-of-life domains, except for "microsocial support" and "social well-being".
Conclusions: In the conditions of the COVID-19 second wave, most students in Russia demonstrated physical asthenia symptoms. Asthenia manifestations were not related to the student's life quality. Students in the pandemic conditions should observe the sleep, rest regime and optimal physical activity. Among students in Russia, the microsocial aspect of life quality (relations with partners, sexual life, relations with friends) are fairly detached from the broader social context (e.g. everyday life safety, healthy physical environment, and so on).

Time to discontinuation in routine clinical practice of the initially prescribed antipsychotic treatment in patients with first-episode psychosis

P. Salas Aranda[1,2]*, C. Garcia Cerdan[1,2], C. Martin Gomez[1,2,3], C. Lorenzo Romo[1,2], M. C. Turrion Gomez[2], M. Isidoro García[4,5] and J. Pérez[1,2,3]

[1]Psychiatry, Salamanca University Healthcare Complex; [2]Unit of Psychiatry and Neuroscience, Institute of Biomedical Research of Salamanca (IBSAL); [3]Medicine, University of Salamanca; [4]Biochemistry and Clinical Analysis, Salamanca University Healthcare Complex and [5]Pharmacogenetics and Precision Medicine Unit, Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1869

Introduction: The CLUMP (CLinical Utility of early intervention including the 5-Step Precision Medicine (5SPM) Method) project is a translational research initiative that aims to improve adherence to antipsychotic (AP) medications and therapeutic outcomes in patients with first-episode psychosis (FEP). CLUMP seeks to apply an early intervention model of Personalised Precision Psychiatry, based on pharmacogenetics, to this clinical group. In this specific analysis, we examine time to discontinuation of the first prescribed oral AP treatments before the implementation of the CLUMP project in Salamanca, Spain, in order to determine the impact the new Personalised Precision Psychiatry model might have on it. Indeed, given the high AP treatment discontinuation rates already identified in pragmatic, randomised controlled trials including FEP patients, these data would offer additional information about such rates in real-world clinical scenarios.

Objectives:

1. To assess time to discontinuation for the first prescribed oral AP treatments in FEP.
2. To identify specific AP with higher retention rates, which might reflect better tolerability and/or effectiveness.

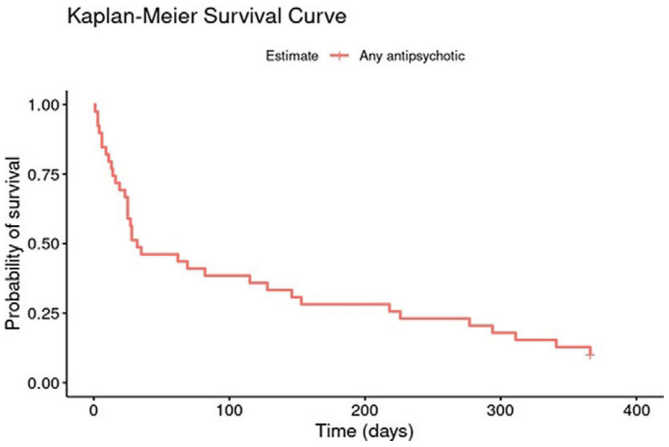
Methods: This study includes a consecutive, retrospective cohort of 42 patients with FEP treated immediately before the CLUMP project implementation, who were followed for at least one year. Kaplan-Meier survival analysis was used to assess AP time to discontinuation during the first year post-treatment initiation.

Results: Table 1 (Image 1) summarises median times to discontinuation and confidence intervals (CIs) for each AP. Survival curves (Image 2 and 3) depict treatment retention trends. The overall median time to discontinuation was 36 days (95% CI: 25-153 days), suggesting an overall high early AP treatment discontinuation. Results also showed very high variability across AP, with Paliperidone (264 days) and Risperidone (72 days) having longer retention times. However, most of the sample was initiated on Risperidone (71.2%), which affects the generalisability of these results.

Image:

Antipsychotic	n	Events (Discontinuations)	Median Time to Discontinuation (days)	95% CI Lower (days)	95% CI Upper (days)
Overall (All)	42	38	36	25	153
Aripiprazole	2	1	32	32	NA
Aripiprazole + Risperidone	1	1	69	NA	NA
Haloperidol	2	2	20,5	16	NA
Olanzapine	4	4	6	3	NA
Paliperidone	2	2	264	226	NA
Quetiapine	1	1	28	NA	NA
Risperidone	30	27	72	27	277

Image 2:



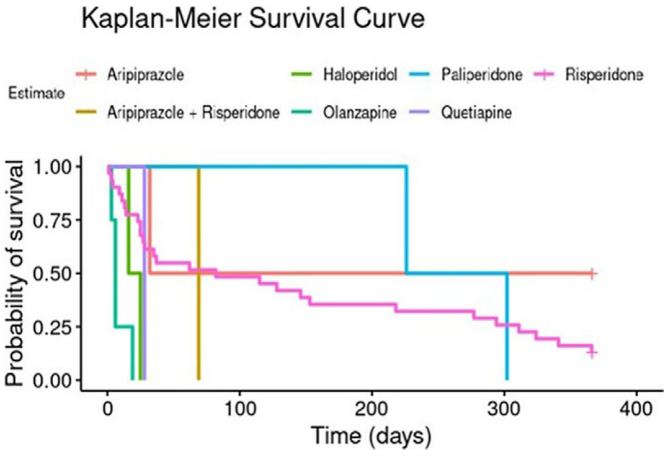


Image 3:

Conclusions: Concurring with previous randomised controlled trials, we identified a high rate of early AP treatment discontinuation in FEP treated in routine clinical practice. For most patients, the first prescribed AP was discontinued within the first month post-treatment initiation. These results emphasise the need for a more personalised AP treatment choice for patients with FEP.

Art and Madness: The role of psychopathology in creativity

F. M. Santos[1]*, P. Coelho[1], P. Jorge[1], A. Silva[1], R. Lopes[1], V. Melo[1], C. Rodrigues[1], C. Matias[1], T. Vieira[1] and L. Delgado[1]

doi: 10.1192/j.eurpsy.2025.1870

Introduction: It has long been believed that a correlation exists between mental illness and artistic ability. This idea dates to antiquity, with Aristotle famously stating, "No great mind has existed without a touch of madness". Recent studies suggest that writers and artists show a higher incidence of depressive disorders (DD) and bipolar disorder (BD) compared to the general population. However, we know that not all artists suffer from mental illness, and most individuals with mental illness are neither artists nor creative geniuses. Thus, numerous questions emerge regarding the true relationship between psychopathology and creativity.
Objectives: In this study, we sought to explore the correlation between psychopathology and creativity.
Methods: In this literature review, research articles on the relationship between creativity and psychopathology are presented.
Results: There is evidence that the genetic predisposition to BD, as well as milder forms of the disorder, is associated with increased creativity. A meta-analysis of 28 studies found a significant positive correlation between the risk of bipolar disorder and creativity (r = 0.224). Mild to moderate manifestations of the disorder can often serve as a source of inspiration, driving creative work. However, this creativity only flourishes when individuals are able to channel their emotional instability and cognitive disorganization into coherent and productive forms. In contrast, severe forms of the disorder tend to inhibit creativity, largely due to impaired concentration and disorganized thinking. Regarding DD, the research presents mixed findings. Some studies suggest a link between depression and lower creativity. A meta-analysis of 39 studies found a weak negative correlation between depressive mood and creativity (r = -0.064). However, other researchers argue that both positive and negative emotions can fuel artistic creativity. The Dual Pathway to Creativity Model supports this view, proposing that creativity—defined as the generation of original and valuable ideas—arises from cognitive flexibility and cognitive persistence. According to this model, dispositional or situational factors can influence creativity by enhancing either flexibility, persistence, or both. Negative mood states, for example, may enhance creativity by fostering persistence.
Conclusions: The relationship between psychopathology and creativity is complex. A genetic predisposition to BD, especially in milder forms, may enhance creativity, but severe cases often impair it due to cognitive difficulties. For DD, the link to creativity is more conflicted. While depression is generally associated with reduced creativity, some models suggest both positive and negative emotions, including those from depressive states, can foster creativity by affecting cognitive flexibility and persistence. In summary, the connection between psychopathology and creativity is multifaceted, with various contributing factors.

Behavioral variant frontotemporal neurocognitive disorder or psychiatric disorder: a diagnostic challenge

M. A. Sava[1]*, S. P. Orrego Molina[1], M. D. S. Manzano Palomo[2], P. Á. Nava García[1] and A. M. Durán Moreno[3]

[1]Psychiatry; [2]Neurology, Hospital Universitario Infanta Leonor and [3]Psychiatry, Hospital Universitario de Fuenlabrada, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1871

Introduction: The behavioral variant of frontotemporal neurocognitive disorder is the most common clinical syndrome within frontotemporal neurocognitive disorders and is primarily characterized by progressive changes in personality and behavior. Due to the heterogeneity of this condition and the lack of sensitive and specific complementary tests, patients are often misdiagnosed with a psychiatric disorder.
Objectives: To describe the clinical case of a patient with a long-standing history of psychiatric pathology who was admitted to the short-stay psychiatric unit due to newly emerged behavioral disturbances, and to conduct a brief review of the literature.
Methods: Case description and literature review.
Results: A 57-year-old male under psychiatric follow-up for Obsessive-Compulsive Disorder, impulse control disorder (kleptomania), and anxiety-depressive symptoms was voluntarily admitted to the short-stay psychiatric unit due to behavioral disturbances. During admission, the patient reported emotional dysregulation, experiencing irritability and difficulties with emotional containment and inhibition, noting feelings of impulsive discontrol and behavioral disinhibition. The family observed changes in the patient's personality over the past months, describing him as aggressive and inappropriate.
Basic complementary tests (blood analysis, urine analysis, and toxicology screening) showed no significant alterations. Brain MRI revealed subtle signs of cortico-subcortical atrophy, predominantly in the frontotemporal regions. Cognitive assessments, including the Mini Mental State Examination, Frontal Assessment Battery and Montreal Cognitive Assessment, indicated deficits suggestive of frontal impairment. The patient had been admitted one month prior due to possible hypomanic symptoms that resolved following pharmacological adjustment, leading to a proposed diagnosis of late-onset Bipolar Disorder Type II. However, after detailed history-taking with family members and additional testing, the diagnosis leaned more towards a frontal syndrome (possible behavioral variant of frontotemporal neurocognitive disorder).
Conclusions: The diagnosis of frontotemporal neurocognitive disorder remains a significant challenge, partly due to the limitations of complementary tests in the early stages of the disease, with diagnosis primarily based on clinical evaluation. Consequently, many patients with frontotemporal neurocognitive disorder initially receive a diagnosis of a psychiatric condition (more frequently if the patient has a personal history of psychiatric issues). Therefore, it is crucial to understand these differences, especially in the early phases of the disease, and to continue investigating new diagnostic modalities.

ADHD in adults and relationship with executive functioning and quality of life

I. M. V. Siqueira[1], L. R. R. Carreiro[1], N. M. Dias[2], J. C. M. O. B. Delorenzi[1], S. M. Blascovi-Assis[1] and A. G. Seabra[1]*
[1]Mackenzie Presbyterian University, Sao Paulo and [2]Federal University of Santa Catarina, Florianopolis, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1872

Introduction: Attention-deficit/hyperactivity disorder (ADHD) is a neurodevelopmental disorder characterized by inattention, disorganization, and/or hyperactivity-impulsivity. It is associated with cognitive deficits and functional impairments. A frequent cognitive impairment, likely related to hypofunctioning of the prefrontal cortex and its connections, involves executive functions, a set of skills related to self-control and goal-directed activities. The disorder also significantly affects quality of life, being associated, for example, with higher unemployment, relationship problems, and lower average income compared to individuals without the disorder.
Objectives: To investigate the performance in executive functions and quality of life in individuals with ADHD compared to a control group, and to relate these with the severity of symptoms.
Methods: Forty individuals aged 18-50 participated, including 10 with an ADHD diagnosis and 30 controls matched for sex, age, and education in a case-control design (3 controls per case). Measures included: a) the Adult Self-Report Scale (ASRS) with 18 items, based on the DSM criteria for ADHD (total score used); b) the computerized Stroop Test (Victoria version) to assess executive functions, with three phases: reading words in black (control 1), naming colors in circles (control 2), and naming colors in words while inhibiting reading (incongruent phase). Reaction times for each part and interference times (part 3 minus part 2) were calculated; c) the WHOQOL questionnaire, assessing quality of life across four domains (physical, psychological, social relationships, and environment), with domain scores used. Given data normality, Student's t-tests compared group means.
Results: ADHD participants had significantly poorer executive functions, with longer reaction times in the Stroop Test part 3 (M = 1.05; SD = .63) compared to controls (M = .69; SD = .32), and higher interference reaction times (M = .28; SD = .34 for ADHD) compared to controls (M = .10; SD = .16). ADHD individuals also reported lower quality of life in social relationships (WHOQOL Domain 3) (M = 3.3, SD = .76) compared to controls (M = 3.8; SD = .65). Significant correlations indicated that more ASRS symptoms were associated with longer reaction times in Stroop Test parts 2 and 3, higher interference reaction times, and lower quality of life in social relationships.
Conclusions: The study highlights deficits in executive functions, particularly inhibition in incongruent situations, and reduced quality of life, especially in social relationships, in individuals with ADHD. These impairments correlate with the severity of symptoms, emphasizing the need to address executive function disturbances and quality of life in ADHD treatment.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1873

Introduction: Nurses play a crucial role in patient care. Indeed, this profession requires a high level of emotional, mental and physical workload. Improving the well-being of these workers means taking into account the impact of workload on their job satisfaction.
Objectives: Our study aims to assess the relationship between perceived workload and job satisfaction among nurses.
Methods: We conducted a descriptive, analytical and cross-sectional survey among nurses using a self-administrated questionnaire. We collected socio-professional data. We assessed perceived workload using the National Aeronautics and Space Administration Task Load Index (NASA-TLX). Job satisfaction was evaluated using the single-item measure of job satisfaction.
Results: Our population comprised 202 nurses, 67% of whom were female. The mean age of participants was 35.1 ± 8.1 years. The nurses' length of service in the department was 6.9 ±7.5 years. The mean score of mental demand, physical demand, performance, effort, frustration level and temporal demand were respectively 77.8±22.6, 76.9±23.5, 67.9±31.9, 81.4±20, 66.6±25.2 and 59.8 ±30.2. The mean score of Raw TLX was 71.44 ±14.8. Among our participants, 74 (37%) were satisfied with their jobs. We found that the job satisfaction was positively correlated with the overall RAW TLX score (p=0.02) and with the physical (p=0.04) and temporal (p=0.00) demands.
Conclusions: Our findings highlight a correlation between high perceived workload and job dissatisfaction. Therefore, it is crucial to assess and improve working conditions to ensure a safe, comfortable and well-equipped environment, thus promoting nurses' satisfaction and quality of care.

Mental health and lifestyle habits among healthcare workers

I. Sellami[1]*, A. Abbes[1], A. Feki[2], A. Haddar[1], H. Halweni[3], M. Hajjaji[1], S. Baklouti[2], M. L. Masmoudi[1] and K. Jmal Hammami[1]
[1]Occupationnal medecine; [2]Rheumatology, CHU Hedi Chaker and [3]General practice, Medecine university, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1874

Introduction: In the health field, healthcare workers (HCWs) need to be fulfilled to improve the quality of care. The mental health of these workers can affect the practice of their lifestyle habits.
Objectives: Our study aims to assess the relationship between mental health and lifestyle habits among HCWs.
Methods: We conducted a descriptive, analytical and cross-sectional survey among HCWs using a self-administrated questionnaire. We

collected socio-professional data. We assessed mental health using the depression anxiety and stress scale (DASS 21).
Results: Our study included 200 healthcare workers, 71% of whom were female. The average age of participants was 42.9 years, with an average job tenure of 14.2 ± 10.1 years. We found that 12.5% of participants were smokers, 5% were former smokers, and 20.5% were passive smokers. Three participants were alcoholics, and none used drugs or chewed Neffa. Additionally, 32% of the population engaged in sports, with an average duration of 4.5 ± 2.9 hours per week.
According to the DASS21, 63% of participants exhibited symptoms suggestive of anxiety, 65.5% showed signs of stress, and 39.5% had depressive symptoms. We found that participation in sporting activities was associated with reduced anxiety ($p = 0.04$).
Conclusions: Our findings highlight a correlation between reduced anxiety and practicing sporting activities. It is crucial to encourage HCWs to maintain regular physical activity to promote an active lifestyle, reduce stress and improve mood in order to enhance the quality of care.

Assessing Mental Distress in Victims of Work-Related Hand Injuries

A. Haddar[1], I. Sellami[1,2*], A. Hrairi[1], M. A. Ghrab[1], H. Zouari[3], A. Feki[4], M. Trigui[3], M. Hajjaji[1], M. L. Masmoudi[1] and K. Jmal Hammami[1]

[1]Occupational medicine, University Hospital Hedi Chaker; [2]LR/18/ES-28, University of Sfax; [3]Orthopedic, University Hospital Habib Bourguiba and [4]Rheumatology, University Hospital Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1875

Introduction: Work-related hand injuries can lead to significant physical impairments. However, their psychological impact is often underestimated. Mental distress, including anxiety, depression, and post-traumatic stress, may arise following such injuries, potentially hindering recovery and affecting both professional and personal life. Given the critical importance of hand function in daily tasks and occupational roles and the prevalence of hand injuries, addressing their psychological dimension is crucial.
Objectives: This study aims to evaluate mental distress among individuals with work-related hand injuries (WRHI) and to identify the associated factors.
Methods: We conducted a cross-sectional study, between January 2021 to December 2022, involving private sector workers, victims of WRHI. Data were collected using a pre-established questionnaire that covered sociodemographic and professional characteristics, details of the occupational accident, and medical information. Psychological distress was assessed using the Kessler Psychological Distress Scale (K6), and functional disability of the hand was evaluated using the Quick Disabilities of the Arm, Shoulder, and Hand (Quick DASH) score.
Results: Our study included 136 workers, with a male-to-female ratio of 7.5. The average age was 41.2 ± 10.9 years, and the average body mass index (BMI) was 26.48 ± 4.4. Blue-collar workers made up 77.9% of the sample (n = 106). In 61.8% of cases, the injury involved the dominant hand. The median of time to return to work was 101.5 days (interquartile range (IQR) [67; 182.5]). Twenty-five participants (18.4%) reported discrimination at the workplace. The median of the Quick DASH score was 34.1 (IQR [13.6; 52.3]). The median K6 score was 8 (IQR [4; 15]), with 42 participants (30.9%) experiencing moderate psychological distress and 45 (33.1%) reporting severe psychological distress. The K6 score showed a significant correlation with the Quick DASH score ($p < 0.001$, $r = 0.297$), BMI ($p = 0.031$, $r = 0.185$), and time to return to work ($p = 0.005$, $r = 0.241$). Those with injuries to the dominant hand had higher K6 scores compared to those with non-dominant hand injuries ($p = 0.043$). Furthermore, the K6 score was associated with reports of workplace discrimination following the accident.
Conclusions: Work-related hand injuries not only lead to physical impairments but also have a considerable psychological impact. These findings highlight the importance of comprehensive rehabilitation programs that address both the physical and psychological aspects of recovery to improve outcomes and support reintegration into the workforce.

Evaluating sleepiness in operating room settings among anesthesia technicians

M. A. Ghrab[1], I. Sellami[1,2*], A. Haddar[1], A. Feki[3], M. Hajjaji[1], M. L. Masmoudi[1] and K. Jmal Hammami[1]

[1]Occupational medicine, University Hospital Hedi Chaker; [2]LR/18/ES-28, University of Sfax and [3]Rheumatology, University Hospital Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1876

Introduction: Anesthesia technicians play a crucial role in operating room ensuring the conduct of anesthesia procedures and monitoring patients. However, the demanding nature of their work involving irregular hours, alertness, extended hours in addition to the exposure to anesthetic agents may influence their performance and vigilance.
Objectives: The aim of this study was to assess signs of sleepiness among anesthesia technicians (AT) and evaluate its associated factors.
Methods: We conducted a cross-sectional study among AT in two University Hospitals in Sfax, Tunisia, between January and July 2024 during periodic health assessment visits. Sociodemographic and professional data were collected. The Epworth Sleepiness Scale (ESS) was used to assess signs of sleepiness.
Results: Our population consisted of 60 AT with a mean age of 47.9 ±7.1 years. Two participants (3.3%) were males. The mean seniority was 24±7.5 years in healthcare and 10.4±8.1 years in the current ward. Forty-five AT (75%) reported using Halogenated Anesthetics. Ninety-five percent of the population had shift work. Fatigue and daytime somnolence were reported by 73.3% and 45% of the population respectively. The median ESS score was 6 Interquartile range IQR [2.25;6]. Excessive sleepiness was found in 21.7% of the population. The ESS score was higher among AT who used halogenated anesthetic, but no significant association was found (p=0.2) in the bivariate analysis.
Conclusions: Assessing vigilance among AT is necessary to maintain patient safety. Organizational factors such as long hours and environmental factors such as effective evacuation system for halogenated agents could cause fatigue and sleepiness in operating room.

Disclosure of Interest: None Declared

EPV1318

Assessing Quality of Life After Return to Work Among Victims of Work-Related Hand Injuries

A. Haddar[1], I. Sellami[1,2]*, A. Hrairi[1], M. A. Ghrab[1], H. Zouari[3], A. Feki[4], M. Trigui[3], M. Hajjaji[1], M. L. Masmoudi[1] and K. Jmal Hammami[1]

[1]Occupational medicine, University Hospital Hedi Chaker; [2]LR/18/ES-28, University of sfax; [3]Orthopedic, University Hospital Habib Bourguiba and [4]Rheumatology, University Hospital Hedi Chaker, Sfax, Tunisia

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1877

Introduction: Work-related hand injuries (WRHI) can have profound impacts on an individual's physical capabilities, and these injuries often carry long-term consequences that extend beyond physical impairment. Upon returning to work, victims may face challenges in performing occupational tasks and daily activities.

Objectives: This study aims to assess the quality of life in workers who have suffered WRHI after returning to their professional activities.

Methods: We conducted a cross-sectional study among victims of WRHI in the private sector after returning to work, from January 2021 to December 2022. Sociodemographic and professional data were collected along with characteristics of the WRHI. Quality of life was assessed using the Short Form-12 (SF-12) score, which evaluates both physical and mental health components (PCS-12 and MCS-12). The Quick Disabilities of the Arm, Shoulder, and Hand (Quick DASH) score was used to measure the functional disability of the hand. Job satisfaction and pain level were auto-evaluated with a scale of 0 to 10.

Results: We included 126 workers, 88.1% of whom were male, with a mean age of 41.3 ± 10.6 years. Tobacco and alcohol use were reported by 42.9% and 9.5% of participants, respectively, while caffeine consumption was noted in 57.9%. The most represented sectors were metallurgy (22.2%) and the chemical industry (16.7%). The median job satisfaction after the accident was 6 (IQR [5; 8]). In 61.9% of cases, the dominant hand was affected. Both rehabilitation sessions and surgical treatment were required for 69% of participants. The median pain level was 5 (IQR [4; 7]), and 47.6% of participants reported sleep disorders following the accident.

The median Quick DASH score was 34.1 (IQR [13.1; 50.6]), and the median Quick DASH work module score was 43.8 (IQR [25; 68.8]). The mean PCS-12 score was 39.5 ± 7.6, while the mean MCS-12 score was 46.8 ± 11.4. The PCS-12 score was significantly associated with caffeine consumption ($p = 0.03$), alcohol consumption ($p = 0.03$), rehabilitation sessions ($p = 0.029$), and sleep disorders ($p < 0.001$). It was also significantly correlated with pain level ($p = 0.005$; $r = -0.247$), Quick DASH score ($p < 0.001$; $r = -0.4$), and the Quick DASH work module ($p < 0.001$; $r = -0.44$).

The MCS-12 score was significantly associated with job satisfaction ($p = 0.008$; $r = 0.237$), Quick DASH score ($p = 0.003$; $r = -0.265$), the Quick DASH work module ($p = 0.012$; $r = -0.23$), and sleep disorders ($p = 0.012$).

Conclusions: Work-related injuries, particularly hand injuries, pose significant challenges to both the professional and personal lives of those affected. Addressing these challenges is crucial to ensuring a successful return to work and social reintegration.

EPV1319

Cognition in Treatment Resistant versus Non-Treatment Resistant Schizophrenia

S. Shah[1]*, K. Patel[1], A. Bhandari[1], A. Porwal[1] and N. Lalwani[1]

[1]B.J. Medical College, Ahmedabad, India

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1878

Introduction: Despite antipsychotic treatment, around one-third of individuals of schizophrenia remain unresponsive.

Objectives: Comparing cognitive impairments in TRS versus non-TRS patients.

Methods: 50 adult patients with schizophrenia(DSM-5) were recruited in this cross-sectional cohort study, categorised into TRS (14) (treatment-resistant schizophrenia) and NTRS (36) (non-treatment-resistant schizophrenia) by modified Kane criteria. Positive and Negative Syndrome Scale (PANSS) and Montreal Cognitive Assessment Scale (MoCA) were used.

Results:

Table 1	TRS	NTRS	Overall
Male(%)	42.8	63.8	58
Female(%)	57.1	36.1	42
AGE (years)	41.7 ± 13.1	41.4±12.3	41.5±12.4
DURATION OF ILLNESS(years)	17.2±10.8	6.3±6.8	9.4±9.4

Table 2	TRS	NTRS	Independent sample students' T test pvalue
MoCA	19.2±6	27.8±5.4	<0.01
TOTAL PANSS	106.3±22.4	57.4±21.	<0.01
POSITIVE PANSS	22.1±7.3	13.8±6.4	<0.01
NEGATIVE PANSS	26.8±5.7	14.1±5.1	<0.01
Generalised PANSS	57.3±13.2	29.4±11.4	<0.01
COMPOSITE SCORE	-4.71±7.6	-0.2±5.6	0.02

MoCA Scores (Table 2) are significantly lower in the TRS group, implying NTRS has a moderate cognitive decline, and TRS has severe cognitive decline. Total PANSS, Positive, Negative,and Generalised PANSS are significantly lower in the TRS group indicating severe symptoms than NTRS.Classifying based onTotal PANSS Score, the TRS has severely ill, while the NTRS has borderline

mentally ill patients. The composite score indicates that the TRS group tends to have more negative symptoms. Computing the data's variances and independent sample Welch's t-test (Image 3) for data with unequal variances and independent sample student's test (Images 1, 2) for data with equal variances were performed. Age does not significantly affect TRS(Table 1). Duration of illness is significantly higher in the TRS group. MoCA domains (i.e., executive function, visuospatial, orientation, and attention) except memory and language have significantly lower scores in the TRS group. Positive symptoms (conceptual disorganisation, excitement, grandiosity, suspicion, and hostility) except delusion and hallucinatory behaviour were significantly higher in the TRS group. Negative symptoms (emotional withdrawal, poor rapport, passive/apathetic social withdrawal, difficulty in abstract thinking, lack of spontaneity and flow of conversation, stereotype thinking) except blunted effect were significantly higher in the TRS group. Generalised symptoms (somatic concern, anxiety, guilt feelings, mannerism and posture, depression, motor retardation, uncooperativeness, unusual thought content, social disorientation, poor attention, lack of judgement, disturbance of volition, poor impulse control, preoccupation, and active social avoidance) except tension were significantly higher in the TRS group.

On the Pathophysiology of Pathological Lying: A Case Report and Literature Review

J. F. Silva[1]*, B. P. Brás[1], C. Machado[1], A. S. Pinto[1] and A. Lopes[1]

[1]Unidade Local de Saúde de Santo António, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1879

Introduction: Pathological lying, traditionally known as pseudologia fantastica or mythomania, is characterized by persistent or compulsive lying that often involves elaborate and fantastical narratives. Although the psychiatric community has yet to reach a consensus about its classification as a symptom or as a distinct diagnostic entity, emerging research about its pathophysiology highlights the involvement of complex interactions between neurobiological, psychological, and social factors.
Objectives: The aim of this study is to explore, through a clinical case of an inpatient in whom pathological lying was identified, the possible causes and underlying mechanisms of this condition.
Methods: A case report presentation followed by a non-systematic review of the literature available at PubMed, ScienceDirect and ResearchGate databases, using the MeSH terms "pathological lying" OR "pseudologia fantastica" OR "mythomania". From a total of 226 abstracts initially screened, we included 51 articles in the final review.
Results: We report the case of a 33-year-old man with a diagnosis of Charcot-Marie-Tooth disease type 2C and comorbid depressive disorder, who was admitted to the emergency department for suicidal ideation. Collateral information from family members was crucial to identify pathological lying, in this case associated with the lack of social relationships, low self-esteem, a desire for autonomy, and poor emotional and behavioral regulation. Although standard blood workup yielded unremarkable findings, imaging studies showed an old lacunar infarction localized to the right hemithalamus. While hospitalized he presented rapid clinical improvement, being discharged with outpatient follow-up. The existing body of evidence on pathological lying fails to capture specific causal factors for this phenomenon. Research into its neurobiological basis examined abnormalities in brain areas responsible for executive functioning, impulse control, and behavioral and emotional responses, such as the prefrontal cortex, the limbic and paralimbic systems, and the right hemithalamus. From a psychological perspective, the pathological liar doesn't have an external motive for lying; instead, the lie seems to be the purpose in itself, being unconsciously produced to fulfill the need for power and autonomy, to elevate one's self-esteem, or to repress reality. In addition, certain environmental factors, including childhood trauma, neglect, or abuse, also seem to play a significant role in shaping this type of behavior.
Conclusions: The current research on the pathophysiology of pathological lying is still limited and vague, depicting a multifactorial entity that would benefit from a multidisciplinary approach integrating Psychiatry, Neurology, and Behavioral Sciences. The development of a more comprehensive conceptual model may help practitioners implement formal assessment and management strategies for people suffering from this condition.

Eco-anxiety and Psychosocial Problems: A Systematic Review

M. T. SİNAN[1]*, C. H. AYHAN[1], M. C. AKTAŞ[1], S. AKTAŞ[2] and K. ASLAN[1]

[1]Mental Health And Pschiatric Nursig and [2]Departman of Psyhciatric, Van Yuzuncu Yil University, VAN, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1880

Introduction: Eco-anxiety, a term that encapsulates the anxiety and distress associated with climate change and environmental degradation, has emerged as a significant psychosocial issue affecting individuals across various demographics. This phenomenon is particularly pronounced among younger generations, who often experience heightened awareness of climate-related threats and their potential impacts on future well-being. The interplay between eco-anxiety and psychosocial problems is complex, involving emotional, cognitive, and social dimensions that can significantly influence mental health outcomes. Research indicates that eco-anxiety is characterized by a future-oriented worry about the potential impacts of climate change, distinguishing it from other eco-emotions such as eco-grief and eco-despair. While many individuals experience eco-anxiety in a non-clinical form, there are instances where it can escalate to pathological levels, leading to significant mental health challenges. This is particularly relevant for young people, who may face multiple life stressors, such as academic pressures and social expectations, which can exacerbate feelings of eco-anxiety and contribute to the development of mental health issues.
Objectives: In this study, the negative effects of climate change will be emphasized and its effects on human health and psychology will be emphasized. The main purpose of the study is to prepare the ground for future studies on eco-anxiety, which addresses the connection between climate change and psychology, and to increase social awareness.
Methods: The study will conduct between October 2024 and January 2025 2023 in 3 databases (PubMed, Cochrane Library, Science Direct) using the keywords "eco-anxiety" "psychosocial problems" and "mental health". These databases were preferred because they contain a significant amount of evidence-based literature in the field of biomedical sciences and psychology. Studies conducted between 2000 and 2024, whose full texts were accessed and written in Turkish and English were included in the study.
Results: 20 national and international research articles on the subject have been reached and the literature review continues. When the literature review is finalized, all study results will be presented together.
Conclusions: Conclusions: In summary, eco-anxiety represents a significant psychosocial challenge that intertwines with various mental health issues. Understanding the emotional, cognitive, and social dimensions of eco-anxiety is crucial for developing effective interventions that address the mental health impacts of climate change. By fostering emotional regulation, acknowledging the role of grief, and promoting community engagement, mental

health professionals can better support individuals grappling with eco-anxiety and its implications for overall well-being.

Evaluating the mental health awareness of stakeholders in cycling teams: Results from a cross-sectional survey

A. Smith[1]*, J. Grana[1], J. Colangelo[1], A. Buadze[2] and M. Liebrenz[1]
[1]Department of Forensic Psychiatry, University of Bern, Bern and [2]Psychiatric University Hospital, University of Zurich, Zurich, Switzerland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1881

Introduction: Sports psychiatry is a developing subdiscipline, which emphasises the need for adequate treatment and prevention schemes to uphold the mental wellbeing of athletes. Previous studies indicate that elite-level male cyclists face distinctive socioenvironmental risk factors, including external pressures from teams, particularly in relation to weight management concerns. However, there has been little attention to the mental health support available within teams and the awareness of relevant stakeholders to psychiatric issues.
Objectives: This study sought to gain perspectives on the level of mental health awareness from stakeholders in elite-level cycling teams (i.e., sporting directors, coaches, and medical staff).
Methods: An anonymous online survey has been compiled containing quantitative and qualitative questions for sporting directors, coaches, or medical staff about their own mental health awareness and literacy. This was distributed to cycling teams and through a national-level federation. The survey link will be available online from the beginning of October 2024 to the end of February 2025. An ethical application was made to the Ethics Committee in the Canton of Bern, who determined that the research fell outside the scope of the Swiss Human Research Act and therefore did not require formal approval.
Results: Preliminary results will be ready in March 2025 in time for the poster display at the European Congress of Psychiatry in April 2025. The findings will provide insights into mental health awareness amongst team stakeholders in men's elite-level cycling. The quantitative data will be studied with descriptive statistics and the qualitative results will be evaluated using thematic content analysis to identify key themes.
Conclusions: Based on prior literature, our hypotheses are that there is limited mental health awareness about the mental health of elite-level riders amongst cycling team stakeholders and scarce knowledge about how to manage these issues should they arise. These findings would underline a need for more attention to this topic within the sport, potentially necessitating the involvement of national federations and regulators.

Disclosure of Interest: A. Smith: None Declared, J. Grana: None Declared, J. Colangelo: None Declared, A. Buadze: None Declared, M. Liebrenz Consultant of: In cooperation with Swiss Cycling, Michael Liebrenz provides mental health support to elite-level riders involved with the Swiss national team.

EPV1323

Perceptions and misperceptions about lithium: Ar-razi hospital experience

A. Souidi[1]
[1]Psychiatry B, Ar-razi hospital, Salé, Morocco
doi: 10.1192/j.eurpsy.2025.1882

Introduction: Lithium enjoyed its first golden age between 1965 and 1990, but interest in the molecule has not waned, on the contrary, the last 20 years have seen a veritable renaissance in lithium publications. This literature is fuelled by the ongoing exploration of lithium's unique mood-stabilizing, anti-suicidal and neuroprotective properties, a panoply of properties never before observed in a single molecule. In spite of this, the literature describes little use of lithium, despite ample evidence of its benefits. Our study points the perceptions and misperceptions of lithium and their effects on it use in our hospital.
Objectives: To study and identify the perceptions and misperceptions of doctors at Ar-razi Hospital about lithium, and thus discuss both of efficacy and safety misperceptions through a litterature review. This study will have as a first objective to correct these mispercetions in order to promote a proper care of our patients.
Methods: This is a descriptive study. Data collection was carried out on 50 psychiatrists and trainees. By using an online and handout forms focusing on physicians perceptions and misperceptions of the efficacy and safety of lithium at Ar-razi Hospital in Salé. Jamovi 2.3 was used for data entry and statistical analysis.
Results: our study results were resumed in 2 images. Image 1 is a table that shows the status of our professionnals and also their use of lithum as first or second molecule.
image 2 resumes efficacy perceptions of lithium among our psychiatrists and trainees.
although many other results will be shown by text:

- 58% thinks that Lithium should not be used in women of childbearing age due to teratogenic risk
- 73% have the perception that Lithium should be avoided in elderly patients suffering from a lack of efficacy data and safety concerns.
- 53% thinks that other thymoregulators are safer and should be systematically used in women of childbearing age with bipolar disorder instead of lithium.
- 84% acclaim that lithium treatment is stopped because of it security profile, when 44% of them thinks that hypothyroidism is prevalent as a secondary effect and causes treatment stop.

Image 1:

Status of participants	Use as 1st molecule	Use after failed of others thymoregulators
Residents 40(80%) Psychiatrists 10 (20%)	12 (24%)	38(76%)

Image 2:

Second-generation antipsychotics (SGA) as effective as lithium	Yes (48%) No (52%)
Rapid-cycling bipolar disorder (RC-BD) responds poorly to lithium in general	Yes (12%) No (88%)
Lithium should be avoided in elderly patients with RC-BD due to lack of efficacy data and safety concerns	Yes (100%)

Conclusions: Our study finds that our hospital professionnals have many misperceptions about lithium, especially about it security, which may affect the treatment plan for many patients. This study and it discussion throught the litterature review will change these perceptions, furthermore give the patients a proper care.
Disclosure of new knowledge is essential to refute misconceptions about lithium and enable patients to access its unique therapeutic constellation.

Disclosure of Interest: None Declared

Mental health professionals dealing with aggression: the experience of Ar-Razi hospital in Salé, Morocco

A. Souidi[1,2*], G. Hami[1], S. Belbachir[2] and A. Ouanass[2]

[1]Ar-razi Hospital, Salé, Morocco and [2]psychiatry B, Ar-razi hospital, Salé, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1883

Introduction: Aggression in the psychiatric environment has negative consequences for both patients and staff. Accurate measurement of patient aggression towards staff, and its prevention, remains elusive. The Staff Observation of Aggression Scale-Revised (SOAS-R) is a measure describing the incidence and characteristics of aggressive events. Although not exclusive to staff aggression, our study used this scale to provide a more or less standardized measure for assessing and understanding the trends and potential triggers of staff aggression. This will enable better management of such situations. This in turn will lead to better working conditions and improved quality of care.
Objectives: To describe the incidence of aggressive events against various mental health staff at Ar-Razi Hospital over the course of a year, their characteristics and the factors involved. this study will provide and enable better managment of these situations, furthermore leading to better work conditions and better quality of care.

Methods:
- Our study is a cross-sectional study, data collection were by a questionnaire sent online to hospital staff, the questionnaire was bases on the SOAS-R items.
- Descriptive and analytical statistical study wad done by Jamovi 2.3 software.
- Statistical differences were calculated using the chi-2 test, and a $p<0.005$ value was considered statistically significant.

Results: Our study results(SOAS-R items) concerning the agressions towards staff of our hospital were resumed in image 1 and 2.
Also the prevalence of participating staff by status in our study was: 78% of physical assaults were against nurses. The association between the prevalence of assaults and staff status was statistically significant using the chi-2 test ($p=0.0037<0.001$).

Image 1:

Prevalence	*N=53(100%)*
Physical and/or verbal aggression	49(92.5%)
Provocation	
Provocation no visible	24(48%)
Provocation by other patient(s)	9(18%)
patient denied something	8(16%)
by request to take treatment	16(32%)
other provocation	8(16%)
Consequences for the victim	
reversible damage to objects	3(6,1%)
irreversible damage to objects	0(0%)
feeling threatened	30(61,2%)
physical pain <10min	7(14,3%)
physical pain >10min	5(10,2%)
visible injury	5(10,2%)
need for treatment	3(6,1%)
need to see a doctor	5(10,2%)1
none	4(28,6%)
Work stoppage after aggression	
temporary work stoppage<10days	4(8.5%)
temporary work stoppage 10-30days	2(4.3%)
temporary work stoppage>30days	1(2.1%)
permanent work stoppage	0(0%)
No work stoppage	41(87.2%)

Image 2:

Prevalence	N=53(100%)	
Patients gender Male Female	49(92.5%)	
Average patients age (20-40 years)	50(94%)	
Most frequent diagnosis (schizophrenia and related disorders)	28(56%)	
Place of attack (most frequent) Emergency department Female department A Male department A Outpatient consutltations	 33(66%) 11(11%) 5(10%) 11(22%)	
Means to calm the aggression	P	V
Talking to him	8(21,1%)	37(74%)
outside the patient calmly	4 (10,5%)	21(42%)
Outside by force	15(39,5%)	13(26%)
VO treatment	6(15,8%)	13(26%)
IV treatment	30(78,9%)	13(26%)
Isolation	25(65,8%)	13(26%)
Physical restraint	30(78,9%)	15(30%)
Nothing	2(5,3%)	2(5,3%)

Conclusions: Agression is known to have negative impacts for both staff and patients. Our study suggests that mental health staff in our facility are victims of aggression. Improved methods of measuring aggression and a wider study of different psychiatric institutions will help to prevent aggression and create a healthy work environment, which in turn will help the staff to develop and improve the quality of care for patients.

The importance of Assertive Community Mental Health Treatment in the rural depopulation

E. Talaya Navarro[1]*, L. Gallardo Borge[1], L. Martín de Francisco Murga[1], M. Gómez Fernández[1], S. Pecheykin Pajomov[1], M. Teijeiro Rebolo[2] and A. Peman Alcazar[2]

[1]Psiquiatría and [2]Complejo Asistencial de Segovia, Segovia, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1884

Introduction: The proposed research work aims to carry out a review of the data of the Assertive Community Treatment Program of Segovia, analyzing its importance in certain profiles of psychiatric patients.

Objectives: Review of data from the Segovia Assertive Community Treatment Program from 2020-2024: age, sex, nationality, marital status, level of education, diagnosis, family history, substance use, population, socio-family situation, economic situation, follow-up and admissions in Mental health, social health coordination and disability.

Methods: Data from the Segovia Assertive Community Treatment Program from 2020-2024.

Results: The majority of patients participating in the Segovia Assertive Community Treatment Program between 2020-2024 were Spanish men between 20 and 60 years old. All patients were single, except three separated and one married. Approximately half of them lived alone and the other half with their family of origin. Most had basic education and half were employed. Regarding the consumption of toxic substances, most of them smoked tobacco and some also consumed alcohol or cannabis, and a small number cocaine. Many of them received a financial benefit and had social-health coordination.

The most common diagnosis is schizophrenia, followed by schizoaffective disorder and delusional disorder, most with psychiatric family history. Other diagnoses that the patients presented were: bipolar disorder, personality disorder and obsessive-compulsive disorder. Some of them also had disabilities.

It is important to highlight that 94.12% of patients live in rural areas, many of them more than 30 minutes away by car and with faced great difficulties with public transportation. Many of them were more previous admissions to Psychiatry and an irregular follow-up in Mental Health, but very few had readmissions during the Program. The majority of patients had psychopharmacological treatment, and 7.14% of them had injectable antipsychotic treatment.

Conclusions: A large percentage of patients in the Assertive Community Mental Health Treatment Program are people who live in a rural environment, with a long distance from the nearest mental health center and with difficulties using public transportation, which is why this program is very useful. In these patients to achieve clinical stability, since these patients had irregular follow-up in Mental Health consultations and had numerous admissions to Psychiatry.

Experiences of deep concentration in individuals with attention deficit hyperactivity disorder (ADHD): An integrative review of the literature

M. B. Terra[1]* and P. M. Etchebest[2]

[1]Department of Internal Medicine and [2]Department of Psychology, Federal University of Health Sciences of Porto Alegre, Porto Alegre, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1885

Introduction: ADHD has been seen by current science as an expression of complex traits that go beyond the symptomatological triad of "inattention-hyperactivity-impulsivity". Among the new notes, experiences of deep concentration (DC) are mentioned as a frequent phenomenon in the daily lives of those with ADHD, which encourages research on this topic.

Objectives: The main objective of this integrative review was to investigate how empirical scientific studies have evaluated, associated and understood this hyperfocused attentional pattern in individuals with a diagnosis or symptoms suggestive of ADHD.
Methods: For searches in the electronic databases PubMed, Scopus, LILACs, Pepsic and Scielo, the terms "attention deficit hyperactivity disorder", "hyperfocus" and "flow state" were chosen. As inclusion criteria, studies were considered with (a) full texts available, (b) with an empirical design, (c) in English and (d) published in any year. In total, 10 empirical studies were analyzed (8 quantitative and 2 qualitative), Regarding the critical analysis of the included publications, relevant data were extracted about: (a) assessment instruments for deep concentration measures, (b) ADHD assessment instruments, (c) associations between hyperfocus, flow and ADHD and (d) general understandings of researchers on the representation of DC experiences in the lives of those with ADHD.
Results: The sudies indicated a plurality of assessment instruments for both CP constructs (hyperfocus, flow, perseveration) and ADHD symptoms. As main findings, the articles suggest a high prevalence of hyperfocus in adults with ADHD compared to those without the disorder, as well as positive correlations between ADHD symptoms, hyperfocus, perseveration, internet addiction and emotional dysregulation. Different perspectives on the manifestation of DC in ADHD were captured from the studies, whose interpretations ranged from harmful behavior to the potentiality of ADHD.
Conclusions: It was observed that, despite the recent expansion of research trying to understand the phenomenon of hyperfocus in the context of ADHD, scientific knowledge on the topic is still quite limited. In addition to having the unprecedented character of bringing together what modern science has postulated about CP in relation to ADHD, this research is relevant because it contributes to expanding the visibility of ADHD beyond the diagnostic criteria established by the DSM-V-TR and ICD-11.

doi: 10.1192/j.eurpsy.2025.1886

Introduction: Self-regulation refers to a structured mental process for initiating, organizing, maintaining, and managing internal and external activities directed toward achieving goals. Each individual exhibits a unique self-regulation style that influences their capacity to adapt to changing circumstances. During the COVID-19 pandemic, a significant rise in anxiety, depression, and stress levels was noted in Russia. Emotional disorders may relate to self-regulation styles, as they affect an individual's adaptation to evolving internal and external stressors.
Objectives: The study investigates relationships between self-regulation styles and depression, anxiety, and stress levels among humanities students and HIV-positive patients, shedding light on how behavioural self-regulation affects emotional responses in different population segments during the pandemic in the Russian Federation.
Methods: Data were collected from January to July 2021 using a Google form. The sample included 35 humanities students from Russian universities and 59 HIV-positive patients. V.I. Morosanova's "Style of Self-Regulation of Behaviour" questionnaire was used to assess self-regulation styles, while the DASS-21, adapted for Russian contexts, measured levels of depression, anxiety, and stress.
Results: We found that in the group of Russian university students, depression had negative correlations with behavioural programming (r_s = -0.421, $p < 0.05$) and with outcome evaluation (r_s = -0.401, $p < 0.05$). In the HIV patient group, depression had negative correlations with modelling (r_s = -0.322, $p < 0.05$) and flexibility (r_s = -0.285, $p < 0.05$), anxiety also with modelling (r_s = -0.270, $p < 0.05$) and flexibility (r_s = -0.261, $p < 0.05$). In both groups, stress was not related to self-regulation behaviour style.
Conclusions: The study highlights the association between emotional disorders and self-regulation was more pronounced in the HIV-positive group. Depression and anxiety corresponded with reduced reality assessment and flexibility in self-regulation. These patients found it more challenging to evaluate internal and external factors and adjust their self-regulatory processes amid changing conditions, indicating a greater vulnerability to disruptions in self-regulation. Within the students' group, depression alone affected self-regulation, particularly diminishing abilities in programming and outcome evaluation. As depressive symptoms worsened, students struggled to effectively plan actions and assess their behaviour and achievements.

Quality of Life and Behavioural Self-Regulation Style in Different Groups of the Russian Population during the Second Wave of COVID-19

V. I. Rozhdestvenskiy[1], V. V. Titova[1]*, I. A. Gorkovaya[1], Y. S. Aleksandrovich[1] and D. O. Ivanov[1]

[1]Department of Psychosomatics and Psychotherapy, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1887

Introduction: Quality of life (QoL) is a comprehensive concept encompassing an individual's satisfaction with various aspects of life, including material, social, spiritual needs, intellectual and physical development, and safety. During the COVID-19 pandemic, the quality of life in Russia declined due to environmental and social disruptions. Behavioural self-regulation, which reflects an individual's ability to manage internal and external conditions, plays a key role in adapting to challenging situations. Thus, exploring the relationship between QoL and self-regulation styles can provide insight into adaptive behaviours under pandemic conditions.
Objectives: The study aimed to explore the interconnections between quality of life and self-regulation styles in humanities students and people living with HIV during the second wave of COVID-19.

Methods: Data were collected from January to July 2021 via a Google form. Participants included 35 Russian university students in humanities and 59 HIV-positive patients. Self-regulation styles were measured using V.I. Morosanova's "Style of Self-Regulation of Behaviour" questionnaire, and quality of life was assessed with the WHOQOL-BREF, adapted for Russian respondents.
Results: In the group of students positive correlations of physical and psychological well-being with programming ($r_s = 0.405$, $p < 0.05$); self-perception — with programming ($r_s = 0.522$, $p < 0.01$), evaluation of results ($r_s = 0.586$, $p < 0.01$) and general level of self-regulation ($r_s = 0.389$, $p < 0.05$); microsocial support — with evaluation of results ($r_s = 0.336$, $p < 0.05$) were found. In the patient group, physical and psychological well-being were associated with outcome evaluation ($r_s = 0.343$, $p < 0.01$); self-image — with modelling ($r_s = 0.605$, $p < 0.01$), outcome evaluation ($r_s = 0.467$, $p < 0. 01$), flexibility ($r_s = 0.444$, $p < 0.01$) and overall level of self-regulation ($r_s = 0.439$, $p < 0.01$); microsocial support — with modelling ($_s = 0.366$, $p < 0.01$); social well-being — with modelling ($r_s = 0.442$, $p < 0.01$) and flexibility ($r_s = 0.346$, $p < 0.01$).
Conclusions: The study found that self-perception was the most frequently correlated factor with self-regulatory behaviour in both students and HIV-positive group, indicating that satisfaction with life, sense of purpose, and emotional stability contribute to self-regulation even in challenging conditions. However, social well-being was a unique influencing factor for people living with HIV, highlighting a dependency on material and societal conditions that was less pronounced in student's group. This suggests that HIV patients are more sensitive to social and environmental stability, whereas students rely more on internal self-regulatory mechanisms for adaptation.

Catatonic syndrome: origin, diagnosis, treatment and iatrogenesis. Case report

M. Viana Perez[1]*, Á. De Vicente Blanco[2], A. Muñoz San Jose[2], Á. Esquembre García[2], C. Herranz Serfaty[2], M. E. Sanchez-Escalonilla Relea[2] and M. Velasco Santos[2]

[1]Psychiatry and [2]Hospital Universitario La Paz, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1888

Introduction: The catatonic syndrome is a heterogeneous syndrome that manifests with a variety of symptoms, whose management is not clearly predefined despite being a clinically diagnosable entity. It is a frequently underdiagnosed and undertreated condition that can lead to the death of the patient, and which originates from a large number of psychiatric and organic pathologies.
Objectives: To present a case highlighting the most significant and representative findings typically observed in catatonic syndrome, as well as to highlight the most relevant data regarding the origin, diagnosis and treatment of this entity.
Methods: This case report describes a single patient. The methodology includes a detailed study of the symptoms manifested by the patient and the main guidelines for therapeutic management.
Results: In this poster, the case of a 24-year-old man who comes to the emergency room with what appears to be catatonic syndrome is presented. The most notable symptoms include mutism with occasional echolalia, facial echomimia, apragmatic and disorganized behavior with a tendency toward inhibition, flexibilitas cerea, and antigravity postures. It was decided to administer high doses of benzodiazepines and subsequently electroconvulsive therapy since one of the most frequently seen evidence in catatonic syndrome is dysfunction in the dopaminergic pathway. The patient presented complications of this treatment such as bronchoaspiration. At the same time, multiple complementary diagnostic tests were performed such as blood tests, brain CT, brain MRI, electroencephalogram, and lumbar puncture, all of them without significant findings. Later, the episode reversed and a psychotic picture with predominance of auditory hallucinations was seen, which progressively improved over weeks with a regimen of antipsychotics (injectable aripiprazole and oral olanzapine).
Conclusions: It is therefore concluded that it would be beneficial for it to be more widely represented in treatment guidelines and clinical trials, which would lead to easier and faster clinical decision-making. In other words, it is concluded that early and effective detection and intervention are of vital importance in the management of the catatonic syndrome under study.

A systematic review assessing the efficacy of doxycycline as adjunct therapy for nodding syndrome

A. A. Kumar[1], R. Walwaikar[2], A. A. Pillai[2], A. Agrawal[3] and F. Sheikh[4]*

[1]GMERS Medical College, Vadnagar; [2]SSPM Medical College and Lifetime Hospital, Sindhudurg, India; [3]Humanitas University, Milan, Italy and [4]Greater manchester mental health trust, Manchester, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1889

Introduction: The rare epileptic seizure syndrome nodding is endemic among African adolescents. While the etiology remains poorly understood, its mechanistic hypothesis suggests a neuroinflammatory disorder that could benefit from mapping Doxycycline as a treatment option. Here, we assess the use of Doxycycline as either monotherapy or adjunct therapy for epilepsy prophylaxis, with a particular emphasis on its intervention for nodding syndrome.
Objectives: The primary objective of this study is to assess the safety and efficacy of Doxycycline for treating nodding syndrome. Also to comment on the likely use of Doxycycline as a form of adjunct therapy when paired with other antiepileptic drugs as a means to optimize the management efforts of nodding syndrome.
Methods: Our analysis included randomized controlled trials and observational studies which were sorted and assessed in accordance to PRISMA guidelines through a systematic search of the literature using all electronic databases, including PubMed, Google Scholar, Scopus, and Cochrane. The search terms included Doxycycline and nodding syndrome. The systematic set of extraction data were limited to studies that included a confirmed adolescent population exhibiting probable symptoms of nodding syndrome with Doxycycline as the primary intervention. Effect sizes will be measured with a random-effects model, and heterogeneity will be calculated with I^2 statistics.
Results: Nine studies in total involving 1,120 subjects were analyzed, that included four randomized controlled trials (RCTs)

assessing the effects of doxycycline monotherapy on 480 subjects, as well as five observational studies exploring the use of doxycycline with first-line anti-epileptic drugs (AEDs) on 640 subjects.
Seizure frequency reduction
Doxycycline administration on its own reduced seizure frequency by 30% relative to the placebo (relative risk [RR] = 0.70, 95% confidence interval [CI]= 0.60 to 0.85, p < .001), whereas, added to AEDs, reduced seizure frequency by 45% (RR = 0.552, 95% CI = = 0.42 to 0.73, p < 0.001; I^2 = 22%, considered low heterogeneity).
Lower severity of symptoms
The overall results suggest improvements in motor functions and cognitive assessments of -0.82 (standardized mean difference, 95% CI = -1.12 to -0.52, p < .001), which may indicate an improvement in motor symptoms.
AED add-on and impact on quality of life
Doxycycline with AED smear resulted in a reduction in seizure frequency of 45% (SMD = -0.68, 95% CI = -0.94 to -0.42, p < .001) and a statistically significant improvement in quality of life of approximately 25% (p < 0.01); effect estimates presented moderate heterogeneity (I^2 = 45%).
Conclusions: Doxycycline has potential for extended use since our findings support a safe and potentially beneficial intervention in nodding syndrome. Our study may serve as a useful guide for the use of antibiotics in other neuropathologies with inflammatory elements.

Postpartum Depression, Pain Catastrophizing, and Coping Strategies in Early Postpartum Women

O. Bouattour[1], N. Messedi[1]*, F. Khanfir[2], R. Ben Jmeaa[1], I. Chaari[1], F. Charfeddine[1], L. Aribi[1], K. Chaabene[2] and J. Aloulou[1]

[1]Psychiatry « B » department and [2]Gynecology department, Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1890

Introduction: The postnatal period is a time of great vulnerability in terms of mental health, with depression being one of the most common complications. This condition can significantly affect how women perceive and process the pain and stress associated with childbirth. Pain experienced during pregnancy and postpartum is linked to psychological distress, often influenced by pain catastrophizing a cognitive tendency to dwell on, magnify, or feel helpless in the face of pain. To manage these challenges, many women rely on coping mechanisms to navigate the significant stressors of this period.
Objectives: The aim of this study is to explore the relationship between postpartum depression, pain catastrophizing, and coping mechanisms in the postnatal period.
Methods: We conducted a cross-sectional descriptive and analytical study targeting women in their first week postpartum who had been admitted to the gynaecology-obstetrics department of the Hedi Chaker University Hospital in Sfax, Tunisia. The study was conducted over a three-month period (October, November and December 2023). We used the Tunisian Arabic version of the Edinburgh Postnatal Depression Scale (EPDS). Pain catastrophisation was assessed using the pain catasrophizing scale (PCS). We used the French version of the coping scale Ways of coping checklist revised (WCC) to evaluate coping strategies.
Results: The study included 220 postpartum women with a mean age of 31.1 ± 6.6. Psychiatric history was recorded in 5.5% of participants, predominantly bipolar disorders (4.1%). Medical or surgical history was reported by 14.1% of women. Among the participants, 28.6% were primiparous, and 71.4% were multiparous. A history of child loss was noted in 4.5% of cases. Spontaneous labor occurred in 65.5% of women, while 17.7% underwent induced labor. Vaginal deliveries were performed in 56.4% of cases, with forceps used in 8.2%. Postpartum recovery was uncomplicated for 86.4% of participants, while complications occurred in 13.6% of cases. Postnatal care was provided by family members for 55% of women. Postpartum depression was observed in 20.9% of participants.The average score of Pain Catastrophizing Scale (PCS) was 24 ± 11, and problem-focused coping was the most frequently employed strategy, with a mean score of 26.51 ± 6.3.
Women with postpartum depression had significantly higher PCS scores (p<0,001). Emotion-focused coping was the predominant strategy used by this group (p=0.003). Conversely, women without postpartum depression were more likely to use problem-focused coping (p<0.001) and social support-based coping (p=0.011).
Conclusions: This study reveals that postpartum depression is associated with higher pain catastrophizing and a greater use of emotion-focused coping. In contrast, women without depression tended to use problem-focused and social support-based coping, suggesting that these strategies may help mitigate postpartum psychological distress.

Psychosis and Spinal Chronic Pain – Our experience

J. Đokić[1], L. Ilić[1]*, S. Momirović[1] and I. Nikolić[1,2,3]

[1]Special Psychiatric hospital "Dr Slavoljub Bakalović", Vršac; [2]Clinic for Neurosurgery, University Clnical Center of Serbia and [3]Medical Faculty, University of Belgrade, Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1891

Introduction: Most common pain in psychosis is headache. On the second place are spinal syndromes. Often patients have chronic spinal pain, and the treatment of neuropathic component is difficult because polymedication and possible drug interaction.
Objectives: The aim of our study was the intersection of the state of therapy and therapeutic response in patients with spinal chronic pain and psychosis.
Methods: This cross-sectional study includes 25 patients treated at the Department for woman chronic psychosis in the SPH "Slavoljub Bakalovic" in Vršac during their hospitalization. The covered period was from April 1st to August 31st 2024.
Results: During our research, 60 female patients with psychosis were treated at our department, and 25 (41.67%) had spinal hronic pain. The average age of the patients was 60 years (41-75), and the duration of symptoms was from 6 months to 11 years (average 2 years and 2 months). Localization was mainly in the area of the lower back (12), cervicobrachialgia (7), lumboischialgia (5) and only in the lower extremities (1). According to the type of pain,

all of them had predominantly neuropathic pain. The average value of pain intensity on the VAS scale was 4 (3.92). All patients were treated with non-steroidal analgesics and 16 of them had benzodiapines in therapy. Along with the mentioned therapy, 9 (36%) patients received a coanalgetic from the group of anticonvulsants and 5 (20%) from the group of antidepressants. Only 4 patients used during the hospitalization supplement based on vitamin B complex. A good therapeutic response was achieved in 20 (80%) patients (reduction of pain on the VAS scale by 2 or more points), partial in 1 patient (reduction of pain on the VAS scale by 1 point). In 4 patients, the prescribed therapy did not reduce pain.
Conclusions: Chronic pain of spinal origin occurs in an approximate percentage as in the general population, but the problem of its treatment is the primary disease and polymedication in the therapy of the primary disease.With a well-balanced therapy, a good therapeutic response in pain reduction can be achieved.

The Effects of an Online Behavioral Activation Program with Informational Support Messages on Patients with Complex Regional Pain Syndrome

M. Jung[1]* and S. Cho[1]

[1]Department of Psychology, Chungnam National University, Daejeon, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1892

Introduction: Complex Regional Pain Syndrome (CRPS) is a chronic neuropathic pain condition that significantly reduces patients' quality of life. Few studies have examined the application of short-term Behavioral Activation (BA) programs for patients with CRPS, and studies that include informational support messages are scarce.
Objectives: This study is intended to investigate the effects of an online BA program, accompanied by informational support messages, on pain intensity, pain interference, pain catastrophizing, depression, life satisfaction, and behavioral patterns in patients with CRPS.
Methods: Two patients with CRPS participated in an eight-session online BA program using a multiple-baseline design. After the first session, participants completed daily activity monitoring sheets, and the baseline was measured. The BA intervention began in the third session, and from that point until the eighth session, participants received immediate informational support messages once they completed their monitoring sheets. The informational support messages consisted of graphs comparing the previous day's pain intensity, depression levels, and activity levels, as well as linear trendline graphs based on recorded data. Additionally, questionnaires were used to measure pain intensity, pain interference, pain catastrophizing, depression, life satisfaction, and behavioral patterns pre-intervention, post-intervention, and at a four-week follow-up, and effect sizes (Cohen's d) were calculated.
Results: Daily activity monitoring sheets indicated that activity levels significantly increased during the intervention phase and were maintained or further increased at follow-up. Depression levels gradually decreased from the intervention phase, but pain intensity showed no significant change.
Questionnaires revealed that pain catastrophizing and depression decreased post-intervention and at follow-up compared to baseline, while life satisfaction increased, and pain avoidance behaviors decreased. However, pain intensity increased compared to baseline, and pain interference decreased at follow-up. Effect sizes, measured by Cohen's d, indicated large effects for all variables except behavioral patterns and pain interference post-intervention, and for all variables except behavioral patterns at follow-up.
Conclusions: These findings suggest that an online BA program with informational support may be effective for patients with CRPS.

A Systematic Review of Chronic Pain in People with Schizophrenia

S. Krug[1]* and M. Edwards[1]

[1]KCL Institute of Psychiatry, Psychology & Neuroscience, London, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1893

Introduction: Previous research has shown chronic pain to be more prevalent in individuals with psychiatric disorders, compared to the general population.
Objectives: We performed a systematic review of studies relating to chronic pain in patients with schizophrenia (PWS), to explore its cause, prevalence and presentation.
Methods: Our search strategy yielded 4963 studies. Once duplicates were removed, and studies were screened according to our inclusion/exclusion criteria, 15 studies on chronic pain and quality of life (QOL) in PWS remained.
Results: Our results showed that the prevalence of chronic pain in PWS was equal to, or greater than, healthy controls. Studies assessing chronic headaches specifically, found headaches to be more prevalent. Studies that compared chronic pain in PWS to individuals with other psychiatric disorders, such as depression or bipolar disorder, found PWS to have lower levels of pain. Pain intensity ranged from mild to moderate and was most frequently reported in the abdomen and head. The presence of pain was associated with anxiety, depression, psychotic symptoms, and older age. No clear links were found between chronic pain and patient gender, education, or wealth. QOL, particularly health-related QOL, was lower in patients with higher levels of pain, and such patients experienced greater functional impairment. However, when PWS performed self-assessments of QOL and health satisfaction, no difference was seen between individuals with and without pain.
Conclusions: These variations in pain perception may be due to disturbances in somatosensation, with PWS being internally more preocccupied. Specifically, computational models suggest this may be due to aberrant salience, where PWS attribute meaning or value to innocuous stimuli. Understanding the link between chronic pain and schizophrenia is essential as this may contribute to premature death. Further research is required to explore the link between comorbidities as a cause of chronic pain in PWS.

Pain and Attention-Deficit/Hyperactivity Disorder: A Closer Look at the Relationship

F. Lobo[1]*, A. M. Fernandes[1], C. Eusébio[1], F. Agostinho[1], L. Figueiredo[1], M. J. Amaral[1], R. Avelar[1] and M. J. Heitor[1]

[1]Departamento de Psiquiatria e Saúde Mental, Hospital Beatriz Ângelo, Loures, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1894

Introduction: Attention-Deficit/Hyperactivity Disorder (ADHD) is a prevalent neurodevelopmental disorder characterized by symptoms of inattention, hyperactivity, and impulsivity. Recent research highlights a significant comorbidity between ADHD and pain, suggesting that individuals with ADHD may experience altered pain perception and a higher prevalence of pain conditions.
Objectives: This review aims to explore the possible link between pain and ADHD, specifically examining the relationship between ADHD and pain perception, the effects of methylphenidate (MPH) on pain thresholds, and the potential underlying mechanism connecting these two conditions.
Methods: A non-systematic review of the literature was conducted, focusing on key studies published in the last 15 years. The search terms included "pain," "ADHD," and "methylphenidate."
Results: Based on this review, several key findings emerged:

- **Dopamine's Role in Pain:** Accumulating data suggest that dopamine is implicated in pain processing. Many regions of the CNS involved in pain processing have high dopamine receptor density, whose activation can be analgesic.
- **Increased Prevalence of Chronic Pain:** Individuals with ADHD show a higher prevalence of chronic pain conditions, indicating a significant comorbidity between ADHD and pain.
- **Altered Pain Perception:** Individuals with ADHD are more likely to exhibit lower pain thresholds and increased pain sensitivity, particularly in untreated individuals.
- **Impact of Methylphenidate:** Methylphenidate, a common treatment for ADHD, partially reverses altered pain responses, suggesting its potential role in normalizing pain perception through dopaminergic modulation.
- **Neuroinflammation as a Link:** Neuroinflammation has been suggested as a potential factor linking ADHD and pain, particularly through dopaminergic dysregulation.

Conclusions: This review underscores the need for increased awareness of the pain-ADHD comorbidity. Understanding altered pain perception in ADHD is crucial for improving patient care and developing targeted treatments. While current evidence suggests treatments like methylphenidate may help modulate pain sensitivity, further research is essential to clarify the mechanisms and establish guidelines for managing pain in ADHD patients.

Disclosure of Interest: None Declared

Alcohol Use Disorder and Chronic Pain – Our experience

S. Momirović[1]*, L. Ilić[1], J. Đokić[1] and I. Nikolić[1,2,3]

[1]Special Psychiatric hospital "Dr Slavoljub Bakalović", Vršac; [2]Clinic for Neurosurgery, University Clnical Center of Serbia and [3]Medical Faculty, University of Belgrade, Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1895

Introduction: Chronic painful conditions in alcohol use disorder (AUD) are often seen and represent a significant problem in their therapy. Its incidence is higher than in the general population and is often associated with AUD relapse. Often, they are very manipulative.
Objectives: The aim of our study was the intersection of the state of therapy and therapeutic response in patients with chronic pain and AUD.
Methods: This cross-sectional study includes 25 patients treated at the Department for male alcoholism in the SPH "Slavoljub Bakalovic" in Vršac during their hospitalization. The covered period was from April 1st to August 31st 2024.
Results: During our research, 48 male patients with AUD were treated at our department, and 25 (52.01%) had horonic pain. The average age of the patients was 52 years (24-80), and the duration of symptoms was from 7 months to 20 years (average 8 years and 4 months). Localization was mainly in the area of the lower back (10), lumboischialgia (9) and only in the extremities (6). According to the type of pain, the majority (23) had predominantly neuropathic pain. The average value of pain intensity on the VAS scale was 4 (4.2). All patients were treated with non-steroidal analgesics and benzodiazepines. Along with the mentioned therapy, 9 (36%) patients received a coanalgetic from the group of anticonvulsants and 12 (48%) from the group of antidepressants. Few patients (7) used before and during the hospitalizations supplement based on Mg and vitamin B complex. A good therapeutic response was achieved in 17 patients (reduction of pain on the VAS scale by 2 or more points), partial in 6 patients (reduction of pain on the VAS scale by 1 point). In 2 patients, the prescribed therapy did not reduce pain.
Conclusions: Chronic pain syndromes in AUD is more frequent than in general population, and early detection and good therapy protocol is very important to reduce symptoms. Pain treatment protocol for AUD patients must be made individually for each patient in order to achieve an adequate therapeutic response and avoid interaction with other drugs in the therapy of AUD. With a well-balanced therapy, a good therapeutic response in pain reduction can be achieved.

EPV1344

Trigeminal Neuralgia – rethinking the "suicide disease" label

R. Neto[1]*, B. Fonseca Silva[1], M. Remelhe[1] and R. Araujo[1]

[1]ULSGE, Vila Nova de Gaia, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1896

Introduction: Trigeminal Neuralgia (TN) is a rare condition characterized by recurrent brief episodes of unilateral and excruciating facial pain, typically triggered by innocuous stimuli. It is historically known as the "suicide disease", emphasizing the severity of the attacks and its impact on patients' mental health.

Objectives: We aim to highlight the risk of psychiatric comorbidities following TN diagnosis and discuss the potential burden depicted by the phrase "suicide disease".
Methods: We presented a case report and conducted a non-systematic review of the literature.
Results: A 72-year-old female patient with history of diabetes, hypertension, dyslipidemia, recurrent thrombophlebitis but no previous relevant psychiatric history, presents with depressive mood, anhedonia, insomnia, reduced appetite and feelings of hopelessness, which began 3 months prior. These symptoms started shortly after she began experiencing paroxysms of intense electric shock-like pain in the right hemiface, allodynia (specially triggered by the wind, talking, chewing and light touch) and lacrimation of the right eye. The patient had multiple consultations with neurology and psychiatry physicians. TN was presumed and the patient initiated treatment with pregabalin and intravenous infusions of lidocaine, as well as antidepressants. Magnetic resonance angiography revealed neurovascular compression of the right trigeminal nerve, supporting the diagnosis. Depressive symptoms aggravated and she experienced recurrent suicidal thoughts as she became aware of the TN diagnosis and experienced debilitating symptoms due to initial suboptimal pain relief. Oxcarbazepine was later introduced in the treatment plan and pain relief was slowly achieved. Suicidal ideation waned despite maintenance of depressive mood. Evidence shows there is a higher risk of newly diagnosed depressive, anxious and sleep disorders following TN diagnosis, most likely due to its deleterious effect at a psychological, behavioral and social level. Currently, however, the phrase "suicide disease" may be an ill-suited one as the lack of information on suicide rates among patients with TN and the availability of new and more efficient therapeutic options do not support its present use.
Conclusions: This case exemplifies the increased risk of new psychiatric comorbidities following TN diagnosis, further aggravating patients' quality of life. Despite its historical significance, the label "suicide disease" seems to lack current applicability and may not only harm patients' understanding and acceptance of the diagnosis, but also exacerbate fear and stress concerning its prognosis.

Disclosure of Interest: None Declared

EPV1345

Psycho-social profile of patients with chronic neuropathic pain and spinal cord stimulation outcome: preliminary finding from an Italian sample recruited at the University Hospital of Verona (Italy)

C. Perlini[1]

[1]Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona-AUOI of Verona, Verona, Italy
doi: 10.1192/j.eurpsy.2025.1897

Introduction: Spinal cord stimulation (SCS) is used to treat chronic neuropathic pain (CNP) resistant to other therapies and procedures. The treatment involves implanting a device that delivers electrical stimulation along the ascending nerve pathways. According to the bio-psycho-social model of pain, the success of SCS is influenced by more than just the technical aspects of the procedure. Psychological and context-related factors also play a crucial role.
Objectives: To profile a sample of Italian patients with CNP in the pre-implant phase from a psycho-social perspective, using such data to predict the SCS outcome.
Methods: Candidates for SCS at the Pain Therapy Center of the University Hospital of Verona (Italy) undergo a psychological assessment at the Clinical Psychology unit before the implantation. This assessment includes an interview to evaluate the impact of pain, coping strategies, and family support, as well as any history of traumatic experiences, psychiatric conditions, and lifetime use of alcohol or substances. Additionally, a series of questionnaires are administered to assess pain (Brief Pain Inventory, BPI), psychopathology (Symptom Checklist 90, SCL-90), personality (Minnesota Multiphasic Personality Inventory, MMPI-2), coping style (Coping Strategies Questionnaire, CSQ), the tendency to catastrophize (Pain Catastrophizing Scale, PCS), family and social support (Multidimensional Scale for Perceived Social Support, MSPSS), and self-efficacy (General Self-Efficacy Scale, G-SES). Patients are evaluated at 6 months follow-up (now ongoing).
Results: To date, 131 patients (mean age 62.6±13.8; 56% females) have been evaluated at baseline. Overall, they show high percentages of somatization (71% of the sample), sleep disturbances (70%), depressive (40%), and obsessive-compulsive (38%) symptoms, together with moderate levels of catastrophizing (18.4±9.4 on the 0-36 range of the catastrophizing CSQ subscale), and a personality profile characterized by health worries (26%), somatic complaints (19%), and cynism (26%). Overall, they perceive a moderate level of self-efficacy (30.83±4.9 on the 0-40 range of the G-SES) and good family or social support (84%).
Conclusions: Patients with CNP who are candidates for SCS show a peculiar psycho-social profile in terms of personality traits, coping strategies, and psychopathology. Using a pre-implant psycho-social assessment has significant implications for clinical practice since it allows to identify patients at a higher risk of SCS failure. It also enables the early detection of individuals who may benefit from psychological support before or after the SCS procedure.

Mental health and disability among patients with chronic sciatica

I. Sellami[1]*, A. Feki[2], A. Abbes[1], H. Bejaoui[3], Z. Gassara[2], M. Hajjaji[1], M. L. Masmoudi[1], K. Jmal Hammami[1], M. H. Kallel[2], H. Fourati[2] and S. Baklouti[2]

[1]Occupationnal medecine; [2]Rheumatology, CHU Hedi Chaker and [3]physical medicine and functional rehabilitation, CHU Habib Bourguiba, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1898

Introduction: Sciatica pain represents a typical symptom of spinal radicular syndromes. Disability due to this pain can affect mental health of patients.
Objectives: Our study aims to assess the relationship between mental health and disability among patients with chronic sciatica.
Methods: We conducted a descriptive, analytical and cross-sectional survey among patients suffering from documented common sciatic pain evolving for more than 3 months. We collected socio-professional data. We used the Hospital Anxiety and Depression Scale (HADS) and the Oswestry Disability Index (ODI).

Results: Our study population was exclusively female, including 69 patients. The mean age of participants was 56.2 ±12.6 years. The most frequent etiology of sciatica pain was a herniated disc, followed by lumbar spinal stenosis and spondylolisthesis. The root path was L5 in 49 cases and S1 in 20 cases. The mean Oswestry score was 25 ± 4.1. The disability was moderate, severe and crippled respectively in 10.1%, 82.6% and 7.2% of patients. Regarding the patients' anxiety levels, it was found that 76.8%, 20.3%, and 2.9% appeared to have mild, moderate, and severe anxiety, respectively. As for the depression levels of patients, 13 were mildly depressed (18.8%), 20 were moderately depressed (29%), and 36 were severely depressed (52.2%). We found that anxiety and depression were correlated with disability ($p = <0.05$, $r = 0.2$).
Conclusions: Our findings highlight a correlation between altered mental health and disability among patients with chronic sciatica. It is crucial to screen psychiatric disorders among these patients in order to improve their well-being.

Digital tools for training speech therapists: diagnosis of speech disorders in children

A. Akhmetzyanova[1]*, Z. Egorova[1] and T. Artemyeva[1]

[1]Department of Psychology and Pedagogy of Special Education, Kazan Federal University, Kazan, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1899

Introduction: The evolution of digital technologies creates new potential in training specialists who work with children with speech development disorders (6A01.0, ICD-11). The use of digital tools, such as video cases depicting real or simulated speech disorders, provides more opportunities for students to acquire practical diagnostic skills in classroom settings before encountering real individuals with speech disorders.
Objectives: Identifying the attitudes of students, future speech therapists, towards the use of classroom-based diagnostic simulation as a form of training.
Methods: Sixty-two second-year students in the Speech Therapy program were surveyed. The future specialists were asked to anonymously answer open-ended questions about which training methods they consider most effective for enhancing their competencies in diagnosing children with speech disorders.
Results: Forty-three students indicated that they would like to increase the number of practical hours in pre-schools and schools, where they can observe real cases of speech disorders. Thirty-nine students responded that during classroom sessions and self-study, they would like to have unlimited access to video materials showcasing the widest possible range of speech disorders.
Conclusions: Future speech therapists are highly interested in the practical study of speech disorders. However, during their internships, students are often limited in their access to diverse range of examples of the disorders. Creating an educational digital resource featuring video cases which allows students to study cases of speech disorders not only during class time but also during independent work at their own convenience and pace will significantly contribute to successful development of diagnostic competencies. Specifics of anticipatory competence of adolescents with motor disorders

A. Akhmetzyanova[1]*, T. Artemyeva[1] and V. Nikiforova[1]

[1]Department of Psychology and Pedagogy of Special Education, Kazan Federal University, Kazan, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1900

Introduction: Anticipatory competence allows an adolescent to act and make important decisions in life and activities with a certain temporal-spatial foresight. However, due to their disorder, adolescents with motor impairments are not always able to anticipate the development of future events, and they experience difficulties in establishing social contacts and understanding the emotional states of others.
Objectives: To study the specifics of anticipatory competence in adolescents with motor disorders.
Methods: The study involved 46 adolescents (aged 12-15) attending educational institutions for children with disabilities, with a history of spastic diplegia, spastic tetraplegia, and ataxia. The research employed the following methods: the "Achenbach's Questionnaire," V.D. Mendelevich's "Test of Anticipatory Competence," V.P. Ulyanova's "Anticipation of the Outcome of a Situation with Norm Violations," and the authors' method "Study of Anticipatory Competence of Adolescents" by A.I. Akhmetzyanova and T.V. Artemyeva.
Results: The study revealed that, although the overall level of anticipatory competence in adolescents with motor disorders is quite high, these children experience difficulties in spatial orientation and in structuring a sequence of actions. They encounter challenges in planning future activities and they frequently experience delays. Adolescents with this pathology demonstrated low anticipatory competence in virtual reality, indicating difficulties in virtual communication with others.
Conclusions: The findings of this study on the specifics of anticipatory competence in adolescents with motor disorders will help develop and implement programs for the social adaptation of children, preparing them for future professional activities and independent living in the community.

Regulation of the Subjective Experience of Safety in Humor among Younger Schoolchildren

A. Akhmetzyanova[1]*, T. Artemyeva[1] and I. Artemyeva[2]

[1]Department of Psychology and Pedagogy of Special Education, Kazan Federal University, Kazan and [2]Institute of Pedagogy and Psychology, Moscow State Pedagogical University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1901

Introduction: Laughter can be regarded as a distinct form of cathartic experience, arising from the violation of various well-established cultural norms. The balance between the emotions of laughter and fear depends on the extent and nature of the norm violation, as well as the specifics of its perception. The development of regulatory functions enables younger schoolchildren to comprehend increasingly complex forms of humor, which involve the transgression of cultural norms—ranging from behavioral violations to breaches of logical and linguistic norms.
Objectives: To examine the specific features of humor perception and production by younger schoolchildren, as well as the potential for regulating their subjective experiences of danger and safety in situations involving norm violations in humor.
Methods: The empirical study involved 360 younger schoolchildren (aged 7-10). The "Sometimes It Happens" (T. Artemyeva) method was used to study humor. The analysis of the schoolchildren's responses was based on the following indicators: identification of rules (norms) in academic, extracurricular, and family interaction situations; the creation of humorous event scenarios; and the selection of event outcomes (adaptive or maladaptive humor).
Results: The study revealed that the development of regulatory functions in younger schoolchildren allows them not to fear violating certain cultural norms or rules of social interaction in a joke. The positive correlation between maladaptive event outcomes and the identification of norms and rules by younger schoolchildren indicates the development of their regulatory function, mastery over their own cognitive processes, and their ability to interpret "dangerous" or "fear-inducing" scenarios as subjectively non-threatening, allowing them to emotionally distance themselves from such situations. Younger schoolchildren recognize the potential of humor in violating cultural norms, understanding that something in the event does not occur as it should according to the rule. In the child's view, adherence to cultural norms guarantees a sense of safety in interactions with adults and peers.
Conclusions: The findings of the study provide a foundation for the development of programs aimed at enhancing the regulatory functions of younger schoolchildren.

EPV1352

Psychometric Properties of the Arabic Version of the Mini-IPIP Five-Factor Personality Scale in Kuwait

B. M. Alansari[1]

[1]Department of Psychology, University of Kuwait, Shuwaikh, Kuwait
doi: 10.1192/j.eurpsy.2025.1902

Introduction: The Mini-IPIP, a 20-item short form of the 50-item International Personality Item Pool-Five-Factor Model measure (Goldberg, 1999), with promising psychometric properties, The Mini-IPIP describes personality in terms of the Five Factor Model, namely Neuroticism, Extraversion, Openness to Experience, Agreeableness, and Conscientiousness. The Mini-IPIP appears to be an alternative to the Ten-Item Personality Inventory (TIPI), and the Big Five Inventory (BFI).
Objectives: The study aims to investigate the psychometric properties of the Arabic version of the Mini-IPIP.
Methods: The Arabic version of the Mini-IPIP scales, and the TIPI was administered to1560 Kuwait university undergraduates (576 males mean age = 21.82±0.70 and 984 females; mean age = 20.95±1.31). The internal consistency reliability, factor structure, and convergent validity of the Mini-IPIP with TIPI & BFI were assessed.
Results: Cronbach's alpha was satisfactory for N (0.82), E (0.73), O (0.75), A (0.81) and C (0.80). Results revealed significant gender differences in N with a favor for females and in E, O & C with a favor for males. PCA showed that Mini-IPIP five factors explains 71.05 % of the total variance. The Mini-IPIP demonstrated good convergent validity with the BFI (r =71, .76, .77, .82, .67 for E, A, C, N, and O, respectively) and with the TIPI (r = .46, .49, .66, .69, .58 for E, A, C, N, and O, respectively).
Conclusions: The findings support the psychometric properties of the Arabic version of the Mini-IPIP as a useful tool for researchers needing a short assessment of the Big Five in research.

EPV1353

Psychometric Properties of the Arabic NEO-FFI-3 among Undergraduates in Kuwait

B. M. Alansari[1]

[1]Psychology, Kuwait University, Shuwaikh Campus, Kuwait
doi: 10.1192/j.eurpsy.2025.1903

Introduction: The reproduction of the structure of the NEO-FFI has been stable across different Arabic cultures. The NEO Five-Factor Inventory-3 (NEO-FFI-3) is the revised version of the NEO-FFI-R, which describes personality in terms of the Five Factor Model, namely Neuroticism, Extraversion, Openness to Experience, Agreeableness, and Conscientiousness. The psychometric properties of the NEO-FFI-3 present a robust verification base in diverse cultures. Although there is an Arabic version of the NEO-FFI, the psychometric properties of the Arabic NEO-FFI-3 are yet unknown.
Objectives: The study aims to investigate the psychometric properties of the Arabic adaptation of the NEO-FFI-3.
Methods: The Arabic version of the NEO-FFI-3 is a 60-item questionnaire, and the NEO-FFI-R 60-item questionnaire was administered to1373 Kuwait university undergraduates (559 males mean age = 20.41±1.43 and 814 females; mean age = 20.60±1.18). The internal consistency reliability, factor structure, and convergent validity of the NEO-FFI-3 with NEO–FFI-R were assessed.
Results: Cronbach's alpha was satisfactory for N (0.72), E (0.82), O (0.79), A (0.82) and C (0.74). Results revealed significant gender differences in N, O & C with a favor for females. PCA showed that NEO-FFI-3 five factors explains 53.98% of the total variance. However, the high mean correlations between the NEO-FFI-3 and NEO–FFI-R scales, with coefficients of (0.87) for the N, (0.85) for the E, (0.84) for the C, (0.78) for the O, and (0.77) for the A.
Conclusions: The findings support the psychometric properties of the Arabic adaptations of the NEO-FFI-3 as useful instruments for assessing the Big Five.

Adherence to treatment in patients with borderline personality disorder (BPD) with gynecological cancer

M. Garza[1], A. Alcorta[2]*, C. Martinez[2] and A. Cantú[2]

[1]Hospital Universitario Dr José Eleuterio González, Monterrey, Mexico and [2]Psicooncología, Medicina de Enlace y Cuidados Paliativos, Hospital Universitario Dr José Eleuterio González, Monterrey, Mexico
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1904

Introduction: The presence of borderline personality disorder (BPD) in cancer patients can be a risk factor for adherence to oncological treatment.
Objectives: To analyze problems related to adherence to treatment of patients with borderline personality disorder (BPD) in comorbidity with gynecological cancer.
Methods: Clinical histories and subsequent interviews of patients ("A" and "B"), both 25 years of age. "A" with a diagnosis of Cervical Cancer in 2022, without adherence to treatment, irritable, unmotivated, with emotional instability in her relationships, chronic emptiness, impulsivity, risky sexual behaviors, self-harm, and suicidal thoughts. B, diagnosed with endometrial cancer in January 2023, presents treatment adherence with extreme fear of abandonment, irritability, anhedonia, anxiety, low self-esteem, impulsivity, and suicidal ideas. Both receive psychotherapy at the Psychooncology and Palliative Care clinic. Scales from the General Health Questionnaire (GHQ-28) and McLean Screening Instrument for Borderline Personality Disorder were applied.
Results: Anxiety, lack of control, and rebellion manifested A's lack of adherence. B's "adherence" is redefined as separation anxiety, currently deposited in her partner and the oncology team. They evoked physical and sexual violence experienced since childhood and drug abuse, which influenced her anger and attitude towards cancer treatment for being "captives" of the disease. Thus, she denied A her dependency needs and B her fear of her partner's abandonment and her suicidal thoughts.
Conclusions: Internal conflicts are expressed through self-destructive behavior: addressing her fears allowed her to continue treatment. Psychotherapy limited his judgment, cognitive, and reasoning lapses. They mentalized stories of abuse, early violence, and behaviors that limited their quality of life before and after cancer, improving their treatment adherence.

Give me my pudding: a case report of hoarding symptoms in a first psychotic episode of a woman with schizotypal personality

M. Almada[1]*, T. Pessoa[1], A. Miguel[1] and R. Correia[1]

[1]Psychiatry, ULSGE, Vila Nova de Gaia, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1905

Introduction: Schizotypal personality disorder is characterized by social and interpersonal deficits, eccentric behaviour, unusual beliefs, magical thinking and blunted affect, and it may represent a predisposition for psychosis. Hoarding disorder, which has recently been recognised in ICD-11, is defined by accumulation and persistent difficulty in discarding ordinary possessions, leading to interfering levels of clutter that compromise the use or safety of living spaces. Hoarding behaviour can occur in a variety of neuropsychiatric disorders, including psychotic disorders. Research suggests an association between schizotypal traits and hoarding symptoms including cognitive deficits, emotional dysregulation or impaired insight, which are also characteristic of psychosis.
Objectives: We aim to present a case of hoarding disorder in a woman with schizotypal personality traits which presented with a first psychotic episode at her fifties.
Methods: We describe a case report and a non-systematic review on the subject.
Results: A 55-years-old woman was admitted to psychiatric emergency department with behaviour changes, marked by significant neglect in self and health-care in addition to social and emotional isolation. She also exhibited somatic, persecutory and autoreferential delusions, as well as auditory hallucinations. She believed that her body had no production of saliva and her meals mostly consisted of chocolate pudding, since she was convinced this was the only food her organism could tolerate. As a consequence, her nutrition was fairly neglected and severe potassium deficits were observed with electrocardiogram changes and fainting episode. Beyond these symptoms, a severe hoarding pattern was found which had worsened over the last years. Supported by family meetings and psychological personality assessment, dysfunctional personality traits stood out, with a difficulty in interpersonal relationships and adaptation to external reality. During hospitalization, we found that psychotic symptoms had months of evolution. Antipsychotic medication was initiated (Paliperidone) with significant improvement of symptomatology, but not full remission.
Conclusions: Upon a comprehensive assessment, we concluded that the patient's dysfunctionality was mainly due to schizotypal personality disorder rather than the acute psychotic episode. This case also suggests the importance of assessing personality traits, in particular schizotypal, in patients with hoarding symptoms. An overlap between hoarding symptoms and schizotypy has previously been reported in literature. Therefore, we highlight that distinction among schizotypal personality traits, psychotic and hoarding symptoms can be challenging among clinical practice. In overall, a broad assessment of symptoms is warranted in order to better understand what is in the basis of patient's dysfunctionality and ensure and effective treatment.

The impact of a mentalization-based psychotherapy program on borderline personality disorder hospitalizations: a protocol for a 20-year analysis using electronic health records

M. Azevedo[1], E. Osório[2,3], R. Barranha[2,3]* and A. R. Ferreira[3,4]

[1]Faculty of Medicine, University of Porto; [2]Psychiatry Service, Unidade Local de Saúde de São João; [3]Department of Clinical Neurosciences and Mental Health, Faculty of Medicine, University of Porto and [4]CINTESIS@RISE, Faculty of Medicine, University of Porto, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1906

Introduction: Borderline personality disorder (BPD) is a severe and complex mental disorder and a major contributor to disability, health-care costs, and societal expenses worldwide. BPD is associated with considerable functional impairment and high healthcare utilization, often co-occurring with other mental disorders such as depression, substance use disorders, and bipolar disorder, further entangling its presentation. Coupled with the high risk of self-harm and suicidal behaviours, this calls for an evidence-based treatment, with a timely intervention to reduce both individual suffering and intensive care utilization. BPD treatment remains challenging. With its neurobiological underpinnings yet to be fully clarified, no medication is specifically approved for BPD, being psychotherapy approaches the treatment of choice. However, since not all patients respond sufficiently to psychotherapy, further research in this area is of utmost importance.
Objectives: To assess the impact of a structured mentalization-based therapy (MBT) program on the number and length of psychiatric hospitalizations of patients with a discharge diagnosis of BPD.
Methods: An observational retrospective study will be conducted using routinely collected health data from adult patients admitted to the inpatient unit in the psychiatry service of the Unidade Local de Saúde de São João (ULSSJ), a University Hospital in Porto, Portugal. Using data from 2003 to 2023, a 20-year analysis will be performed, allowing for the comparison of hospitalizations before and after the program introduction. The study was approved by the Ethics Committee of ULSSJ under the approval n.º 337-23.
Results: The number and length of hospitalizations before and after the implementation of this program will be compared, to evaluate its impact. Findings will be reported using the RECORD guidelines and disseminated via publication in peer-reviewed journals.
Conclusions: With this analysis we expect to enhance the understanding of the impact of psychotherapies on this disorder and, hopefully, demonstrate that implementing a MBT program for BPD patients may lead to a decrease in the number and length of hospitalizations due to BPD, which may be indicative of more effective treatment and lower healthcare costs associated with this disorder.

EPV1357

Borderline pattern - an indicator of the severity of personality disorders

A. Bogdanovska Toskic[1]* and S. Arsova Hadzi-Angjelkovska[2]
[1]Psychiatry, General Hospital, Kumanovo and [2]University Clinic of Psychiatry, Skopje, North Macedonia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1907

Introduction: The borderline pattern is an optional diagnostic specification in ICD 11 that includes the diagnostic criteria for borderline disorder. With the introduction of the dimensional diagnosis of personality disorders by grading the severity of the disorder and determining the pathological traits, a debate has been opened about the need for the borderline pattern specifier.
Objectives: The objective of the study is to determine the relationship of the borderline pattern with the level of personality functionality and its role in the differentiation of patients with and without personality disorder.
Methods: An analytical cross-sectional study was conducted to determine the degree of severity of personality disorder and borderline pattern in patients diagnosed with personality disorder according to ICD 10 compared to healthy individuals. LPFS-BF-2.0 was used to assess the degree of personality functioning, and BPS was used to assess the existence and intensity of a borderline pattern.
Results: Two groups between the ages of 18 and 65 were included in the study, the first of 17 people (*N* 17, 41% women) (mean age 34.29, SD 13.85) with a diagnosed personality disorder according to ICD 10 and the second a control group of 22 healthy subjects (*N* 22, 59% female) (mean age 33.18 years, SD 11.76). The first respondent group had LPFS-BF-2.0 scores of 29.88 (SD 4.93) and BPS 38.06 (SD 7.3). The control group had LPFS-BF-2.0 scores of 17.22 (SD 3.99) and BPS 20.09 (SD 6.05). A high correlation was found between LPFS-BF-2.0 and BPS, $r(39)=0.82$ $p=0.0000$. The differences between the two groups were high both according to the level of personality functionality $t(37)=8.849$ $p<0.00001$ and according to the intensity of the borderline pattern $t(37)=8.401$ $p<0.00001$.
Conclusions: According to the obtained results for the high correlation between the intensity of the borderline pattern and the level of functionality of the person, it is concluded that the borderline pattern is an indicator of the degree of severity of a personality disorder. The significant difference between the levels of personality functionality and the borderline pattern in both groups can be used in the differential diagnosis of persons with and without personality disorder and other mental disorders, which would have implications for the therapy plan.

Disclosure of Interest: None Declared

EPV1358

Shoplifting as disinhibition in individuals with a borderline pattern

A. Bogdanovska Toskic[1]* and S. Arsova Hadzi-Angjelkovska[2]
[1]Psychiatry, General Hospital, Kumanovo and [2]University Clinic of Psychiatry, Skopje, North Macedonia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1908

Introduction: Pathological traits according to the dimensional diagnostic system for personality disorders include a certain set of emotional, cognitive and behavioral features. In different people, a certain trait manifests itself in a different behavioral form, while the same trait can manifest itself in several people similarly.
Objectives: To analyze shoplifting in individuals with borderline personality disorder through pathological traits.
Methods: A non-systematized literature review was performed, with keywords: borderline personality disorder, shoplifting, and a case series was presented.
Results: This is a series of three cases of people with borderline personality disorder, who were also assessed according to ICD 11 criteria with LPFS-BF 2.0, PSQ-11 and BPS. The first person is a female, 20 years old, a student, LPFS-BF 2.0 - 34, on PSQ-11 elevated values for all pathological traits, except for anankastia and BPS – 47. She is occasionally depressed and continuously abuses marijuana for a long period of time. The second person is the also female, age 21, student, LPFS-BF 2.0 - 31, on PSQ-11 elevated values for negative affectivity and disinhibition and BPS – 46.

Occasionally has obsessive controlling and criticizing thoughts and several episodes of self-harm, incidental substance abuse. The third person is a 20-year-old male, unemployed, LPFS-BF 2.0 - 32, PSQ-11 elevated values for negative affectivity and disinhibition and BPS – 41. He is occasionally paranoid, has a history of self-harm and occasional excessive use of benzodiazepines. All three give information that they occasionally steal from markets and large stores, but they do not steal from people. As a reason for stealing, they cite a lack of funds at a given moment for a particular item they wanted, but also the need to steal, the inability to refrain and the excitement they feel at that moment.

Conclusions: Negative affectivity and disinhibition appear as common pathological traits in all three people. Disinhibition, characterized by impulsivity due to a rush of immediate emotions and thoughts, without thinking about the consequences and the need for immediate gratification, manifests itself in these individuals through shoplifting. Occasional shoplifting, without practice of other forms of stealing, is a disinhibitory phenomenon.

Evaluation of a psycho educative group intervention for family members of patients with severe personality disorder undertaken within a mental health centre in Forlì, Italy

R. Casadio[1], A. Campana[1], L. Nervegna[1], C. Barbara[1] and M. Pacetti[1]*

[1]DSMDP, CSM Forlì, forlì, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1909

Introduction: Severe personality disorders have a significative impact not only on patients but also among their families, causing emotional distress and relevant burden related to care giving. Psycho-educational intervention targeting family members can improve their understanding of the disorder and their ability to cope with symptoms.

Objectives: Forlì Mental Health Centre multi-professional team undertake this study with the scope to evaluate the efficacy of a nine sessions' psycho-educational program targeting a group of family members, based on the dialectical behavioral therapy (DBT) principles and skills.

Methods: 12 participants completed the program and filled self report questionnaires administered at the first (t0) and ninth (t1) session: Symptom Checklist - 90 (SCL-90) and Zarit Burden Interview (ZBI). They also answered a qualitative format investigating their subjective experience.

Results: Results at baseline (t0) indicate high scores on the SCL-90 subscales such as Somatisation (mean = 1,21; st. dev = 0,91), Depression (mean = 1,08; st. dev = 0,86), Sleep disturbances (mean = 1,39; st. dev = 1,03).

Statistical analysis suggest an increase of SCL-90 subscales, at the end of the program (t1), such as Somatisation (mean = 1,38; st. dev = 0,85), Obsessions and compulsions (mean = 1,19; st. dev = 0,78), Depression (mean = 1,40; st. dev = 0,93), Paranoia (mean = 0,93; st. dev = 0,78), Sleep disturbances (mean = 2,18; st. dev = 1,03). ZBI questionnaire total scores indicate an increase of perceived caregiving burden(mean = 42; st. dev = 24,7). Qualitative indicators were administered at the end of the program showing a general satisfaction for the intervention described as "useful", "important", "helpful", "comforting". The most liked session was the one about "validation" skill.

Conclusions: Despite the perceived psychological distress and burden' increase, participants have intended the psycho-educative program as useful and worth it. Results suggest that their learnings may be paired with complementary skills and their generalization to enable a significative reduction of psychological impact of caregiving. Future development will include a follow up session to explore this possibility.

EPV1361

Efficacy of transcranial magnetic stimulation in borderline personality disorder

M. Chelidze[1]*, M. Chelidze[1] and M. Chelidze[1]

[1]Psychiatry, Todua clinic, Tbilisi, Georgia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1910

Introduction: Transcranial Magnetic Stimulation is non-invasive neuromodulation technique that manages various mental disorders, including Borderline Personality Disorder (BPD) that is characterized by impulsive behavior, emotional lability, aggressiveness and unstable mood. TMS may decreases some core symptoms of borderline personality disorder by targeting specific brain regions involved in emotion regulation, aggression management and impulse control.
magnetic fields stimulate nerve cells in prefrontal cortex, involved in emotional regulation, also influences neural circuitry, that diminish symptoms like aggressiveness, dysregulation and problems in interpersonal relationships.

Objectives:

- **Treatment effectiveness assessment in reducing symptoms like problems in interpersonal relationships, mood swings, impulsivity, aggressiveness, sometimes paranoid ideations**
- **management of affect, anxiety and depressive states**
- **Changes in neural circuitry:** alterations in brain activity patterns
- **Safety profile** of TMS in individuals with BPD, also adverse reactions
- self assessment of the pationt regarding symptom relief
- **Compare with medications**

Methods: Type of Study: Randomized controlled trial (RCT)

Duration: 10-14 weeks

Setting: Outpatient department of Todua clinic

Inclusion Criteria:

- Adults aged 18-65 y
- Diagnosis of Borderline Personality

Exclusion Criteria:

- Contraindications (e.g., metal implants in the skull or brain)
- substance abuse disorder or psychiatric illness (cognitive disorder, schizophrenia, bipolar disorder)

Results: The results have shown a really promising outcome:

1. **reduced symptom severity: impulsivity, aggressiveness, self-harming, emotional instabiliyu, mood swings, improved mood and decreased anxiety and depressive states.**
2. **Changes in neuronal circuits:** TMS changed total brain activity in a positive way, it regulated limbic system functioning tha correspondingly improved the symptoms.

3. **This technique is really safe and very well tolerated with** few side effects, most of them were mild, such as headache.
4. **Improved Quality of Life**

Conclusions: In conclusion, Transcranial Magnetic Stimulation leads to significant reductions in main symptoms, such as mood swings, impulsivity, aggressiveness, emotional dysregulation and self harm. moreover, this technique is very well-tolerated, with minimal side effects, like mild headache.
Changes in brain activity shows how TMS facilitates symptom improvement, especially when combined with psychotherapy or medications.
TMS promises to be an innovative technique nin the management of core symptoms of BPD and improving patients' quality of life.

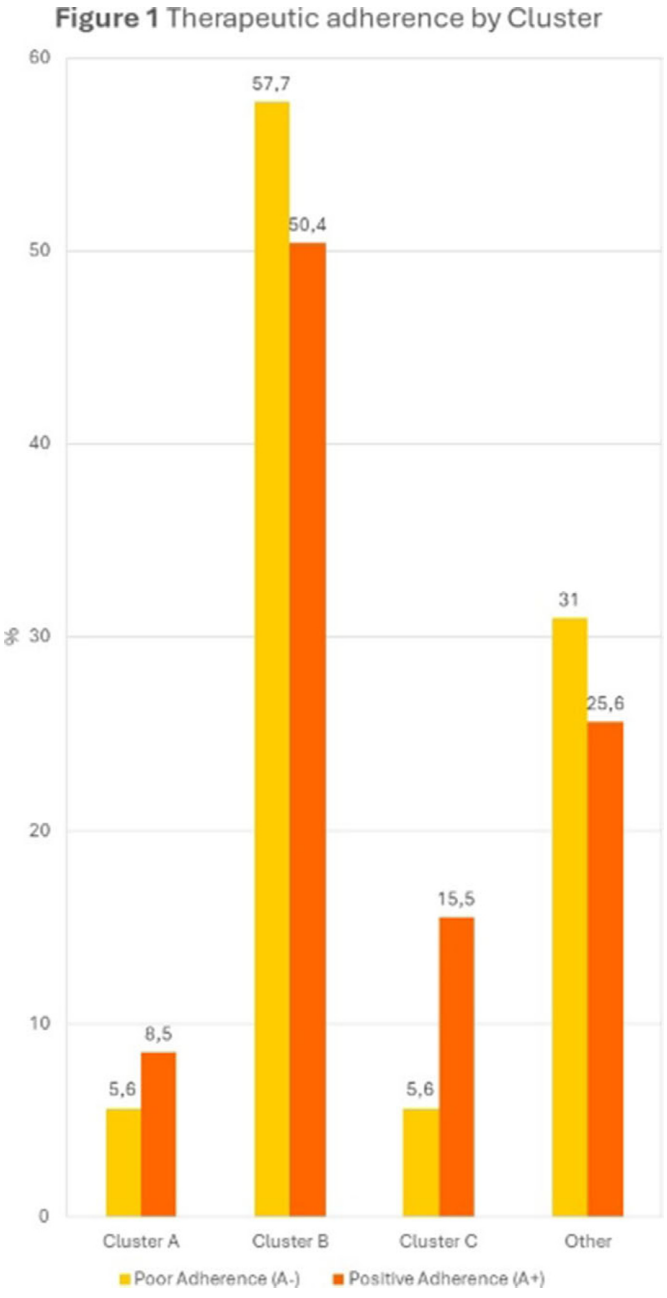
doi: 10.1192/j.eurpsy.2025.1911

Introduction: Personality disorders (PD) are defined as enduring and pervasive patterns of internal experience and behavior that deviate markedly from the expectations of the individual's culture, causing distress and functional impairment (APA, 2013). Pharmacological therapy can be crucial to manage specific symptoms or psychiatric comorbidities, improving the quality of life of these patients. Adherence to pharmacological treatment is often reduced in patients with PD, representing a significant challenge for clinicians (Åkerblad et al., 2008). Few studies have explored this topic, highlighting the need for further research.
Objectives: The aim of the present study was to assess medication adherence in patients with primary diagnosis or comorbidity of PD in different clinical settings of an Italian psychiatric department, considering clinical and socio-demographic differences.
Methods: A sample of **200 patients diagnosed with PD** was recruited from various psychiatric services from the Department of Psychiatry at Luigi Sacco University Hospital, in Milan. Diagnoses were made through a structured clinical interview based on DSM-5 criteria (APA, 2013). The patient's adherence to treatment was evaluated using the **Clinician Rating Scale (CRS)**, with a cut-off of ≥ 5 defining adherence subgroups [**Positive Adherence (A+): score ≥ 5; Negative Adherence (A-): score < 5].**
Results: Positive adherence to pharmacological treatment was observed in **64.5%** of the sample, with significantly higher rates in patients with **Cluster C**(15.5% vs. 5.6%, p<0.005)(Figure 1). Furthermore, higher rates of positive adherence emerged in patients with a **positive family history** (60.3% vs 45.5%, p < 0.005). Finally, the analyzes between the different clusters revealed a significantly **higher lifetime prevalence of suicidal thoughts in Cluster B** (63.0%, p<0.05) and that the **majority of Cluster A** (60%, p<0.05) came **from territorial mental health services**, while the **majority of Cluster C** (66.7%, p<0.05) **from day hospital services** (Figure 2).

Image 1:



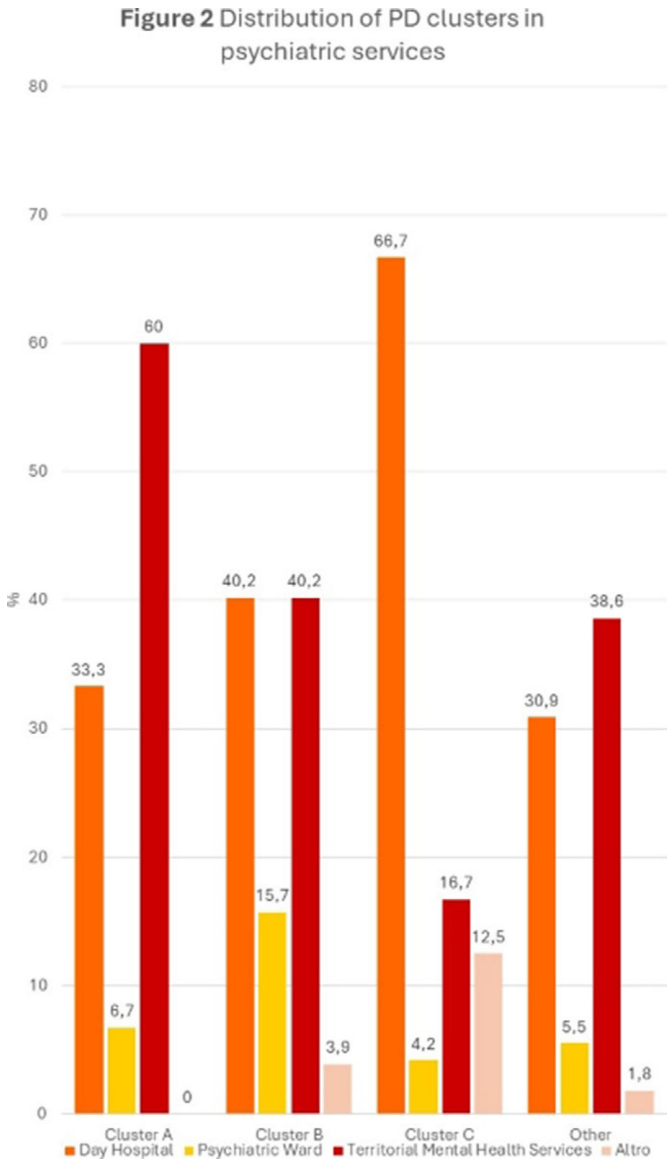


Image 2:

Conclusions: The study found significantly higher treatment adherence rates in Cluster C patients, suggesting a **possible link between the anxious traits characteristic** of this group **and greater compliance**. Furthermore, a positive family history was associated with higher adherence rates, highlighting **the role of family influences in adherence**. Analyzing the differences between socio-demographic and clinical variables in the different clusters, it emerged that the prevalence of lifetime suicidal thoughts was significantly higher in Cluster B and that the patients in Cluster A mainly came from local mental health services and those in Cluster C from day hospital services. These findings highlight **the importance of personalized interventions to meet the specific needs** of each Cluster in order to optimize treatment adherence and therapeutic outcomes.

Challenges of the Maternal Role in Women with Schizotypal Personality Disorder

N. Curk Fišer[1]

[1]Intensive Care Unit, University Psychiatric Clinic Ljubljana, Ljubljana, Slovenia

doi: 10.1192/j.eurpsy.2025.1912

Introduction: Children born to mothers with mental health disorders are at a significantly increased risk of developing insecure attachment patterns.

Objectives: Demonstrate with clinical case that mothers with schizotypal personality disorder tend to be less sensitive and responsive, and more intrusive in their interactions and caregiving (Høivik et al. BMC Psychiatry Int 2018; 18, 198; Willinger et al. ANZJP Int 2002, 36, 5; Vebeke et al. al. APA Int 2017, 8 54-63; Ripoll et al.).

Methods: The clinical case presented below highlights functional decline in a woman with schizotypal personality disorder during pregnancy and the transition to motherhood.

Results: The 39-year-old mother of a 16-month-old son, employed as a saleswoman, has been in outpatient psychiatric treatment for 6 years. She has been hospitalized 6 times, 4 of which occurred in the year after childbirth.

Her psychiatric history began at age 33, when she was first admitted due to an impulsive outburst, involving aggression toward objects. Psychological evaluation revealed impulsivity alongside paranoid ideation. Treatment (aripiprazole, quetiapine, and paroxetine) led to clinical improvement, and she continued psychotherapy for psychosis. For 5 years, she maintained regular employment, entered a relationship, and became pregnant, at which point she discontinued pharmacotherapy.

At 32 weeks of pregnancy, she became disorganised, refusing food and gynecological examinations, leading to psychiatric hospitalization. A combination of haloperidol, quetiapine, and lorazepam stabilized her condition, although negative symptoms, cognitive impairments and schizotypal features persisted. She gave birth to a healthy son via planned cesarean section and continued postnatal care under a psychiatrist and clinical psychologist.

Within the year postpartum, she experienced 4 additional hospitalizations, primarily due to mood destabilization linked to non-adherence to oral and depot pharmacotherapy. Each time, her condition improved upon reintroduction of therapy. By her penultimate discharge, a social coordinator was appointed, as she struggled with childcare, expressing emotional detachment from her child. Her fourth hospitalization was characterized by disorganization and impulsivity, after which she ended her relationship with her partner. Currently, she resides with her mother and remains on quetiapine, clozapine, and aripiprazole. With her consent, her partner and his mother assumed childcare responsibilities. The patient reports feeling emotionally relieved and stable, and has agreed to resume depot pharmacotherapy.

Conclusions: This case underscores the importance of early identification and timely intervention in perinatal psychiatry. Effective treatment of maternal mental illness, doesn't necessarily lead to secure attachment formation between mother and child, nor does it guarantee better cognitive or socio-emotional outcomes in the offspring.

The effect of a specialised intervention program for borderline personality disorder on the need for acute hospitalisations: A retrospective observational study

I. da Fonseca Pinto[1], A. L. Cardoso[1], A. da Silva Moreira[1], C. Sousa Reis[1], H. Ginja[1], I. Mangas Palma[1], J. Tavares Coelho[1], E. Osório[1,2] and R. Barranha[1,2]*

[1]Department of Psychiatry and Mental Health, University Hospital Center of São João and [2]Department of Clinical Neurosciences and Mental Health, Faculty of Medicine of Porto University, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1913

Introduction: Borderline personality disorder (BPD) often results in recurrent acute hospitalisations, significantly burdening healthcare systems. Specialised intervention programs aim to stabilise patients and reduce hospital admissions. This study investigates the impact of a structured BPD Intervention Program at the Local Health Unit of São João on reducing the need for acute hospitalisations.
Objectives: The objective of this study is to assess the effect of integration into the BPD Intervention Program on the frequency of acute hospitalizations. Furthermore, we aim to investigate the relationship between clinical and sociodemographic factors, as well as the need for inpatient care.
Methods: This is a retrospective longitudinal study with quantitative statistical analysis of data from 293 patients referred for suspected BPD at the São João Local Health Unit. The analysis included 163 patients who had their BPD diagnosis confirmed. We collected data from hospital records, focusing on the number of hospitalisations before and after program admission. We also analysed variables such as the program's follow-up duration.
Results: The mean age at the time of the first evaluation was 24.6 years, with symptoms typically starting at a mean age of 14.2 years. The majority of participants (94%) were female. The program's integration led to a significant reduction in hospital admissions. Prior to the program, patients had an average of 1.01 hospitalisations per patient (median = 0). After integration, the average decreased to 0.66 hospitalisations per patient (median = 0). We are conducting further analyses to explore associations between additional factors and hospitalisation outcomes.
Conclusions: Integration into the BPD Intervention Program is associated with a decrease in acute hospitalizations. This clearly supports the idea that specific interventions can help stabilise BPD patients. The findings also highlight how personalised care can reduce strain on healthcare costs. Future research should evaluate the long-term benefits of the program, including its impact on the duration of hospital stays and the lasting effects of reduced hospitalisation rates after program completion.

Short Dark Tetrad - Polish version (SD4-PL) - examination of psychopathy, narcissism, Machiavellianism and sadism - preliminary psychometric properties of the tool in Polish conditions

P. Dębski[1,2]*, P. Pałczyński[2], M. Garczarczyk[2], M. Piankowska[2], K. Haratyk[2], M. Noras[2], M. Szostak[2] and M. Meisner[2]

[1]Department of Psychiatry, Faculty of Medical Sciences in Zabrze, Medical University of Silesia, Katowice and [2]Institute of Psychology, Faculty of Social Sciences and Humanities, Humanitas University, Sosnowiec, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1914

Introduction: The Dark Tetrad of Personality includes factors commonly recognized as socially aversive. So far, they have been recognized as psychopathy, narcissism and Machiavellianism. Nowadays, sadism has also been included in the scope of dark personality traits. There are many tools for examining the Dark Triad of Personality, while tools dedicated to the Dark Tetrad are under development. One such tool is The Short Dark Tetrad scale (SD4) by Paulhus et al. (2021), which, due to its popularity, may enable cross-cultural research in the future.
Objectives: The aim of the study was to assess the preliminary psychometric properties of the Short Dark Tetrad tool - Polish version (SD4-PL).
Methods: 972 people with an average age of 34.39±11.09 SD years were recruited for the study. The 28-item Short Dark Tetrad scale (SD4) was translated into Polish (SD4 Pl) and used for a study. As part of the statistical analyses, a confirmatory factor analysis (CFA) was used, based on the structural equation modeling. The internal consistency of the tool was also assessed.
Results: Confirmatory factor analysis (CFA) parameters turned out to be satisfactory. The original structure of the tool was maintained, which consists of four 7-item scales dedicated to psychopathy, narcissism, Machiavellianism and sadism. The obtained psychometric parameters turned out to be similar to the results obtained in several countries where the Short Dark Tetrad scale has already been introduced. Satisfactory measures confirming the reliability of the tool (Cronbach's α) were also obtained, ranging between 0.68 and 0.79.
Conclusions: Short Dark Tetrad - Polish version (SD4-PL) presents satisfactory psychometric properties. By maintaining the original structure of the tool, it opens the possibility of examining its equivalence with other language versions and, in the future, the possibility of conducting international research focusing on factors such as psychopathy, narcissism, Machiavellianism and sadism.

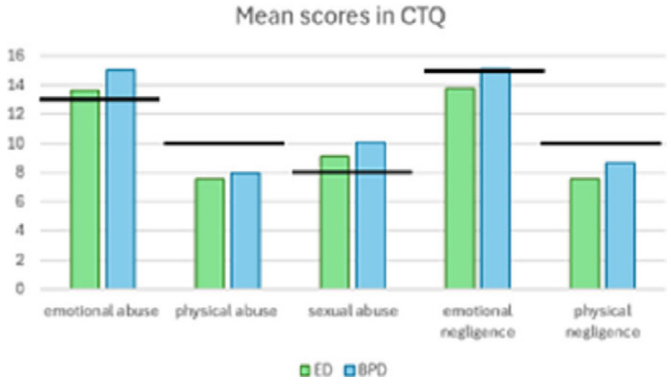
Childhood trauma as a transdiagnostic factor in Borderline Personality Disorder and Eating Disorders: Relation with Impulsive-Unstable Symptomatology



B. Marcos-Diaz[1,2]*, A. Gálvez-Marlín[1,2], N. Fuentes-García[1,2], P. Mola-Cardenes[1], J. M. López-Villatoro[1,2], A. B. Calvo-Calvo[2], M. Díaz-Marsá[1,2,3] and J. L. Carrasco[1,2,3]

[1]Hospital Clínico San Carlos; [2]Universidad Complutense de Madrid and [3]Centro de Investigación Biomédica en Red de Salud Mental, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1915

Introduction: Recent literature shows that childhood trauma might be associated with developing an eating disorder (ED) or borderline personality disorder (BPD) on the long term. These two

disorders have a great comorbidity, and they share many common symptoms.
Objectives: The aim of this study is to test if childhood trauma could be a transdiagnostic factor for both diagnostics, as well as analysing if trauma could be related to the severity of impulsive and instability symptomatology which characterize both of these diagnoses.
Methods: The sample consisted of 45 patients with a diagnosis of either ED (n=21) or BPD (n=24). Childhood trauma was assessed using the CTQ (Childhood Trauma Questionnaire). Impulsive-unstable symptomatology was assessed using the BIS (Barrat's Impulsivity Scale), CSV (Feeling of Emptiness Questionnaire) and STAXI (State-Trait Anger Expression Inventory), HARS (Hamilton's Anxiety Rating Scale), MADRS (Montgomery-Asberg Depression Rating Scale). Differences between groups were measured for the CTQ using the *t* test. The relationship between test results and trauma was measured via regression analyses.
Results: Both groups had high scores of emotional and sexual abuse, and the BPD group also showed high scores in emotional negligence. There were no statistically significant differences between groups relating to trauma symptoms (see *Figure 1*) Moreover, significant relationships were found between childhood trauma and higher levels of impulsivity (R^2adj = 0.14; p = .006), feelings of emptiness (R^2adj = 0.15; p = .005), anxiety (R^2adj = 0.13; p = .008) and depression (R^2adj = 0.08; p = .037).

Image 1:

Conclusions: Out preliminary study shows that childhood trauma is a transdiagnostic factor between BPD and EDs, and it's related to the aggravation of impulsivity and instability symptomatology.

Borderline Personality Disorder and Autism Spectrum Disorder: A Case Report

R. F. Dionísio[1]*, C. Portela[1], D. Areias[1], S. M. Sousa[1], M. F. Santos[1] and C. Fonseca[1]

[1]Hospital de Magalhães Lemos, Unidade Local de Saúde de Santo António, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1916

Introduction: Autism spectrum disorders (ASD) are underdiagnosed in women due both to diagnostic bias, and the quieter, less visible signs and symptoms of female autism. Distress generally only becomes manifest during mid childhood and adolescence, when mental illness gets misidentified as the primary cause. The symptomatic overlap of ASD and Borderline Personality Disorder (BPD) has been noted and at the cognitive level, ASD includes difficulties in reading others emotions and core cognitive features of BPD also include altered social cognition.
Objectives: The aims of this paper are to present a case report of a patient diagnosed with BPD and ASD and to provide a summary of the current literature concerning this double diagnosis.
Methods: A description of the case is made and relevant articles were identified by searching the following terms: "borderline personality disorder" and "autism/autism spectrum disorders". Research was restricted to articles concerning humans and published between 2014 and 2024 in English.
Results: The case report describes a young female of 19 years old that was evaluated in an emergency context due to suicidal ideation and was then referred to both psychiatry and psychology. She was diagnosed with BPD and ASD in adolescence while she was seeing a child psychiatrist. In the consultations she reports marked emotional dysregulation, irritability, difficulties in tolerating some textures and increased sensitivity to noise and light, as well as frequent worries about peer relationships and self-image with a need to do things differently to fit in.
Despite some controversial results and lack of homogeneity in the methods used for the diagnostic assessment, subjects with BPD reported higher scores on tests evaluating the presence of ASD compared to a non-clinical population and hypothesized the presence of unrecognized ASD in some BPD patients or vice versa, while also describing a shared vulnerability towards traumatic events.
Conclusions: This case illustrates a common and complex clinical challenge, where the double doses of emotional dysregulation and disrupted social interchange overwhelm either ASD or BPD approaches considered separately. Diagnostic differentiation is crucial toward targeted therapeutic interventions (psychopharmacological and psychosocial). It is still difficult to draw accurate conclusions based on the recent literature. Research in sex/gender difference is still limited, with heterogeneous results, and further studies are needed to enlighten the clinical similarities and diagnostic overlap between ASD females and BPD.

EPV1369

Male Hysteria: Main Psychopathological Theories and Clinical Presentations (Narrative Literature Review)

S. Elloumi[1]*, S. Kolsi[1], A. Bouaziz[1] and W. Abbes[1]

[1]Psychiatry, University hospital, Gabes, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1917

Introduction: Hysteria has been historically linked primarily to women; however, its importance in men has recently gained attention. This is why we found it interesting to study male hysteria. Therefore, understanding psychopathological theories offers a valuable framework for highlighting its clinical characteristics.

Objectives: Describe the main psychopathological theories of male hysteria and its key clinical specifications referring to the theories.
Methods: We conducted a narrative literature review of articles and thesis published between 2009 and 2022, using databases such as PubMed, Google Scholar, and HAS (Haute Autorité de Santé) with predefined keywords such as "men", "hysteria", "masculine" and "conversion". This review culminated in a narrative synthesis that aims a cohesive discussion integrating key findings from the literature.
Results: The bibliography first distinguished between two pairs in order to define masculine hysteria: Anatomical (male/female) and psychological (feminine/masculine), highlighting that masculine hysteria can occur in both men and women. Therefore, a male may identify with either masculine hysteria or feminine hysteria, the latter of which can be related to male homosexuality.
Research indicates that masculine hysteria is associated with theories of sexual identity conflict, which involve the repression of feminine traits and fears of castration. Additionally, cultural norms often restrict men's emotional expression, favoring strength over vulnerability, along with personal, relational, and environmental influences.
Clinical observations suggest that masculine hysteria typically presents with physical symptoms and dramatic expressions. The type and intensity of these symptoms may vary based on different early life experiences.
Conclusions: Referring to literature, the specific clinical signs leading to a diagnosis of men hysteria seem to be difficult to identify and not well developed. We also concluded that hysteria is too much related to lived gender rather than anatomical gender.

Alexithymic traits and dissociative episodes in borderline patients

S. Costantini[1], L. Ghidetti[2]*, M. Benassi[2], M. Pacetti[3], D. Salmaso[3] and R. P. Sant'Angelo[4]

[1]Mental Health, Ausl Romagna; [2]Psychology, University of Bologna, Cesena; [3]Mental Health Department, Ausl Romagna, Forlì and [4]Mental Health Department, Ausl Romagna, Cesena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1918

Introduction: The biopsychosocial theory (Paris, 1996) considers the complex interaction of biological, psychological, and social factors in the development and manifestation of borderline personality disorder. Among the environmental factors are unstable family relationships, unresolved traumatic experiences, and adverse life events that can foster alexithymia and dissociative defense mechanisms, as supported by several studies in the literature (Carano et al., 2011; Caretti et al., 2005; Macrì et al., 2022).
Objectives: The present study aims to investigate these constructs in a population of borderline patients admitted to the Psychiatry Department at Bufalini Hospital in Cesena.
Methods: The sample was selected using the SCID PD (Structured Clinical Interview for DSM-5), followed by the administration of the following scales: TAS-20 (Toronto Alexithymia Scale), DES II (Dissociative Experiences Scale), SHI (Self-Harm Inventory), and BSQ (Body Shape Questionnaire). Multivariate analyses were applied, including non-parametric correlations (Spearman's Rho) between variables using SPSS software.
Results: The sample consisted of 20 individuals (F = 17; M = 3) with a mean age of 27.57 years (SD = 7.83). Regarding the TAS, 85% of the participants reported clinically significant scores (Tot >50) compared to the healthy adult population, whose Italian mean is 44. For the DES, 70% of the sample reached clinically significant scores (Tot >30), whereas the healthy adult population scores below 10.
The data revealed a statistically significant positive correlation between high TAS-20 and DES II scores, indicating a relationship between alexithymia and dissociative symptoms. Furthermore, while a trend toward correlation was observed between TAS-20 and BSQ, as well as DES II and BSQ, and SHI and BSQ, these correlations were not statistically significant.
Conclusions: In line with previous literature, most individuals with borderline personality disorder exhibit alexithymia (85%) and experience dissociative episodes (70%). The present findings demonstrate a significant relationship between alexithymia and dissociative symptoms, highlighting how individuals with greater difficulty recognizing and describing their emotions tend to report more frequent episodes of depersonalization and derealization. This suggests that those with such difficulties may use dissociation as a defensive strategy to avoid intense emotions and stressful situations. Additionally, it would be valuable to further explore the relationship between body satisfaction, dissociative symptoms, alexithymia, and self-harm, as these manifestations may be linked to emotional processing difficulties. These findings contribute to a better understanding of emotional and dissociative dynamics in patients with borderline personality disorder and underscore the importance of integrated assessment during treatment.

EPV1371

The effect of LITHIUM in mood improvement in patient with borderline personality disorder; A systematic review

S. Ghorani[1]* and M. Zamir[1]

[1]Qazvin medical university, 22 bahman hospital, QAZVIN, Iran, Islamic Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1919

Introduction: Considering the need to conduct studies on the treatment of BPD and considering the high prevalence of this disorder and its negative effect on the quality of life, especially in young age range and possibility of this disorder being in the Bipolar spectrum, it is necessary to investigate the effect of lithium on mood improvement in patients with BPD. So, this study aimed to investigate the effect of lithium on mood improvement in these patients.
Objectives: Due to the lack of an FDA approved treatment, as well as discussed in the introduction, we dicided to compare the effect of lithiumin mood improvement in this disorder with the effect of other mood stabilizers and antipsychotics.
For this reason, we reviewed the published articles on the effects of other mood stabilizers and antipsychotics on improving the mood of this patints and compare them with those related to lithium in order to make better treatment decision.
Methods: This study presents a comprehensive review of the studies conducted related to the effect of lithium in improving mood in

BPD patients. We conducted a systematic review based on PRISMA guidelines of published and indexed articles from the following databases;
EMBASE, MEDLINE, Google scholar, SCOPUS.Cochrane Library, PsycINFO.
KEY WORD: Lithium, Mood stabilizer, borderline personality disorder. Of the 131 retrieved articles, 9 included our inclusion criteria.
Results: The review of 9 selected studies showed that lithium is useful in reducing emotional and impulsive behaviors, mood stabilization and suicidal tendencies and was more effective than placebo in preventing recurrence of mood disorders. In the study significant heterogeneity was found between all group of patients which could be due to the difference in the selection of participants and different exposure in the pre-study phase. Quantitative data on participants general health and social functioning were not reported and the direction of effect was the same in all studies.
Conclusions: No studies reported a negative effect for lithium and compared to other mood stabilization, it is more effective in controlling emotional and mood changes and aggression, also its side effects are less if controlled regularly and consistently. However, due to the small number of studies in this field and small sample size in studies, we suggest that more studies be conducted in all age groups.

The Psychopathology of Ink: Tattoos as a Window into Personality (Disorders)

T. Grahovac Juretić[1]*, A. Mančić[1], E. Dadić-Hero[1], M. Letica-Crepulja[1] and K. Ružić[1]

[1]Department of psychiatry, University Hospital Centre Rijeka, Rijeka, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1920

Introduction: Tattoos, once viewed primarily as symbols of rebellion or cultural affiliation, have become increasingly prevalent and socially accepted across diverse populations. This shift raises questions about the psychological motivations behind body art, particularly in individuals with personality disorders.
Objectives: These case studies explore the potential significance of tattoos in the context of personality psychopathology, examining how tattoos may serve as externalized representations of inner conflicts, identity fragmentation, and unmet emotional needs.
Methods: Through the lens of theory, we will discuss how tattoos can function as a form of self-expression and self-regulation, offering insight into defense mechanisms such as splitting, projection, and sublimation in individuals with borderline, narcissistic, and antisocial personality disorders.
Results: The presentation will also explore the therapeutic implications of tattoos, considering their potential as entry points for understanding the symbolic and emotional worlds of patients with personality disorders. We will also reflect on the clinician's role in addressing tattoos in psychotherapy, balancing sensitivity with inquiry, and understanding how body art may influence the therapeutic alliance.
Conclusions: Through the session we aim to deepen our understanding of tattoos as meaningful psychological markers in modern psychiatric practice.

Disclosure of Interest: None Declared

EPV1374

EEG Features in Young Patients with Syndromally Different Subtypes of Borderline Personality Disorder

A. F. Iznak[1]*, A. A. Kuleshov[2], ?. V. Iznak[1], E. V. Damyanovich[1] and V. G. Kaleda[2]

[1]Laboratory of Neurophysiology and [2]Department of Youth Psychiatry, Mental Health Research Centre, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1921

Introduction: The study of the neurobiological characteristics of borderline personality disorder (BPD) in youth is actual due to its high prevalence, but quantitative EEG studies of BPD have yielded mixed results.
Objectives: The aim of the study was to assess the EEG features in patients with different clinical subtypes of borderline personality disorder (BPD).
Methods: Total of 52 patients aged 16-25 years (mean age 20.4 ±3.2 years) with BPD (F60.31 by ICD-10) were enrolled in the study. Three groups of patients with different subtypes of BPD (with predominance of "affective storm", "addictive adrenalin mania" and "cognitive dissociation") were identified based on clinical and psychopathological characteristics. A pre-treatment multichannel resting EEG was recorded with measurements of EEG spectral power and coherence in narrow frequency sub-bands. Between-group differences in clinical and neurophysiological parameters were identified using Mann-Whitney criteria.
Results: The groups did not differ in EEG spectral power values, but significant ($p<0.05$) differences between the groups were revealed in the spatial organization of the EEG namely in the number of "highly coherent" functional connections (with coherence coefficients above 0.9) that was the least in the group with "cognitive dissociation". Low values of the number of such connections in the alpha2 EEG sub-band (9-11 Hz) in the frontal-central-temporal brain regions reflect a relatively poor functional state of the prefrontal cortex in this group.
Conclusions: The noted features of the spatial functional organization of brain activity in patients with different BPD subtypes may underlie differences in their clinical conditions, in control of emotions and behavior.

Disclosure of Interest: None Declared

EPV1375

The Impact of Intensive Care Unit Patient Care on Hostility Levels Among Relatives

Z. C. Konstanti[1]*, S. KOTROTSIOU[2], M. KOURAKOS[1], S. MANTZOUKAS[3], E. KOTROTSIOU[4], V. KOULOURAS[5] and M. GOUVA[1]

[1]DEPARTMENT OF NURSING, UNIVERSITY OF IOANNINA RESEARCH LABORATORY OF PHYCHOLOGY OF PATIENTS, FAMILIES AND HEALTH PROFESSIONALS, SCHOOL OF HEALTH SCIENCES, IOANNINA; [2]DEPARTMENT OF NURSING, UNIVERSITY OF PATRA, PATRA; [3]DEPARTMENT OF NURSING, UNIVERSITY OF IOANNINA RESEARCH LABORATORY OF INTEGRATED HEALTH, CARE AND WELL BEING, SCHOOL OF HEALTH SCIENCES, IOANNINA, Greece; [4]DEPARTMENT OF NURSING, FREDERICK UNIVERSITY, NICOSIA, Cyprus and [5]DEPARTMENT OF ICU, MEDICINE SCHOOL, UNIVERSITY OF IOANNINA, IOANNINA, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1922

Introduction: Hostility is defined as an enduring tendency in individuals to perceive the opinions and actions of others as negative or to anticipate aggression. This study examines how the Intensive Care Unit (ICU) admission of a critically ill family member influences the hostility levels of their relatives.
Objectives: This study aims to assess the hostility levels of family members of ICU patients, focusing on their sociodemographic characteristics and the closeness of their relationship to the patient.
Methods: The study included first-degree relatives, close relatives, and intimate friends of ICU patients. Data were collected via written questionnaires completed by relatives during the first week of the patient's ICU stay. Instruments used were a sociodemographic questionnaire and the Hostility and Direction of Hostility Questionnaire (HDHQ).
Results: A total of 223 family members (mean age: 41.5 ± 11.9 years), representing 147 critically ill patients, participated. Among the participants, 81 (36.3%) were male and 142 (63.7%) were female. The majority were the patients' children (40.8%), siblings (19.3%), or companions (16.1%). The mean hostility scores for male and female relatives were 20.54 ± 8.16 and 19.36 ± 7.43, respectively, with no statistically significant difference (P = 0.271). However, a statistically significant difference (P = 0.030) was found between relatives living in the same household as the patient (21.38 ± 8.47) and those living separately (18.92 ± 7.13).
Conclusions: This study highlights elevated hostility levels among relatives of ICU patients, suggesting that hostility may fluctuate in response to external stressors such as the critical illness of a loved one. The findings support the notion that hostility, while a personality trait, may also function as an adaptive behavior influenced by situational challenges, such as those faced when a family member is admitted to intensive care.

The Fine Line Between Chaos and Creation: Exploring the Link Between Borderline Personality Disorder Traits and Creativity

M. Rosa[1]*, T. Rocha[1], J. F. Cunha[1], J. Moura[1], J. Leal[1], I. Lopes[1], D. Seabra[1] and N. Ramalho[1]

[1]DPSM, ULS Arco Ribeirinho, Barreiro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1923

Introduction: Borderline Personality Disorder (BPD) is primarily characterized by emotional dysregulation, impulsivity, and unstable relationships. While much of the research on BPD focuses on its impairments, recent studies suggest a possible link between certain BPD traits and enhanced creativity. Emotional intensity, cognitive disinhibition, and non-linear thinking—common in individuals with BPD—are also characteristics frequently associated with creative processes. This review aims to synthesize existing literature exploring the connection between BPD traits and creativity.
Objectives: The primary objective is to review and summarize the existing literature on the association between BPD traits and creativity, focusing on how emotional and cognitive aspects of BPD may facilitate creative thinking.
Methods: A non-systematic review of the literature was conducted by searching academic databases such as PubMed, PsycINFO, and Google Scholar for articles published up to 2023. Search terms included "Borderline Personality Disorder," "creativity," "personality traits," and "emotion regulation." Articles were selected based on relevance to the topic, focusing on studies that explored the link between BPD traits and creativity.
Results: The review identified studies showing a nuanced relationship between BPD traits and creativity. Individuals with BPD traits may access a wider range of emotional experiences, which can enhance creative expression. Impulsivity was linked to spontaneous idea generation and creative risk-taking, although it may also hinder the focus needed for refining creative work. Some research points out that the extreme emotional dysregulation associated with BPD can undermine creative productivity. While emotional intensity might inspire originality, it can also lead to difficulty in structuring ideas, or an inability to complete creative tasks. A few studies even suggest that high levels of interpersonal difficulties, common in individuals with BPD, may further complicate the consistent pursuit of creative projects, as social conflicts or emotional crises might divert focus and energy. In contrast, a smaller body of literature found that individuals with BPD traits might excel in creative fields that value expression, such as art, music, or writing, where emotional intensity and non-linear thinking can be channeled into meaningful creative outputs.
Conclusions: While the reviewed literature suggests that certain BPD traits may enhance creativity, the relationship is complex and multifaceted. Emotional intensity and impulsivity, while potentially beneficial for creative output, can also disrupt focus and long-term creative endeavors. Overall, while BPD traits may foster creativity, they also pose challenges to sustaining long-term creative productivity.

The Rise of Borderline Personality Disorder in Kyrgyzstan: A Two-Year Review

E. Molchanova[1]

[1]Psychology, American University in Central Asia, Bishkek, Kyrgyzstan
doi: 10.1192/j.eurpsy.2025.1924

Introduction: Borderline Personality Disorder (BPD) was historically an underdiagnosed condition in Kyrgyzstan, often identified only in extreme cases, such as when individuals engaged in self-harm or displayed severe emotional instability. Traditionally, psychiatric consultations for BPD were initiated not by the individuals themselves but by concerned family members, typically parents.

As mental health was heavily stigmatized in Kyrgyz society, especially personality disorders, many individuals likely went undiagnosed or untreated.
From 2020 to 2022, the Institute of Behavioral Health at the American University of Central Asia (AUCA) identified only 15 cases of BPD, However, since 2022, there has been a significant rise in BPD diagnoses, with over 70 cases recorded in just two years.
Objectives: This study aims to examine the factors contributing to the increase in BPD diagnoses in the Kyrgyz Republic over the past two years.
Methods: The study's methodology includes the analysis of secondary data provided by mental health organizations, including the AUCA Institute of Behavioral Health, which has tracked BPD cases in recent years. Additionally, anecdotal reports from practicing clinicians offer insights into the evolving nature of mental health diagnoses and treatments in Kyrgyzstan.
Results: Several key factors have contributed to the rise in BPD diagnoses in Kyrgyzstan over the past two years. First, socio-economic stressors have intensified, particularly following the political and economic challenges of 2022. Financial instability and high unemployment rates have exacerbated psychological stress for many individuals. These conditions often worsen emotional dysregulation, a core feature of BPD, particularly for those already predisposed to the disorder. Second, the proliferation of social media has played a notable role in shaping mental health patterns, especially among young people. Increased social media exposure has been linked to feelings of inadequacy, identity confusion, and emotional instability—all key components of BPD. Third, domestic violence and trauma remain significant public health concerns in Kyrgyzstan. BPD has long been associated with adverse childhood experiences, including emotional neglect, sexual abuse, and physical violence, making trauma a significant factor in the development of the disorder. As trauma rates rise, so too does the likelihood of developing BPD, especially in those with preexisting vulnerabilities. Moreover, the reduction in stigma surrounding mental health in recent years has also contributed to the rise in diagnoses. Consequently, mental health professionals are now diagnosing BPD earlier and more frequently than in previous years.
Conclusions: The sharp increase in BPD cases in Kyrgyzstan can be attributed to a combination of socio-economic, psychological, and cultural shifts. Addressing underlying socio-economic and trauma-related factors remains crucial.

The Battle with Cancer when you have a Personality Disorder

A. P. C. Pedro Costa[1]*, M. Mousinho[1], A. Matos Pires[1], G. Simões[2], A. I. Gomes[2] and A. R. Coelho[3]

[1]Departamento de Saúde Mental, Unidade de Saúde do Baixo Alentejo, Beja; [2]Departamento de Psiquiatria e Saúde Mental, Unidade Local de Saúde da Região de Aveiro, Aveiro and [3]Serviço de Oncologia Médica, nstituto Português de Oncologia de Coimbra Francisco Gentil, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1925

Introduction: Personality disorders are often comorbid with anxiety and depression disorders, complicating the diagnostic process. Cancer patients with personality disorders who face the anxiety and discomfort associated with the diagnosis, symptoms, and medical treatment may encounter challenges. They might distort reality as a means of emotional self-preservation or display aggression.
Objectives: This review seeks to delve into the challenges in cancer patients exhibiting dysfunctional personality traits or personality disorders.
Methods: A non-systematized literature review was carried out on PubMed and Google Scholar. The following terms were searched: ("personality disorders" OR "personality traits") AND ("cancer" OR "cancer patients").
Results: Personality traits persistently influence behavior patterns, choices, environmental interactions, and stress responses. Personality can impact cancer development and progression through multiple avenues: by perpetuating unhealthy lifestyle behaviors rooted in personality traits; through negative affect such as depressive or anxious symptoms, as well as ineffective coping mechanisms; and by serving as an etiological factor for somatic diseases or mental disorders that predispose individuals to cancer. While some epidemiological studies have reported a positive association between personality and cancer development or progression, the majority find no significant correlation, leading researchers to conclude that there is no substantial link between personality and an increased risk of cancer.
Conclusions: Meeting the diverse challenges associated with cancer requires adaptability, flexibility, and resourcefulness. Research suggests that specific personality traits, like neuroticism and negative affectivity, are linked to lower quality of life among cancer patients, while extraversion and optimism are correlated with more favorable outcomes.

Cariprazine treatment in patients with borderline personality disorder and psychotic symptoms

P. Perez-Melendez Perez[1]*, P. D. S. Calderon[1], H. Vizcaino Herrezuelo[1] and C. Delgado Marmisa[1]

[1]Psychiatry Department, Hospital Universitario Puerta de Hierro, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1926

Introduction: Psychotic symptoms are frequently observed in individuals with borderline personality disorder. Numerous case reports in the scientific literature support this finding. This symptoms can significantly impair the patients daily functioning and quality of life. Antipsychotic medications have demonstrated efficacy in managing both psychotic symptoms and emotional dysregulation in this population.
Objectives: This case report aims to explore the use of cariprazine in managing psychotic symptoms in patients with borderline personality disorder.
Methods: This case report describes a 28-year-old woman who sought mental health treatment for symptoms including emotional instability, lability, irritability, anxiety, and impulsivity. Her history includes childhood sexual abuse, which she identified as a significant source of distress. She also reported chronic auditory pseudo-hallucinations with derogatory content and visual pseudo-hallucinations of "small spiders." She reported these experiences as

distressing and disruptive to her daily life. The patient recognized the unreal nature of these hallucinations.
Results: After initiating treatment with cariprazine 2.5mg, the patient demonstrated significant clinical improvement, including a reduction in the severity and impact of psychotic symptoms and a decreased risk of self-harm. Due to this positive response, cariprazine was continued, and the patient experienced increased emotional stability without requiring further acute care.
Conclusions: Studies have suggested the efficacy of second-generation antipsychotics in treating patients with borderline personality disorder. Beyond the remission of psychotic symptoms, these medications can lead to improvements in both affective and behavioral functioning.

The role of white matter in the symptomatology of dissociation in patients with borderline personality disorder

P. Podwalski[1]*, B. Dawidowski[1], L. Franczak[1], L. Zwarzany[2], W. Poncyliusz[2] and J. Samochowiec[1]

[1]Department of Psychiatry and [2]Diagnostic Imaging and Interventional Radiology Unit, Pomeranian Medical University, Szczecin, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1927

Introduction: Borderline personality disorder (BPD) is characterized by instability in the area of one's own self and affective reactions, instability in relationships, and impulsive behavior. BPD patients experience dissociative or quasi-psychotic symptoms much more often than the general population. These symptoms directly affect the daily functioning of patients, often preventing them from taking up professional work or having a stable family life. The etiology of dissociative experiences in BPD patients is still unknown. One of the biological models suggests that biological changes in the brain occur on the basis of a traumatic experience, which can produce symptoms. The arcuate fasciculus (AF) is a structure of white matter that interconnects Broca's area and Wernicke's area in the brain. AF is often considered in the context of research on psychotic symptoms. For this reason, we hypothesize that AF may be related to dissociative symptoms in BPD patients.
Objectives: The aim of our study was to investigate a relationship between the integrity of AF and symptomatology of dissociation in patients with borderline personality disorder.
Methods: 45 BPD subjects and 43 healthy controls (HC) participated in the study. A DTI analysis was performed on all study participants. The psychopathology of BPD was assessed using the Dissociative Experiences Scale - Taxon (DES-T). The AF analysis was then conducted using fractional anisotropy (FA) parameter.
Results: BPD significantly more often than the control group experienced dissociative experiences. We could not identify differences in the integrity of the AF between the two groups. Nevertheless, we examined the correlation between the quality of the AF structure and the severity of dissociative symptoms (r=-0.0299, p=0.039).
Conclusions: The attenuation of the structure of AF may be involved in symptomatology of dissociation in patients with BPD. Further structural brain studies are needed in the BPD population.

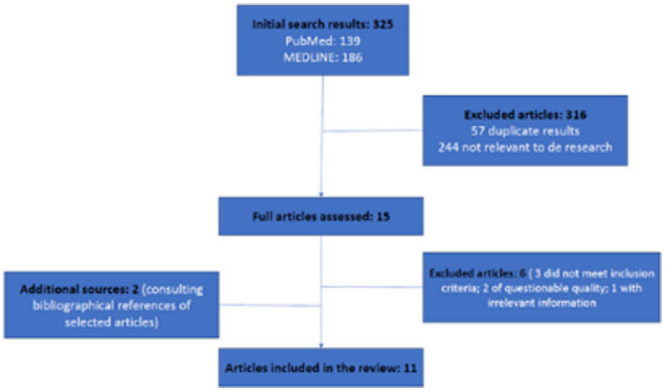
EPV1385



Community prevalence of borderline personality disorder and associated sociodemographic factors. Systematic review

I. Ramos Suárez[1]*, B. G. Martínez[2] and M. G. Jiménez[1]

[1]Psychiatry, San Cecilio University Clinical Hospital and [2]Psychiatry, Granada University of Medicine, Granada, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1928

Introduction: Borderline Personality Disorder (BPD) is one of the most prevalent and debilitating personality disorders in mental health. It is characterized by a persistent pattern of instability in interpersonal relationships, self-image, and affect, along with marked impulsivity.
Available epidemiological data suggest that BPD affects approximately 1-2% of the general population. However, variability in diagnostic criteria and assessment methodologies has made it difficult to obtain comparable results across different studies and geographic contexts.
Objectives: This systematic review aims to synthesize current evidence on the epidemiology of BPD, exploring its prevalence and its sociodemographic correlates.
Methods: This systematic review focused on studies examining the prevalence of Borderline Personality Disorder (BPD) in the general population, as well as the associated sociodemographic factors.
Articles that assessed the prevalence of BPD in adult community populations were included. BPD had to be diagnosed according to the DSM-IV, DSM-5, or ICD-10 criteria, and studies needed to use structured interviews or validated questionnaires. The minimum sample size for included studies was 300 participants to ensure the robustness of the data.
Studies focusing on specific populations (such as hospitalized patient groups) and those that did not differentiate between BPD and other personality disorders were excluded.
An extensive search was conducted in the PubMed and MEDLINE databases.
Results: The initial search yielded a total of 325 results: 139 articles from PubMed and 186 from MEDLINE. Finally, 11 articles were included in the final review. The search and selection process is detailed in the provided image.
The prevalence of Borderline Personality Disorder (BPD) in the general population varied considerably among the included studies. Notably, no studies from Africa or Asia met the inclusion criteria for this review, limiting the generalizability of the results on a global scale. Most of the included studies were conducted in European countries and the United States. Overall, the results suggest variability in BPD prevalence rates depending on geographic region and diagnostic methods employed.
Sociodemographic variables such as gender, age, ethnicity, education level, marital status, income level, location of residence, and employment status showed varying degrees of association with Borderline Personality Disorder (BPD).

Image 1:

Conclusions: The final conclusions will be included in the full version of the systematic review, once all sociodemographic variables have been thoroughly evaluated. This detailed analysis will also assess the extent of these variables' involvement, along with how the different diagnostic criteria used may influence the prevalence of Borderline Personality Disorder (BPD) observed in the samples from the various countries included in the study.

EPV1386

Navigating the Storm: Understanding Affective Instability and Its Implications

A. F. Reis[1]

[1]Psychiatry and Mental Health, Unidade Local de Saúde da Arrábida, Setúbal, Portugal
doi: 10.1192/j.eurpsy.2025.1929

Introduction: *Affective instability* (AI) is a psychophysiological symptom reported in many neurological and psychiatric conditions. It has assumed more relevance in the psychiatric literature as a criterion for borderline personality disorder (BPD). Although extensively clinically used, its definition remains vaguely defined, and it ends up being used interchangeably with *affective lability* or *emotional dysregulation*, and it is often mistaken for *mood lability*, as described in bipolar disorders. To accurately diagnose this symptom and document variations in emotional experiences, it is essential to identify the factors associated with AI.
Objectives: We aim to review the current definitions and conceptualizations of AI to provide more accurate use of the term.
Methods: Narrative literature review.
Results: Current definitions of AI highlight the oscillation of emotions, often described as a series of intense emotional highs and lows that can shift within hours or even minutes, making it challenging for individuals to maintain a stable emotional baseline, significantly affecting an individual's relationships, self-identity, and coping mechanisms. It is a complex construct, encompassing affective valence, affect amplitude, affective shifting with random patterning, reactivity thresholds to environmental triggers, and affective dyscontrolled modulation. Neurobiological research suggests that dysregulation in emotional processing areas of the brain, such as the amygdala and prefrontal cortex, may contribute to these rapid emotional shifts.
Conclusions: AI is a multifaceted construct with significant implications for mental health. The current definitions and conceptualizations underscore the complexity of emotional regulation and the need for a holistic approach to understanding and treating individuals experiencing these emotional fluctuations. Continued research into the neurobiological, psychological, and environmental underpinnings of affective instability will enhance the understanding of this phenomenon and improve treatment strategies for affected individuals.

Alexithymia is associated with submissive behavior in a public goods game

A. Carvallo[1], J. Gonzalez[1], V. V. Orozco[1], J. Hanna[1], J. A. Fernandez[1], J. Ayala[1], A. Barros[1], M. F. Aguirre[1], K. Arroyo[2], P. Campodonico[3,4], F. Munoz-Rubke[5] and M. E. Riveros[6,7]*

[1]Facultad de Medicina CAS, Universidad del Desarrollo; [2]Facultad de odontología y Ciencias de la Rehabilitación, Universidad San Sebastian; [3]Centro de Química Médica, Universidad del Desarrollo; [4]Facultad de Medicina UDD (FM, UDD), Instituto de Inovacion en Medicina (ICIM), Santiago; [5]Instituto de Psicología, Universidad Austral de Chile, Puerto Montt; [6]Centro de Fisiología celular e Integrativa, Universidad del Desarrollo and [7]Facultad de Medicina (FM, UDD), Instituto de Inovacion en Medicina (ICIM), Santiago, Chile
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1930

Introduction: Alexithymia is a relatively stable personality construct that reflects the difficulty in distinguishing and describing one's own emotions along with a concrete and externally directed style of thinking. Alexithymia increases the risk of development and worsens the course of several psychiatric illnesses, such as depression or addiction. It is also associated with the development of eating disorders and psychosomatic illnesses. Additionally, it has a negative impact on the ability to regulate emotions and is also associated with a reduced empathic capacity, interpersonal problems and even violent behaviors. Interestingly, in intimate partner violence, it has been observed that alexithymia is associated with both exercising and receiving abuse. However, social behavior, in dynamics of cooperation within pairs and groups of several individuals, has not been studied much in relation to alexithymia.
Objectives: We evaluated the impact of alexithymia in social behavior in three aspects: generosity, trust and submission.
Methods: After completing an online survey that evaluated their levels of alexithymia using the TAS-20, as well as depression and loneliness, 67 participants (27 men), aged 19 to 46, attended our laboratory. There, after answering the PANAS survey, they played three economic games using tiles: the Dictator game, the Trust game, and the Public Goods game. Each participant played in a group of four, with three of the group members being confederates whose contributions were pre-established and consistent across all sessions and participants. In the Public Goods game, confederates initially contributed a significant percentage (80-95%) of their endowment in the first round, but in subsequent rounds, they drastically reduced their contributions to nearly nonexistent levels.

After playing all three games, the PANAS was reassessed. Finally, on the same day as the face-to-face session, participants completed a second online survey that assessed cognitive and emotional empathy, early life adversity, resilience and perceived stress.
Results: In the Public Goods game, the number of rounds in which participants contributed more than their initial contribution in the first round was used as a measure of submissive behavior. This variable correlated with the participants' level of alexithymia (β=0.544). Additionally, this same index was also negatively associated with empathy and positively related to reported loneliness. A similar pattern was observed between alexithymia and empathy (β=-0.323) and loneliness (β=0.473). In contrast, total contributions made in the Public Goods game, the Dictator game (generosity), and the Trust game did not correlate with alexithymia.
Conclusions: Our results suggest that alexithymia is connected to greater submissive behavior in group interactions. It is possible that its link to reduced empathy and increased loneliness contributes to this behavior.

Using the big five inventory to evaluate the personality traits of medical staff

N. Rmadi[1]*, A. Hrairi[1], I. Ben Hnia[1], O. walha[2], N. Kotti[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupational medicine department, Hedi chaker university hospital, University of Sfax and [2]familiy medicine department, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1931

Introduction: Personality traits are enduring and stable characteristics that reflect an individual's behaviour, thoughts and feelings. Research indicates that specific traits can affect not only the well-being of healthcare professionals but also their interactions with colleagues and patients.
Objectives: This study aims to assess the personality traits of healthcare professionals using the Big Five Inventory (BFI).
Methods: A descriptive cross-sectional study was conducted among healthcare personnel who consulted the department of occupational medicine of Hedi Chaker Hospital of Sfax to September 2024. The survey was conducted through a self-questionnaire that included sociodemographic data, lifestyles. We also used BFI which measures the Big Five personality traits through five key dimensions: extraversion, agreeableness, conscientiousness, neuroticism and openness.
Results: The study involved 41 consultants (12 men and 29 women) with an average age of 31.2 ± 7.4 years. An urban origin was identified in 87.8% of the cases. Medical staff scored 3.36 ± 0.52 for extraversion, 3.21 ± 0.56 for agreeableness, 3.22 ± 0.61 for conscientiousness, 3.01 ± 0.78 for neuroticism and 3.2 ± 0.65 for openness. A significant association was found between neuroticism and urban versus rural origin (p=0.001). Moreover, associations were found between BFI dimensions: agreeableness with extraversion (p=0.007, r=0.41) and openness (p=0.002, r=0.46).
Conclusions: This study highlights the importance of assessing personality traits among healthcare professionals. Understanding these personality dimensions can provide valuable insights for improving workplace dynamics, enhancing team collaboration, and ultimately fostering better patient care outcomes.

Investigating the Impact of Alexithymia and Dissociation on the Severity of Symptoms in Severe Personality Disorders

L. Ghidetti[1], S. Costantini[2], D. Salmaso[3], M. Benassi[1], R. P. Sant'Angelo[4]* and M. Pacetti[3]

[1]Psychology, University of Bologna; [2]Mental Health, Ausl Romagna, Cesena; [3]Mental Health Department, Ausl Romagna, Forlì and [4]Mental Health Department, Ausl Romagna, Cesena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1932

Introduction: Severe personality disorders are characterized by deeply ingrained patterns of thought, behavior, and emotional functioning, along with impaired mental functioning in the areas of self-stability and identity formation. The challenges in interpersonal relationships and overall functioning result in a significant reduction in the capacity to adapt to social roles.
Objectives: In this context, the present study aims to explore the severity of symptoms (SPrDP) in correlation with alexithymia (TAS-20) and dissociation (DES II) in individuals under the care of the Department of Mental Health of Forlì-Cesena.
Methods: The sample was selected using the SCID PD (Structured Clinical Interview for DSM-5), followed by the administration of the following scales: SPrDP (Parma's Scale), TAS-20 (Toronto Alexithymia Scale), and DES II (Dissociative Experiences Scale). Multivariate analyses were applied, including non-parametric correlations (Spearman's Rho) between variables using SPSS software.
Results: The sample consists of 55 individuals (F=38; M=17), of whom 42 have borderline personality disorder (BPD), 3 have narcissistic personality disorder (NPD), 6 have histrionic personality disorder (HPD), 3 have obsessive-compulsive personality disorder (OCPD), and 1 has dependent personality disorder (DPD). The analysis did not reveal a significant correlation between SPrDP and the TAS-20 and DES II scales, although a trend was observed that could correspond to more compromised personality functioning in the presence of high scores on these scales. Furthermore, a statistically significant correlation was found between TAS-20 and DES II. Higher marginal means for TAS-20 were observed in individuals with OCPD. For DES II, the highest estimated marginal means were found in individuals with OCPD and BPD.
Conclusions: The symptom severity measured by SPrDP was not statistically significant in relation to TAS-20 and DES II. However, the presence of a trend between the scales suggests the possibility of further investigation with a larger sample. Additionally, the statistically significant correlation between alexithymia and dissociation may indicate that difficulties in identifying and managing intense emotions lead to the use of dissociative defense mechanisms. The higher average alexithymia scores in individuals with OCPD suggest a possible emotional rigidity with a tendency to control or suppress emotions. The frequency of dissociative symptoms observed in individuals with BPD and OCPD may indicate the centrality of alexithymia and dissociation in the impairment of emotional and relational functioning in severe personality disorders. Further studies are necessary.

Neurohormonal markers of stress in Borderline Personality Disorder: interplay between oxytocin and cortisol

M. Teixeira De Almeida[1,2]*, L. Quattrocchi[1,2], N. Perroud[1,2] and T. Aboulafia Brakha[1]

[1]Department of Psychiatry, Geneva University Hospitals and [2]Faculty of Medicine, University of Geneva, Geneva, Switzerland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1933

Introduction: Borderline personality disorder (BPD) is characterized by important attachment issues and emotion dysregulation, particularly in response to psychosocial stressors. Emotions (mainly anger and sadness) may therefore be felt and expressed more intensively. Even though stress response is mainly regulated by cortisol, oxytocin is also involved in this response, and both hormones interact in a temporal dynamic. A previous pilot study carried-out by our group has shown that oxytocin displays less variation in naturalistic setting and lower reactivity during a stress task in patients with BPD when compared to healthy subjects.
Objectives: We are now carrying out a larger-scale study to better understand the interplay between cortisol and oxytocin in everyday life and during stressful situations, but also which other factors may influence these hormonal changes like medication, hormonal contraceptives, childhood adverse events and other psychiatric comorbidities.
Methods: We aim to recruit 120 participants (60 per group). Each participant undergoes three visits. First visit: explanation of the global procedure and risks, signature of informed consent, as well as psychological screening and distribution of questionnaires and salivettes (to be returned during the second visit). Second visit: return of questionnaires and return of part of the salivettes collected during the morning + additional saliva sample and assessment of emotional state. Third visit: experimental procedures and return of remaining samples of salivettes collected in the previous days for circadian assessment (the afternoon of the second visit). Thus, the day of the third visit participants perform an experimental task, the Trier Social Stress Test (TSST), involving stress reactivity.
Results: Currently, 28 BPD patients and 39 healthy controls completed protocol. We analyzed hormonal preliminary data of the first 20 participants of each group. Our initial analyses showed a hyporeactivity of cortisol during stress in BPD patients compared with healthy subjects ($F= 5.27$, $p = .005$).
Conclusions: Recruitment is still ongoing and further analyses will be conducted. Our study may offer a better understanding of the neurobiological underlying stress dysregulation in BPD, which may help to contribute to the development of new psychotherapeutic and pharmacological approaches.

Disclosure of Interest: None Declared

EPV1392

The relation between emotional intelligence and dark triad traits, limitations of research

M. Valeriia[1]

[1]General, child, forensic psychiatry and narcology, P.L. Shupyk National Medical Academy of Postgraduate Education, Kyiv, Ukraine
doi: 10.1192/j.eurpsy.2025.1934

Introduction: The war has affected every Ukrainian to some extent. With the mobilization comes the increased risk of people with dark triad traits (DT) (psychopathy, machiavellianism and narcissism) to be exposed to stress on the battlefield. Being vulnerable, these individuals are in need of protection for their mental health. One of such protections is the emotional intelligence (EI). This makes the relation between DT and EI highly valued as the basis for future development of effective measures against stress disorders for combatants.
Objectives: The aim of this research is to study the existing knowledge exploring the relation between the emotional intelligence and dark triad traits and to determine the limitations of these studies.
Methods: In order to analyse this relation the literature review of scientific studies on the topic of the relation between the EI and DT was conducted.
Results: The literature sources published in 1994-2023 years were reviewed for this study. 1,87% of studies showed that DT related negatively to general EI. 5,66% showed that some facets of DT related positively to some facets of EI, while 2,83% showed negative relation. 2,83% demonstrated that psychopathy (P) related positively to general EI, 13,21% reported negative relation, 0,94% showed no relation, 2,83% demonstrated mixed relation. 5,66% reported that some facets of P related positively to some facets of EI, while 38,68% discovered negative relation. 14,15% demonstrated that narcissism (N) related both positively and negatively to general EI, 4,72% observed no relation. 16,98% found that some facets of N related positively to some facets of EI, 21,7% showed negative relation. 5,66% demonstrated that M related positively to general EI, 7,55% reported negative relation. 10,38% found that some facets of M related negatively to some facets of EI.
Conclusions: Among reviewed papers most of them reported that some facets of DT related positively to some facets of EI, with P mostly relating negatively to general EI and some of its facets, N mostly relating positively to some facets of EI and M mostly relating negatively to general EI and some of its facets. Found and known limitations of mentioned studies included: sample population being too heterogenous, sample population including criminal offenders only, size of sample population being too small, use of self-report measures, lack of unified approach to measure EI, possibility of comorbidity influencing EI, possibility of individual's secondary gain influencing EI measure, non-exclusion of individuals with mental disorders from general population. This highlights the need to take mentioned limitations into account in order to acquire accurate data in further research on the topic.

Phenomenology of Anorexia Nervosa in Cambodia: A Transcultural Approach

S. Bora[1]*, R. Ngin[1] and S. Vilhem[2]

[1]Cambodian Children's Fund, Phnom Penh, Cambodia and [2]University of Lausanne, Lausanne, Switzerland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1935

Introduction: Anorexia Nervosa (AN) is a complex psychiatric disorder often understood through a Western lens. This study explores AN in the Cambodian context, where the condition is not traditionally recognized, to uncover cultural and transcultural aspects of the illness.
Objectives: This research aims to conduct an in-depth phenomenological exploration of AN cases in Cambodia, documenting the lived experiences of individuals and identifying cultural or transcultural elements within the universal description of AN.
Methods: Employing a qualitative research approach grounded in phenomenology, this study will involve in-depth interviews with Cambodian individuals experiencing AN. The data will be analyzed using both descriptive and interpretive phenomenological methods, ensuring the bracketing of researcher bias and fostering co-creation of interpretations.
Results: Expected outcomes include a comprehensive phenomenological account of AN in Cambodia, shedding light on the lived experiences of individuals and potentially revealing unique cultural dimensions of the disorder. The study will contribute to the understanding of AN from a transcultural perspective, highlighting both universal and culturally specific aspects.
Conclusions: This research is anticipated to provide valuable insights into the phenomenology of AN in a non-Western context. The findings may have implications for clinical practice, research, and cross-cultural understanding of AN, emphasizing the importance of patient-centered approaches and the exploration of lived experiences in psychopathology.

Disclosure of Interest: S. Bora Grant / Research support from: International Exchange Award from the Renewing Phenomenological Psychopathology funded by the Wellcome Trust, R. Ngin: None Declared, S. Vilhem: None Declared

EPV1396

Kierkegaard and Anxiety: Bridging Philosophy, Psychotherapy, and Art

F. Cunha[1]*, I. Santos[1], R. Cabral[1], P. Pires[1], C. Cunha[1] and S. Borges[1]

[1]ULS Viseu Dão-Lafões, Viseu, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1936

Introduction: Søren Kierkegaard's philosophy, particularly his exploration of anxiety, serves as a cornerstone in existential thought. His concepts of "authenticity," "choice," and the confrontation with the self underlie much of the contemporary understanding of anxiety as both a psychological and philosophical experience. Kierkegaard's works, especially *Either/Or*, offer a profound analysis of human freedom, responsibility, and the resulting anxiety. The objective of this analysis is to bridge the philosophical with the practical and artistic, providing a multidimensional understanding of anxiety.
Objectives: This study seeks to explore Kierkegaard's conceptualization of anxiety, its application in psychotherapy, and its resonance in contemporary culture. Specifically, it investigates how these ideas can aid individuals in confronting existential anxiety in therapeutic settings.
Methods: A philosophical and qualitative approach is used, analyzing Kierkegaard's *Either/Or*. The study incorporates interpretations from existential thinkers, psychotherapists and artists. Theoretical analysis is coupled with psychological insights, exploring anxiety as a pathway to self-awareness.
Results: Kierkegaard presents anxiety as inherent to human freedom and choice. His stages of life—the aesthetic, ethical, and religious—represent different ways of engaging with anxiety. In the aesthetic stage, individuals pursue pleasure but encounter despair when they confront their limitations. The ethical stage offers structure but introduces existential guilt. The religious stage, requiring a leap of faith, is seen as the highest form of existence, where anxiety leads to transcendence. Kierkegaard's ideas are reflected in existential psychotherapy, where anxiety is viewed not only as a symptom but as a catalyst for personal growth. Elliott Smith's *Either/Or* album mirrors these themes, portraying modern struggles with freedom, despair, and self-doubt. Songs like "Between the Bars" and "Ballad of Big Nothing" articulate the tension between aesthetic escape and ethical responsibility, offering a visceral interpretation of Kierkegaard's philosophical concerns.
Conclusions: Kierkegaard's exploration of anxiety offers profound insights into human existence, emphasizing the need to confront, rather than avoid, existential dilemmas. His framework of life stages provides a guide for understanding the progression toward authenticity, where anxiety is a key driver. The study shows that Kierkegaard's ideas remain relevant in psychotherapy, helping individuals navigate anxiety to achieve self-realization. Ultimately, this research affirms that embracing anxiety is crucial for personal freedom, growth, and authenticity, aligning with Kierkegaard's vision of a life well-lived.

Explorations of the convergence of narrative therapy with psychoanalysis

L. Mehl-Madrona[1,2]* and B. Mainguy[3]

[1]Native Studies, University of Maine, Orono; [2]Psychiatry Residency, Northern Light Acadia and [3]Wabanaki Health and Wellness, Bangor, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1937

Introduction: Two seemingly different paradigms for psychotherapy appear to have converged in narrative psychotherapy and psychoanalysis.
Objectives: We wanted to explore the philosophical perspectives of some of their practitioners to understand this seemingly emergent paradigm.

Methods: We interviewed narrative psychotherapists and practitioners identifying as narrative psychoanalysts about their philosophical foundations in order to explore this apparent convergence. We used constructivist grounded theory to produce common themes. We also put the interviews through an AI program -- Perplexity to explore how well it correlated with our non-AI analysis.
Results: Both groups of practitioners believed that that we construct stories to give us identity and meaning in our lives. The practitioners who came from a psychoanalytic perspective described their coming to understand that psychoanalysis is embedded in stories that ciients and therapists tell. Patients and analysts bring, create, and modify stories in analytic work. Both types of practitioners described the importance of cultivating an active listening attitude on the part of the clinician. Jacques Lacan was often quoted as saying that the greatest gift we can give our clients is to listen without judgment or interpretation. Narrative therapists were more inclined to mention Hermans' dialogical self-theory while psychoanalytically trained therapists spoke of object relations theory with both supporting a philosophy of making meaning together. Both groups of practioners mentioned the importance of meaning being constructed within a particular context. Both groups mentioned the importance of reflective practices, Buddhism, and Indigenous philosophies to support the introspective elements of this technique along with therapy being grounded in our relationships with others. Both groups emphasized the importance of showing how creating new life narratives over time transforms our sense of self, relationship, and meaning.
Conclusions: Qualitative analysis of these two groups of practitioners' philosophies of psychotherapy supports the idea of a convergence between narrative psychotherapy and psychoanalysis which may promise to enrich both groups.

Perspectives on Approaches in Psychiatry: A Resident Survey in Tunisia

K. Njeh[1] and A. Aissa[2]*

[1]Psychiatry A, Razi psychiatric hospital and [2]Hopital Razi, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1938

Introduction: The field of psychiatry encompasses a range of approaches that guide both clinical practice and training.
This study aims to explore residents' views on these diverse approaches, identifying trends and preferences that could inform the development of psychiatric education and clinical practice in the region.
Objectives: The objective of this study is to assess the perspectives of psychiatry and child psychiatry residents in Tunisia on different approaches to mental health care and to identify their preferences and attitudes towards evidence-based psychiatry.
Methods: A cross-sectional survey was conducted among 31 psychiatry and child psychiatry residents in Tunisia through an online survey.
The survey utilized a combination of yes/no questions and gradual questions to gather data on residents' perspectives regarding various psychiatric approaches.
Data collection was carried out throughout the month of july 2024.
Results: This study included 31 participants with an average age of 28.1 years.
Less than half of the participants (45.2%) reported that they believe the brain is the sole source of mental disorders, with a notable proportion identifying as non-theist.
A majority of residents (80.5%) agreed that medicine should be grounded in the scientific method. However, only 14 participants agreed that "Evidence-based approaches should be the only approaches in psychiatry," and 15 participants agreed that "The biological approach should be the primary focus in psychiatry."
Most residents considered most approaches to be evidence-based. In contrast, the psychodynamic approach was less frequently viewed as evidence-based.
Nearly all residents (n=27) believed that an integrative approach is beneficial in psychiatric practice.
More than half of the participants (54.8%) rated their training in Evidence-Based Psychiatry as limited. Despite this, 24 participants reported that they often try to adhere to evidence-based guidelines when treating patients.
The main barriers to implementing Evidence-Based Psychiatry were identified as a lack of resources in psychiatric departments or hospitals (41.9%) and insufficient training (38.7%).
Conclusions: The results indicate that while there is strong support for evidence-based medicine and the integration of multiple theoretical models, there are differing views on the predominance of specific approaches in clinical practice.
The majority of residents acknowledge the importance of grounding psychiatric practice in empirical evidence, yet there is less consensus on making evidence-based approaches the exclusive or primary focus.
Despite recognizing the benefits of integrating diverse approaches, many residents perceive limitations in their training and resources, which affect their ability to adhere fully to evidence-based practices.
The findings underscore the need for enhanced training in Evidence-Based Psychiatry and improved resources within psychiatric departments and hospitals.

Lonely but not alone: integrating social alienation and mental health in urban environments

F. Poukhovski-Sheremetyev[1]* and I. Gold[2]

[1]Department of Psychiatry and [2]Department of Philosophy, McGill University, Montreal, Canada
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1939

Introduction: The modern urban landscape is increasingly characterized by the paradox of social isolation in physical proximity. Research consistently reveals a troubling link between social alienation and mental health issues, including a heightened risk for psychosis among vulnerable groups. As cities expand and diversify, understanding and mitigating the detrimental effects of urban alienation becomes crucial. This presentation explores the complex relationship between urban living, social alienation, and mental health, emphasizing the need for psychiatrists to have a more holistic understanding of socio-urban phenomena.

Objectives:
1. To assess the clinical impact of urban alienation on mental health based on multi-disciplinary literature.
2. To particularly examine urban mental health concepts from outside psychiatry that may be relevant to clinical practice.
3. To identify possible strategies for integrating these interdisciplinary insights into daily practice and public mental health policy.

Methods: We performed a multi-disciplinary literature review, analyzing studies from psychiatry, sociology urban studies, critical theory, and public health to evaluate the impact of social alienation on mental health. Special attention was paid to identifying both gaps and overlaps between disciplines.
Results: We grouped findings into three major disciplinary areas: psychiatry, sociology, and urbanist theory. While each of these fields has unique histories and contributions, the literature lacks consistent integration among them. For clinicians in particular, there is significant conceptual language that has not yet entered the psychiatric lexicon. Across fields, it is noted that city-dwellers face alienation due to resource limitations, systemic issues, ideological pressures, and cultural barriers. Proposed solutions vary significantly based on discipline, including community-building activities, mental health support services, and inclusive urban planning.
Conclusions: There is a breadth of research on cities, alienation, and mental health, and yet little integration of the disciplines. Addressing social alienation in urban environments requires psychiatric thought to move beyond isolated clinical interventions and toward collaborations with community organizations, policymakers, and urban planners. By aligning mental health expertise with the broader social and physical context, psychiatry can contribute to more meaningful, holistic interventions. Consequently, there is a pressing need for academic research bridging these fields, enabling more effective solutions that enhance community well-being in urban settings.

One more grammar for causality - understanding interventionism

N. Ramalho[1]*, T. Rocha[1], J. F. Cunha[1], J. C. Moura[1], J. Leal[1], D. Seabra[1], I. Lopes[1], G. Santos[1], M. Rosa[1] and A. Garcia[1]
[1]Psychiatric and Mental Health Department, ULSAR, Barreiro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1940

Introduction: The role of causality in reality has sparked a long and ongoing debate that began with Aristotle, but in its modern form, having reverberated to this day, found its origin in Hume. In psychiatry, causality gains additional layers since the domain of intelligibility does not extend as broadly as it does to the natural sciences, due to the nature of both its object and its method.
Objectives: To explore proposals for understanding causality in psychiatry and mental illnesses.
Methods: A non-systematic literature review was conducted using the PubMed/MEDLINE and PhilPapers databases with the search terms "causality," "psychiatry," "interventionism," and "causal grammar." Reference bibliography was also consulted.
Results: Causal interventionism is a way of understanding causality, where performing an intervention in groups allows the distinction between causality and mere correlation, utilizing counterfactuals that are verified in light of that intervention. The idea of causal grammar allows causal explanation to be thought of as a matter of finding a family of interventions in variables that make a difference to the outcome variable, governed by the causal grammar of that domain.
Conclusions: While each of the positions addresses certain issues —interventionism tackling various levels of explanation of causality in psychiatry, whether biological or psychodynamic, and causal grammar seemingly overcoming mechanismism—neither is fully satisfactory: in interventionism, the unfolding of causes, and in causal grammar, the pre-theoretical intuition seems challenged.

EPV1406

A different perspective on post-traumatic emotional disorders from the perspective of quantum philosophy

H. Yildiz[1,1,1]
[1]dr.huseyin yildiz office, kocaeli, Türkiye
doi: 10.1192/j.eurpsy.2025.1941

Introduction: In the past, traumas have always occurred and continue on a social and individual level in humanity's journey to this day. While there were world wars, atomic bombs dropped on Hiroshima and Nagasaki, Nazi concentration camps, the events of September 11, the events in Bosnia and Herzegovina, and the Iraq wars, today the Ukraine war, the Israeli-Palestinian conflict and many more continue on a national and regional level, and are increasing day by day on an individual level.
Objectives: The aim of this study is to offer a different perspective on mood changes in individual and social life after trauma.
Methods: In this study, qualitative and quantitative research methods were used.
Results: From the perspective of quantum thought, matter is energy and this is expressed with Einstein's famous formula e=mc2. From the perspective of quantum thought, an external effect on a system in equilibrium causes a temporal displacement, a new form of existence in that system. For example, when an external effect is applied to a system A, the new energetic position of the system A will be A', and its temporal dimension will be t at the beginning, but will become t' as a result of the interaction. This t' can be called temporal displacement. Just as the disruption of the voodoo biological clock on an individual level causes psychological and emotional changes, it is possible that post-traumatic temporal displacement - this can be any kind of trauma - will cause mood changes and disorders in mood states on a social and individual level.
Conclusions: The aim of this discussion is to perceive how the breaks in the temporal and energy processes of societies and individuals can create changes in their emotional states in the context of quantum philosophy. In terms of quantum thought, every intervention made to the system from outside or inside causes a temporal shift and energetic changes in the system. This temporal shift should not be understood as a disruption of the biological clock, but should also be perceived as a new energy and a new form of existence in the time cycle of the system after the trauma.

Post-Traumatic Stress Disorder

EPV1407

Use of Vortioxetine in the Treatment of Major Depressive Disorder and Post-Traumatic Stress Disorder: A Case of Functional Recovery

R. Albillos Pérez[1]*, M. Fernández Rodríguez[1], S. Castelao Almodóvar[2], P. Sanz Sánchez[1], R. González Núñez[1], C. Alguacil Núñez[1] and A. Castelao Escobar[1]

[1]Psiquiatría, Hospital Universitario Puerta de Hierro Majadahonda and [2]Psiquiatría, Hospital Universitario El Escorial, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1942

Introduction: Vortioxetine is an antidepressant with multimodal action that exerts its numerous effects by modulating neurotransmission in multiple systems, achieving not only antidepressant effects but also procognitive ones, along with an appropriate tolerability profile. Currently, vortioxetine is only approved for the treatment of major depressive disorder (MDD) in adults. There is currently no unified consensus on the most appropriate pharmacotherapy for post-traumatic stress disorder (PTSD), so this clinical case raises the possibility of using drugs with multimodal action, such as vortioxetine, in patients with comorbid PTSD and MDD.
Objectives: To describe a clinical case of comorbid PTSD with MDD, highlighting the use of drugs with multimodal action.
Methods: A 26-year-old woman began follow-up for an 8-month history of depressive mood, with apathy, anhedonia, and constant rumination about a significant life event, impacting her basic activities of daily living, along with death-related thoughts and fear of acting on them. She also presented with highly limiting tics, difficulty concentrating, mental blocks, slowed thinking, and mixed insomnia. The patient directly relates these symptoms to a traumatic event during her adolescence, which involved sexual abuse and threats during a conflicted romantic relationship. Over the years, she has experienced sequelae related to the traumatic event, such as avoidance behaviors regarding sexual matters, flashbacks with dissociative episodes during periods of heightened anxiety, difficulties in social relationships, and feelings of guilt, fear, and disgust. Treatment with Vortioxetine was prescribed, with progressively increasing doses over the following consultations until reaching 20 mg/day. After several visits to the emergency department during this time, the patient was referred to a psychiatric day hospital.
Results: Thanks to this combined therapeutic plan, the patient has shown significant functional recovery, with marked improvement in the affective domain, regaining interest and enjoyment; and in the cognitive domain, demonstrating an increase in her ability to concentrate and in processing speed. Additionally, she has been able to maintain adequate sexual activity during this time.
Conclusions: Antidepressants with serotonergic action present sexual side effects, so treatment must be individualized in patients for whom this area is particularly relevant, considering drugs with a lower rate of side effects in this regard. The complete functional recovery of MDD includes cognitive symptoms as one of the primary therapeutic objectives, so it is important to consider using drugs that are effective in improving the affected cognitive domains. Post-traumatic stress disorder could benefit from the use of drugs with multimodal action, although more studies are needed in the future.

EPV1408

Resilience in patients with post-traumatic stress disorder

R. Barbarić[1]* and S. Burić[1]

[1]Psychiatry, University clinical hospital, Mostar, Bosnia and Herzegovina
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1943

Introduction: Resilience was first introduced into psychology and psychiatry from technical sciences and afterwards thorough medicine and healthcare. It represents a complex set of various protective and salutogenic factors and process important for understanding health and illness, and treatment and healing processes. It is defined as a protective factor that makes an individual more resilient to adverse events that lead to positive developmental outcomes. Resilience is a positive adaptation after stressful situations and it represents mechanisms of coping and rising above difficult experiences, i.e., the capacity of a person to successfully adapt to change, resist the negative impact of stressors and avoid occurrence of significant dysfunctions. It represents the ability to return to the previous, so-called "normal" or healthy condition after trauma, accident, tragedy, or illness. In other words, resilience refers to the ability to cope with difficult, stressful and traumatic situations while maintaining or restoring normal functioning. The higher the resilience, the lower the vulnerability and risk of illness (Babic R, et al. Psychiatria Danubina 2020; Vol. 32, Suppl. 2, 226-232). In the development of post-traumatic stress disorder (PTSD), there is a positive association with negative emotions, on the other hand, PTSD symptoms are negatively correlated with positive emotions (Deborah JC. TD collection for University of Nebraska – Lincoln, 2001), which often depends on resilience which is inversely proportional to the onset of PTSD and as such plays an important role in treatment of anxiety disorders, depression and stress reaction (Green et al. Assessment 2014; 21:443-5, Connell et al. Fr J Psychiatry (Johannesburg) 2013; 19:16, Zerach et al. sr J Psychiatry Relat Sci 2013; 50:91-98).
Objectives: The aim of this research was to investigate the connection between resilience and post-traumatic stress disorder.
Methods: Socio-demographic questionnaire (personal creation).
Resilience questionnaire – Croatian version (Connor-Davidson Resilience Scale 25).
Clinical questionnaire for ptsd, diagnostic version for current and lifetime PTSD - Croatian version (Clinician Administered PTSD Scale, CAPS-DX).

	Resilience	
CAPS-DX (PTSD)	r	p
Reexpiriencing symptoms	-0.446	<0.001
Avoidance symptoms	-0.561	<0.001
Arousal and reactivity symptoms	-0.509	<0.001
CAPS-DX total	-0.542	<0.001

Results:

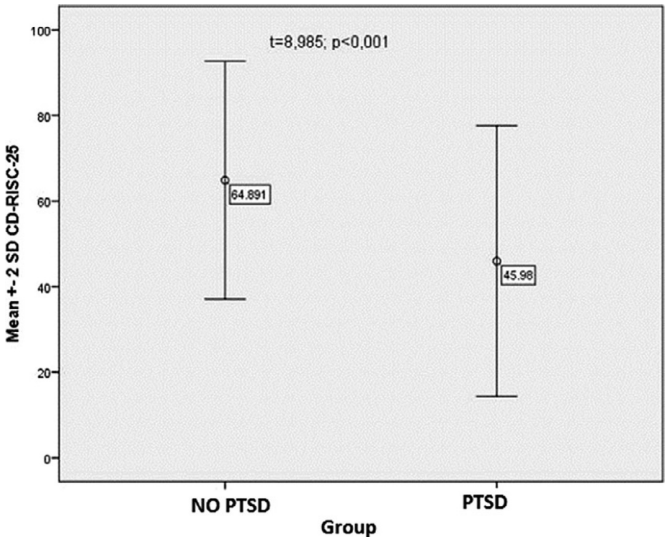

Image:

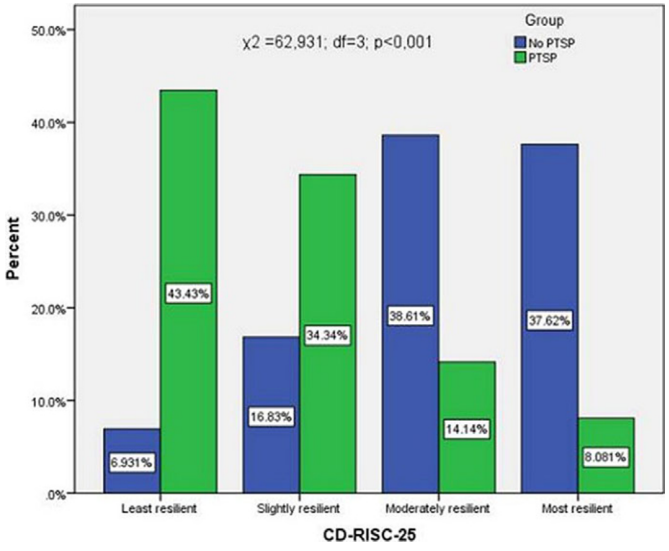

Image 2:

Conclusions: The level of resilience had an impact on the onset, development and outcome of PTSD.
People without PTSD show a statistically higher level of resilience compared to respondents with PTSD.
Respondents without PTSD are statistically significantly more represented in the groups with moderately high resilience, while those with PTSD are the most in the group with the least resilience.

Post-Traumatic Stress Disorder Following a Suicide Attempt

S. Ben Aissa[1]*, R. Khouloud[1], N. Chaima[1], L. Amine[1] and M. Wahid[1]

[1]Psychiatry D, Razi Hospital, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1944

Introduction: Post-traumatic stress disorder (PTSD) is an anxiety disorder that develops when a person is exposed to death, perceives a threat to their safety, or witnesses a traumatic event, either personally or vicariously. It is a condition that affects over 70% of adults who have experienced trauma at least once in their lives. What happens in the case of individuals who have attempted suicide? Do they also frequently develop PTSD?
Objectives: To determine if individuals who have attempted suicide are at risk of developing PTSD as a result of their suicide attempt. If such a connection is proven, what therapeutic measures could be proposed to prevent the onset of this disorder?
Methods: This is a descriptive study using a survey of patients at the Department of Psychiatry D at RAZI Hospital, who have made one or more suicide attempts during the year 2023.
Results: 20 patients (80%) exhibited a moderate to severe depressive episode at the time of their suicide attempt. The average number of suicide attempts was 1.53. The methods used for the suicide attempts included medication ingestion, observed in 15 patients (60%), phlebotomy in 4 (16%), jumping from a height in 2 (8%), hanging in 2 (8%), and ingestion of toxins in 2 (8%). 14 patients (56%) required hospitalization in a medical unit following the suicide attempt. 9 out of 25 patients (36%) developed PTSD according to DSM-5 criteria.
Conclusions: A significant proportion of suicide attempt survivors may develop PTSD related to the suicide attempt. PTSD related to a suicide attempt could serve as a viable target for assessment and intervention to improve quality of life and reduce the risk of future suicide among individuals who have attempted suicide. However, more studies are needed to evaluate the risk of PTSD in this population.

EPV1410

Erectile Dysfunction in Veterans with Post-Traumatic Stress Disorder

Y. Ben Othmene[1]*, A. Baatout[1], W. Kabtni[1], K. Kefi[1], S. Eddif[1], H. Kefi[1] and A. Oumaya[1]

[1]Psychiatry, Military Hospital, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1945

Introduction: The mental health burden of post-traumatic stress disorder (PTSD) is significant for all those affected, with a higher incidence among veterans due to military trauma and the particular strains of military duty. It results in detrimental effects on life quality and functional impairment in various domains, including sexual dysfunction (SD).
One of the most prevalent yet underreported sexual dysfunction in Tunisian veterans is erectile dysfunction (ED).

Objectives: The aim of the current study was to assess the prevalence of ED and its severity among Tunisian veterans with PTSD versus those without it.
Methods: A cross-sectional descriptive and analytical survey was conducted between September and November 2024 on Tunisian veterans seeking consult, using a data file and 2 self-report questionnaires :
The PTSD Checklist for DSM-5 (PCL-5) to assess current PTSD symptoms with a cut-off score of 33 or higher to detect PTSD cases.
The IIEF-5 (International Index of Erectile Function 5) to evaluate ED with six categories: [1-4]: uninterpretable, [5-7]: severe, [8-11]: moderate, [12-16]: mild to moderate, [17-21]: mild and [22-25]: no ED.
To analyze the obtained data, IBM SPSS was used.
Results: Fourty veterans were enrolled in this study with an average age of 38.5 [24-61] years. The majority (67.5%) were married, followed by 25% single individuals, 5% divorced and 2.5% in a relationship. Most of the participants (77.5%) were smokers and 25% reported alcohol consumption, with 20% of them being regular drinkers and 80% consuming alcohol occasionally. None reported using cannabis or other illicit drugs. Regarding medical history, 32.5% had health issues with the most common being varicocele, diabetes, arterial hypertension and myocardial infarction.
Among the veterans, 50% had PTSD. Ninety-five percent had received psychiatric follow-up, and 78.9% were on antidepressants.
In the control group with no PTSD (50%), 85% had a psychiatric follow-up, with 76.5% taking antidepressants.
In patients with PTSD, 75% reported ED, while 15% had no SD and 10% had an uninterpretable score. ED was mild to moderate in 46.7%, mild in 33.3% and moderate in 20%. No severe cases of ED were observed in this group.
In contrast, in patients with no PTSD, ED was only reported in 60% of cases and was even severe in 33.3% of patients.
No significant correlation was found between ED and PTSD (p= 0.3).
The prevalence of ED in the overall sample was 67.5% with only 11.1% of them using sexual enhancers.
Conclusions: This study suggests that while PTSD may exacerbate ED in some individuals, other factors such as comorbid psychiatric or medical condition and the use of a variety of medications may play a more significant role in the underlying cause. Given its significant impact on quality of life, early screening and treatment are essential.
Additionally, further research is needed to understand the underlying causes of ED and to develop more targeted interventions.

Disclosure of Interest: None Declared

EPV1411

Comorbid Anxiety, Depression and PTSD in Tunisian Military Veterans

Y. Ben Othmene[1]*, A. Baatout[1], K. Kefi[1], W. Kabtni[1], S. Eddif[1], H. Kefi[1] and A. Oumaya[1]

[1]Psychiatry, Military Hospital, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1946

Introduction: Intrusion, hyperarousal, avoiding triggers and alterations in cognition and mood are the symptoms defining a post-traumatic stress disorder (PTSD).
While PTSD can occur in individuals from all walks of life, its prevalence and severity are higher among military veterans, exacerbating the impact of other mental health disorders such as anxiety and depression and impairing quality of life.
Objectives: The current study sought to determine the prevalence of comorbid anxiety and depression with PTSD among Tunisian military veterans.
Methods: A cross-sectional descriptive and analytical survey was conducted between September and November 2024, focusing on Tunisian veterans seeking consult, using a data file and 2 self-report scales :
The PTSD Checklist for DSM-5 (PCL-5) to assess current PTSD symptoms with a cut-off score of 33 or higher to detect PTSD cases.
The Hospital Anxiety and Depression (HAD) scale, which consists of two subscales: the Anxiety (A) subscale and the Depression (D) subscale. For both subscales, scores are ranging from 0 to 21: [0-7]: normal, [8-10]: borderline case, [11-21]: an abnormal level of anxiety or depression.
To analyze the obtained data, IBM SPSS was used.
Results: The study enrolled 24 veterans diagnosed with PTSD, with the majority being male (87.5%). Mean age of the participants was 34 [23-50] years. Most (58.3%) were married, 33.3% were single, 4.2% were divorced, and 4.2% were in a relationship.
A significant proportion of the surveyed (79.2%) were smokers, while 29.2% reported occasional alcohol consumption. None reported using illicit drugs, such as cannabis.
Regarding medical history, 29.2% had medical health conditions including asthma, diabetes, hypertension, herniated disc, and kidney stones.
In terms of psychiatric care, 95.8% were under regular psychiatric follow-up and 54.2% reported having a support system.
Regarding psychiatric comorbidities, 95.8% (N=23) of participants presented with anxiety symptoms with 4.2% falling into the borderline category. For depression, 66.7% reported depressive symptoms, 25% were classified as borderline cases and 8.3% showed no depressive symptoms.
Median PCL-5 score was 55.5±12.15. Half of the population (N=12) had a score higher than 55. All of them exhibited depressive symptoms. In contrast, among those with lower scores, only 33.3% had depressive symptoms, 50% had borderline cases and 16.7% had no depressive symptoms.
A significant correlation was found between **PCL-5** scores above 55 and the presence of depressive symptoms (p=0.02), suggesting a strong association between higher PTSD severity and depression in this sample.
Conclusions: This study reveals a high prevalence of comorbid anxiety and depression among Tunisian Military veterans suffering from PTSD with a significant association between higher PTSD severity and depressive symptoms, highlighting the need for integrated mental health care that addresses both PTSD and its comorbidities.

Disclosure of Interest: None Declared

Fight or Flight Freeze- A Case Report Paper, PTSD patient

A. Botica[1]*, N. Kurtovic[1], M. Strikic[2] and T. Glavina[1]

[1]Psychiatry, University Hospital Centre and [2]Psychiatry, 2Mental Health Service, Teaching Institute for Public Health, Split, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1947

Introduction: Post-traumatic stress disorder (PTSD) is a mental health condition that violates everyday functioning, and it is a result of a traumatic event or life-threatening event. Symptoms of PTSD are nightmares, flashbacks, symptoms of negative emotions and perception, avoidance behavior, and social avoidance and it can affect children. Dissociative symptoms are a part of dissociative disorder in the form of anxiety disorder, but these symptoms can occur in dissociative form of PTSD.
Objectives: The goal of this paper is to present a patient who is under neurological treatment, diagnosed with spastic paraplegia, and under psychiatric treatment diagnosed with PTSD, depression, and possible dissociative disorder.
Methods: This is a case report paper. A male patient, 57 years old, participated in Homeland War in Croatia for a duration of 18 months. He experienced many traumatic events and life-threatening events, such as the death of his friends. The first psychiatric symptoms occurred after war experiences, and the symptoms manifested as headache, insomnia, grumpiness, and paralyzing fear which led to the feeling that his legs were "taken away". Similar symptoms persisted even after the war ended and in other stressful situations along with difficulty walking. He went under neurological testing and it turns out that it might be spastic paraplegia. He was diagnosed with prolactinoma, and since 2019 he has been in psychiatric ambulance treatment in the Daily Hospital of Clinical Hospital Split, diagnosed with PTSD, depression, and dissociative disorder.
Results: We used psychotherapy methods such as socio-therapeutic and group psychotherapy, along with pharmacology therapy (sertraline, diazepam, olanzapine).
Conclusions: Pharmacology interventions might affect PTSD patients in a positive way and help them to function in everyday activities.

Disclosure of Interest: None Declared

EPV1414

Post-traumatic stress disorder: a need for alternative approaches

M. V. Chiappe[1,2]

[1]University of Medicine. Pharmacological Chair UBA and [2]Hospital de Emergencias Psiquiatricas Alvear, Buenos Aires, Argentina
doi: 10.1192/j.eurpsy.2025.1948

Introduction: Post-traumatic stress disorder (PTSD) is a mental health statue that arises from traumatic events featuring by intrusive memories of the incident, difficulty in interpersonal relationships, recurrent distress, avoidance of similar situations and flashbacks. Although conventional treatments such as cognitive behavioral therapy (CBT), exposure therapy, selective serotonin reuptake inhibitors (SSRIs), and medications like prazosin are widely used and supported by scientific evidence, an increasing number of individuals are turning to alternative treatments. For instance, mind-body practices have demonstrated therapeutic benefits for stress reduction, including decreased anxiety, depression, and anger, as well as improved pain tolerance, self-esteem, relaxation, and coping abilities. Practices such as yoga, tai chi, and meditation, which involve physical postures, stretching, and deep breathing, are gaining popularity for managing PTSD symptoms. Additionally, lifestyle changes, diet, mindful breathing, Ayurvedic medicine, and somatic therapies like dance therapy are increasingly recognized as valuable tools for improving quality of life in trauma survivors Clinicians should discuss mind-body interventions with their patients and educate them about the potential benefits of them to maximize the diversity of treatment options.
Objectives: This review aims to explore both conventional and alternative approaches for PTSD treatment, including psychotherapy, psychopharmacology, and complementary practices such as exercise, diet, meditation, yoga, deep breathing, and dance therapy.
Methods: The study is a literature review conducted through PubMed.
Results: The studies included in this review exhibited considerable heterogeneity, with varying designs, intervention methods, and study durations, as well as differing use of control groups. As a result, conducting a true meta-analysis was not feasible.
Conclusions: "Mind-body practices" incorporate numerous therapeutic effects on stress responses, including reductions in anxiety, depression, and anger, and increases in pain-tolerance, self-esteem, energy levels, ability to relax, and ability to cope with stressful situations.
Given the limitations in the current evidence for conventional treatments and the growing use of complementary and alternative approaches, there is a pressing need for more comprehensive re-search into these alternative therapies. Future studies should aim to evaluate the effectiveness of mind-body interventions and other complementary practices as potential treatments for PTSD.

Post traumatic stress disorder in postpartum: when guilt delays recovery. A case report

R. De Hita Santillana[1]*, M. L. Costa Ferreira da Silva[1], M. del Valle Martin[2] and E. Fiori[3]

[1]Hospital Universitario Jose Germain; [2]Hospital Universitario Severo Ochoa, Leganés and [3]Universidad Europea de Madrid, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1949

Introduction: PTSD is a mental disorder that may develop after exposure to threatening or horrifying events. PTSD is characterized by the following: 1) re-experiencing the traumatic event or events in the present in the form of vivid intrusive memories, flashbacks, or nightmares. Re-experiencing may occur via one or multiple sensory modalities and is typically accompanied by strong or overwhelming emotions, particularly fear or horror, and strong physical sensations; 2) avoidance of thoughts and memories of the event or events, activities, situations, or people reminiscent of the event(s); and 3) persistent perceptions of heightened current threat. The symptoms persist for at least several weeks and cause significant impairment in personal, family, social, educational, occupational, or other important areas of functioning.
Some reviewes found that PTSD is prevalent during pregnancy and after birth and may increase during postpartum if not identified and treated. It can affect women, their relationship and birth outcomes aswell as infant emotion regulation and development. The findings indicate that there are links between psychological, traumatic and birth-related risk factors as well as the perceived social support and the possible PTSD following childbirth in mothers and partners.
Objectives: A case report is presented alongside a review of the relevant literature regarding the prevention, diagnosis, and treatment of PTSD.

Methods: We present a case report of a 34-year-old woman with no previous contact with Mental Health Services. She got pregnant unexpectedly in the context of a long stable relationship. At the beginning she was feeling uncertain about carrying on with the pregnancy but finally decided to keep it. She states she felt well throughout the pregnancy. The night after giving birth her baby suffered from a cardiorespiratory arrest, which was noticed by the nursing team but not by the mother. The baby recovered with no medical sequelae but the patient started feeling depressed and presenting anergy, apathy, irritability, flashbacks, and intrusive memories of her sick baby and insomnia, checking every hour during the night that her child was still breathing. Later she developed separation anxiety from her baby, not being able to leave her in the kindergartner nor to leave her alone with other family members (including the father). Guilty feelings were persistantly observed during the therapy sessions.
Results: Psychotherapeutic and pharmacological treatment was started with moderate improvement. Since breastfeeding was a rewarding experience and enforced the mother-daughter bond it was taken in consideration for the therapeutic plan.
Conclusions: The postpartum period is of special vulnerability and early treatment of symptoms in mothers is of great importance. Early diagnosis in maternity services should be a priority.

doi: 10.1192/j.eurpsy.2025.1950

Introduction: Depression is commonly comorbid with post-traumatic stress disorder (PTSD) symptoms. There is a lack of studies evaluating trauma-informed interventions for people with depression and PTSD symptoms.
Objectives: We examined whether an online, easily accessible, trauma psychoeducation program would be helpful for people with both depressive and PTSD symptoms.
Methods: Participants with depression (PHQ-9 ≥ 10) and co-occurring PTSD symptoms were recruited online and randomly assigned to the intervention group (i.e., a 10-session online program based on *Be a Teammate With Yourself*) or the control group. Outcome measures included the Brief-COPE, a subscale of the Endorsed and Anticipated Stigma Inventory, and the Post-traumatic Maladaptive Beliefs Scale. These outcomes were assessed at baseline, posttest, and 2-month follow-up. Qualitative feedback was also obtained from the participants.
Results: 35 participants were randomly assigned to the intervention group, and 34 to the control group. With only email reminders, 9 participants in the intervention group and 14 in the control group completed posttest and follow-up surveys. Completers-only analyses were conducted. One-way repeated measures ANOVA showed that the intervention group had significant reductions in post-traumatic maladaptive beliefs, with a large effect size ($F = 4.152$, $p = .035$, Partial Eta Squared = 0.342). The control group did not have such changes. Both groups did not have significant changes in coping and self-stigma. Of 12 participants who provided feedback, 100% agreed that the program could help them remain hopeful for recovery, and 91.6% agreed that they were satisfied with the program. The qualitative feedback also supported the usefulness and acceptability of the programme.
Conclusions: Participation in this program was associated with significant decreases in post-traumatic maladaptive beliefs. Completers were satisfied with the program. Given a small sample with a high dropout rate (66.6%), the results should be interpreted with caution.

The relationship between complex PTSD and dissociation: A longitudinal study

H. W. Fung[1]*, C. M. Li[2], C. H. O. Huang[3], M. Y. C. Wong[4], T. Y. N. Tsui[5] and A. K. C. Chau[6]

[1]School of Nursing, The Hong Kong Polytechnic University, Kowloon, Hong Kong; [2]Department of Psychiatry, Yale University School of Medicine, New Haven, United States; [3]Department of Social Work and Social Administration, The University of Hong Kong, Pokfulam; [4]Department of Health and Physical Education, The Education University of Hong Kong, Taipo, Hong Kong; [5]School of Psychology, Australian Catholic University, Melbourne, Australia and [6]Department of Psychiatry, the University of Hong Kong, Pokfulam, Hong Kong
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1951

Introduction: Complex post-traumatic stress disorder (C-PTSD) is closely associated with dissociative symptoms. Both of which are common responses to trauma and stress. Yet, not all individuals with C-PTSD experience high levels of dissociation. Currently, little is known about the bidirectional relationship between C-PTSD and dissociative symptoms.
Objectives: This study aimed to examine whether C-PTSD and dissociative symptoms would predict each other over time.
Methods: A total of 340 participants (M_{age}=21.04 years; SD=2.00; 83.8% female) from Hong Kong and Taiwan completed the Multiscale Dissociation Inventory (MDI) and the International Trauma Questionnaire (ITQ) at two separate time points (M days apart = 129.4 days; SD = 7.91). Hierarchical multiple regression analyses were conducted to examine the relationship between C-PTSD and dissociative symptoms.
Results: The analyses controlled for age, gender, education level, trauma exposure, and baseline severity of the dependent variables. Results indicated that when the MDI subscales were added into the model, baseline emotional constriction significantly predicted subsequent C-PTSD symptoms (i.e., total ITQ scores) (β=.126, p=.008), and significantly improved the model's explanatory power (R^2=.67, ΔR^2=.029, $\Delta F = 4.772$, $p < .001$). Nevertheless, when the

same analysis was conducted, none of the six C-PTSD symptom clusters at baseline predicted the total MDI scores at follow-up ($\Delta F = 1.000$, $p = .425$).

Conclusions: The study findings suggested that dissociative symptoms in general, and emotional constriction in particular, predicted subsequent levels of C-PTSD symptoms, while C-PTSD symptoms did not predict subsequent levels of dissociation. These results highlighted that proactive management of dissociative symptoms might be an important part of the treatment of C-PTSD. This study provided a foundation for future research to investigate the underlying mechanisms by which emotional constriction influences C-PTSD severity. Future research should also evaluate dissociation-focused interventions for people with C-PTSD.

Does prazosin improve sleep disturbances and other trauma-related symptoms?

T. M. Gómez Lezcano[1]*, C. Fernandez Natal[1], P. Campos Abraham[1], M. M. Gonzalvo Navarro[1], M. B. Sanjose[1], M. V. Sánchez[1] and J. Correas Lauffer[1]

[1]Psychiatry Department, Hospital Del Henares, Coslada, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1952

Introduction: Post-traumatic stress disorder (PTSD) is characterized by intrusive thoughts and flashbacks involving the traumatic event, hypervigilance and avoidance behavior. On the other hand, complex post-traumatic stress disorder (complex PTSD) can result from experiencing chronic trauma. It involves similar stress reponses, such as flashbacks, nightmares, and also avoidance of places and situations related to the traumatic event. Sleep disturbance is a central element of both disorders (PTSD and complex PTSD). While nightmares qualify as a re-experiencing symptom, initiation and maintenance of sleep stem from a hyperarousal state (Paiva et al., 2021). Evidence implies that treatment for PTSD-related sleep disturbance also improves other trauma-related symptoms. As pharmacological therapy, some clinicians use prazosin, an adrenergic inhibitor, which is a lipophilic drug originally developed to treat hypertension. It blocks α1 receptor sites and ameliorates the increase in noradrenergic activity in PTSD-diagnosed individuals (Lipinska G et al. 2016). Studies differ regarding the effectiveness of this drug to alleviate sleep disorders and other trauma-related symptoms (Bajor et al., 2022; Yücel et al., 2020; Zhang et al., 2020; Petrakis et al. 2016).

Objectives: Through this case series study we want to understand the utility and effectiveness of prazosin in patients diagnosed with PTSD and complex PTSD for the improvement of nightmares and other PTSD-related symptoms.

Methods: For this purpose we have reviewed in 10 patients with a diagnosis of either PTSD (4 out of 11) or complex PTSD (7 out of 11) the improvement of nightmares and other trauma-related symptoms, especially flashbacks. The patients indicated whether there was no, partial or total improvement of these symptoms. The doses used were between 1 to 2mg.

Results: In this Case series study (n= 11), we focus on the reports from PTSD - and complex PTSD-diagnosed (4 out of 11 vs 7 out of 11) patients treated with prazosin regarding their sleep disturbance and other trauma-related symptoms.

Forty percent of the patients report a reduction in the frequency and intensity of nightmares, while 3 patients of the sample reported absolute extinction of nightmares.

Our findings reveal almost half of the patiens (4 out of 11) expressed as well a reduction in other PTSD symptoms, specifically in flashbacks.

We have not found a significant better outcome in either PTSD or complex PTSD- diagnosed patients. The entire sample were female patients.

Improvements in hypervigilance and avoidance behavior have hardly been reported in enrolled patients (3 out of 11).

Conclusions: In our sample, the use of prazosin appears to be an acceptably good option, especially for the improvement of nightmares. Nevertheless, further studies should be conduced.

Childhood traumatization among elite athletes – preliminary study

N. M. Szeifert[1,2,3], B. Sebok[4,5], A. Lenart[6] and X. Gonda[7]*

[1]Department of Sports Medicine, Semmelweis University; [2]National Institute of Sports Medicine; [3]Eotvos Lorand University, Doctoral School of Psychology; [4]School of PhD Studies Workgroup for Science Management, Semmelweis University; [5]Dr. Manninger Jenő Trauma Center; [6]Department of Psychology and Sport Psychology, Hungarian University of Sports Science and [7]Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1953

Introduction: Achieving excellent sport performance is based both on physical strength and mental endurance. Research demonstrated that children experiencing early maltreatment and traumatization are at an increased risk of high-risk behaviours, bullying, and mental and somatic disorders lasting into adulthood effecting academic and sport performance, relations and life management. Research found that individuals with a history of trauma had a significantly lower chance of being diagnosed with depression or anxiety if they had participated in team sports as adolescents. Also later in life, sport is very beneficial to cope with stressful life events.

Objectives: We aimed to explore occurrence of early traumas in elite athletes and a control group using the Childhood Trauma Questionnaire (CTQ) and the Early Trauma Inventory Self Report-Short Form (ETISR-SF).

Methods: The sample included 57 subjects, 50.9% elite athletes and 49.1% leisure time athletes (controls). Participants (64.9% males, 35.1% females) provided demographic data (age 18-58 years, mean age = 31.96 years, SD = 8.920) and completed the ETISR-SF and the Childhood Trauma Questionnaire-Short Form (CTQ-SF). Analysis of Fisher's Exact Test was performed for evaluating the occurrence of early traumatization.

Results: The ETISR-SF and CTQ subscales scales did not show significant difference in any type of traumas in elite athletes compared to the control group (general traumas p=0.092, emotional abuse p=1.000, physical abuse p=0.592, sexual abuse p=0.297). Occurrence of each trauma type in the two groups were as follows. Elite athletes: sexual trauma (10.34%), physical trauma (55.17%),

emotional trauma (44.83%), general trauma (55.17%); Controls: sexual trauma (21.43%), physical trauma (64.29%), emotional trauma (46.43%), general traumas (78.57%).
Conclusions: The occurrence of different type of trauma in our sample is in line with the literature. Physical and emotional abuse among athletes is high. Presumably, those athletes perform better who experience less trauma. The best way to produce resilient athletes is to provide a challenging and supportive sport environment, where athletes feel physically and psychologically safe in their experiences of success and failure.

EPV1421

Beyond Nightmares: How Sleep Issues Might Trigger Post-Traumatic Stress Disorder

O. Inanc

Gulhane Training and Research Hospital, Ankara, Türkiye
doi: 10.1192/j.eurpsy.2025.1954

Introduction: Post-traumatic stress disorder (PTSD) is a psychiatric condition that arises after exposure to traumatic events and is characterized by intrusive memories, emotional dysregulation, and hyperarousal. Sleep disturbances, such as insomnia and disrupted circadian rhythms, are often reported in PTSD. However, recent studies suggest that sleep disorders may not only be a consequence of PTSD but could also contribute to its development (DeViva, 2021; Seo et al., 2022). Sleep is crucial in emotional regulation, memory consolidation, and stress recovery. Disruptions in sleep patterns may impair these processes, increasing vulnerability to psychiatric conditions such as PTSD (Zhou, 2023). This systematic review evaluates current evidence on whether sleep disturbances serve as a precursor or risk factor for PTSD across various populations. Understanding the role of sleep disturbances in the onset of PTSD is critical for developing early intervention and prevention strategies.
Objectives: This systematic review aims to evaluate whether sleep disturbances act as a risk factor for the development of PTSD by synthesizing recent evidence from diverse populations.
Methods: A comprehensive literature search was conducted using the keywords "PTSD" and "sleep disturbance" in the database on PubMed. Out of 143 studies published within the last five years, eight articles that specifically examined sleep disturbances as a risk factor for PTSD were selected for this review.
Results: The review of selected studies highlights a strong association between sleep disorders and an increased risk of PTSD development across various populations. Poor sleep quality was associated with a 60% greater likelihood of developing PTSD. In a nationally representative sample of U.S. veterans, over 22% reported poor sleep quality, which was a significant predictor of PTSD. (DeViva, 2021). In a study of 67,905 college students, those with sleep disturbances had significantly higher rates of PTSD (52.3% vs. 33.0%) and depression (47.7% vs. 13.2%). (Wang et al., 2022). Moreover, emotional dysregulation, often exacerbated by sleep disorders, was found to aggravate PTSD symptoms further. The studies also indicated that interventions targeting sleep disorders, such as cognitive behavioral therapy for insomnia, not only improved sleep quality but also contributed to a reduction in trauma-related symptoms, suggesting potential for PTSD prevention (Ranney, 2022).
Conclusions: This review highlights that sleep disturbances are a significant risk factor for the development of PTSD. Early identification and treatment of sleep disorders could serve as a preventative strategy for individuals exposed to trauma. Future research should explore the underlying mechanisms of this relationship and the effectiveness of sleep-focused interventions in reducing PTSD risk.

Complex PTSD in Digital Age: Case of Ukrainian Refugees – Victims of War Crimes

M. Jishkariani[1]*, N. Okribelashvili[2] and G. Berulava[1]

[1]Clinical Department, Psycho - Rehabilitation Centre "EMPATHY" and [2]Psychiatry, TSU, Tbilisi, Georgia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1955

Introduction: This study includes the characteristics of Compex PTSD among Ukrainian IDPs who experienced the horrors of the war - during the Russia-Ukraine war in 2022-2024. It also reflects the new and permanent stressors characteristic of the digital age.
Objectives: Objective of the Study was to identify how cyber age and modern technologies affected on outcomes of traumatic stress.
Methods: The study was carried out iamong the victims of the Ukrainian war temporarily displaced in Georgia. A specially developed questionnaire based on the guidelines of the Istanbul Protocol was used.
Results: A total number of direct target beneficiaries applied to the Empathy was n = 68 persons; Most refugees were with experience of war crimes. **Mainly two types of life threatening traumatic events was identified:** Locally in place of war and Russian occupation; They flowed from Ukraine through the Russian territory and additionally are with experience of ill – treatment during the filtration procedures in the so-called "filtration camps". Chronic Repetitive Traumatic Stressors were identified as well: Misinformation; Adhering to online war scenes, the vast amount of information flow; Inability to dissociate from warfare. Observed: Rapid development of C - PTSD in 52 persons of total 68. Alongside with PTSD symptoms reveled: Affective Dysregulation – aggression, self – aggression, depression; Feeling of Guilty – for not being in Ukraine, not supporting to their relatives and Country; Problems in interpersonal relations; Addictive behavior; Additional stressors related to the digital warfare and disinformation supported the prolongation of multi natural stressors that consequently created significant problems for recovery.
Conclusions: The results were discussed in the context of Carl Jaspers' conception regarding reactive conditions. According to his concept, reactive psychoses develop on the basis of a conflict between a person and an unbearable reality for him, and at the same time, this reality is necessarily reflected in the clinical picture of the disease. However, it should be noted that by the 60s, delayed forms of reactive states were described, i.e., forms far removed from the traumatic moment, during which Jasper's criterion of "time connection" is violated, although the traumatic event is fully reflected in the clinical picture. The reason for this is mainly the prolonged process of intrapsychic processing and final realization of the trauma. **The rapid development of complex PTSD under**

the combined influence of endless multi-stress factors was revealed; The researchers were faced with an effective treatment - the search for ways of rehabilitation in the current multi-stress conditions. Furthermore studies have to be addressed to create new complex recovery strategies in modern multi – face unsolved stress situations.

Professional future of military personnel suffering from post-traumatic stress disorder

Z. Fourati[1], S. Kamoun[1], H. Ziedi[1], M. Ahmed Ali[1], N. Khaterchi[1] and A. Amri[1]*

[1]Occupational health department, Military Occupational Health Center, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1956

Introduction: Post-traumatic stress disorder (PTSD) is a disabling condition that develops after exposure to a traumatic event. Military personnel are particularly affected by this psychiatric condition, which profoundly alters their personal, social and professional lives. Professional redeployment is most often the decision taken to keep these military personnel in the army.
Objectives: To identify the professional future of military personnel suffering from PTSD
Methods: Retrospective descriptive study conducted at the Military Centre for Occupational Medicine and Occupational Safety between 2017 and 2022 among active military personnel requesting occupational redeployment.
Results: We collected 22 cases of professional redeployment for PTSD, representing 24% of all requests for redeployment. Our study population was exclusively male, with a mean age of 30 ±9 years, mainly from the army (19 cases), divided into officers (3 cases), non-commissioned officers (12 cases) and enlisted men (7 cases). The traumatic event responsible for the PTSD was a mine explosion (8 cases), a road accident (6 cases), a gunshot wound (6 cases), a fall from a parachute (1 case) and an air accident (1 case). All patients had previously been exempted from certain military duties, mainly carrying weapons (22 cases), guards duty (5 cases) and driving vehicles (5 cases). When the decision to reclassify was taken, the military personnel was affected to a mainly administrative post (19 cases), a gardening post (1 case), a plumbing post (1 case) and a catering post (1 case).
Conclusions: This study highlights the fact that PTSD in the military represents a serious and complex challenge that requires special attention. It is imperative to put in place preventive measures and provide appropriate management of PTSD. That can support the military personnel affected and maintain the operational capability of the troops.

EPV1425

Dissociative Identity Disorder in Patients Under Stress

N. Kissa[1]*, A. Korchi[1], N. Ait Bensaid[1], S. Bahetta[2] and A. Ouanass[2]

[1]University psychiatric hospital Arrazi and [2]University Psychiatric Hospital Arrazi of Salé Faculty of Medicine and Pharmacy – Mohammed V University of Rabat, Salé, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1957

Introduction: Dissociative Identity Disorder (DID), as defined in the DSM-5-TR, involves two or more distinct personality states within an individual, along with memory gaps for daily or traumatic events [1]. It is strongly associated with early trauma, such as childhood abuse, and linked to severe psychiatric comorbidities, including depression, anxiety, and self-harm, with an elevated risk of suicide attempts [2][3]. Stress-related neurobiological responses, particularly HPA axis hyperactivity, contribute to identity fragmentation in DID patients. Treatment, often through cognitive-behavioral therapy, aims to integrate dissociated states, reduce self-destructive behaviors, and improve quality of life [2][3].
Objectives: In this case study, we present two compelling cases of dissociative identity disorder following a state of stress. We hope this case study will help reveal the possible association of the disorder with stress
Methods: This is a retrospective and descriptive case study aimed at exploring the manifestations and associated factors of dissociative identity disorder in patients who have experienced traumatic events.
Results: ***Clinical Case Summary of Case 1 :***
A 24-year-old student developed dissociative identity disorder after witnessing a fatal accident caused by a drunk driver. This trauma fragmented his personality into three identities: a child expressing needs through crying, a rebellious adolescent who smokes, and a feminine, seductive personality. These identities appear involuntarily, especially during periods of stress, causing him anxiety and memory loss regarding these episodes.
Clinical Case Summary of Case 2 :
A 23-year-old single, unemployed patient with a long psychiatric history was admitted following a suicide attempt by jumping. She experiences recurrent depressive episodes, suicidal thoughts, and engages in self-harm to manage her anxiety. Salma has dissociative identity disorder, with an alternate identity named "RUBY" that emerges under stress, driving her towards self-destructive behaviors and exacerbating her distress. Her history includes significant childhood trauma, such as sexual abuse and physical violence, contributing to her identity dissociation. She also exhibits alcohol abuse, consuming up to 1 liter daily to manage her anxiety.
Conclusions: Dissociative identity disorder is a complex condition, often linked to early trauma, characterized by the presence of multiple distinct identities within the same individual. This disorder causes significant distress and impacts patients' daily functioning, especially in stressful situations. Treatment primarily involves therapeutic approaches aimed at integrating the different identities and reducing self-destructive behaviors. Understanding and managing this disorder require a personalized approach and long-term follow-up.

Disclosure of Interest: None Declared

EPV1426

A system of personality-oriented treatment of stress-related disorders in war-affected adults

H. Kozhyna[1], O. Druz[2], I. Chernenko[2], K. Zelenska[1], K. Marushchenko[3] and A. Kondratenko[1]*

[1]Department of Psychiatry, Narcology, Medical Psychology and Social Work, Kharkiv National Medical University, Kharkiv; [2]Psychiatric Clinic (with rooms for drug-addicted), National Military Medical Clinical Centre "Main Military Clinical Hospital" of the Ministry of Defense of Ukraine and [3]Department of Military Therapy, Ukrainian Military Medical Academy, Kyiv, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1958

Introduction: War is the most powerful psychosocial stressor affecting all segments of modern Ukrainian society.
Objectives: It was conducted a comprehensive examination of 176 patients of both sexes: Group I consisted of 101 military personnel; Group II - 97 volunteers; Group III - 95 IDPs in order to develop a system of personality-oriented treatment of stress-related disorders in persons affected by war.
Methods: Clinical and psychopathological examination, which included a structured interview and patient's observation aimed at studying influence of socio-psychological and biological factors on development of post-stress disorders. Psychodiagnostic method include use: M-PTSD; HADS; HAM-A, HAM-D; Questionnaire of neuropsychological stress by T.A. Nemchin; State-Trait Anxiety Invertory; Methods of diagnosing coping behaviour in stressful situations; Impact of Event Scale-Revised; Clinical Administered PTSD Scale-CAPS; Traumatic Stress Questionnaire; Colombian Suicide Intentions Severity Scale; Methods for determining suicide risk and assessing self-awareness of death in patients with depressive disorder (Kozhyna H.M., Zelenska K.O., 2015); Methods for 'Diagnosing the level of social frustration (Wasserman L.I., modified by Boyko V.V., 2002).
Results: Clinical structure of stress-related disorders was presented by PTSD and adjustment disorders. Clinical structure of PTSD was represented by anxious, dysphoric, asthenic and somatoform syndromes. System of personality-oriented treatment was developed, including differentiated use of psychopharmacotherapy, psychotherapy and psychoeducation; creation of re-adaptive atmosphere; formation of health-centered lifestyle and based on a salutogenic approach. Pharmacotherapeutic component of developed program included differentiated, targeted use of SSRIs, SNRIs, antipsychotics, tranquilizers and anxiolytics. Psychotherapeutic program was based on identification of dominant resource channels for overcoming stress and finding inner stability using integrative model of psychological survival after severe stress, Basic Ph. Psychotherapeutic support included trauma-focused CBT for all patients, EMDR therapy with additional use of Pucelik Consulting Group's PTSD Self-Management Program for servicemen patients in Group I; individual crisis therapy for patients in Group II; and interpersonal therapy for patients in Group III. For anxious depressive reactions, CBT and art therapy were used for all patients; with the additional use of problem-solving therapy for patients of Group I; Group II - individual crisis therapy; Group III - mindfulness techniques, relaxation training.
Conclusions: Effectiveness of developed system of personality-oriented treatment of stress-related disorders was proved, and positive dynamics of mental state, reduction of psychopathological symptoms, increased resistance, reduced levels of social and psychological frustration were established.

EPV1429

The Effects of Deliberate Rumination and Prolonged Grief on Approach-Avoidance Behavior

Y. Son[1]*, C. Lee[1] and M.-H. Hyun[1]
[1]Chung-Ang University, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1959

Introduction: In the Cognitive-Behavioral Conceptualization of Complicated Grief, avoidance strategies toward bereavement-related stimuli contribute to the development and maintenance of prolonged grief. Traumatic events, such as bereavement, often lead to intrusive negative thoughts and evoke painful emotions. For individuals experiencing prolonged grief, avoidant coping can deteriorate their symptoms. Deliberate rumination on the loss, as an active information-processing strategy to understand and find meaning in the traumatic experience, may promote adaptation to life after the loss.
Objectives: This study aims to examine the impact of prolonged grief on approach-avoidance behaviors and to evaluate the effects of a deliberate rumination intervention.
Methods: Data were collected from 41 Korean adults aged 18 and above, who had experienced bereavement at least 12 months prior. Participants were randomly assigned to either a deliberate rumination intervention group (n=21) or a distraction intervention group (n=20). The Approach-Avoidance Task (AAT) was used to measure implicit approach-avoidance behaviors toward bereavement-related and neutral stimuli in each group, with assessments conducted both before and after the intervention.
Results: The study results revealed no significant differences in approach-avoidance tendencies according to the level of prolonged grief for both bereavement-related and neutral stimuli. However, a significant interaction effect between group and time of measurement was observed for bereavement-related stimuli [$F(1,39)=4.431$, $p<.05$], but not for neutral stimuli [$F(1,39)=.424$, *n.s.*].
Conclusions: Although this study did not identify significant avoidance tendencies according to prolonged grief levels, it experimentally showed that deliberate rumination influences avoidance strategies among individuals experiencing prolonged grief. This finding implies significance in suggesting effective intervention approaches for those with pathological grief.

Post-Traumatic Stress Disorder and Cognitive Impairment: The Great Unknown

S. Orrego[1]*, M. Sava[1], S. Rozas[2], D. Castro[1], M. Delso[1], M. Nadales[1] and M. S. Manzano[3]
[1]Psiquiatria, Hospital Universitario Infanta Leonor; [2]Psiquiatria, Hospital Universitario Jose Germain and [3]Neurologia, Hospital Universitario Infanta Leonor, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1960

Introduction: Accumulating evidence identifies post-traumatic stress disorder (PTSD) as a significant risk factor for the development of dementia, with affected individuals demonstrating a two-fold increase in dementia risk compared to the general population.

Additionally, the development of dementia in these patients may exacerbate the clinical manifestations associated with PTSD, complicating proper management and treatment.
Objectives: To describe a clinical case of a patient with a history of PTSD presenting with cognitive impairment, and to provide a brief review of the literature.
Methods: Case description and literature review.
Results: A 65-year-old male patient, originally from Colombia, with a documented history of PTSD secondary to kidnapping and armed conflict, presented to psychiatric services in Spain for initial assessment and treatment. The family reports neglect of self-care, persistent hypervigilance, nightmares, and night screams, as well as multiple attentional failures, learning difficulties, and memory impairments. The patient was referred for a neurological consultation where the evaluation included a Mini-Mental State Examination (MMSE) scoring 16/30. Cranial MRI showed no abnormalities, and amyloid PET was negative. An FDG PET scan revealed discrete hypometabolism of the medial prefrontal cortex, which could be indicative of possible frontotemporal dementia.
Conclusions: The prevalence of dementia is rising globally. PTSD has been identified as a modifiable risk factor for developing dementia. Furthermore, studies show that the relationship between these conditions is bidirectional, with late-onset PTSD also potentially developing in patients with a diagnosis of dementia. The mechanisms underlying this relationship are poorly understood. It is hypothesized that both conditions share common pathophysiological pathways. PTSD manifestations in patients with dementia are often difficult to recognize, which is believed to result in an underdiagnosis of the condition. Additionally, these clinical manifestations can be confused with neuropsychiatric symptoms associated with dementia, further complicating diagnosis. The relationship between PTSD and dementia may be modifiable if patients with PTSD are provided with appropriate diagnosis and treatment, thereby improving their quality of life and prognosis.

Aggression, autoaggression and stress in people with a heart attack

V. Jovanovska[1]* and K. Petkovska[2]

[1]Psychiatry, PHI General Hospital Kumanovo, Kumanovo and [2]PMI Nuhi Jusufi, Kumanov, North Macedonia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1961

Introduction: A human represents wholeness of biological, psychological and social nature and below impact of psychosocial stress preserves the homeostasis of the organism manifests a complete biopsychosocial response is therefore necessary in professional practice to be taken psychoneuroendocrine immunological approach in treating certain somatic and psychological.
Objectives: Determining emotions, various types of aggression in people who have experienced a heart attack and is currently under the influence of chronic psychosocial stress of moderate intensity.
Methods: The examination was conducted on an outpatient basis on 14 subjects aged 51 to 72. age of male and female who experienced a heart attack. Applied: Azingerova aggression scale, PSQ stress test, Zung anxiety scale, Zung depression scale.
Results: The respondents show a stress reaction at the level of moderate stress (30-60) with dominant feelings of: fatigue, tension, dissatisfaction, overload. Anxious symptoms are at the level of mild to moderate (45-59). Depressive symptoms are at the mild level (50-59). They have higher values on the aggression test. In both sexes (male and female) they have the highest values in self-aggression. Somewhat lower is verbal aggression while emotional aggression has average values. In the female gender, aggression is the lowest through physical force, while the use of aggression through physical force is occasional for men. Both sexes show little aggression towards objects around them.
Conclusions: In people with somatic diseases, in the case of a heart attack, emotions are high an important factor for their stability, especially the negative ones, and therefore it is necessarily needed an integrative approach to treatment, taking into account the mental state as a whole especially when they are in a state of psychosocial stress.

Systematic Assessment of Stellate Ganglion Block in Post-Traumatic Stress Disorder: Exploring Clinical Utilization and Significance

S. Prasad[1], N. Jain[2], G. S. Gill[3], A. K. Bachu[4] and S. Gunturu[1]*

[1]Psychiatry, BronxCare Health System, New York, United States; [2]Riga Stradins University, Riga, Latvia; [3]Case Western Reserve University, Cleveland and [4]Psychiatry, University of Arkansas for Medical Sciences, Little Rock, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1962

Introduction: Post-traumatic stress disorder (PTSD) is a chronic condition resulting from exposure to traumatic events. The utilization of stellate ganglion block (SGB) as a potential treatment for PTSD has garnered increased interest in recent years. SGB acts by blocking sympathetic outflow, offering promise in alleviating autonomic dysfunction associated with PTSD symptoms. However, the evidence supporting SGB's efficacy compared to established recommendations remains limited.
Objectives: To bridge this knowledge gap, a systematic review was conducted following PRISMA guidelines to assess the clinical applications and implications of stellate ganglion block (SGB) in the management of post-traumatic stress disorder (PTSD). The study aimed to identify pertinent literature, synthesize findings from diverse sources, evaluate outcomes of SGB therapy for PTSD, analyze factors such as anesthesia preferences and procedural methods, scrutinize symptom alleviation post-SGB sessions, explore reported side effects and symptom recurrence, and shed light on existing limitations within the current discourse on SGB's utility in treating PTSD.
Methods: The systematic review involved the evaluation of 14 studies meeting predetermined inclusion criteria, incorporating a total of 550 participants. Notably, the majority of participants were military service members and veterans, with a median age of 36.9 years. The review focused on anesthetic practices, procedural techniques, timing of SGB administration, and symptom progression post-SGB therapy sessions.
Results: Analysis of the selected studies highlighted the prevalent use of 0.5% ropivacaine as the preferred anesthetic for SGB, with the

right-sided technique being the most commonly employed. Timing of the initial SGB session varied widely, with symptom improvement typically observed immediately or within the first week post-procedure. Positive outcomes often coincided with reductions in alcohol intake, medication use, and enhanced mood. Recurrence of symptoms was noted, necessitating additional SGB sessions, while reported side effects were predominantly mild and transient in nature.
Conclusions: While promising, caution is advised when interpreting the benefits of SGB due to challenges such as the absence of standardized clinical trial data, variabilities in reported outcomes, and potential reporting biases. Addressing these limitations through standardized assessment and reporting in future studies is crucial to enhance comprehension of SGB's efficacy, safety, tolerability, and appropriate indications for treating PTSD. This endeavor is pivotal in advancing a more nuanced understanding of SGB's role as a therapeutic modality in PTSD management.

Navigating Diagnostic Overlaps: A Case Report of Paranoid Schizophrenia, Borderline Personality Disorder, and Hidden PTSD in a Patient with an Orphanage Background

F. S. Pricope[1]

[1]Drug Addiction Department, Cluj County Emergency Clinical Hospital, Cluj-Napoca, Romania
doi: 10.1192/j.eurpsy.2025.1963

Introduction: Diagnosing psychiatric disorders in individuals raised in orphanages is challenging due to symptom overlap. Trauma from institutional life can mimic symptoms of both Post-Traumatic Stress Disorder (PTSD) and paranoid schizophrenia (Hermenau et al. *J Trauma Stress* 2011; 24: 513-516). For example, PTSD symptoms like intrusive memories may resemble schizophrenia's delusions when trauma affects threat perception. Additionally, PTSD-related attachment issues can exacerbate paranoia (Patel et al. *J Trauma Dissociation* 2016; 17: 123-136). Accurate diagnosis requires careful assessment of trauma history and symptom differentiation (Robinaugh et al. *Depress Anxiety* 2011; 28: 305-311).
Objectives: Challenges of symptoms overlapping in schizophrenia, borderline personality disorder, and PTSD.
Effects of orphanage background and early trauma on psychiatric symptoms.
Diagnostic methods and evolving treatment plans.
Methods: Patient ZN, a 37-year-old female with paranoid schizophrenia and borderline personality disorder (BPD), has had 11 admissions over six years at our clinic. Despite treatment with DSM-5 criteria, PANSS, and BEST scales, using antipsychotics, mood stabilizers, and benzodiazepines, there was no significant improvement. This year, her hospitalizations increased, particularly after developing a strong attachment and maternal feelings toward a doctor who treated her three times consecutively. PTSD, relevant due to her orphanage background and initially unassessed, was later identified through screening. Data were recorded through clinical notes, informed consent was obtained, and the case study's single-case design limits generalizability.
Results:
Conclusions: In conclusion, diagnosing PTSD, paranoid schizophrenia and BPD in orphanage-raised adults is challenging due to trauma, overlapping symptoms, and disrupted attachment. This case highlights the complexities of diagnosis and treatment, emphasizing the need for a comprehensive and adaptable approach.

Diagnosis and treatment of post-traumatic stress disorder (PTSD) through the analysis of two clinical cases

M. E. Sánchez-Escalonilla[1], A. Muñoz San Jose[1]*, P. Aguirre[1], M. Viaña[1], C. Herranz[1], I. Diéguez[1], Á. Esquembre[1] and M. F. Bravo[1]

[1]Hospital Universitario La Paz, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1964

Introduction: Ongoing global conflicts have significant implications for the mental health of affected populations, with PTSD being one of the most prevalent disorders among those exposed to active violence.
Objectives: To understand the importance of PTSD diagnosis and treatment in individuals exposed to active violence through the review of two clinical cases.
Methods: A clinical evaluation, diagnosis, treatment and follow-up of two patients (A and B) during their admission to our hospital and a literature review of diagnosis and treatment of PTSD.
Results: We studied two patients from Armenia, a country currently engaged in armed conflict, who sustained injuries from a bomb explosion. Patient A had burns covering 18% of Total Body Surface Area (TBSA) and three fingers amputated, while B had burns in 50% of TBSA. Both were admitted to the Intensive Care Unit, where psychiatric evaluations were conducted, and then they were transferred to the plastic surgery unit for further care until discharge. During the first week of admission, symptoms such as flashbacks, nightmares, emotional numbness, feelings of fear, hopelessness, excessive guilt, insomnia, hypervigilance and episodes of depersonalization or derealization began to appear. Patient A exhibited an externalizing profile of symptoms (nocturnal agitation, crying and verbalization of guilt-related ruminations), while B presented an internalizing profile (affective numbness and dissociative episodes). Both cases were diagnosed with PTSD after more than a month of persistent symptoms. Psychopharmacological treatment was initiated after 20 days of hospitalization. Patient A was treated with quetiapine 200 mg/day for nocturnal agitation and sertraline 100 mg/day; while Patient B started sertraline 100mg/day and mirtazapine 15 mg/day. According to literature, first-line pharmacological treatment for PTSD includes SSRIs such as sertraline or fluoxetine. As a second-line we found mirtazapine, antipsychotics and prazosin. Benzodiazepines are not a choice and should be used cautiously (Schrader et al. MM 2021; 118 (6), 546-551). First-line treatment for PTSD is trauma-focused therapy and eye movement desensitization and reprocessing (EMDR) (Mann et al. TI 2023). In our case, such therapy was not possible to start due to language barriers and the severity of patients'

physical conditions. Notably, current clinical trials are exploring the use of psychedelics in therapy to improve PTSD symptoms (Krediet et al. IJNP 2020; 23 (6), 385-400).
Conclusions: PTSD is a relatively common mental disorder, affecting up to 11% of war victims. Early detection of symptoms is crucial to start an appropiate psychotherapeutic treatment. Although psychopharmacological interventions are recommended as a second-line treatment, they may sometimes be the only feasible option, as demonstrated in these two clinical cases.

Evaluation of the post-traumatic stress disorder in midwives

I. Sellami[1]*, A. Abbes[1], A. Feki[2], M. L. Masmoudi[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupationnal medecine and [2]Rheumatology, CHU Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1965

Introduction: In addition to the typical risks associated with healthcare professions, being a midwife carries a significant psychological and emotional burden. This responsibility extends not only to the mother's well-being but also to the newborn's, making the role particularly vulnerable to psychosocial risks, often driven by high-stress situations.
Objectives: To assess the post-traumatic stress disorder (PTSD) experienced by midwives.
Methods: We conducted a cross-sectional study using a self-administered questionnaire distributed to midwives in the Sfax region. The questionnaire consisted of a first part relating to socio-demographic and professional data and a second part relating to the evaluation of the PTSD in midwives using the Impact of Event Scale (IES).
Results: Our population comprised 74 midwives with an average age of 45.6 ± 10.3 years. Only 21.6% reported engaging in regular physical activity. The midwives worked in both public and private health facilities, with a mean of job tenure of 20.3 ± 10.6 years. A stressful event in their professional life was reported by 68.8% of midwives. The PTSD was detected in 30 midwives (40.5% of the midwifery population surveyed), 8 of whom had severe symptoms. The traumatic events reported by the midwives were related to injury to the newborn, injury to the parturient or working conditions.
We found that the factors related to the PTSD were the number of dependent parents, a history of anxiety, depression or hypothyroidism, and working fixed hours. Physical activity was a protective factor against post-traumatic stress. A statistically significant link was found between severe forms of PTSD and taking leave in the last three months. Binary logistic regression confirmed that while physical activity was protective, anxiety, depression, and hypothyroidism were independent risk factors for PTSD.
Conclusions: PTSD is a common issue among midwives. It should be studied and identified early in at-risk populations to prevent lasting consequences.

Investigating the effect of the South African Adolescence Sleep Intervention (SAASI) on adolescent sleep and PTSD: A pilot randomized control study

S. Suliman[1]

[1]South African Medical Council Unit on the Genomics of Brain Disorders, and Department of Psychiatry, Stellenbosch University, Cape Town, South Africa
doi: 10.1192/j.eurpsy.2025.1966

Introduction: South African adolescents are exposed to significant levels of trauma exposure, resulting in high levels post-traumatic stress disorder (PTSD). Sleep disturbances are among the most frequently reported difficulties faced by those dealing with PTSD.
Objectives: The current study aimed to determine the feasibility and preliminary efficacy of the SAASI on PTSD symptom severity and sleep disturbance when delivered in group format to South African adolescents with PTSD.
Methods: Sixty-one adolescents with PTSD diagnoses and sleep disturbance were randomly assigned to either one individual and four group sessions of the sleep intervention (SAASI) or a control group. At baseline, post- and 1-month follow-up participants completed the Child PTSD symptom scale for DSM5 (CPSS-5) and the Pittsburgh Sleep Quality Index (PSQI) among other sleep and psychiatric measures. The trial was registered on the Pan African Trial Registry (PACTR202208559723690).
Results: There was a significant but similar decrease in PSQI scores in both groups over time indicating no overall intervention effect. Interaction between groups on the CPSS-5 was also not significant. Despite this overall finding, the mean difference in CPSS-SR-5 scores increased over time, with the difference between groups post-treatment and at the 1-month follow-up suggesting that PTSD symptom severity decreased more in the intervention group than the control group. The dropout rate was higher than expected for both the intervention and control groups. Reasons provided for dropout were mostly school commitments or travel related.
Conclusions: Conclusions: Early findings suggest a trend towards dual improvement in sleep quality and PTSD symptom severity in adolescents with a sleep disturbance and PTSD receiving a group sleep intervention (SAASI). Further investigation in a properly powered RCT with detailed retention planning is indicated.

doi: 10.1192/j.eurpsy.2025.1967

Introduction: Background: The United Nations defines Human Trafficking as "the recruitment, transportation, transfer, harbouring, or receipt of people through force, fraud or deception, with the aim of exploiting them for profit," and says it is practiced everywhere in the world. Studies show that women who have been

trafficked for sex have higher levels of fear, are more isolated, greater trauma and mental health needs than other victims of crime, high rates of physical and sexual violence, memory loss, sexually transmitted diseases, and traumatic brain injuries. The present study attends to explore the mental health profile of a cohort of trafficked women from Egypt.

Objectives: Studies show that women who have been trafficked for sex have higher levels of fear, are more isolated, greater trauma and mental health needs than other victims of crime, high rates of physical and sexual violence, memory loss, sexually transmitted diseases, and traumatic brain injuries.The present study attends to explore the mental health profile of a cohort of trafficked women from Egypt.

Methods: This study included detailed mental health assessments of 42 trafficked women in and around Cairo in Egypt. Data was collected by social workers. Assessments, Diagnosis and interventions were done by the author with the help of two clinical psychologists.

Results: This snapshot study shows very convincingly that there's a high burden of mental ill health among the trafficked women. Suitable therapeutic interventions may provide effective management and prevention of further deterioration of mental health issues of these vulnerable trafficked women.

Conclusions: This snapshot study shows very convincingly that there's a high burden of mental ill health among the trafficked women.Suitable therapeutic interventions may provide effective management and prevention of further deterioration of mental health issues of these vulnerable trafficked women.

Perceived work-related stigma in healthcare workers and presence of post-traumatic stress disorders (PTSD) symptoms

C. Vincent[1,2*], H. Scarlett[2,3], M. Melchior[2,3] and C. Vuillermoz[2,4]

[1]Team of social epidemiology, Institut Pierre Louis d'Epidémiologie et de Santé Publique; [2]Inserm; [3]Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris and [4]Université de Versailles, Saint-Quentin-en-Yvelines, France

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1968

Introduction: Previous research has demonstrated a relationship between work-related stigma during the COVID-19 pandemic and posttraumatic stress disorder (PTSD). Whilst it is possible that shared social characteristics explain the link between stigma and PTSD, this article hypothesizes that work-related stigma is itself associated with symptoms of PTSD.

Objectives: This study examined whether work-related stigma was associated with PTSD symptoms one year after the onset of the COVID-19 pandemic in a sample of French healthcare workers (HCWs).

Methods: Data were based on an online survey that recruited HCWs working during the first wave of the COVID-19 pandemic. The presence of PTSD symptoms was assessed using the Posttraumatic Stress Disorder Checklist (PCL-5) with a cut-off score of ≥33. Work-related stigma was defined as the perception of having been treated differently and unfairly because of one's profession.The relationship between work-related stigma and PTSD symptoms was tested using propensity scores including all relevant confounding factors: financial and social support, and work-related,or pandemic-related factors.

Results: Among the 655 respondents, 71.6% were physicians, 11.1% were nurses, and 17.3% had other occupations. A total of 53 participants (8.7%) presented symptoms of PTSD. We found an association between work-related stigma and PTSD symptoms (OR 2.13, 95% CI [1.04;4.35]) one year after the onset of the COVID-19 pandemic adjusted for propensity scores including relevant confounding factors.

Conclusions: Our findings suggest that work-related stigma is associated with PTSD symptoms among HCWs. This association was independent of social characteristics known to influence both stigma and PTSD. Work-related stigma may be a propitious occupational risk factor to target in order to improve HCWs work conditions and mental health.

Understanding the path to ketamine-assisted group therapy for firefighters diagnosed with post-traumatic stress disorder: a qualitative study

T. Walia[1*], V. Tsang[2] and K. Sattler[3]

[1]Biology, McMaster University, Hamilton; [2]Medicine and [3]University of British Columbia, Vancouver, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1969

Introduction: Firefighters face routine occupational risks and high-stress environments. Accordingly, 96.4% are exposed to a potentially traumatizing event throughout their career (Nazari *et al.* Work 2020; 67(1):215-222). This is accompanied by high rates of trauma-related mental illnesses (TRMI) such as PTSD. First-line treatments of TRMI remain limited. A novel treatment that has emerged, Ketamine-Assisted Therapy (KAT) has shown meaningful improvements in PTSD treatment (Ragnhildstveit *et al.* Ther Adv Psychopharmacol 2023; 6:13).

Objectives: The primary objective was to synthesize prevalent themes among participants, shedding light on their journeys to accessing KAT as well as highlighting internal motivations and societal barriers that exist.

Methods: In this study, there are six working firefighters, diagnosed with TRMI. They have enrolled in but not begun the 12-week Roots to Thrive (RTT) KAT program. Interviews were conducted individually and transcribed for further analysis. Data from the interview responses was analyzed by two independent reviewers and coded to create main themes of focus. The inconsistencies were managed by the third senior reviewer.

Results: The major themes prevalent among participants include social stigma, self-advocacy/education, logistical barriers and feeling stuck with previous treatments.Throughout the interviews, participants indicated that the use of ketamine and their mental illness diagnosis were stigmatized. Some kept their treatment a secret from family members while others reported telling very few colleagues about their PTSD. In response to traumatic events at work, one participant explained that the prevalent attitude was "Suck it up. Move on." The lack of administrative support prompted several participants to teach themselves about psychedelics and mental health in order learn about treatment possibilities. Logistical

barriers included barriers to physically commuting, paying for and having time away for the KAT sessions. They pointed out that aside from the price of the treatment itself, paying for cabs and ferries adds to the costs. Each of the participants detailed their journey with trauma and mental illness before KAT. A common sentiment expressed was that they couldn't cope anymore with symptoms like night terrors and extreme anxiety. Participants discussed a gradual build-up and burnout, as one explained, "You continually are always going to other trauma calls, so it kind of builds up layer, layer, layer after layer." A reoccuring theme in their experiences was trying different treatment modalities (EMT, EMDR and CBT) with little permanent success.
Conclusions: Greater funding, awareness and administrative support is needed for firefighters diagnosed with PTSD to successfully receive and undergo treatment.

EPV1445

The Beneficial Effect of Self-Compassion on PTSD and Complex PTSD Symptoms among Israeli Female Veterans: The Role of Coping Strategies

G. Zerach[1]

[1]Psychology, Ariel University, Ariel, Israel
doi: 10.1192/j.eurpsy.2025.1970

Introduction: There is consistent evidence that increased self-compassion (SC) is associated with less posttraumatic stress disorder (PTSD) symptoms. However, knowledge about the contribution of SC to military-related posttraumatic sequelae among women combat veterans is sparse. Moreover, the underlying mechanism for the beneficial effect of SC remains to be determined.
Objectives: The present study aims to examine the contribution of SC to PTSD and complex PTSD symptoms among female veterans as well as the mediating roles of coping strategies in these possible associations.
Methods: In a cross-sectional study, a volunteer community sample of Israeli women combat veterans (n = 885) and non-combat veterans (n = 728) responded to online self-report questionnaires.
Results: Combat veterans reported higher levels of PTSD symptoms but not complex PTSD symptoms, SC, or coping strategies, as compared to non-combat veterans. Moreover, among combat and noncombat veterans, SC was associated with lower levels of PTSD and complex PTSD symptoms beyond adverse childhood experiences and combat exposure. Notably, SC was inversely and indirectly associated with higher levels of PTSD and complex PTSD symptoms through maladaptive coping strategies for both combat and noncombat veterans.
Conclusions: Reports of higher SC among female veterans are associated with less severe PTSD and complex PTSD symptoms. Moreover, maladaptive coping strategies might serve as mechanisms that link SC to military-related posttraumatic consequences.

EPV1446

Digital Phenotyping for Real-Time Monitoring of Nonsuicidal Self-Injury Thoughts

C.-Y. Ahn[1]* and J.-S. Lee[1]

[1]Department of Psychology, Kangwon National University, Chuncheon-si, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1971

Introduction: Digital phenotyping offers a valuable method for predicting and preventing nonsuicidal self-injury (NSSI) in daily life by providing objective, ecologically valid measurements at multiple time points. This approach quantifies an individual's phenotype by capturing self-injury-related markers such as mood, step counts, and heart rate.
Objectives: The aim of this study is to identify real-time predictors and to elucidate the dynamic trajectory of NSSI in individuals.
Methods: This study targets individuals in their 20s residing in South Korea who engaged NSSI on five or more days during the past year, and a total of 56 participants were included in the current study. Once participants were enrolled, active (e.g., ecological momentary assessment) and passive (e.g., heart rate, step count) data were collected via a smartphone app and wrist-worn wearables for 14 days. Initially, a random forest algorithm was employed to assess the relative importance of passive and active data in predicting NSSI thoughts. Subsequently, a multilevel logistic regression model was used to capture variability at both the within-person and between-person levels.
Results: After inputting passive data into the random forest algorithm, the model demonstrated an accuracy of 0.619. Among the variables, walking stride had the highest importance score at 0.28, followed by heart rate (0.18) and heart rate variability (0.17). Subsequently, when analyzing the random forest algorithm with active variables, the model's accuracy was found to be 0.666. In this case, anger toward others had the highest importance score at 0.26, followed by depression (0.22) and anger toward oneself (0.19). In a separate analysis using multilevel logistic regression models for each passive variable, none of the variables produced significant results in either the fixed or random effects analyses. However, when active variables were entered into separate multilevel logistic regression models, all emotional variables yielded significant results in the fixed effects analysis: depression (0.746, $p < .001$), anxiety (0.521, $p < .001$), anger toward oneself (0.475, $p < .001$), anger toward others (0.403, $p < .001$), loneliness (0.329, $p < .001$), and shame (0.557, $p < .05$). In contrast, none of the variables showed significant results in the random effects analysis.
Conclusions: The findings from this study could offer insights into novel mechanisms underlying the occurrence of self-injurious thoughts and their prediction in daily life. Additionally, this advanced approach may help identify optimal strategies for NSSI prevention and enable the delivery of personalized, real-time interventions.

Genetic Dete`rminants of Clozapine-Induced Metabolic and Neurological Side Effects: A Comprehensive Investigation

C. Kalogirou[1]*, C. Christou[2], M. Peyioti[3], T. Soumala[4] and G. Schoretsanitis[5]

[1]University of Patras, Patras, Greece; [2]Marien Hospital, Dusseldorf, Germany; [3]Hospital of Alexandroupolis, Alexandroupolis; [4]University of Ioannina, Ioannina, Greece and [5]Psychiatrische Universitätsklinik Zürich (PUK), Zürich, Switzerland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1972

Introduction: Clozapine remains one of the most effective antipsychotic medications for treatment-resistant schizophrenia. However, its use is limited by significant metabolic and rare neurological side effects. The variability in patients' susceptibility to these adverse effects suggests an unidentified genetic predisposition, which is critical to personalizing treatment.
Objectives: This review aims to systematically investigate the genetic variants involved in the development of metabolic and neurological side effects in patients treated with clozapine. Specifically, it seeks to elucidate the pathways participating in the occurrence of these adverse reactions and identify genetic markers for personalized therapeutic approaches.
Methods: A literature search was conducted across multiple databases for studies published in recent years. Data were extracted from cohort studies and case-control studies based on predefined criteria, using keywords such as "clozapine", "metabolic side effects", "neurological side effects", "pharmacogenetics".
Results: Preliminary results identified that variants in the **FTO** gene, known for its role in adipogenesis and energy homeostasis, were linked to enhanced adiposity and altered leptin signaling, contributing to the metabolic syndrome. Similarly, **APOE** gene was strongly correlated with increased risk of severe weight gain, dyslipidemia, and insulin resistance due to association with impaired lipid transport and metabolism.
In the context of neurological side effects, SNPs within the **DRD2** Taq1A polymorphism, which affects dopamine receptor density and signaling, were associated with a higher incidence of extrapyramidal symptoms and tardive dyskinesia in patients on clozapine. The **COMT** Val158Met polymorphism, known to modulate prefrontal catecholamine degradation, was linked to cognitive impairments and clozapine-induced sedation.
Next-generation sequencing (NGS) enlightens rare SNPs, copy number variations (CNVs) and novel variants in genes related to drug metabolism, such as **CYP1A2** and **CYP2D6**, allowing for the identification of complex genetic interactions. Furthermore, patients with high **polygenic risk scores** (PRS) exhibited a markedly increased likelihood of developing severe metabolic and neurological side effects, underscoring the utility of PRS in stratifying patient risk.
Conclusions: In summary, our findings demonstrate that genetic factors are key contributors to the development of clozapine-induced metabolic and neurological side effects. Variations in genes related to drug metabolism, neurotransmitter regulation, and metabolic pathways significantly influence individual susceptibility to these adverse effects. A deeper understanding of pharmacogenetic approaches could offer the potential for more personalized and precise treatment strategies, reducing adverse effects and improving drug tolerance.

Individualised network connectivity-based targeting to improve outcomes of transcranial magnetic stimulation in difficult-to-treat depression

T. T. Raij[1]*, E. Komulainen[1], D. B. Aydogan[2] and M. Stenroos[3]

[1]University of Helsinki and Helsinki University Hospital, Helsinki; [2]University of Eastern Finland, Kuopio and [3]Aalto University School of Science, Espoo, Finland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1973

Introduction: Transcranial magnetic stimulation (TMS) is an established treatment for difficult-to-treat depression (DTD), demonstrating moderate efficacy. In comparison to other non-invasive treatments in psychiatry, TMS can be relatively accurately directed at specific cortical subregions. TMS is typically targeted at the dorsolateral prefrontal cortex (DLPFC) based on scalp measurements. However, the DLPFC is a large and functionally heterogeneous region, with inter-individual variability in the localisation of target functions. The functional connectivity of the stimulation target with other brain areas has been shown to correlate with treatment outcomes. Nonetheless, the clinical benefits of connectivity-based individualised targeting remain to be demonstrated in randomised clinical trials, and the connections to be considered in such targeting are still inadequately understood.
Objectives: To test whether individualised network connectivity-based localisation improves outcomes, and to further investigate the relationship between clinical results and the stimulated connections
Methods: In this ongoing study, we acquire functional and structural MRIs from adult volunteers with DTD, referred to clinical TMS. We focus on brain regions associated with depression and emotion regulation to target the core affective symptoms of depression. We compute the individual connectivity distribution of these regions within the DLPFC. We then employ a realistic individual head conductor model to determine the coil position that aligns the distribution of TMS-induced electrical effects with the individual connectivity distribution. These coil positions, along with standard scalp-measure-based coil positions, are entered into the neuronavigation system, and patients are randomised 1:1 for the targeting used to receive intermittent theta burst stimulation over 20-25 sessions. Patients and outcome assessors remain blind to the targeting method, with the primary outcome being the change in the Montgomery-Åsberg Depression Rating Scale from before to after treatment.
Results: Interim analysis conducted by independent evaluators, based on results from the first 20 patients per group, suggested over 80% power to detect group differences at an alpha level of 0.048, with 40 patients in each group.
Conclusions: To our knowledge, these would be the first results from a randomised prospective trial indicating the superiority of functional targeting over standard scalp measure-based targeting. While these targeting methods require further refinement, clinical applications will depend on the balance between effectiveness and cost compared to standard targeting. Related studies exploring the relationship between targeted brain connections and clinical outcomes may illuminate the brain-level mechanisms underlying recovery from depression.

Anticipatory Competence of Adolescents with Mental Disorders in the Prevention of Deviations

A. Akhmetzyanova[1]*, T. Artemyeva[1] and U. Zhirnova[1]

[1]Department of Psychology and Pedagogy of Special Education, Kazan Federal University, Kazan, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1974

Introduction: Theoretical analysis of the problem of anticipatory competence in adolescents with mental disorders highlights its insufficient study as an integral ability that contributes to their adaptation in society and the prevention of deviant behavior.
Objectives: To identify and study the relationship between anticipatory consistency and deviations in adolescents with mental disorders.
Methods: The study involved 25 adolescents aged 12-14 (6A00.0, ICD-11) attending an educational institution for children with disabilities. The following methods were used: the "Test of Anticipatory Solvency" by V.D. Mendelevich, the "Test of Propensity for Deviant Behavior" by E.V. Leusa and A.G. Solovieva, and the "Study of Anticipatory Solvency in Adolescents" by A.I. Akhmetzyanova and T.V. Artemyeva.
Results: Adolescents with mental disabilities exhibit varying degrees of motor clumsiness and difficulty judging distance in visual space. They struggle to predict the consequences of their actions and are not always able to foresee conflict situations in social settings, nor respond adequately in such interactions, which often leads to the development of antisocial behavior. The majority of adolescents with mental disorders (56% of the subjects) exhibit a situational predisposition to delinquent behavior, indicating a tendency to put their own norms and values in conflict with those of the group. Correlation analysis revealed a statistically significant relationship between personal-situational anticipatory consistency and the scale of delinquent behavior (r=0.416).
Conclusions: The findings of this study can be useful to practitioners working with adolescents with mental disorders, helping them to plan and organize corrective interventions that consider the development of this essential skill. Anticipatory competence is one of the factors necessary for successful socialization and the prevention of deviant behavior in adolescents.
This paper has been supported by the Kazan Federal University Strategic Academic Leadership Program (PRIORITY-2030).

Predisposition to boredom and anxio-depressive disorders among nurses : A cross-sectionl descriptive study

I. Kacem[1], A. Ghenim[1], O. Ajmi[2], M. Bouhoula[1], N. Belhadj[1], A. Chouchane[1], S. Ben abderrahmen[1], A. Aloui[1]* and N. Mrizak[1]

[1]Departement of Occupational Medicine and [2]Department of psychiatry , Farhat Hached Academic hospital, Sousse , Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1975

Introduction: Bore-out affects three times as many employees as burn-out. It results from a lack of activity during work, and the healthcare sector, due to its monotony, promotes the emergence of these disorders
Objectives: Study the predisposition of hospital nurses to boredom, and investigate a possible relationship between this predisposition and their anxiety-depression profile.
Methods: This is a cross-sectional descriptive study conducted in April 2022 involving all nurses at the Sahloul University Hospital in Sousse. We used a pre-established questionnaire that included two validated tools: the Boredom Proneness Scale (BP) and the Hospital Anxiety and Depression Scale (HAD).
Results: A total of 65 nurses took part in this study. The mean age was 36.62 ± 4.82 years and the sex ratio was 0.38. According to the BP Scale, 13 nurses were inclined towards boredom (20%). A predisposition to boredom has been observed among staff with less than 8 years of seniority (p= 0.001), those with no extracurricular activities (p= 0.020), those with a moderate or severe workload (p= 0.008), and those whose profession had no impact on their relationships with others (p= 0.012).The depression score on the HAD scale was moderate (32%), average (20%), and severe (12%). The HAD scale revealed that 29% of people had mild anxiety, 23% had moderate anxiety, and 12% had severe anxiety. No statistically significant relationship was found between the boredom disposition scale and the HAD scale.
Conclusions: Bore-out can worsen anxiety and depressive disorders by causing boredom and frustration. It is crucial to promote an engaging and varied work environment to protect employees' mental health.

Can a difference in socioeconomic levels influence executive functioning in a Tunisian population?

M. Ben Hmida[1]*, D. Le Gall[1], T. Bellaj[2] and R. Ben Rejeb[2]

[1]Psychology, Université d'Angers, Angers, France and [2]Psychology, Université de Tunis, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1976

Introduction: Poverty's impact on mental health and quality of life is well documented. Studies have shown that the high stress levels associated with poverty increase the risk of mental illness. Moreover, cognitive abilities seem to be influenced by a low socioeconomic level. Conversely, individuals who benefit from a better socioeconomic situation since childhood and throughout adulthood are more likely to succeed academically and professionally.
Objectives: This paper examines the relationship between socioeconomic status and executive functioning in healthy Tunisian adults. It aims to determine if socioeconomic differences influence executive processes.
Methods: We conducted an experimental study with 95 Tunisian adults (ages 20-55) from the city of Tunis, divided into 4 socioeconomic

groups (low, lower middle, higher middle, and high). We used objective and subjective socioeconomic measures and assessed cognitive and behavioral executive functioning through various tests, including the Stroop and Hayling tests, verbal fluency tasks, and the BRIEF questionnaire.
Results: ANOVA analyses didn't show global differences between groups, but Fisher Post Hoc tests revealed that participants from the highest socioeconomic group (group 4) performed better on several tasks. Group 4 showed faster processing times on Stroop tasks, better scores on the Digit Span Task, verbal fluency tasks, and the Modified Card Sorting Test, indicating a better processing speed and stronger cognitive flexibility and working memory. Behavioral executive measures also favored group 4 in areas such as working memory and task control.
Conclusions: This study highlights the clear advantage of higher socioeconomic status in executive functioning. Further research could develop strategies to improve cognitive functioning and quality of life for individuals with a lower socioeconomic level.

Modifiable risk factors and their joint effect on Schizophrenia: A perspective study

S. Chen[1]*, Q. Dong[2], E. Fernandez-Egea[3], X. Li[2], A. Dayimu[3], D. Liu[2], H. Wang[2], F. Jiang[2] and L. Xu[2]

[1]London School of Hygiene & Tropical Medicine, London, United Kingdom; [2]Shandong University, Shandong, China and [3]University of Cambridge, Cambridge, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1977

Introduction: Schizophrenia is a severe psychiatric disorder affecting 50% of patients intermittently and 20% chronically, with high unemployment rates (80-90%) and reduced life expectancy. Although genetic and neurodevelopmental factors are established non-modifiable risk factors, knowledge gaps persist regarding prevention strategies, particularly the combined impact of modifiable risk factors.
Objectives: The aim of this study is to identify the modifiable risk factors and to estimate their joint effect on Schizophrenia.
Methods: We conducted an exposure-wide association study (EWAS) using the UK Biobank cohort to systematically evaluate 206 potentially modifiable factors associated with schizophrenia risk. The study population comprised individuals without schizophrenia at baseline, with diagnoses determined using ICD-10 criteria. We employed Cox proportional hazard regression models with Bonferroni correction (significance threshold: $P<1.91\times10^{-4}$) to identify significant factors. The identified factors were categorized into six domains: lifestyle, local environment, medical history, physical measures, psychosocial factors, and socioeconomic status (SES). Domain-specific, weighed, and standardized scores were calculated based on coefficients from Cox models, adjusting for covariates. Scores were stratified into tertiles (favorable, intermediate, unfavorable) for risk assessment. Population attributable fractions (PAFs) were calculated to quantify prevention potential.
Results: The study cohort included 498,351 participants (54.45% female; mean age: 56.55 years) followed for a mean duration of 14.37 years, during which 1,345 participants developed schizophrenia. We identified 86 significant modifiable factors, with disability (HR 6.23, 95% CI 5.48-7.07), depression (HR 5.06, 95% CI 4.93-5.20), and anxiety disorders (HR 3.69, 95% CI 3.12-4.36) showing the strongest associations. Our analyses suggested that transitioning unfavorable profiles to intermediate and favorable status (Estimation 1) could prevent 59.6% of schizophrenia cases, while shifting both intermediate and unfavorable profiles to favorable (Estimation 2) could prevent 90.4% of cases. In Estimation 2, the preventive potential was highest for SES (18.0%), followed by medical history (17.5%), lifestyle factors (17.0%), psychosocial factors (14.3%), physical measures (12.8%), and local environment (10.8%).

Image:

Table1. Weighted and unweighted PAF for the six domains

	Estimation 1			Estimation 2		
Domains	**Unweighted PAF**	**Communality**	**Weighted PAF**	**Unweighted PAF**	**Communality**	**Weighted PAF**
Lifestyles	0.239	0.282	0.116	0.536	0.252	0.170
Local environment	0.189	0.211	0.091	0.341	0.526	0.108
Medical history	0.107	0.236	0.051	0.552	0.317	0.175
Physical measures	0.273	0.319	0.132	0.402	0.144	0.128
Psychosocial factors	0.137	0.604	0.066	0.449	0.401	0.143
SES	0.289	0.349	0.140	0.567	0.360	0.180
Overall weighted PAF			0.596			0.904

Weighted PAF was calculated after considering the overlap between risk factors. In estimation 1, we shifted the unfavorable profile to intermediate favorable ones. In estimation 2, we shifted all factors to the favorable profile. SES, socioeconomic status.

Conclusions: This analysis identifies multiple modifiable risk factors for schizophrenia, demonstrating substantial prevention potential through multi-domain interventions. Socioeconomic, medical, and lifestyle factors emerge as key targets for prevention strategies. The consistency of associations across genetic risk strata suggests interventions could be beneficial regardless of genetic predisposition, informing targeted prevention strategies and public health policies.

doi: 10.1192/j.eurpsy.2025.1978

Introduction: The rising rate of suicides among physicians is a critical and concerning issue that has not garnered enough attention. Personal, social, economic factors and working conditions are complicating this problem and a holistic approach is required to work towards a solution.
Objectives: The aim of this study was to investigate the views of psychiatry residents and young psychiatrists working in EPA member countries on the causes, consequences and solutions of physician suicides.
Methods: Under the umbrella of EPA Suicide Prevention and Suicidology Section, a 24-question survey regarding thoughts and beliefs on physicians's suicide was developed by a group of young researchers participating in EPA Summer School 2023. The questionnaire was disseminated through EPA Early Career Psychiatrists (ECP), European Federation of Psychiatric Trainees (EFPT) email groups, communication platforms for sub-working units, and various national psychiatric associations via their email and social media channels. The goal is to collect data over at least six months. Preliminary results will be shared with participants at the EPA 2025 Congress.
Results: When the initial data is analysed, it is seen that 160 people answered the questionnaire. 69% of the participants were female, 29.4% were male, 1.2% preferred not to say. The proportion of specialists was 64.4% and 35.6% of residents. Detailed responses to the questionnaire and the suggestions of the participants will be shared in detail with the congress participants in the presentation.
Conclusions: This study aims to explore the perspectives of residents and early-career specialists on an issue that is stigmatized within the medical community and often avoided in open discussions. Understanding how young physicians perceive and evaluate this issue amidst increasingly challenging living and working conditions will provide valuable insights, guiding future interventions aimed at addressing and mitigating this burden.

Implementation of a low-threshold, community-based consultation for young adults with early symptoms of mental disorders – a study protocol

V. Komanek-Prinz[1], A. Schleussner[1], S. Hartmann[1], C. Diefenbach[1]* and A. Reif[1]

[1]Department of Psychiatry, Psychosomatic Medicine and Psychotherapy, Goethe University Frankfurt, University Hospital, Frankfurt am Main, Frankfurt/Main, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1979

Introduction: If untreated, mental health disorders are a leading cause of premature death due to physical illness and suicide. Typical onset is around the age of 15, and about 75% emerge by the age of 25. Thus early diagnostics and treatment to prevent chronic outcomes by early interventions is indispensable. We set up an intervention project in Frankfurt/Main, Germany, focusing on this vulnerable group aged 18 to 29.
Objectives: The project aims to assess if a low-threshold, early-on psychosocial consultation model significantly reduces early symptoms of mental disorders among young adults and to evaluate whether community-based consultations reduce stigma and increase early service utilisation. We intend to measure changes in mental health literacy. Alongside consultations, we identify cooperation partners and give workshops to raise awareness and reduce stigma.
Methods: A team of university psychologists and psychiatrists developed the project with community organisations and local foundations. Consultations take place in a non-stigmatizing, informal setting: the space is not within a clinic, centrally located and easily accessible. Services may be utilised anonymously and without registration of health insurance. We offer qualified diagnostics, brief solution-focused counselling, psychoeducation, early pharmacological treatment, group therapy and referral pathways to specialised care when needed. Using questionnaires, we will refine the program for potential up-scaling. Since September 5th, 2024, 12 patients aged between 17 and 34 years have already made use of the offer. Pre-intervention symptoms at baseline were initially assessed while post-intervention symptom assessments will take place 3 months later. Qualitative data will be analysed via thematic coding. Quantitative data for symptom alteration will be collected via Likert scales and analysed using paired t-tests and regressions. Qualitative feedback will be collected via surveys. We hypothesise that psychological well-being will improve post-intervention. Additionally, we expect an increased mental health literacy, alongside increased utilisation and acceptance of mental health services.
Results: Yet to follow.
Conclusions: Community-based mental health consultations represent a feasible early intervention strategy for young adults. Results are expected to support expanding such models to other community structures and refining protocols for scalability. We aim to optimise service delivery, assess long-term outcomes, and examine cost-effectiveness for potential implementation on a broader scale.

Impact of childhood traumas and early substance abuse in deviant behaviors

M. Gambini[1]*, D. Marazziti[1], A. Arone[1], V. Caruso[1], F. Weiss[1], A. Coccoglioniti[1], G. Russomanno[1] and L. Foresi[1]

[1]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1980

Introduction: Youth violence, particularly among men, is a significant global issue. The primary causes leading to detention orders are drug-related crimes, armed robberies, and terrorism. In addition to social and environmental factors, early attachment experiences and stressors can significantly affect lifelong development, especially during adolescence, impacting learning, behavior, emotions, and health. Thus, identifying underlying traits of chronic deviant behavior, such as attention-deficit/hyperactivity disorder (ADHD) and drug, may help clarify the mechanisms driving different problem behavioral disorders throughout life and be crucial in structuring effective prevention programs for these people.
Objectives: This study aimed to examine clinical and psychopathological features in imprisoned young adults with comorbid substance use disorder (SUD).
Methods: The study was conducted in Colombia at a detention center for young adults who committed serious crimes during adolescence. Forty participants with SUD were included and assessed using six questionnaires and clinical interviews, aiming to examine their clinical and psychopathological characteristics.
Results: The mean age of initial drug contact was 12 years, and the most consumed drugs were cannabis, alcohol and cocaine/amphetamines. Significant positive correlations were found between emotional dysregulation and hyperactivity (p=0.010), inattention (p=0.003), executive dysfunction (domains of inhibition (p=0.001) and initiative (0.001), mood swings (p=0.027) and childhood trauma. Individuals with psychostimulant substances disorder showed a significant positive correlation with the "Authority" domain (p=0.043), and those using sedative substances also with the "Resentment/Self-Sufficiency" and "Violent Childhood" domains.
Conclusions: Our findings suggest that greater impulsivity during childhood exposure to violence represents a predictor of emotional dysregulation, with a large impact later. Impulsivity and difficulty accepting negative emotions are positively associated with executive dysfunctions, especially in inhibitory control, emotional regulation, and initiative. A permissive childhood, characterized by a lack of guidance and boundaries, can be a predictor of committing murder later in life. Taken together, these findings highlight the

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1981

Introduction: Work-related stress significantly impacts employees' overall health and can lead to unhealthy lifestyle behaviors, such as poor diet, lack of physical activity, and inadequate sleep.
Objectives: This study aimed to explore the potential link between occupational stress and different lifestyle behaviors among workers in different companies in Sousse, Tunisia.
Methods: A cross-sectional study was conducted over a three-year period in Sousse, Tunisia, involving employees from various workplace settings. Data were collected using a pre-established questionnaire that assessed sociodemographic characteristics, health-related behaviors—including sleep quantity and quality, cigarette smoking, alcohol consumption, physical activity (measured with the Global Physical Activity Questionnaire), and eating habits—as well as occupational characteristics. Occupational stress was evaluated using a validated Arabic version of the Karasek scale. Binary logistic regression was employed to calculate adjusted odds ratios with 95% confidence intervals.
Results: The study included 154 participants, predominantly female (56.5%), with a mean age of 39.99 ± 9.91 years. Approximately 34.6% had 11 to 20 years of seniority. Job strain and iso-strain were reported by 31.8% and 25.5% of workers, respectively. Job strain prevalence was observed in 32% of smokers, 41% of alcohol users, 40 % among those who do not meet the recommended levels of physical activity. In terms of sleep quality, 29.9% indicated poor sleep. Notably, our study revealed a significant association between job strain and good sleep quality (aOR=6.14; CI95%:1.72-21.95, p=0.005).
Conclusions: These findings highlight a concerning prevalence of unhealthy lifestyle behaviors among workers in Sousse, Tunisia, with significant associations between occupational stress and sleep quality. Addressing these issues through workplace wellness programs may enhance employee health and overall job satisfaction.

Nature- based interventions. The key role of variables: nature connectedness and social connectedness

M. Gawrych[1]* and M. W. Romaniuk[2]

[1]Institute of Psychology and [2]The Maria Grzegorzewska University, Warsaw, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1982

Introduction: The nature-based therapeutic perspective includes: green therapy, blue therapy, animal-assisted therapy, and natural landscape therapy. Until now researchers haven't clearly recognized underlying mechanisms of nature-related mental health well-being.

Objectives: The study aimed to clarify the relationships between experienced nature connectedness (NC) and social connectedness (SC) before and after blue nature based intervention and mental health (WHO-5, PHQ-4)
Methods: Study group included 54 adults (Mean = 30.6; SD 13,2). Participants completed semi-structured questionnaires before and after blue interventions (one week high sea sailing under supervision of two psychologists). The questionaire measured following variables: nature connectedness, social connectedness, well-being, and mental health.
Results: Results showed a significant increase in social and nature connectedness as well as in mental well-being after the blue interventions. Full results will be shown on the e-poster.
Conclusions: The mental health and wellbeing benefits of contact with nature are becoming increasingly recognized in psychology and medicine. The findings support hypothesis that nature connectedness and social connectedness increased after nature based interventions, and therefore they seem to be important factors conected with mental health.

EPV1460

The importance of an exquisite approach: a case report of Perinatal loss

A. Junquera[1]* and A. Gockel[2]

[1]Psychiatry, HM Purta del Sur, Mostoles and [2]Psychiatry, Fuenlabrada University Hospital, Fuenlabrada, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1983

Introduction: Perinatal loss is a painful process that we encounter on a regular basis in clinical practice but for which there is no adequate specific training. The treatment given to the mother will be decisive in mitigating the psychological consequences.
Objectives: To raise awareness of the need to develop specific training plans in perinatal psychiatry. Such training should provide tools for an adequate psychotherapeutic approach, as well as updated protocols on the management of psychopharmacological medication.
Methods: Descriptive report of a case of a women who came for consultation after having suffered an intrapartum fetal loss, based on the follow-up of the patient, with emphasis on the interventions performed during her stay in the hospital.
Results: We report the case of a 39-week pregnant woman who suffered an intrapartum fetal loss. The psychiatry team was notified and the resident doctor in psychiatry, without prior assessment of the patient, prescribed lorazepam every 8 hours. The mother at that moment, as a result of the shock, refused to see the baby, which was immediately accepted by the staff without a suitable intervention to inform about the benefits of adequate perinatal care (spending time with the baby, use of swaddling clothes to avoid heat loss, memory box, avoid rushing). After being discharged from hospital, she only attended a gynecological check-up, with no relevant findings. Five months later, the patient attended a psychiatry consultation with a major depressive episode, reporting significant feelings of guilt for not having been able to say goodbye to her baby. She did not remember clearly anything of what happened and presented panic attacks when she had to go to the hospital, as well as the presence of self-harming ideas. At the same time, she expressed anger at the treatment received from the staff, to whom she attributes the fact that she was not able to spend time with the baby.
A recent study (Cassidy, 2023) shows how the use of sedatives has become normalized in Spanish hospitals in order to compensate for the deficits in training and resources offered by the health system. Sedatives produce an alteration of consciousness, influence decision making and the formation of memories, which will make it more difficult to go through a perinatal grief, which in itself has its difficulties because it is considered a silenced grief.
Conclusions: Quality health care in perinatal loss should focus on providing the mother with exquisite care, centred on respect for each mother's time. This allows the establishment of a relationship that lowers fear and avoids impulses to flee, encouraging autonomy and the ability to decide, leaving the use of psychotropic drugs as a last resort for pain management.

The Effect of the EMDR Flash Group Technique on Test Anxiety, Traumatic Stress, and Coping Mechanisms in Students Taking a Gap Year

D. Kubilay[1], A. B. Yaşar[2], C. Çitil[3], B. Uğur[4]*, S. Kütük[5], I. G. Sevil[6], S. Yılmaz[7], G. Ç. Koban[7] and G. Bedel[8]

[1]Psychology, Logos Psychiatry Clinic; [2]Psychiatry, Istanbul Gelisim University, Istanbul; [3]Psychology, Sivas Cumhuriyet University, Sivas; [4]Psychology, Istanbul Bilgi University; [5]Psychology, Sehit Kamil Balkan School; [6]Psychology, Istanbul Ozyegin University; [7]Psychology, Istanbul Gelisim University and [8]Psychology, Y, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1984

Introduction: Test anxiety is a widespread issue affecting students' academic performance and mental health. Students taking a gap year after failing the university entrance exam are particularly vulnerable to traumatic stress and future exam anxiety. An effective group intervention, such as the EMDR Flash Technique, can provide timely support to this group. This technique, an extension of EMDR, involves rapid eye blinking with relaxing imagery during dual stimulation sets, efficiently processing up to five memories per session.
Objectives: The project's primary objective is to examine how the EMDR Flash Group Technique addresses traumatic stress and exam-related anxiety in gap year students, while promoting adaptive coping strategies. By tackling anticipatory and future-focused stress, the intervention aims to lower the risk of developing mood and anxiety disorders.
Methods: This randomized controlled study will be conducted with a total of 300 students. Participants will be randomly assigned to one of three groups: the EMDR Flash Group Technique, a single-session psychoeducation seminar, and a waitlist control group. Symptoms will be measured at pre-treatment, post-treatment, and follow-up. The assessment tools include the Socio-demographics Scale, Test Anxiety Inventory, Coping with Stress Scale, and the Impact of Event Scale. This study will address the following

hypotheses: H1: EMDR Flash Group Technique will decrease the level of test anxiety. H2: It will decrease traumatic stress based on previous test experiences. H3: It will develop functional coping mechanisms.

Results: A significant reduction in exam anxiety levels is expected in the EMDR Flash Group participants, supporting its effectiveness in managing stressors and preventing the development of anxiety disorders. Additionally, there will be a decrease in traumatic stress symptoms (re-experiencing, avoidance, and hyperarousal), demonstrating its effectiveness as an early intervention for trauma-related disorders. Participants are expected to develop more functional stress management skills, emphasizing the technique's role in reducing dysfunctional coping mechanisms and enhancing resilience. Overall, the EMDR Flash Group Technique will demonstrate its effectiveness as an early intervention model for managing anxiety and preventing the progression of related psychological issues.

Image 1:

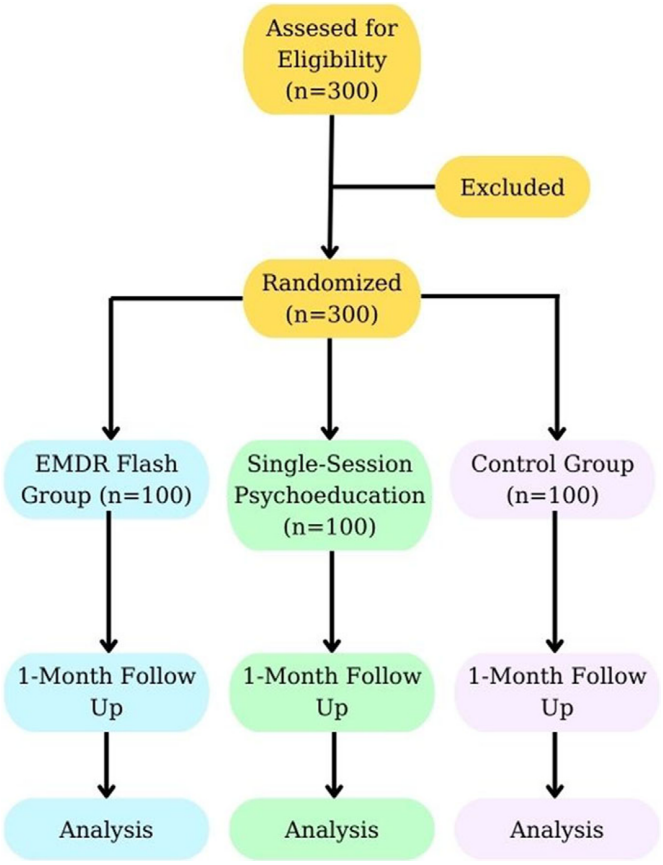

Image 2:

GROUP	INTERVENTION	MEASUREMENT TIME POINTS	SAMPLE SIZE (n)
1	EMDR FLASH GROUP TECHNIQUE	PRE-TREATMENT POST-TREATMENT 1-MONTH FOLLOW UP	100
2	SINGLE - SESSION PSYCHO-EDUCATION	PRE-TREATMENT POST-TREATMENT 1-MONTH FOLLOW UP	100
3	NO INTERVENTION (WAITLIST)	PRE-TREATMENT POST-TREATMENT 1-MONTH FOLLOW UP	100

Conclusions: Unlike traditional EMDR protocols that focus primarily on past traumas, our approach uniquely integrates past, present, and future-focused elements, creating a holistic framework for managing both past traumatic experiences and anticipatory anxiety about future challenges. By employing a group-based format, this protocol not only offers the potential for a more scalable and efficient intervention, but also provides a deeper understanding of how EMDR can be adapted to address psychiatric disorders in youth.

Disclosure of Interest: None Declared

EPV1462

Adjustments disorders among residents, burnout and depression

S. V. Kuzmina[1]* and A. D. Shurigina[1,2]

[1]psychiatry and medical psychology, Kazan state medical university and [2]Republican Psychiatry hospital, Kazan, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1985

Introduction: In 2022, studies were conducted, the results of which revealed that nursing staff are at greater risk of developing anxiety

disorders, and the development of these symptoms is influenced by work schedule and workload level. Also, do not forget about the relationship between anxiety and affective disorders and emotional burnout syndrome (EBS), which is important in diagnosis

Objectives: The purpose of the study is to evaluate the role of the phenomenon of burnout as a predictor of the development of anxiety and depression based on a comprehensive assessment of EBS and anxiety-affective symptoms among medical residents; identify risk factors for the development of EBS.

Methods: A questionnaire including socio-demographic characteristics (gender, age, place of residence), the Maslach Burnout Inventory (MBI) questionnaire; questionnaire scale: PHQ-9 (via Google platform); clinical interviewing was carried out among 98 residents

Results: two profiles of respondents – surgical (57.1%) and therapeutic (42.9%), 73.5% - female, 26.5% - male. The majority were in the age range from 25-29 years (77.6%). The most closely related to burnout is the time spent working at the clinical base and the workload outside of residency. 21% have mild depression, 24% have moderate depression, and 10% have severe depression, which further requires the identification of a correlation between two indicators of EBS and affective symptoms; 31.6% have severe emotional burnout, which affects education and the quality of medical care provided.

Conclusions: The question of the relationship between EBS and depressive symptoms remains open. In our simultaneous study, the relationship between the burnout index and the results of PHQ-9 is traced, which may suggest that EBS is considered as a risk factor for the development of affective symptoms of depression and requires further investigation of the problem It should be noted the importance of introducing digital technologies for the examination of employees and the timely detection of signs of EBS

Navigating Grief in Wartime: Needs Assessment and Help-Seeking Behaviors among Bereaved in Ukraine

I. Leshchuk[1], ?. But[1], Y. Zelenko[1], O. Khaustova[1]*, O. Chaban[1] and I. Frankova[1,2,3]

[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]Vrije Universiteit Amsterdam and [3]ARQ National Psychotrauma Centre, Amsterdam, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1986

Introduction: Traumatic losses are prevalent during armed conflicts and known to be a risk factor for prolonged grief disorder (Shevlin et al., 2024). Social support and psychoeducation are protective factors for prolonged grief disorder (Al-Gamal et al., 2018). Ukrainians are known to avoid seeking help or support after exposure to traumatic events (Quirke et al., 2021). Not much is known about help-seeking and supporting behavior following the loss of a loved one amidst the ongoing war in Ukraine.

Objectives: The aim of this exploratory study was to assess the experiences, needs, and help-seeking behavior of those in bereavement and those supporting them during the war in Ukraine.

Methods: An online questionnaire was designed by co-authors; data was collected in November 2023 via phone calls among users of the Opinion Internet panel by Factum Group Ukraine. Inclusion criteria were: a) Ukrainians aged 18-55; b) Internet users residing in Ukrainian cities with more than 50,000 residents before the full-scale invasion; c) those who currently live in Ukraine or abroad. The survey evaluated respondents' experiences of enduring the loss of a loved one and supporting persons in grief after the full-scale invasion of Ukraine, as well as the need for support and information about the grieving process.

Results: Fifty-three percent of survey respondents (n=400) were female. A quarter of the respondents lost a loved one since February 24, 2022 (15% due to death, 14% due to violent death, 5% missing in action), while 9% refused to respond.

Among those in bereavement, the majority (63%) reported that it was vital for them to better understand their own grief process. One-third reported the need for additional support in coping with the loss. One-fifth (21%) of those experiencing loss sought support as the experience became unbearable. Among those seeking professional care, there was a difference in the frequency of approaching different specialists. Twenty percent of the respondents reported that they did not seek help but were willing to.

The majority of respondents (62%) reported supporting a person who experienced loss. However, only 49% of them felt confident enough to do so. The majority (82%) of respondents said that they considered it important to have information on ways to support loved ones in grief.

Conclusions: Despite the fact that a third of people required support and care while experiencing a loss, only 1 in 5 approached mental health professionals or other healthcare specialists. Half of those who wanted to support their loved ones did not feel confident enough. Raising awareness among the population about the process of coping with loss, normalizing seeking support, and providing possible options for supporting people in grief is of high importance for the people of Ukraine affected by the full-scale war.

Exploring Mental Illness Stigma, Help-Seeking Attitudes, and Behaviors on Social Media: A Machine Learning Approach

Y.-J. Lien[1]* and H.-P. Feng[1]

[1]National Taiwan Normal University, Taipei, Taiwan, Province of China
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1987

Introduction: Mental health literacy (MHL) plays a crucial role in promoting help-seeking behavior. However, negative attitudes toward mental illness still pose a substantial barrier. Social media platforms provide a valuable opportunity to explore the relationship between stigma, help-seeking attitudes, and behaviors through the application of natural language processing (NLP) and machine learning (ML) techniques.

Objectives: This study aims to investigate how attitudes toward reducing mental illness stigma and help-seeking influence actual help-seeking behavior among social media users.

Methods: We analyzed 1,506,333 posts from mental health-related Post Text Table (PTT) forums between January 2018 and January 2024. Posts were preprocessed and categorized into three categories: reducing mental illness stigma, help-seeking attitudes, and help-seeking behaviors. Using Bidirectional Encoder Representations from Transformers (BERT) for scoring, the model achieved a

precision of 0.81 and accuracy of 0.89. Logistic regression was then applied to assess the predictive value of stigma reduction and help-seeking attitudes on help-seeking behavior.
Results: The study found that for each one-unit increase in score measuring attitudes toward reducing mental illness stigma, he likelihood of help-seeking behavior increased by 1.35 times (95% CI: 1.21–1.50, $p < 0.001$). Similarly, stronger help-seeking attitudes were associated with a 1.41 times higher likelihood of help-seeking behavior (95% CI: 1.16–1.71, $p < 0.05$). Binary logistic regression analysis further demonstrated that users with more pronounced stigma-reducing attitudes and positive help-seeking attitudes were 1.76 times (95% CI: 1.43–2.17, $p < 0.001$) and 2.62 times (95% CI: 1.48–4.65, $p < 0.05$) more likely to engage in help-seeking behavior, respectively.
Conclusions: This study highlights that stronger attitudes toward reducing mental illness stigma, along with more positive help-seeking attitudes, significantly predict help-seeking behavior. By leveraging machine learning and natural language processing, it offers novel insights into how social media discussions influence mental health behaviors, providing a valuable foundation for future interventions aimed at reducing stigma, fostering positive attitudes toward help-seeking, and encouraging actual help-seeking behaviors.

EPV1465

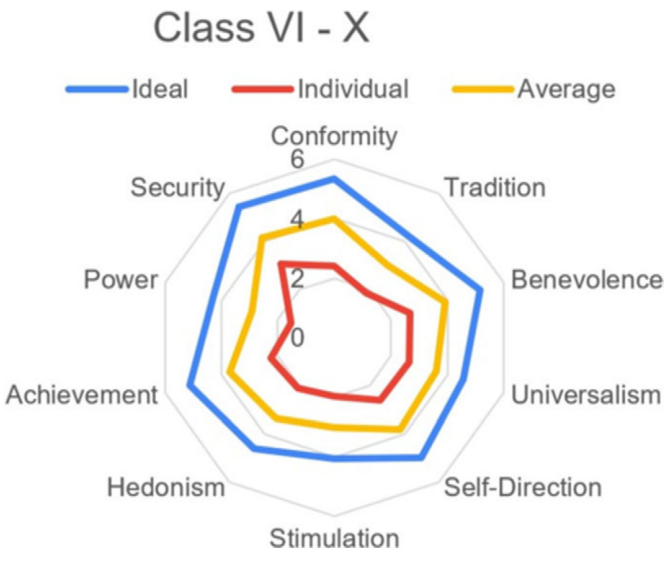
On the impact of top-level sports on the prevention of mental disorders

A. Magay[1,2*], G. Idrisova[3] and Y. Nozdrunov[2]

[1]Mental Health Research Center of Russian Academy of Medical Sciences; [2]Sports Medicine of the Federal Medical and Biological Agency of Russia and [3]Russian Paralympic Committee, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1988

Introduction: Athletes with physical impairments may experience symptoms of depression and anxiety. At all stages of sports training, it is necessary to consider athletes' mental state depending on the functional ability – class of a para table tennis player (Rice et al. 2016, Hamer et al. 2008).
Objectives: This study examines features of psychological training for the Russian national para table tennis team (class 1-10), bearing in mind function classes, mental health, and sports achievements of each team member.
Methods: Participants from 2 groups of national para table tennis players (class 1-10) who were training for the 2020 Tokyo Paralympics were analyzed. Group 1 (n=5, 2 males, 3 females) consisted of athletes classified within classes 6-10 (players who compete standing). Group 2 (n=5, 3 males, 2 females) consisted of athletes classified within classes 1-5 (players that compete in a wheelchair). Participants had no mental health complaints at the moment of the study and took part in the process voluntarily. Within these groups, 8 para table tennis players participated in the Tokyo Paralympics and won 5 medals of different merits.
Stages of the study:
Stage 1: developing a differentiated training approach, assessing individual value differences (Schwartz Value Survey, SVS), measuring the quality of life (SF-36), and designing a tailored psychological training approach for each Group.
Stage 2: psychological skills training, quality of life assessment (SF-36), and evaluation of the results of the self-report questionnaire (psycho-emotional state, level of motivation, and satisfaction) right after the end of the Games.
Results: The most significant values in Group 1 are the following: security, conformity, benevolence, self-direction, and achievement. Less pronounced values are the following: power and stimulation (fig. 1). Significant values in group 2 are security, universalism, benevolence, self-direction, and conformity. Virtually not pronounced values are hedonism and power. (fig. 2).
The preparation strategy for Group 1 should focus on adaptive coping strategies (active attitude, emotional support, instrumental support, positive reinterpretation). Group 2 should focus more on social support and foster communication with coaches and teammates.
Quality of life measurement (SF-36) and analysis of the self-report questionnaire show the reduction of the anxiety level and demonstrate a steady increase in the level of motivation, sense of fulfillment, and satisfaction with the achieved results. The result of dynamic observation indicates improvement in quality of life.

Image 1:



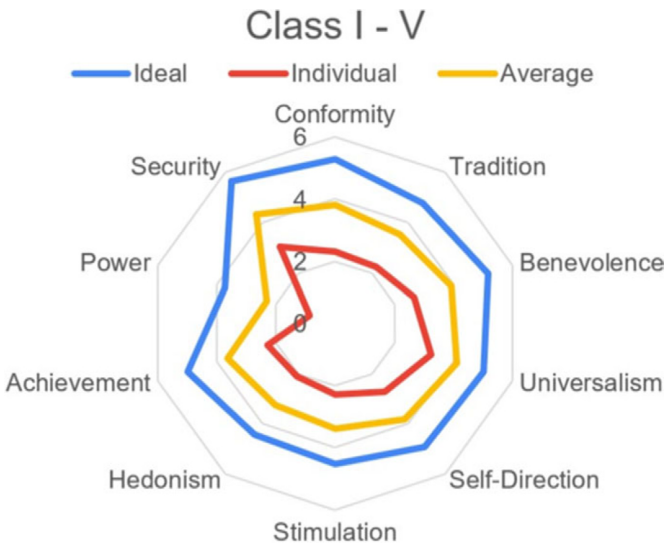


Image 2:

Conclusions: Psychological methods used in complex (integrated, comprehensive) training correlate positively with athletes' performance and beneficially affect their psycho-emotional state. Functional class plays a significant role in choosing psychological methods for coaching para table tennis players and finding an appropriate way to interact with the national team.

Risk factors of emotional burnout in medical workers of the neurosurgery center: experience of Ukraine

M. Markova[1*], A. Regush[2], V. Pliekhov[1] and A. Markov[3]

[1]Sexology, Psychotherapy and Medical Psychology, Kharkiv National Medical University, Kharkiv; [2]Center of X-ray endovascular neurosurgery, Kyiv City Clinical Hospital № 1 and [3]Psychology, Academy of Labour, Social Relations and Tourism, Kyiv, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1989

Introduction: In the modern scientific discourse, there is a lack of data on risk factors for the occurrence of emotional burnout in employees of neurosurgical medical institutions. This is what determines the relevance of the study.
Objectives: To determine the prevalence and risk factors of emotional burnout among medical workers of a neurosurgery center.
Methods: In 2022-2024, a prospective study of the medical workers involved in emergency care for patients with acute ischemic stroke, in particular mechanical thrombectomy, was conducted at the Center for X-ray Endovascular Neurosurgery of the Kyiv City Clinical Hospital № 1. The average age of the sample was 32.2 ± 5.8 years. The gender structure was: 40 (80.0%) men and 10 (20.0%) women. The clinical-psychopathological, psychodiagnostic and statistical methods were used. The psychodiagnostic method was implemented by using the Maslach Burnout Inventory (MBI, C. Maslach et al., 1997).
Results: It was determined that such a criterion as the gender of medical workers of the neurosurgery center does not affect the severity of any component of emotional burnout ($p > 0.05$). Statistically significant differences in the prevalence of high rates of emotional burnout components were determined between groups of medical workers with different specializations. In particular, it was determined that working in the center as a neurosurgeon is reliably associated with high rates for such components as "Emotional exhaustion" ($p=0.04$) and "Depersonalization" ($p=0.006$). A direct correlation was also established between the length of total work experience, length of service in the neurosurgery center and the number of working hours per month with the intensity of manifestations of emotional burnout in the selected contingent of individuals.
Conclusions: The prevalence of emotional burnout among medical workers of the neurosurgery center has been established for various components of this phenomenon: "Emotional exhaustion" – 52.0%, "Depersonalization" – 40.0%, "Reduction of personal achievements"– 50.0%, which indicates a high level of stress, which negatively affects the mental health of the selected contingent. The risk of developing emotional burnout among the medical workers increases with increasing workload, length of service and length of service in the center. An absolute risk factor for emotional burnout is working as a neurosurgeon. The development of psychotherapeutic measures aimed at overcoming the manifestations of emotional burnout in medical workers and increasing their resilience to stressful working conditions of the neurosurgery center is promising.

Early intervention: determinants of neurodevelopmental outcomes in very preterm children

A. Riera-Martín[1,2*], A. Calvo[1], M. Estévez-Domingo[3], Á. Iruin-Sanz[4] and M. Moreno-Íñiguez[4]

[1]Department of Personality, Assessment and Clinical Psychology, Complutense University of Madrid, Madrid; [2]Basque Health System (Osakidetza), Biogipuzkoa Health Research Institute; [3]Basque Health System (Osakidetza), Donostia University Hospital and [4]Basque Health System (Osakidetza), Outpatient Mental Health Network of Gipuzkoa, San Sebastián, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1990

Introduction: Based on previous studies, we already know that very preterm birth constitutes an important risk factor for neurodevelopmental disorders and psychopathology.
Objectives: The present study aims to identify those variables that might impact the neurodevelopment of children born below 32 weeks gestation and 1.5 kg of weight, and their parents, in a three-year follow up.
Methods: This is a prospective observational study implemented at Donostia University Hospital between January 2018 and December 2021. Inclusion criteria: newborns with gestational age < 32 weeks and/or birth weight < 1.5 kg, and their parents. Participants were 113 newborns, 87 mothers and 77 fathers. Children's neurodevelopment was evaluated through the Bayley Scale of Infant and

Toddler Development- Third Edition (Bayley-III) at their first, second and third years of life. Parents' predictive variables, evaluated during the period of time in which their children were hospitalized in the Neonatal Intensive Care Unit (NICU), were parents' mental health (postpartum depression, anxiety and general symptoms), postnatal bonding, and obstetric variables. To analyze the study's dependent variables, step linear regression models (cognition, receptive and expressive language, fine and gross motor skills) at first, second and third year were employed.
Results: Parents' mental health, especially phobic anxiety in fathers and paranoid ideation in mothers, as well as postnatal maternal bonding, significantly predicted neurodevelopmental difficulties in children during their first three years of life. Children's gestational age at birth and fathers' obsessive-compulsive symptoms predicted neurodevelopmental difficulties in several models, although not as expected, in a counterintuitive manner. In terms of cognition and fine motor skills, the model's predictors were not significant at age three.
Conclusions: According to our results, we consider an early mental health intervention for parents of newborns in need of hospitalization at the NICU to be of major importance. This intervention should be implemented during the hospitalization period, focusing on both parents (father included) and addressing bonding issues from a preventive perspective.

Self-care behaviours and psychological heath of university staff

A. Abbes[1], I. Sellami[1]*, A. Feki[2], S. Baklouti[2], M. L. Masmoudi[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupationnal medecine and [2]Rheumatology, CHU Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1991

Introduction: Mindfulness involves being aware of both your thoughts and emotions as well as your surroundings. Regular practice of mindful self-care can enhance the overall well-being. For university staff, these practices can help counteract negative effects on mental health.
Objectives: Our study aims to evaluate the practice of mindful self-care and its impact on the psychological health of university staff.
Methods: We conducted a descriptive, analytical and cross-sectional survey among university staff. The survey was carried out during a one-day training session on mental health promotion using a self-administrated questionnaire. We collected socio-professional data. We assessed psychological health using the depression anxiety and stress scale (DASS 21) and self-care behaviours using Mindful Self-Care Scale (MSCS).
Results: Our study included 65 participants, 67.7% of whom were female. The average age was 53±6.8 years, and the average job tenure was 21.3±8 years. We found that 36.9% of participants experienced mild to moderate stress, 35.4% had mild to moderate depression, 7.7% had severe to extremely severe depression, and 23.1% had severe to extremely severe anxiety.
The average mindful self-care score was 102.8±26.3. The means for specific aspects of mindful self-care were: mindful relaxation 12.6 ±4.5, physical care 19.9±5.6, self-compassion and purpose 20.7 ±7.6, supportive relationships 15.4±5.6, supportive structure 13.4 ±4.6, and mindful awareness 14.5±4.8.
We found a negative correlation between anxiety and depression and mindful self-care ($p = 0.02$, $r = -0.2$). In female participants, stress was also negatively correlated with mindful self-care ($p = 0.02$, $r = -0.3$).
Conclusions: According to our findings, mindful self-care may be a potential strategy for anxiety, depression and stress management available to university staff. Given the considerably poor psychological health in the study population, we recommend to increase awareness of mindful self-care in university staff.

Felt presence and its determinants in young adults: Results from three independent samples

J. Maciaszek[1], M. Rejek[1], T. Bielawski[1], M. Błoch[1], A. Senczyszyn[1] and B. Misiak[1]*

[1]Department of Psychiatry, Wroclaw Medical University, Wroclaw, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1992

Introduction: Felt presence (FP) is a phenomenon that might appear in individuals with mental and neurological disorders as well as those without any specific morbidity. Some studies have indicated that FP is closely related to psychotic symptomatology. Yet, the mechanisms underlying its occurrence remain largely unknown.
Objectives: The present study aimed to investigate whether FP is associated with widely known risk factors of psychosis.
Methods: Data from three independent samples of non-clinical young adults were analyzed. Self-reports were administered to assess psychopathological symptoms (samples 1 – 3), neurodevelopmental risk factors for psychosis (sample 1), social defeat components (sample 2), childhood trauma, and loneliness (sample 3). A total of 4782 individuals were surveyed across all three samples.
Results: Unadjusted analyses showed that the following factors are associated with higher odds of FP: obstetric complications, childhood trauma, non-right-handedness, a lower education level, unemployment, minority status, humiliation, perceived constraints, and loneliness. However, only minority status and a lower level of education were associated with higher odds of FP after adjustment for other psychopathological symptoms, age, and gender. Importantly, hallucination-like experiences across all recorded modalities and paranoia were associated with higher odds of FP in all samples. Depressive symptoms were weakly associated with FP in two samples.
Conclusions: Findings from the present study suggest that the majority of known risk factors for psychosis contribute to the emergence of FP through the effects on psychotic experiences. Low educational attainment and minority status might be the only risk factors independently contributing to the emergence of FP.

The Impact of GLP-1 Receptor Agonists (GLP-1 RAs) on Mental Health: A Systematic Review

S. Tempia Valenta[1]*, A. Nicastri[2], F. Perazza[2], F. Marcolini[1], V. Beghelli[1], A. R. Atti[1] and M. L. Petroni[2]

[1]Department of Biomedical and Neuromotor Sciences and [2]Department of Medical and Surgical Sciences, Alma Mater University of Bologna, Bologna, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1993

Introduction: Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) are a class of pharmacological agents that have gained significant attention and utility in managing metabolic disorders, particularly type 2 diabetes mellitus and obesity, often in combination with behavioral therapy. These agents mimic the physiological actions of GLP-1, a hormone released from the gastrointestinal tract in response to food intake, thereby stimulating insulin secretion, suppressing glucagon release, slowing gastric emptying, and promoting satiety through both peripheral and central nervous system mechanisms. Beyond their metabolic benefits, GLP-1 RAs have shown potential antidepressant and anxiolytic effects, which may be mediated through neuroprotective mechanisms, reduction of neuroinflammation, and modulation of neurotransmitter systems.
Objectives: This systematic review aims to synthesize existing evidence on the effects of GLP-1 RAs on mental health outcomes, including both potential therapeutic benefits across various psychiatric disorders and the risk of associated adverse mental health effects.
Methods: This systematic review was conducted across PubMed/MEDLINE and Web of Science. Inclusion criteria encompassed human and animal studies examining the impact of GLP-1 RAs on mental health. Data from 81 selected studies were extracted and analyzed, focusing on mental health outcomes and reported adverse effects.
Results: GLP-1 RAs exhibit potential beneficial effects on depressive symptoms, cognitive function, and reduced risk of suicidal ideation in animal and human models through antioxidative, anti-inflammatory mechanisms, and modulation of neurotransmitter pathways. Additionally, GLP-1 RAs were effective in reducing alcohol and substance use and binge eating behaviors. Adverse psychiatric effects associated with GLP-1 RAs, including depression, anxiety, and suicidal ideation, are noted in pharmacovigilance analyses, with variations among different GLP-1 RAs.
Conclusions: Our systematic review highlights the potential role of GLP-1 RAs in psychiatric care, underscoring their potential therapeutic benefits across a spectrum of mental health conditions. Animal studies consistently demonstrate positive outcomes, revealing antidepressant effects, modulation of addictive behaviors, and improvements in eating disorders through various neurobiological mechanisms. Human studies present a more nuanced landscape with conflicting evidence regarding the impact of GLP-1 RAs on depressive symptoms and other psychiatric outcomes, suggesting a need for further rigorous investigation. Despite these promising findings, significant limitations, such as study heterogeneity, funding biases, and the predominance of animal model data, temper definitive conclusions. Longitudinal and rigorous studies are warranted to elucidate the long-term effects and safety profile of GLP-1 RAs in psychiatric contexts.

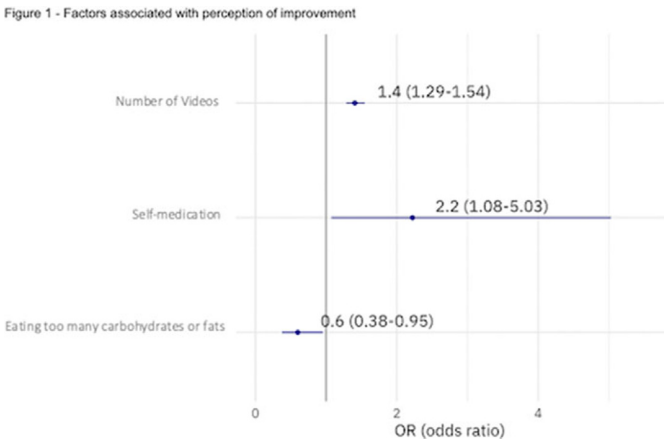
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1994

Introduction: The COVID-19 pandemic set up a global health crisis, with an impact on the daily lives of the population. The effectiveness and importance of Single-Session Interventions (SSI), have increasingly been demonstrated, which also found expression during the Pandemic and remote care and has shown a significant impact in reducing symptoms, reducing relapses and hospitalizations, increasing positive attitudes, improving treatment adherence, and reducing the length of hospital stay for various mental disorders. It is considered an easy-to-access and economical tool.
The Hospital de Clínicas de Porto Alegre (HCPA) and the Brazilian Ministry of Health developed the TELEPSI. This Project aims to: provide telecare using different types of psychotherapeutic approaches to health professionals, teachers, and essential service workers during the Pandemic in Brazil.
Objectives: This study aims to investigate the predictors of perceived improvement after the Single Session Intervention with Enhanced Psychoeducation (SSI-EP) with support videos in frontline professionals during the Covid 19 Pandemic.
Methods: he COVID-19 pandemic set up a global health crisis, with an impact on the daily lives of the population. This study analyzed data from a large trial including frontline workers from April 2020 to December 2021. We included all participants randomized to SSI-EP.
Results: The final sample consisted of 709 subjects, 82.8% were health professionals, 87.8% health professionals. One month after the intervention, 558 (78.7%) have improved emotional symptoms. Factors associated with better outcomes were the number of videos watched by the participants and use of medications without a medical prescription. Excessive consumption of carbohydrates and fats was negatively associated with improvement.

Image:

Table 1. Descriptive statistics of sociodemographic and clinical variables of study participants (n = 709).

Variables	Overall (n = 709)
Sex	
Female	621 (87.8%)
Age	
Mean (SD)	37.7 (10.1)
Median [Min, Max]	37.0 [19.0, 72.0]
Profession	
Health Professional	587 (82.8%)
Teacher	67 (9.4%)
Essential Services*	55 (7.7%)
Number of videos watched (follow-up)	
Mean (SD)	5.68 (2.31)
Median [Min, Max]	6.00 [1.00, 12.0]
Number of absences at work	
Mean (SD)	2.0 (5.70)
Median [Min, Max]	0 [0, 60.0]
Perceived improvement	
About the same or worse	151 (21.2%)
Better	558 (78.7.%)



SD = Standard deviation. Mi
* For example: professionals with jobs that could not stop during the Pandemic as drivers, delivery men, police officers, garbage collectors.

Image 2:

Table 2. Which video in the patient's perception helped the most (n = 635).

Videos	Overall (n = 635)
Normal and excessive anxiety	127 (20%)
Sleep hygiene	73 (11.5%)
Physical exercise	38 (6%)
Sadness and Depression	38 (6%)
Anger and Irritability	36 (5.7%)
Stress and stress reaction	30 (4.7%)
Burnout	28 (4.4%)
Healthy eating	28 (4.4%)
Taking care of children	19 (3%)
Fear of contagion	16 (2,5%)
Social support	14 (2.2%)
How to protect yourself from COVID-19	13 (2%)
Excessive exposure to the news	5 (0,8%)
Excessive use of social media	4 (0.6%)
Use of alcohol and drugs	4 (0.6%)
Caring for the Elderly	2 (0.3%
All videos	94 (14.8%)
None	66 (10.4%)
Missing	74 (10.4%)

Image 3:

Conclusions: This new TELEPSI proposal that combines online SSI based on Psychoeducation with the sending of support videos proved to be effective, as we saw in the main article in which a significant proportion of participants improved. The participant's perception of improvement, corroborates the data found on the improvement of symptom scales and some factors associated with this outcome, such as videos. This was an interesting finding and the importance of studying and exploring and studying more and more digital interventions, which can offer access to many people and have low implementation costs. We believe that in this way we will be able to better indicate such new psychotherapeutic strategies in a more personalized and adapted way. Enhanced psychoeducation is an effective and low-cost approach to improving symptoms. More research is needed to compare its effectiveness with other intervention strategies. Furthermore, its application must be explored beyond the context of the pandemic and social isolation.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1995

Introduction: The COVID-19 pandemic had a major impact on the world's emotional health, and knowledge is limited about the efficacy of traditional interventions in this context. The TelePSI Project, initiated by the Hospital de Clınicas de Porto Alegre in collaboration with the Brazilian Ministry of Health, aimed to provide online

mental health care to essential services professionals during the pandemic. Single session of enhanced psychoeducation (EP) is an innovative strategy proposed by TelePSI, suggesting lifestyle changes based on individual risk and protective factors or physical, emotional, psychological, and well-being.

Objectives: Single-session interventions are an effective strategy for reducing emotional distress. Enhanced psychoeducation, which includes empathic listening, risk stratification, symptom monitoring, and habit modification is particularly suitable for single-session interventions. We investigated predictors of response to an online enhanced psychoeducation intervention among essential service professionals during the pandemic in Brazil.

Methods: The TelePSI Project, financed by the Brazilian Ministry of Health, was a nationwide initiative that served more than 3,300 individuals in various psychotherapeutic modalities. Data were collected from April 2020 to December 2021. We included all participants with high levels of emotional distress who received single-session interventions

Results: Final sample 460 individuals (89.1% women, 81.1% health professionals). After 1 month, 300 participants were reassessed. Overuse of social media, use of social networks to contact family and friends, playing video games, smoking, drinking alcohol, and spending time with pets were associated with less improvement in symptoms, whereas playing an instrument and previous psychological treatment were associated with greater symptom improvement. This highlights the impact of lifestyle factors on the efficacy of single-session interventions.

Image:

Table 1 Descriptive statistics of the participants' sociodemographic and clinical variables (n=460)

Variable	Overall
Sex	
Female	410 (89.1)
Age

Playing an instrument	-4.63	2.27	0.042

SE = standard error.
‡ Minus sign = less improvement; plus sign = more improvement.
† Change in Patient-Reported Outcomes Measurement Information System after 1 month of follow-up.

Image 3:

Conclusions: Online EP with support videos, as proposed by TelePSI, appears to be an effective intervention strategy for healthcare professionals with symptoms of anxiety, depression, and irritability. Although a significant proporion of the participants improved, some variables were associated with less improvement, such as spending time with pets, tobacco use, alcohol use, and playing video games. In this study, we set out to analyze variables associated with participant improvement because, by evaluating these factors, we can better understand this new model of psychoeducation, which represents a promising alternative for individuals during crises such as the COVID-19 pandemic. Furthermore, the intervention should be explored beyond the context of the pandemic and social isolation. Further research on TelePSI is forthcoming, including a comparison of intervention arms

Specifics of anticipatory competence of adolescents with intellectual disabilities

A. Akhmetzyanova[1]*, T. Artemyeva[1] and M. Ilyushina[1]

[1]Department of Psychology and Pedagogy of Special Education, Kazan Federal University, Kazan, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1996

Introduction: Anticipation forms the basis of all human activity, enabling people to plan and carry out their activities, as well as to communicate and interact with others. Well-developed anticipatory abilities allow adolescents to successfully adapt to society, establishing effective communication with adults and peers.
Objectives: To study the specifics of anticipatory competence in adolescents with intellectual disabilities.
Methods: The study involved 40 adolescents (aged 12-15) attending educational institutions for children with disabilities and intellectual impairments (6A00.0, ICD-11). The research employed the following methods: the "Achenbach's Questionnaire," V.D. Mendelevich's "Test of Anticipatory Competence," V.P. Ulyanova's "Anticipation of the Outcome of a Situation with Norm Violations," and the authors' method "Study of Anticipatory Competence of Adolescents" by A.I. Akhmetzyanova and T.V. Artemyeva.
Results: The study results show that adolescents with intellectual disabilities are capable of predicting future situations. However, these children exhibit insufficient development in the key components of anticipatory competence: personal-situational, spatial, and temporal anticipation. Adolescents in this group experience difficulties in anticipating conflict situations in interpersonal relationships and in predicting others' responses to their own behavior. The methods' results indicate that adolescents with intellectual disabilities often exhibit spatial anticipatory incompetence: common traits in this group include general motor awkwardness and difficulties in spatial orientation (M=41.65; N=52); sometimes they cannot predict the timing of a stressful situation in advance and struggle with time orientation (M=39.45; N=42). While most adolescents with intellectual disabilities recognize and understand societal norms and rules, they face significant difficulties in accepting them (M=11.05; MAX=32).
Conclusions: The data obtained in this study allow for the development of programs aimed at adapting adolescents to society, taking into account their ability to predict future situations and their anticipatory competence in various spheres: family relationships, virtual reality, and academic and extracurricular activities.

Assessment of the needs and demand for psychiatric care among medical students: cross-sectional study

A. Ben Haouala[1]*, N. Faouel[2], E. Abouda[2], L. Gassab[2], B. Amamou[2] and A. Mhalla[2]

[1]Research Laboratory "Vulnerability to psychotic disorders", Faculty of Medicine and [2]Psychiatry, University Of Monastir, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1997

Introduction: Studying medicine is a demanding and time-consuming course of study, which can be a major stress factor and affect quality of life (QOL). Medical students are at high risk of developing mood disorders. This could lead to a need for psychiatric care (PC) that is not necessarily equivalent to the demand.
Objectives: Determine the prevalence of depression, anxiety and stress in medical students, assess their QOL and subjective need for PC.
Methods: This was a descriptive cross-sectional study conducted over a 5-month period in a Tunisian medical school. Sampling was stratified random. Sociodemographic and clinical data were collected using a questionnaire. Depression, anxiety and stress were assessed using the Depression Anxiety and Stress Scale: DASS-21. QOL was assessed using the generic 36-item Short-Form Health Survey (SF-36). Subjective assessment of difficulties and need for help was carried out using the "KIT ELADEB: Lausanne Self-Assessment Scales for Difficulties and Needs".
Results: The study included 308 students with a median age of 21. Some (18.8%) were smokers, 15.9% drank alcohol, and 5.2% used psychoactive substances (PAS). A Family psychiatric history (PH) was present in 15.4% of cases, and 14.3% of students had personal PH. Median DASS scores were: depression 18 (interquartile range (IQR) = 16-27), anxiety 20 (IQR = 18), and stress 16 (IQR = 42). The rates of extremely severe and severe depression were 27.6% and 12.3% respectively, while 50.6% had extremely severe and 12% severe anxiety. Some 29.2% of students had severe to extremely severe stress. Mean SF-36 scores were 61.19 ± 16.83, referring to the Léan cut-off value (66.7), 58.1% had impaired QOL, 15.9% of participants had consulted a psychiatrist, 78.9% had felt the need to do so, and 59% had foregone such help. Factors associated with severe depression included advanced age (p=0.007), graduate education (p<10-3), PAS use (p<10-3), and PH (p<10-3). Anxiety was predicted by female gender (FG) (p=0.04), SPA use (p=0.03), and PH (p<10-3). Stress was associated with age (p=0.039), course of study (p=0.008), lack of leisure activities (p=0.003), smoking (p=0.004), alcoholism (p=0.009), use of PAS (p=0.003), and PH (p=0.000). Students who consulted a psychiatrist were more likely to have depression (p<10-3), stress (p<10-3), and impaired QOL (p<10-3). Participants who expressed a subjective need to consult a psychiatrist were significantly associated with FG (p<10-3), depression (p<10-3), anxiety (p<10-3), stress (p<10-3), and alterations in the mental health (p=0.008), vitality (p=0.006), social functioning (p=0), and general QOL (p=0.002) dimensions of the SF-36.
Conclusions: The obvious deterioration in the mental health and QOL of medical students, and the mismatch between the need for and demand for PC, should initiate a debate on recommendations to improve the well-being of our future doctors.

Promoting mental health in Portuguese college students - A pilot study with Yoga-based relaxation techniques

A. Ilharco[1], M. Pocinho[2], M. J. Brito[3,4]* and A. P. Amaral[2,5]

[1]Unidade Local de Saúde de Coimbra; [2]Escola Superior de Tecnologia da Saúde de Coimbra, Instituto Politécnico de Coimbra; [3]Serviço de Psiquiatria, Unidade Local de Saúde de Coimbra; [4]Instituto de Psicologia Médica, Faculdade de Medicina da Universidade de Coimbra, Coimbra and [5]Centro de Investigação e Inovação em Educação (inED), Politécnico do Porto, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1998

Introduction: Mental health of higher education students is a relevant topic, especially for students in the health field. The development of relaxation techniques in this population is increasingly recognized as crucial to promote psychological well-being and reduce distress.
Objectives:
1) Study the associations between mental health and lifestyle in Portuguese college students in the health field; 2) Evaluate the effectiveness of a Yoga-based relaxation techniques on mental health and physiologic variables.

Methods: Study 1 had a cross-sectional design, with 107 participants, 76,6% females, average age of 21,33 years (SD=4,88).Study 2 employed a pretest-posttest design, with 3 timepoints: T0, T1, T2, with T2 being a follow-up after 3 months. Participants: 11 students, 81,8% females, average age of 26,82 years (SD=11,59).
Measures: 1) Mental Health Inventory (MHI-38); 2) Lifestyle questionnaire. In study 2, the intervention consisted of six face-to-face sessions, lasting 60 minutes each, with practical training of Yoga-based relaxation techniques and evaluation of heart and respiratory rate, and blood pressure before and after each session.
Results: Study 1 – 32,7% presented Distress, and we found significative correlations between sleep quality perception, global health perception and Mental Health (p<.001); male students who practice physical activity have more Positive Affect. Study 2 – In all sessions, the physiologic variables decrease in T1, and Distress and Anxiety decrease significantly in T1 (p=0,037; p=0,031, respectively). After the follow-up, the improvement in mental health remains significative (p<0,001).
Conclusions: The results suggest a relevant percentage of students with distress, and that the intervention program with Yoga-based relaxation techniques contribute to decrease heart, respiratory and the blood pressure rate. After the intervention and the follow-up, there is a decrease in distress in Portuguese college students. Suggestions for future studies would be to replicate the intervention with a control group and a larger sample.

EPV1480

A pilot study to promote mental health by developing emotional awareness and regulation in college students

J. T. B. D. Aguiar[1,2], M. J. Brito[3,4]* and A. P. Amaral[5,6]

[1]Faculdade Ibiapaba; [2]Centro Integrado de Atenção à Saúde de Tianguá-CE, Tianguá, Brazil; [3]Serviço de Psiquiatria, Unidade Local de Saúde de Coimbra; [4]Instituto de Psicologia Médica, Faculdade de Medicina da Universidade de Coimbra; [5]Escola Superior de Tecnologia da Saúde de Coimbra, Instituto Politécnico de Coimbra, Coimbra and [6]Centro de Investigação e Inovação em Educação (inED), Politécnico do Porto, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1999

Introduction: Emotional awareness and emotion regulation are essential skills for psychological well-being, especially in college students, who frequently experience stressful situations and emotional challenges. Therefore, interventions aimed at developing skills such as stress management and frustration tolerance can be important to enhance emotional awareness and regulation, contributing to the promotion of mental health in this population.
Objectives: This study aimed to evaluate the effectiveness of a mental health promotion program, focusing on the development of emotional awareness and regulation in college students.
Methods: This study employed a pretest-posttest design, and non-parametric tests were used. Measures:
1) Depression Anxiety and Stress Scale (DASS-21); 2) Difficulties in Emotion Regulation Scale (DERS) and an interview with six open questions to evaluated the individual perception of the impact of the intervention. Participants: nine Portuguese female college students, with an average age of 19,77 years (SD=1.48). The intervention consisted of six face-to-face sessions, lasting 60 minutes each, with theoretical and practical aspects for skill training of stress management, emotional regulation, and frustration tolerance.

Results: The results suggested a decrease in levels of anxiety (p=.07), depression (p=.03), and stress (p=.07) after the intervention. There was also a decrease in emotional regulation difficulties for the participants (p=.01), notably in difficulties regarding strategies (p=.02), impulses (p=.03), and non-acceptance (p=.05). For the subscales of awareness, goals, and clarity, although the results showed a decrease, there was no statistical significance. It stands out from the analysis of the students' answers to the open questions, that they developed their emotional regulation skills and they also highlighted the importance of the close supervision and support throughout the process, as well as the practical nature of the sessions.
Conclusions: The results suggest that the intervention program can contribute to enhance emotion regulation and promoting mental health of college students. Suggestions for future studies would be to replicate the intervention with a larger sample and with group control.

The Influence of Individual Characteristics, Personality Traits, and Life Events on Academic Stress: A Survey among Third-Year Medical Students at Humanitas University

D. Caldirola[1,2]*, S. Daccò[1,2], F. Cuniberti[2], V. Butti[1], M. Grassi[1], A. Spiti[3] and G. Perna[1,3]

[1]Department of Biomedical Sciences, Humanitas University, Pieve Emanuele, 20090 Milan; [2]Humanitas San Pio X, 20159 Milan and [3]IRCCS Humanitas Research Hospital, Rozzano, 20089 Milan, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2000

Introduction: Medical students face a demanding academic journey, where stress can significantly impact their well-being and performance. Both personal and environmental factors contribute to this burden, yet research on academic stress in Italian medical schools remains limited.
Objectives: We investigated the impact of various factors on perceived academic stress among third-year medical students during the pre-clinical phase of their studies.

Methods: A cross-sectional, anonymous, self-reported online survey was distributed to third-year medical students at Humanitas University (Milan, Italy) over a 10-day period in April 2024. The survey included various questions on sociodemographic factors, lifestyle behaviors (e.g., sports activity, diet, smoking, alcohol binge drinking), satisfaction with sleep and sexual activities, smartphone and video game use, significant life events, and objective academic performance. Additionally, several validated questionnaires were included to assess academic stress, personality traits, psychological dispositions (e.g., proneness to boredom, procrastination, impulsivity, perfectionism, intolerance of uncertainty, worry), coping strategies, resilience, attentional control, feelings of loneliness, and perceived social support. Data were analyzed using hierarchical multiple linear regression, with a significance level at 0.05.
Results: Seventy-six students (70.4%) out of 108 who provided their informed consent completed the survey; 58 (76.3%) were female and 18 (23.7%) were male, with 53 (69.7%) being Italian and 23 (30.3%) from other countries. Higher academic stress was significantly associated with the female gender, a higher burden of negative life events, and greater propensity for impulsivity and worry. In contrast, passing more exams and experiencing positive life events were associated with lower academic stress. No other statistically significant associations were found. The independent variables collectively explained about 60% of the variation in academic stress (adjusted R^2, $p<0.001$).
Conclusions: Our preliminary findings provide insights into the factors influencing the multifaceted nature of academic stress. These results may help educators, administrators, and policymakers create a more supportive learning environment and offer psychological support to reduce academic stress in vulnerable students. Enhancing the psychological well-being of medical students could help prevent potential mental health conditions in this population. Further studies with larger samples and a prospective design are warranted.

Mental health and nature connectedness. A step toward a new mental health definition?

M. Gawrych

The Maria Grzegorzewska Univeristy, Warsaw, Poland
doi: 10.1192/j.eurpsy.2025.2001

Introduction: Recent studies have shown the mental health is broad concept. Nature connectedness seems to be one of important factors affecting it.
Objectives: to clarify the concept of mental health in term of nature connectedness.
Methods: The MEDLINE database (through PubMed) was searched for articles in this field published in 2010–2024. Mental health-related descriptors (i.e., "mental health" or "mental disorders") and the "nature/ social connectedness" terms were used in particular searches.
Results: The selected publications were categorized and then analysed. Strong nature connectedness is associated with higher mental well-being. Full results will be presented.
Conclusions: Nature connectedness can play a crucial role in understanding some aspects of mental health as well as mental health prevention.

On the path to setting meaningful goals in the care for mental health patients: initial results of the adaptation of Mental Health Quality of Life Questionnaire (MHQoL) in a Hungarian clinical and non-clinical sample

V. Pribula[1,2], L. P. Elek[1], T. Szekeres[3], T. A. Renko[1,2], P. Ruscsak[4], G. Vizin[4] and X. Gonda[1]*

[1]Department of Psychiatry and Psychotherapy; [2]Department of Clinical Psychology; [3]Department of Internal Medicine and Oncology, Semmelweis University and [4]Institute of Psychology, Department of Clinical Psychology and Addictology, Budapest, Eotvos Lorand University, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2002

Introduction: The concept of health is beyond the absence of disease; it encompasses the physical, mental, and social well-being of an individual, as well as their quality of life. Consequently, research into this multifaceted concept has become a crucial aspect of healthcare. With progress in medicine it has become increasingly evident that the primary objective of medical interventions is not merely to prolong life, but also to enhance its quality. A number of quality of life measures have been developed; however, the majority of these focus exclusively on physical health, and fail to fully encompass the dimensions that are crucial for the quality of life of individuals with mental health issues. The Mental Health Quality of Life (MHQoL) questionnaire, developed by Van Krugten et al., encompasses the seven most fundamental dimensions of mental health-related quality of life.
Objectives: Our aim was to develop and test a Hungarian adaptation of the Mental Health Quality of Life (MHQoL) questionnaire and to compare the results in healthy subjects with those from individuals diagnosed with psychiatric disorders.
Methods: Our ongoing research so far involved 189 participants, including 157 psychiatrically healthy subjects and 32 patients diagnosed with a mental disorder who completed the MHQoL as part of a larger test battery. Data were analysed using confirmatory factor analysis, reliability analysis and an independent samples t-test.
Results: Confirmatory factor analysis showed that all items exhibited a satisfactory fit with the model. The factor weights for each item ranged from 0.45 to 0.79. MHQoL exhibited exemplary internal reliability, with Cronbach alpha index value of 0.81 and individual item-specific reliability coefficients ranging from 0.7 to 0.81. Independent samples t-tests showed significant differences between healthy and patient groups for items pertaining to future vision, mood, relationships and physical health, as well as when MHQoL mean total score and the mean scores of psychological well-being.
Conclusions: Our preliminary results support that MHQoL is a suitable and reliable tool for assessing quality of life in relation to mental health, offering valuable insights into the domains in which psychiatric illnesses have the most significant impact on patients' quality of life. The objective of our future research is to further validate the MHQoL questionnaire, including patients with different psychiatric diagnosis in order to contribute to the concept of healthcare that focuses not only on the elimination of symptoms

but also on the improvement of quality of life, personalized to the needs of patients suffering from different psychiatric syndromes.

Effects of Progressive Muscle Relaxation and Breathing Exercises with Music on Stress Levels and Bio-Psycho-Social Responses of Nursing Students in Clinical Practice: A Randomized Controlled Trial

N. Karabulut[1]* and Ç. YÜKSEL[2]

[1]Nursing, Ankara University and [2]Nursing, University of Health Sciences, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2003

Introduction: Clinical practice involves many stress factors for nursing students. Stress in clinical practice causes positive or negative outcomes for students. Students show physical, emotional and behavioural reactions to stress. Therefore, progressive muscle relaxation and breathing exercises with music can be a method that students can easily learn and apply, reducing stress and negative bio-psycho-social responses.
Objectives: This study aimed to examine the effects of progressive muscle relaxation and breathing exercises accompanied by music on the stress levels of undergraduate nursing students and their bio-psycho-social responses to stress.
Methods: This randomized controlled study was conducted at a university in Turkey with ethics committee approval. A total of 154 undergraduate nursing students were randomized, 77 in the intervention group and 77 in the control group. 44 of the students were sophomores, 52 were third-year students, and 58 were fourth-year students. Progressive muscle relaxation and breathing exercises were applied to the intervention group for six weeks with music. No intervention was applied to the control group during the research period. Research data were collected using the Personal Information Form, the Perceived Stress Scale for Nursing Students, and the Biopsychosocial Response Scale for Nursing Students. The scales were applied to the intervention and control groups before the exercises, at the end of the six-week exercises, and two weeks after the exercises ended. Data were collected between October 2022 and January 2023. Shapiro-Wilk test was used in the analysis of normality of data; Independent Samples t-test, Dependent Samples t-test, and Analysis of Variance were used in the analysis of variables.
Results: In the pre-test measurements of the groups, it was found that there was no significant difference in terms of the students' stress levels in clinical practice and bio-psycho-social response scores ($p>0.05$). In the post-test and follow-up measurements, it was seen that the stress and bio-psycho-social response scores were significantly lower in the intervention group than in the control group ($p<0.05$). There was also a significant group*time interaction between the groups in terms of stress and bio-psycho-social response scores ($p <0.05$).
Conclusions: The findings showed that the intervention helped students reduce their stress levels and negative bio-psycho-social responses to stress, and the effects were found to be sustained in the short term. These positive results are promising in the use of progressive muscle relaxation and breathing exercises with music as an effective and easy method to reduce the stress level and negative physical, emotional and behavioral responses to stress in the clinical practice of undergraduate nursing students.

Climate change and natural disasters: global challenges for mental health, resilience, and recovery

F. Kraxner[1]* and S. Tanyeri Kayahan[2]

[1]Psychiatry, Hospital Affoltern am Albis, Zürich, Switzerland and [2]Psychiatry, Republic of Türkiye Ministry of Health Yalvac State Hospital, Isparta, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2004

Introduction: Climate change is the biggest threat of the 21st century and poses a significant risk to mental well-being by aggravating social injustice, by which children and adolescents are particularly affected. To avert the scenarios predicted by scientists, it is not only necessary for politicians to act quickly and thoroughly but also to rethink our self-understanding as those responsible for planetary health and to face this crisis with a fundamental rearrangement of priorities.
Objectives: Highlighting and summarizing current knowledge on climate change and its effects on mental health were aimed.
Methods: To emphasize the global challenges related to mental health, facts and figures of climate change and the actual status quo of climate-related mental health were gathered through an online review of existing resources.
Results: According to the Glasgow Climate Pact of the United Nations Framework Convention on Climate Change, the world is currently heading for a global warming of 2.7°C, accepting the destruction of habitats and ecosystems. The warnings regarding climate change from the scientific community are becoming increasingly clear. The Lancet Countdown, a review by scientists from 43 leading institutes around the world, shows visible impacts of climate change on human health. The Intergovernmental Panel on Climate Change report confirms a global increase in climate change-associated morbidity and mortality in 2023, as well as the impact on mental health. The climate crisis threatens mental health ubiquitously. In this context, new terms as "eco-anxiety", "eco-paralysis", and "solastalgia" are already being used. Eco-anxiety describes the fear of directly experiencing climate change. While this fear results in a change towards environmentally friendly behavior in some people, others fall into eco-paralysis. Knowledge about climate change can lead to paralysing fear and denial. Trauma from experiencing extreme weather events or forced relocation also trigger psychological distress in young people. In addition to eco-anxiety, the term solastalgia is increasingly used to describe the existential pain caused by experiencing irreversible climate-related changes in the environment. Surveys show that anxiety about the future has increased among young adults in recent years. The interconnections between climate change and mental health also include stress reactions and emotional suffering, strained social relationships, helplessness, grief, and increased risk of suicidal behavior.
Conclusions: Considering many health care professionals do not yet carry out any corresponding preventive measures regarding climate change and its effects on mental health, the self-image of physicians must be rethought and sharpened as communicators

and ambassadors. To address this global topic, it is urgent to strengthen research, training, policies, advocacy, and data collection.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2005

Introduction: A growing body of research has demonstrated the positive effects of Acceptance and Commitment Therapy (ACT) delivered in the workplace on employees' well-being and psychological flexibility. Delivering ACT in the workplace aims to enhance employee performance and reduce stress levels by promoting psychological flexibility, a skill to consciously live in the present, observing thoughts and emotions, and engaging in value-driven actions.
Objectives: The short-term effects of a 5-week ACT-based psychological flexibility training program were tested.
Methods: Participants were 21 corporate employees (62 % women, *Mage* = 43.9 years, SD = 9.5) recruited from a large company in the financial sector. The six core processes of psychological flexibility were examined before the first training session and after the fifth training session of the 5-week training. Psychological flexibility, value-driven living, thought suppression, five facets of mindfulness and cognitive fusion were assessed.
Results: Results showed a statistically significant difference in one core process of psychological flexibility, namely *Contact with the present moment. Acting with awareness*, *Describing* and *Nonjudge* showed significant difference before and after the training. Presumably, changes in *Cognitive defusion* and *Non-reactivity* are also evident, however results did not show significant difference.
Conclusions: The present research has provided further empirical evidence for the effectiveness of ACT-based psychological flexibility training with regard to three aspects of *Contact with the present moment*, which is a core process of psychological flexibility (*Acting with awareness, Describing,* and *Nonjudge*). The findings provide a basis for future research to investigate longer-term effects, including monitoring how participants in the research program practice the learnt techniques in their everyday lives.

Assessement of educational burnout among medical students

I. Baati[1], N. Regaieg[1]*, H. Trigui[1], M. Ben Jemaa[2], F. Cherif[1], I. Feki[1], F. Guermazi[1] and J. Masmoudi[1]

[1]Psychiatry A Department and [2]Epidemiology department, University of Sfax, Faculty of medicine of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2006

Introduction: Burnout is characterized by emotional exhaustion, depersonalization, and reduced personal accomplishment. Medical students are particularly susceptible to academic burnout compared to students in other disciplines, due to the demanding nature of their training, which offers limited time and resources.
Objectives: Our study aimed to assess academic burnout in a sample of students from the Faculty of Medicine of Sfax, Tunisia, as well as the link between these two entities.
Methods: This was a cross-sectional and descriptive study, conducted using GOOGLE FORMS in February and March 2024, with a sample of students from the Faculty of Medicine in Sfax, Tunisia. Data collection was carried out based on a questionnaire including an information sheet and the Maslach Burnout Inventory-Student Survey (MBI-SS) assessing academic burnout according to a three-dimensional structure : Emotional Exhaustion (EE) due to the study requirements; Cynicism (CY), which refers to a detached attitude towards one's studies and Academic Effectiveness (AE) linked to a sense of achievement as a student.
Results: Our study included 154 students. They were predominantly females (64.9%). Their median age was 22 years (IQR = [20 – 23 years]).
According to the MBI-SS, the prevalence of academic burnout was 98.1%.
The distribution of scores showed that academic burnout was mild in 15.9% of cases, moderate in 43.7% of cases and severe in 40.4% of cases.
The median scores on the EE, CY and AE dimensions were 17 (IQR = [13 – 20]) ; 11.5 (IQR= [7 – 16]) and19 (IQR = [15 – 23]), respectively.
The distribution of medical students according to the level of academic burnout is illustrated in Figure 1.
Conclusions: Our results showed that medical students experience high levels of educational burnout. To mitigate this high prevalence, it essentiel to raise awareness about its symptoms and to implement educational programs focused on mindfulness and well-being. Higher education institutions play a vital role in supporting students' professional development and resilience by fostering a healthy learning environment and providing psychological and pedagogical support.

Portuguese version of the Climate Change Distress and Impairment Scale

A. T. Pereira[1,2]*, C. Cabaços[1,3], C. C. Marques[1,2], M. J. Soares[1,1], A. I. Araújo[1,2] and A. Macedo[1,2]

[1]Institute of Psychological Medicine, Faculty of Medicine University of Coimbra; [2]Institute for Biomedical Imaging and Translational Research (CIBIT), University of Coimbra, Coimbra and [3]Institute for Biomedical Imaging and Translational Research (CIBIT), University of Coimbra, Coimbraimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2007

Introduction: The term "climate change distress" has been proposed to capture the broad range of negative emotional reactions associated with Climate Change/CC. Although it can be an adaptive reaction that motivates climate action to mitigate a real threat, for a growing number of people climate distress impairs subjective well-being and daily functioning, causing significant suffering to such an extent it often necessitates psychological support.
Hepp et al. (2023) developed the Climate Change Distress and Impairment Scale/CC-DIS, comprising 23 items to distinguish CCDistress (spanning eco-anxiety, -anger, -sadness) and CCImpairment that may indicate a need for intervention.
Objectives: To analyse the psychometric properties of the Portuguese version of the CC-DIS.
Methods: Participants were 590 adults, recruited through social media (64.6% women; Mean age=34.40±16.18; range: 18-75) completed an online survey including: preliminary Portuguese versions of CC-DIS; Pro-Environmental Behavior Scale/PEBS (Pereira et al. 2024); and Depression Anxiety and Stress Scales-21/DASS-21 (Pais-Ribeiro et al., 2004). Total sample was randomly divided into two sub-samples: one (n=290) for exploratory factor analysis/EFA and the other (n=300) for confirmatory factor analysis/CFA
Results: RESULTS and DISCUSSION: EFA and parallel analysis resulted in two factors (explained variance= 58.60%). CFA of this two-factor model resulted in "acceptable" fit indices (χ2/df=2.772; CFI=.892; TLI=.872; GFI=.846; RMSEA=.0796; p<.001), with standardized factor loadings ranging from .490 to .844. Cronbach's alpha coefficients were .90 for CCDistress and 0.85 for CCImpairment.
CCImpairment, but not CCDistress, correlated significantly and moderately (r=.25) with DASS-21, suggesting that these last two may be relatively independent phenomena.
With PEBS, the correlation coefficients were both significant (p<.001): .43 for CC-Distress, .22 for CC-Impairment. Both CCDistress and CCImpairment were significant predictors of collective (R^2=17.5%; b) and political (R^2=17.2%; b) pro-environmental actions, but only CCDistress predicted personal actions (R^2=22.9%, p<.001;), which suggests the more maladaptive nature of CCImpairment.
Such as reported by Hepp et al. (2023), CCDistress mean scores were moderate to high (3.71±0.63); CCImpairment were low to moderate (2.13±0.72) and only the former significantly differ by gender (higher in women). This suggests that individual factors, other than gender (e.g., personality traits), may be more relevant to understand psychopathological reactions to CC.
Conclusions: The Portuguese CCDIS presented good validity (construct, convergent and discriminant) and reliability. It can be used to better understand and improve CC adaptation in our country, which, like Spain, is located in Southern Europe, the area of the globe projected to to be at the highest risk for CC negative impacts.

Psychometric assessment of proximal and distal concerns in the context of climate change

A. T. Pereira[1,2,3,4]*, C. Cabaços[1,5], C. C. Marques[1,4], M. J. Soares[1,1], A. I. Araújo[1,4] and A. Macedo[1,4]

[1]Institute of Psychological Medicine, Faculty of Medicine University of Coimbra; [2]Institute of Psychologicam Medicine, Faculty of Medicine, University of Coimbra; [3]Coimbra Institute for Biomedical Imaging and Translational Research (CIBIT); [4]Institute for Biomedical Imaging and Translational Research (CIBIT), University of Coimbra, Coimbra and [5]Institute for Biomedical Imaging and Translational Research (CIBIT), University of Coimbra, Coimbraimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2008

Introduction: Contemporary global crises, including Climate Change/CC, has increased the interest in Future Anxiety/FA. As an emotional response to the anticipation of threats in the distant rather than proximal future, FA is broader than worry, which generally focuses on particular issues and fluctuates depending on specific circumstances.
Objectives: To analyze the psychometric properties of the Portuguese versions of Dark Future Scale (DFS; Zaleski et al. 2019), composed of 5 items to evaluate FA; and Climate Change Worry Scale (CCWS; Stewart 2021), a 10-items measure of proximal worry about CC; to explore whether they evaluate distinct or overlapping constructs.
Methods: 590 adults (64.6% women; mean age=34.40±16.18) answered DFS, CCWS (preliminary), Climate Change Distress and Impairment Scale/CC-DIS and Pro-Environmental Behaviours Scale/PEBS. Exploratory Factor Analysis (EFA; with a subsample of n=290) and Confirmatory Factor Analysis (CFA; n=300) were performed. DFS and CCWS structures tested with CFA were based on previous EFA results, including a model combining items from both scales.
Results: DFS: CFA evidenced the good fit of the unidimensional model, χ2/df=3.314, CFI=.995, TLI=.990, GFI=.989, RMSEA=.060, p<.001; alfa=.91.
CCWS: the unidimensional model (similar to the one found in the original version) (χ2/df=2.076; CFI=.982; TLI=.970; GFI=.965; RMSEA=.0590; p<.001; a=.90) and the two-factors model, with F1 composed of 6 items related to CC concerns and F2 of 4 items related to perceived interference (χ2/df=2.561; CFI=.973; TLI=.956; GFI=.956; RMSEA=.0611; p<.001; aF1=.75, aF2= .89) presented good fit.
DFSandCCWS: the 2-factor model, with each scale being one factor (χ2/df=2.312; CFI=.962; TLI=.951; GFI=.928; RMSEA=.065; p<.001) and the 3-factor model, where CCWS divides into 2 factors (χ2/df=2.248; CFI=.964; TLI=.954; GFI=.926; RMSEA=.063; p<.001) resulted in good fit. FA correlated with CCWSTotal/F1/F2 (r>.25). Correlations with CCDIS were r=.36 for FA and r<.55 for CCWSTotal/F1/F2; only CCWS total and dimensional scores correlated with PEB (r>.45) (all p<.001). When predicting CCDIS, FA adds 4% (R change, p<.001) to the variance explained by CCWS dimensions (R^2=49.7%). Only CCWSConcerns (b=.345) but not CCWSInterference predicted PEB.
Conclusions: DFS and CCWS Portuguese versions have adequate validity and reliability. Their moderate correlation and the validity of the measurement models tested suggest that they evaluate

distinct constructs. FA seems more maladaptive than CCW: although it increments CC-DIS prediction, it does not correlate with PEBS. The same applies to CCWSInterference, which emphasizes that the CCWS two-factor structure may be useful to delimit CCW's normal/pathological nature. We intend to use these scales in an ongoing research project on psychological factors associated with CC mitigation and adaptation.

The paradox of mentally ill psychiatrists: a punch to the mental-health related myths and prejudices around the profession of psychiatry

G. N. Porfyri[1] and V. Tarantili[2]*

[1]National and Kapodistrian University of Athens, Athens and [2]General Hospital of Argos, Argos, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2009

Introduction: As reported by studies and against the general conception, psychiatrists are not immune to the mental health challenges. More specifically, -more than any other medical specialty- they are at high-risk for burnout, depression, even suicide. It is a striking fact that according to research, in a medical centre which was exclusively designated for healthcare professionals, 89% of psychiatrists struggled with mental health issues; while 8% faced substance abuse problems and only 2% complained for corporal matters. Furthermore, when suffering from depression or any other mental health disorder, psychiatrists fear that their personal data will leak among colleagues, that they will be unable to professionally evolve or that they will be shamingly judged, avoiding to seek medical help.
Objectives: To explore the risk factors of poor mental health among psychiatrists and to highlight interventions to reduce the mental-health related stigma in this particular category.
Methods: A review of 39 articles -from 2010 to 2024- on PubMed and Google Scholar regarding mental health problems among psychiatrists.
Results: Numerous risk factors of psychiatrists' poor mental health have been identified, such as:
Female gender,
Younger age,
Race minority,
Prior mental health problems,
Residency or early career stage,
Working in non academic, multidisciplinary, inpatient, community, and government settings,
>50 h of work per week and/or more than 20 h of direct clinical face time per week,
Insufficient support from relatives, workplace, and colleagues,
Lack of supervision,
Lack of control over schedule,
Experiencing loneliness,
Experiencing work unsatisfaction,
Experiencing traumatic events such as patient's suicide or receiving threats.
Conclusions: Action against mental health-related stigma among psychiatrists needs to be taken, such as destigmatizing campaigns designated to remind that psychiatrists -as normal human beings- can suffer from mental health problems in the same way a cardiologist could have a cardiac attack. Apart from destigmatizing mental health issues among psychiatrists, legislation in every country needs to be changed in order to protect psychiatrists from work overload, while security of mental health professionals must be maintained in every clinical setting preventing the reception of threats or even physical abuse. Additionally, female psychiatrists should be institutionally empowered through mentorship programs, sponsorship support, responsive caregiving programs, and innovational directions to manage implicit and explicit prejudices, sexual harassment, and remuneration discrepancies.

EPV1495

A qualitative exploration of the perceptions of Cardiff University medical students towards the barriers faced by the LGBTQ+ population when accessing mental health care

E. Sammut[1]*, A. Hassoulas[2] and S. Edney[2]

[1]Mount Carmel Hospital, Attard, Malta and [2]Cardiff University, Cardiff, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2010

Introduction: Several mental disorders are more common within the LGBTQ+ population, including depression, anxiety, eating disorders, and substance use disorders. Despite this, LGBTQ+ individuals face more barriers when accessing mental health services than the general population.
Objectives: The primary aim of this study was to assess the perceptions of Cardiff University medical students on the barriers faced by LGBTQ+ individuals when accessing mental health help. The study also aimed to assess recommendations Cardiff University medical students have for improvement of services and to make them more accessible to LGBTQ+ individuals.
Methods: A qualitative approach was used. An online questionnaire was created and distributed among Cardiff University medical students. It included 10 open-ended questions about their knowledge of LGBTQ+ mental health, the barriers to accessing it, and recommendations to decrease these barriers. Thematic analysis was performed on the answers.
Results: The questionnaire had 12 participants. The thematic analysis produced 22 subthemes, which were grouped into the following five themes: i) perceptions of LGBTQ+ mental health, ii) factors affecting LGBTQ+ mental health, iii) general barriers to accessing mental health help, iv) LGBTQ+-specific barriers to accessing mental health help, and v) recommendations to improve access to mental health services. A scoping review was conducted on this subject to further analyse the current research. The scoping review produced nine studies, and the main themes that emerged were mental health stigma, LGBTQ+ discrimination, lack of LGBTQ+-affirmative services, the pathologisation of LGBTQ+ status, and financial barriers.
Conclusions: It was evident that more formal training on LGBTQ+ mental health at an undergraduate level for health professionals is needed, and that a lack of this is causing barriers to adequate

provision of mental health services to this population. Furthermore, existing mental health services need to be more LGBTQ+--affirmative. Further research with a higher response rate could provide more generalisable results.

EPV1496

The Role of Ketogenic Diet in Treatment of Mental Illnesses

A. V. Samokhvalov[1,2,3,4]

[1]Dr. Sam's Health; [2]ASU/CPC/Interventional Psychiatry, Homewood Health Centre, Guelph, Ontario; [3]Department of Psychiatry & Behavioural Neurosciences, McMaster University, Hamilton, Ontario and [4]Homewood Research Institute, Guelph, Ontario, Canada
doi: 10.1192/j.eurpsy.2025.2011

Introduction: Ketogenic Diet (KD) has been introduced as a treatment option for epilepsy over a century ago and since then it had gained and lost its popularity. Its current revival is heavily sensationalized and KD is promoted as a cure-it-all for a wide range of mental illnesses. The present review aims to review the validity of the evidence supporting KD use in psychiatry.
Objectives:
1. To review the origins and types of ketogenic diet as well as the possible rationale for its use in psychiatry
2. To provide a narrative review of effectiveness of ketogenic diet for management of major mental illnesses

Methods: Scoping review of research articles published in PubMed without restrictions in terms of language or publication date.
Results: We conducted a scoping review using a wide range of keywords. There are multiple studies dedicated fully or partially on ketogenic diet and a variety of mental illnesses. Majority of studies are focused on low-carbohydrate diets and not necessarily on KD per se, which complicates interpretation of findings. At the same time, we were able to identify multiple case studies and case series as well as some open-label and placebo-controlled studies involving small groups of participants receiving KD mostly as an adjunct treatment for their respective condition. There was a significant degree of heterogeneity both in terms of methodological aspects and clinical outcomes of these studies, which do not allow for further data synthesis at this point. At the same time, there are some indications that KD may be useful in certain clinical scenarios.
Conclusions: The objective data on impact of ketogenic diet on major mental illnesses are scarce, but show some promise. Further research is needed to elaborate both the mechanisms and the degree of impact of ketogenic diet on mental health. There is not enough evidence to suggest that ketogenic diet is an independent treatment option for any psychiatric condition, but at the same time it can be suggested as an adjunct measure.

Mindful self-care and mental health among workers

A. Abbes[1], I. Sellami[1]*, A. Feki[2], S. Baklouti[2], M. L. Masmoudi[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupationnal medecine and [2]Rheumatology, CHU Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2012

Introduction: Self-care refers to actions individuals take to maintain their health and prevent or manage illness. It increases awareness and offers a chance to improve workers' quality of life. Mental health plays a key role in influencing self-care behaviours among workers.
Objectives: Our study aims to assess self-care behaviours and mental health among workers.
Methods: We conducted a descriptive, analytical, cross-sectional survey among workers. We collected sociodemographic, professional characteristics and self-care behaviours using Mindful Self-Care Scale (MSCS). Anxiety and depression were assessed using the Hospital anxiety and depression scale (HADS).
Results: Our population comprised 116 female workers with a mean age of 41.5 ± 10.9 years. The mean of tenure of job was 12.8 ± 9.5 years. According to the HADS, the mean score of anxiety and depression were respectively 7.7 ± 5.2 and 7.9 ± 4.With the reference to HADS, 20 (17.2%) and 27 (23.3%) participants presented symptoms of anxiety and depression, respectively. Regarding the patients' anxiety levels, it was found that 50%, 32.8%, and 17.2% appeared to have mild, moderate, and severe anxiety, respectively. As for the depression levels of patients, 56 were mildly depressed (48.3%), 33 were moderately depressed (28.4%), and 27 were severely depressed (23.3%). The mean of mindful self-care score was 99.2 ± 34.6. The mean of mindful relaxation, physical care, self-compassion and purpose, supportive relationships, supportive structure and mindful awareness were respectively 12.4 ± 5.2, 19.3±4.9, 20.7±8.9, 16.1±7.3, 13.2±6.3 and 13.8±4.7. Mindful relaxation and physical care were negatively correlated with anxiety ($p = 0.01$, $r = -0.2$).
Conclusions: Our study found that workers with lower anxiety levels were more likely to engage in self-care. In the workplace, this leads to increased productivity and reduced attrition, as healthy employees are more productive and satisfied with their jobs. Therefore, providing mental health training for workers is essential to ensure their well-being.

EPV1498

Assessment of Well-Being and its determinants Among University Staff

A. Abbes[1], I. Sellami[1]*, A. Feki[2], M. Hajjaji[1], S. Baklouti[2], M. L. Masmoudi[1] and K. Jmal Hammami[1]

[1]Occupationnal medecine and [2]Rheumatology, CHU Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2013

Introduction: Well-being enables people to cope with life's stressors and to contribute well to community life. It is associated with better productivity in the workplace.
Objectives: Our study aims to assess well-being and its determinants among university staff.

Methods: We conducted a descriptive, analytical and cross-sectional survey to assess well-being and its determinants among university staff. The survey was carried out during a one-day training session on mental health promotion using a two-part questionnaire. The first part assessed socio-professional characteristics. The work ability was assessed using the Work Ability Score (WAS) questionnaire. Perceived physical workload was assessed by the Borg score. The second part assessed participants' well-being using the Mental Health Continum Short Form (MHC-SF) questionnaire.
Results: Our population comprised 65 participants, 67.7% of whom were female. The mean of perceived physical workload was 4.7±1.5. The job satisfaction mean was 3.8±1.3. We found that 56.9% of our participants (n=37) had good to excellent work ability and 43.1% rated their work ability as poor to moderate. The mean MHC-SF score was 41.2±16.1. The mean scores for emotional, psychological and social well-being were 8.4±4.2, 19.9±7.2 and 12.8±6.3 respectively. Sixty percent of participants reported languishing to moderate mental health and 40% were flourishing. Bivariate analysis showed that participants' wellbeing was associated with high work ability and high perceived physical workload.
Conclusions: Well-being among university staff deserves to be studied given its impact on work performance. Actions to promote well-being among these staff are urgently needed not only to improve the well-being and productivity of this population but also to prevent a negative influence on students.

Disclosure of Interest: None Declared

EPV1499

Work ability and mental health among healthcare workers

I. Sellami[1]*, A. Abbes[1], A. Feki[2], A. Haddar[1], H. Halweni[3], M. Hajjaji[1], S. Baklouti[2], M. L. Masmoudi[1] and K. Jmal Hammami[1]
[1]Occupationnal medecine; [2]Rheumatology, CHU Hedi Chaker and [3]General practice, Medecine university, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2014

Introduction: Mental health can affect the quality of life and productivity of healthcare workers (HCWs). It is important to determine the effect of mental health on work ability among these workers to implement adequate interventions.
Objectives: Our study aims to assess the relationship between work ability and mental health among HCWs.
Methods: We conducted a descriptive, analytical and cross-sectional survey among HCWs using a self-administrated questionnaire. We collected socio-professional data. We assessed work ability using the work ability index (WAI) and mental health using the depression anxiety and stress scale (DASS 21).
Results: Our population comprised 200 HCWs, 71% of whom were female. The mean age of participants was 42.9 years. The mean of the tenure of job was 14.2 ±10.1 years. We found that 5.5% presented mild to moderate stress, 3% severe to extremely severe stress, 4.5% presented severe to extremely severe depression, 7.7% presented severe to extremely severe anxiety and 2.5% presented severe to extremely severe depression. Using the WAI, we found that 63% of participants perceived poor to moderate work ability and 37% perceived good to excellent work ability. Work ability was negatively correlated with stress ($p = 0.005$, $r = -0.19$), depression ($p = 0.003$, $r = -0.2$) and anxiety ($p = 0.003$, $r = -0.2$).
Conclusions: Our findings highlight a correlation between HCWs' altered mental health and poor work ability. Therefore, actions to promote mental health among these workers are urgently needed not only to improve the work ability and productivity of this population.

Factors associated with resilience among medical residents in Tunisia

H. Daoud[1], I. Sellami[1,2]*, A. Feki[3], M. Hajjaji[1], M. L. Masmoudi[1] and K. Jmal Hammami[1]
[1]Department of Occupational Medicine, Hedi Chaker Hospital; [2]LR/18/ES-28, Sfax university and [3]Department of rheumatology, Hedi Chaker Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2015

Introduction: Resilience plays an essential role in many settings, including medical resident training. This group undergoes a unique educational process that demands the development of both clinical and interpersonal skills, as well as a high level of personal responsibility for patient care.
Objectives: The aim of this study was to evaluate resilience among medical residents and identify the factors that influence it.
Methods: We conducted a cross-sectional study involving medical residents in training at Tunisian hospitals. Data were collected anonymously through a questionnaire-based survey using Google Forms between October 2023 and January 2024. Participants completed a sociodemographic form, followed by two scales: the Brief Resilience Scale (BRS) to measure resilience and the Perceived Stress Scale (PSS-4) to assess mental health disorders.
Results: Our study included 127 participants, with the majority being women (74.8%). The average age was 27.24 ± 1.34 years. Most participants were single (81.8%), and only 5.5% were international residents. Approximately one-third (37%) engaged in physical activity. A psychiatric history was reported in 17.3% of the residents. The mean Brief Resilience Scale (BRS) score was 3.167 ± 0.77. Low resilience scores were observed in 34.6% of participants, while only 6.3% had high resilience scores. The mean Perceived Stress Scale (PSS-4) score was 7.08 ± 2.7. Univariate analysis revealed that lower resilience levels were more common among females ($p = 0.000$) and residents with a history of psychiatric disorders ($p = 0.06$). Additionally, lower resilience levels were associated with higher stress levels ($p = 0.00$; $r = -0.512$).
Conclusions: The study highlights the need for targeted interventions to enhance resilience among medical residents, particularly for those in vulnerable subgroups. Improving resilience through tailored support strategies can significantly benefit their overall well-being and training outcomes.

Attentional skills following serious traumatic cervical spine injuries in young sports men

?. Syrmos

Aristotle University, Thessaloniki, Greece
doi: 10.1192/j.eurpsy.2025.2016

Introduction: Cervical spine injuries are serious traumatic situations
Objectives: Aim-Aim of this study was to evaluate the attentional skills in cases with serious cervical spine injuries, in young sports men.
Methods: Material and Methods-10 young male amateur sports men (1 soccer player, 1 basketball player, 1 volley-ball player, 1 hand ball player, 1 boxer, 1 long runner, 1 fast runner and 3 swimmers) were participated in this study, 20 days more or little less after serious cervical spine injuries. Range of age 19-39 years and mean age 29 .We used specific performance tests, letter cancellation exam, naming trials and iq tests.
Results: Results-All of them(10,100%) reported deficits in all areas of attention function and also cognitive and emotional status.9 of them(90%) reported also difficulty in complex task activities, especially when time limits were imposed.
Conclusions: Conclusions-All these exams are good and efficient tools in order to evaluate this kind of patients.

Disclosure of Interest: None Declared

EPV1502

Mental health literacy and its associated factors among undergraduate students: preliminary findings from SMILE Project

A. I. Teixeira[1,2*], S. Lima[1,2], V. Pereira[1], F. Pinto[1,2], T. Morgado[3] and S. Martins[2]

[1]Health Sciences, Nursing School of Tâmega e Sousa IPSN-CESPU; [2]Innovation in Health and Well-Being – Research Unit, Instituto Politécnico de Saúde do Norte, CESPU and [3]Coimbra College of Nursing and the Leiria College of Health; UICISA:E and RISE@CINTESIS, Penafiel, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2017

Introduction: Mental health literacy (MHL) is crucial for undergraduate students as it empowers them to recognize, understand, and address mental health challenges. This knowledge contributes to improved happiness by reducing stigma, fostering resilience, and promoting positive coping strategies. Enhanced emotional well-being results from effective stress management and the ability to seek help when needed. Ultimately, mental health literacy positively influences academic life satisfaction by creating a supportive environment, reducing the impact of stressors, and fostering a holistic approach to well-being in the challenging context of higher education.
Objectives: To assess the association between MHL and satisfaction with academic life, happiness, psychological well-being and psychiatric symptoms in undergraduate students. It also aimed to analyse the relationship between MHL and sociodemographic and clinical characteristics of these students.
Methods: Under the ongoing prospective project called "SMILE", this preliminary study integrated a sample of undergraduate students from a private higher education institution in northern of Portugal. The research protocol included a semi-structured interview (sociodemographic and clinical data) and the Mental Health Literacy Questionnaire (MHLq-SVa), Satisfaction with Academic Life Scale (SALS), Subjective Happiness Scale (SHS), Psychological Well-Being Scale (PWBS) and Depression Anxiety Stress Scale (DASS). Non-parametric statistical tests were used, as the data did not follow a normal distribution.
Results: Twenty-four students were evaluated (75% female, 92% single; mean age=25.5y y.o.). Around 67% were nursing students and 42% in their 4th year. Regarding support needs for mental health problems, 74% had support at some point in their lives and about 17% were currently receiving support. (22% were taking psychotropic medications). Also, 57% had a family history of mental disorders. Women had a greater knowledge of mental health problems (MHI domain), compared to men (median=28vs.25; p=0.025). This MHL domain was negatively correlated with satisfaction with the academic environment (rs= -0,571). Higher scores in MHL total and in its self-help strategies domain were identified among students with previous mental health support needs (median=72vs69.5, p=0.20; median=19vs18, p=0.44, respectively). Lower level of erroneous beliefs/stereotypes (MHI domain) were more evident in students with family mental health history (median=15vs13.5, p=0.007). No relations were found between MHL and other assessed variables.
Conclusions: These findings are important for designing interventions to promote mental health in academic contexts, aimed at positive and healthy changes in the academic environment, particularly in line with their expectations and needs, with the aim of reducing levels of psychological distress.

EPV1503

Job Satisfaction and Psychological Distress Among Healthcare Professionals

M. Theodoratou[1,2*], H. Vavatsikou[1], E. Denazi[3] and I. Papathanasiou[1]

[1]Social Sciences, Hellenic Open University., Patras, Greece; [2]Psychology, Neapolis University Pafos, Pafos, Cyprus and [3]Psychology, National Kapodistrian University of Athens, Athens, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2018

Introduction: Job satisfaction and psychological distress are pivotal elements in the overall well-being of healthcare professionals, whose work environment is inherently challenging and stressful. High levels of job satisfaction are essential for the health, motivation, and performance of the workforce, and for ensuring high-quality patient care and the effective functioning of the healthcare organization. Conversely, psychological distress among healthcare workers can result in burnout, a reduction in the quality of care provided, and an increase in turnover rates. This study examines the complex factors influencing job satisfaction and psychological distress, with the aim of providing a comprehensive understanding that can inform the development of interventions and policy changes within healthcare settings.
Objectives: The purpose of this study is to explore the factors that contribute to job satisfaction and psychological distress among

medical and nursing staff. By identifying conditions that lead to increased satisfaction or distress, the research seeks to propose actionable strategies to improve the working environment and reduce psychological strain among healthcare workers.
Methods: This research employed a quantitative approach utilizing a specifically designed questionnaire that incorporated the DASS21 (Depression, Anxiety, and Stress Scale) and the K6+ scale for measuring psychological distress. The sample consisted of 132 healthcare professionals, selected through the snowball sampling method. The questionnaire was based on a comprehensive review of the literature and included measures to assess job satisfaction, anxiety, stress, and psychological distress.
Results: The findings indicate that the majority of healthcare workers perceive limited opportunities for job advancement and salary increases. Furthermore, communication within organizations is perceived as moderate, and employees report that their efforts are not adequately recognized or rewarded. These factors are associated with both job dissatisfaction and increased psychological distress, as measured by the DASS21 and K6+ scales.
Conclusions: The findings of this study highlight the imperative for systemic reforms within healthcare organizations to enhance job satisfaction and mitigate psychological distress among healthcare personnel. It is recommended that strategies include the creation of more transparent pathways for career advancement, the fostering of a supportive and communicative work environment, and the implementation of recognition programs that validate and reward employee contributions. It would be beneficial for future research to investigate the long-term impact of such interventions in order to ascertain their efficacy in maintaining positive changes within healthcare settings.

Disclosure of Interest: None Declared

EPV1504

Burnout in emergency medical and paramedical teams

M. Trabelsi Ajili[1]*, M. Jemai[2], B. Hattay[1], S. Othmani[1], H. Hedhli[1] and S. Jouini[1]

[1]Emergency, Charles Nicolle's Hospital and [2]Emergency, Hospital of Charles Nicolle, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2019

Introduction: Burnout is defined by the WHO as "a feeling of intense fatigue, loss of control and inability to achieve concrete results at work". Among the most affected populations, are medical and paramedical teams, particularly those exposed not only to a sustained work rhythm but also to frequent confrontations with suffering and death, such as emergency staff.
Objectives: Evaluate the frequency of burnout among medical and paramedical staff and determine the factors associated with it.
Methods: A 1-month cross-sectional study (November to December 2023) was conducted in the emergency department of Charles Nicolle's hospital, Tunis. We included all medical and paramedical staff. Data were collected using an anonymous online questionnaire on Google Forms. We used the Maslach Burnout Inventory (MBI) as a rating scale.
Results: Forty-five forms were completed. The average age was 29 ±2 years, with a male predominance (69%). Twenty-four percent were already being treated for a psychiatric condition. The average length of service in the emergency department was 8 ± 2 years.
The prevalence of burnout was 98%. Burnout was high in 43% of study participants. Fifty-two percent had a high level of burnout, 63% had a high level of depersonalization and 88% had a low level of sense of personal accomplishment. High burnout was more common among women (79% vs. 21%). Of the participants with high burnout: 31.6% were family doctors, 21% were nurses; 15.7% were emergency physicians (residents or seniors in emergency medicine) and 15.7% were emergency technicians.
Burnout risk factors were divided schematically into 3 categories: among organizational risk factors, 98% complained of work overload with insufficient human and material resources, 44% reported the absence of listening and support from hierarchy, and 31% experienced the feeling that their missions were imprecise. Among the professional risk factors, 78% reported an incompatibility between salary and workload, 67% did not receive any words of recognition from the patient or his family, and 53% did not have any specific training in stress management. Not being able to take time off as they wished was the most reported personal risk factor (76%).
A desire to improve working conditions was present in 80% of participants.

Image:

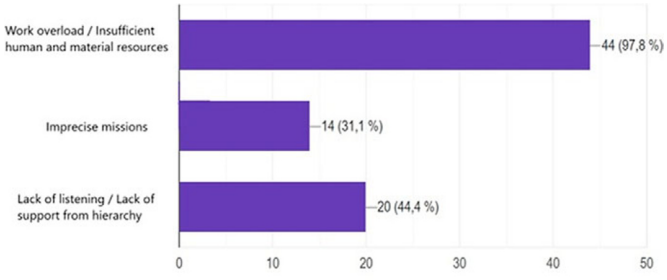

Figure 1 : Organisational risk factors

Image 2:

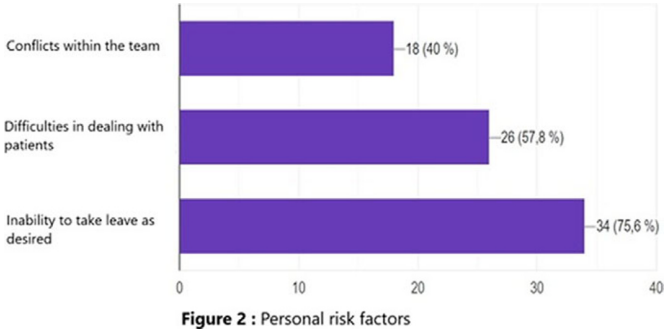

Figure 2 : Personal risk factors

Image 3:

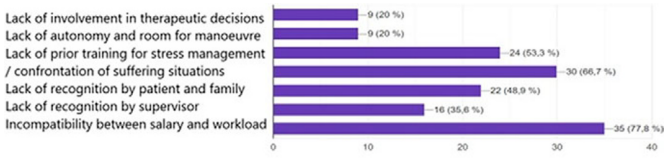

Figure 3 : Professional risk factors

Conclusions: A very high prevalence of burnout has been found within the emergency care team, which could explain their despair of the healthcare system and the increasing exodus rate leading to a potential medical and paramedical desert in Tunisia. It would therefore be urgent to improve working conditions and provide more facilities for young doctors and nurses, particularly in emergency departments.

EPV1505

Positive psychiatry in Ayurveda: A Historical review

W. Upadhyaya[1]* and S. Bhat[2]

[1]Thriftwood College and [2]Old age Psychiatry, Essex partnership University NHS Foundation Trust, Chelmsford, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2020

Introduction: Ayurveda is Indian traditional medicine that has a considerable presence in Europe. Incidentally the definition of health developed by the WHO since 1946 has striking similarities with the ones found in Ayurveda texts dating back few millenia ago. The encouragement Ayurveda provides in the pursuit of a flourishing life resonates with the principles and philosophy of Positive psychiatry. So this begs the question did Ayurveda have concepts resembling positive psychiatry and if so, what were the tenets. To this aim we review an Ayurveda text dating back to 3000 BC called Charaka Samhita.
Objectives: To explore concepts related to positive psychiatry and psychology in Charaka Samhita.
Methods: Relevant chapters and sections in Charaka Samhita were screened for descriptions or recommendations for mental health and a meaningful life.
Results: Similarities between Positive Psychiatry and Ayurveda Psychiatry were present. As a part of psychotherapy Ayurveda recommends cultivation of spiritual awareness, wisdom fortitude/ resileance and practice meditation. It further encourages the pursuit of ethically reasonable desires, material prosperity and righteous- religious conduct. For the healthy individuals, it recommends maintaining robust physical and mental health, actively accumulating wealth ethically and attain spiritual liberation.
Conclusions: We conclude Ayurveda had its own version of Positive Psychiatry and delineates ways to achieve it.

Nurturing Bonds: Parental Attachment, Breastfeeding Attitudes and Parenting Styles in Greece

A. Kondyli[2], I. Koutelekos[1], D. Briana[3] and A. Zartaloudi[1]*

[1]University of West Attica; [2]MSc in General Pediatrics and Pediatric Subspecialties - Clinical Practice and Research and [3]University of Athens, Athens, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2021

Introduction: The emotional bond a person forms with their parents during childhood is a crucial factor that influences the choices they make and the parenting style they adopt when they become parents themselves. Conversely, the parenting approach one chooses and the decisions made in raising their children will impact their future relationship with their child.
Objectives: To explore (a) the type of emotional bond that the participants had developed with their own parents during their childhood, (b) their attitudes towards breastfeeding, and (c) their parenting style.
Methods: A cross-sectional study was conducted using self-administered questionnaires completed by 862 parents—both mothers and fathers—who had received support from a private maternity and breastfeeding support center in Athens.
Results: Participants who received higher levels of care from their parents during childhood were negatively associated with exclusive breastfeeding ($p = 0.041$), shorter durations of breastfeeding ($p < 0.001$), and a positive attitude toward breastfeeding beyond 12 months ($p = 0.002$). Mothers who received high care from their parents tended to adopt a more supportive parenting style ($p < 0.001$), in contrast to those who experienced high levels of control ($p = 0.001$). A supportive maternal style was positively associated with natural weaning ($p = 0.018$). In contrast, a more authoritarian maternal style was positively associated with non-exclusive breastfeeding ($p = 0.012$), abrupt weaning ($p = 0.021$), introducing solid foods as the first food ($p = 0.001$), parents and children not sharing the same room ($p < 0.001$), and the implementation of sleep training ($p < 0.001$). Maternal permissiveness was positively associated with not breastfeeding ($p = 0.011$), non-exclusive breastfeeding ($p = 0.002$), pacifier use ($p < 0.001$), introducing pureed foods as the first foods ($p = 0.001$), and the use of sleep training ($p = 0.001$). For fathers, a shorter duration of room-sharing with the child was significantly associated with a stricter parenting style ($p = 0.023$). The more children a mother had, the more likely she was to adopt an authoritarian or permissive parenting style ($p < 0.001$), and the same was true for fathers ($p < 0.001$). Additionally, older paternal age was positively associated with a more authoritarian parenting style ($p = 0.001$). An overall positive breastfeeding experience was associated with being less authoritarian, strict, or permissive ($p = 0.003$; $p = 0.005$; $p < 0.001$, respectively).
Conclusions: Breastfeeding may act as a catalyst for parents to adopt a more supportive parenting style toward their children, regardless of the type of bond they developed with their own parents. This study could serve as a foundation for more extensive research on breastfeeding, early parental choices, attachment bonds, and parenting practices.

EPV1507

The Influence of Parenting Style and Breastfeeding Attitudes on Child Behavior

A. Kondyli[2], A. Zartaloudi[1]*, I. Koutelekos[1] and D. Briana[3]
[1]University of West Attica; [2]MSc in General Pediatrics and Pediatric Subspecialties - Clinical Practice and Research and [3]University of Athens, Athens, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2022

Introduction: Parenting style plays a crucial role in shaping a child's development and behavior. Supportive parenting has been associated with positive child outcomes, while authoritarian or permissive styles may lead to less desirable behaviors. Breastfeeding, known for its numerous benefits to both mother and child, may also interact with parenting approaches to influence a child's emotional and social development.
Objectives: To explore (a) the parenting style of the participants, (b) their attitudes towards breastfeeding, and (c) the behavioral characteristics of their children.
Methods: A cross-sectional study was conducted using self-administered questionnaires completed by 862 parents—both mothers and fathers—who had received support from a private maternity and breastfeeding support center in Athens.
Results: Mothers who adopted a more supportive parenting style had a more positive perception of their children's behavior compared to more authoritarian, strict, or permissive mothers. Specifically, these supportive mothers viewed their children as less anxious ($p = 0.015$), more willing to share ($p = 0.001$), less irritable ($p = 0.006$), more affectionate ($p = 0.009$), more expressive of their emotions ($p < 0.001$), generally obedient ($p < 0.001$), better at maintaining attention ($p < 0.001$), less nervous in new situations ($p = 0.019$), and less easily frightened ($p = 0.028$). Fathers with a more supportive parenting style also perceived their children as sharing more readily ($p < 0.001$). Additionally, a longer duration of breastfeeding was associated with children who expressed their emotions more easily ($p = 0.042$) but were less obedient ($p = 0.021$). Finally, a more positive overall evaluation of the breastfeeding experience correlated with less agreement that the child is hyperactive ($p = 0.020$), irritable ($p = 0.004$), unreceptive to affection ($p = 0.034$), easily distracted ($p = 0.004$), and easily scared ($p = 0.002$).
Conclusions: These findings highlight the importance of supportive parenting and positive breastfeeding attitudes in promoting favorable behavioral outcomes in children. Health professionals can use this information to encourage parenting practices that foster healthy child development.

EPV1508

Nurturing Choices: How Sociodemographic Factors Affect Attitudes toward Breastfeeding

A. Kondyli[1], I. Koutelekos[2], D. Briana[3] and A. Zartaloudi[2]*
[1]MSc in General Pediatrics and Pediatric Subspecialties - Clinical Practice and Research, University of Athens; [2]University of West Attica and [3]University of Athens, Athens, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2023

Introduction: The benefits of breastfeeding for mothers, infants, and society as a whole are well documented. These benefits appear to be linked to the duration of breastfeeding for both mother and child. Despite this knowledge, the rates of exclusive breastfeeding and continued breastfeeding at 6 and 12 months in Greece are exceptionally low.
Objectives: To explore Greek parents' attitudes towards breastfeeding according to their sociodemographic characteristics.
Methods: A cross-sectional study was conducted using self-administered questionnaires completed by 862 parents—both mothers and fathers—who had received support from a private maternity and breastfeeding support center in Athens.
Results: The choice of breastfeeding was positively correlated with parents' higher educational level ($p<0.001$), normal delivery ($p<0.001$), residence in Athens or another urban area (($p=0.017$), positive attitude towards breastfeeding during pregnancy ($p<0.001$) and for breastfeeding after 12 months ($p<0.001$), previous breastfeeding experience ($p<0.001$), not using a pacifier ($p<0.001$), introducing whole foods at 6 months ($p<0.001$), co-sleeping with their baby ($p<0.001$) and not implementing sleep training ($p<0.001$). Accordingly, the duration of breastfeeding was positively associated with living in another urban area ($p<0.001$), and unemployment ($p=0.009$). Longer duration of breastfeeding showed children who were exclusively breastfed ($p<0.001$), who weaned naturally ($p<0.001$), who were born naturally ($p<0.001$), who did not take a pacifier ($p<0.001$), who started with whole foods ($p<0.001$), who stayed longer in their parents' room ($p<0.001$), who did not receive sleep training ($p<0.001$) and those whose parents were informed about breastfeeding ($p<0.001$).
Conclusions: This study could serve as a foundation for more extensive research on breastfeeding. Findings can be utilized by health professionals to enhance their awareness, empathy, and effectiveness regarding issues related to breastfeeding.

Exploring post-COVID-19 mental health disorders: a study protocol for the adult population of Tirana

L. Zikaj[1]*, V. Qemalli[2], G. Qirjako[3], E. Roshi[3] and S. Qirjako[4]
[1]Lab Department, Polyclinic of Specialties No.3; [2]Psychiatry department, Community Mental Health Center No. 3; [3]Department of Public Health and [4]University of Medicine, Tirana, Albania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2024

Introduction: The COVID-19 pandemic has emphasized the crucial need to understand the lasting mental health effects on individuals.
Objectives: This study aims to investigate the occurrence and connections of post-COVID-19 mental health disorders among adults treated at a community mental health center in Tirana. By closing existing knowledge gaps, it seeks to lay the groundwork for tailored interventions.
Methods: Employing a historical cohort study design, data will be collected from Tirana residents diagnosed with COVID-19. Comprehensive clinical and laboratory assessments will focus on mental health outcomes post-infection. Demographic, socio-economic, psychiatric, and biomarker data will be analyzed to provide a thorough

understanding of post-COVID-19 mental health disorders in the study cohort.
Results: Preliminary findings are expected to provide valuable insights into the occurrence and connections of post-COVID-19 mental health disorders among Tirana's adult population. Statistical analyses will identify potential risk factors, informing the development of interventions. Robust data presentation will enhance the credibility and applicability of the study outcomes.
Conclusions: This study promises to elucidate the public health implications of post-COVID-19 mental health disorders in Tirana, guiding targeted interventions. Recommendations based on study findings aim to strengthen mental health services and implement tailored interventions, addressing the unique needs of the community.
Main Messages:
Assessing post-COVID-19 mental health disorders in Tirana informs targeted interventions.
Study findings guide public health actions to enhance mental health services in the community.
Key words: Post-COVID-19 mental health disorders; Tirana; community mental health center

EPP157

Mental Well-being of Medical Students in the Visegrad Four Countries: A Cross-Sectional Exploratory Study

B. Gács[1]*, A. Matuz[1] and Dr. Z. Varga[1]

[1]Department of Behavioural Sciences, University of Pécs, Medical School, Pécs, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.488

Introduction: The mental health of medical students is a critical concern, as their well-being directly influences academic performance and the overall success of educational institutions. The high academic demands, heavy workload, and emotional stress encountered by medical students can lead to significant mental strain, potentially resulting in mental disorders. Understanding these factors is essential for developing effective support mechanisms.
Objectives: This study aimed to investigate the mental well-being of medical students across the Visegrad Four countries (Hungary, Czech Republic, Poland, Slovakia) by identifying key predictors of well-being and categorizing students into well-being clusters based on psychological and physical health indicators.
Methods: A cross-sectional exploratory study was conducted using an anonymous, English-language online questionnaire. The survey gathered general demographic data, health-related information, and academic attitudes. Mental well-being was assessed using the Warwick-Edinburgh Mental Well-being Scale (WEMWBS), coping strategies were evaluated with the Brief COPE inventory, and somatic symptoms were measured using the Patient Health Questionnaire-15 (PHQ-15). Regression analysis was performed to identify predictors of mental well-being, and a two-step cluster analysis was employed to classify students into distinct well-being groups.
Results: A total of 1,703 medical students (467 males) participated in the study. Regression analysis identified adaptive problem-focused and emotion-focused coping, social support, satisfaction with the university experience, healthy eating habits, and a sense of control over personal health as positive predictors of mental well-being. In contrast, maladaptive coping strategies (avoidant and passive) and frequent somatic symptoms were negative predictors. The cluster analysis revealed three distinct groups: (1) a stable group with high well-being and satisfaction, low somatic symptom frequency, and low incidence of mental disorders; (2) a risk group with moderate well-being, low satisfaction, higher somatic symptom frequency, and increased incidence of mental disorders; and (3) a problematic group characterized by low well-being, low satisfaction, high somatic symptom frequency, and frequent mental disorders.
Conclusions: The findings suggest that enhancing adaptive coping strategies, the sense of control, and perceived social support may significantly improve mental well-being of medical students. Furthermore, identifying risk and problematic groups can support the development of targeted interventions. These insights not only contribute to a better understanding of medical students' mental well-being but also offer practical implications for designing preventive and supportive programs to address mental disorders.

EPV1510

High-sensitivity C-reactive protein and cyclothymic temperament as predictors of suicidal risk

L. Cavallo[1]*, G. Longo[1], L. Orsolini[1] and U. Volpe[1]

[1]Unit of Clinical Psychiatry, Department of Neurosciences/Department of Experimental and Clinical Neurosciences (DIMSC), Polytechnic University of Marche, Ancona, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2025

Introduction: An increasing number of studies have investigated the role of inflammation in mood disorders, like an altered C-reactive protein (CRP) hematic level. Some studies have also shown an association between suicidal behavior and increased CRP levels.
Objectives: The objective of this study was to evaluate the association between specific clinical features and high sensitivity CRP (hsCRP) levels with suicidal risk in mood disorders inpatients.
Methods: A naturalistic, observational, cross-sectional study was carried out by retrospectively recruiting 353 adult inpatients affected by severe mental illness (SMI), excluding patients affected by inflammatory pathology, alcohol/substances use disorders or treaded by anti-inflammatory/immunosuppressive therapy. In this sample 241 patients suffering from mood disorders were selected. HsCRP levels were measured at the ward admission. All patients were assessed with subscale 5 of the Mini International Neuropsychiatric Interview (MINI-5-s), TEMPS-M, BPRS, HAM-D21, YMRS, CGI-S, CGI-I, MOCA, MDQ, MSRS.
Results: A logistic regression analysis was performed to ascertain the effects of hsCRP and personality trait on the likelihood of suicidality risk. The logistic regression model was statistically significant, $\chi 2$ (2) = 32.868, $p < 0.001$. The model explained 18.7% (Nagelkerke R2) of the variance in subjects with a suicidality risk and correctly classified 76.8% of cases. According to the logistic regression model, suicidality risk is negatively predicted by the total score of the YMRS (exp(B)=0.969, IC95%=0.947-0.993, p=0.01) and hostility subscale of the BPRS (exp(B)=0.905, IC95%=0.819-1.000, p=0.05) while it is positively predicted by the cyclothymic temperament subscale of

the TEMPS-M (exp(B)=1.066, IC95%=1.017-1.118, p=0.008) and hsCRP (exp(B)=1.090, IC95%=1.012-1.174, p=0.024).
Conclusions: The study suggests the potential transdiagnostic association between low grade inflammation, temperament and suicidal risk in patients affected by mood disorders. Our preliminary findings could support a routine introduction of hsCRP hematic measurement, due to its relatively low cost, for its possible utility as an early trans-diagnostically biomarker for suicidal risk. The findings could also lead to developing a model to identify subjects who may benefit from a combined anti-inflammatory and psychopharmacological treatment strategy during the acute illness phase. A neuroinflammatory approach could further help stage and subtype mood disorder patients in more homogenous samples and investigate short- and long-term treatment implications, clinical course, and prognosis. Further research studies should consider all illness phases and how specific temperament and chronotype may influence treatment response, illness course, and outcomes.

Psychopathological features, neuroendocrine correlates and clinical chemistry markers in bariatric surgery candidates: preliminary assessments

E. Diadema[1,2]*, M. Simoncini[1], M. Violi[1], A. Bordacchini[1], G. Giannaccini[1], L. Betti[1], L. Palego[1], A. Cimino[1], S. Fantasia[1], M. Nannipieri[1] and C. Carmassi[1]

[1]University of Pisa, Pisa and [2]University of Siena, Siena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2026

Introduction: Obesity represents a heterogeneous group of clinical conditions, underpinned by a multifactorial pathogenesis. People affected by severe obesity could be eligible for Bariatric Surgery (BS). Generally, researchers agree on the complex interplay between a variety of biochemical and neuroendocrine factors in determining body weight regulation, as well as on the quite common co-exhibition of severe obesity and psychopathological symptoms. Both obesity and mood disorders resulted as chronic low grade pro-inflammatory states and it has been stressed the relevance of traumatic life events in overweight conditions, but few is known about underlining trajectories and neurobiological correlates. BS candidates have high rates of lifetime psychiatric disorders, supporting a comprehensive assessment of psychopathological and peripheral biomarkers in this population.
Objectives: Aim of this cross-sectional survey was the investigation of possible relationships between hematochemical parameters and specific psychopathological features in a sample of BS candidates.
Methods: Seventy-seven subjects with severe obesity undergoing the BS preoperative multidisciplinary evaluation at the University Hospital of Pisa were investigated. Psychopathological data were obtained by self-report instruments exploring a series of full-blown and sub-threshold symptoms of mood and post-traumatic-stress disorders, as well as for emotional eating features: the *Mood spectrum-self report (MOODS-SR) lifetime*; the *Trauma and Loss Spectrum self-report (TALS-SR) lifetime*; the *Emotional Eating Scale (EES)*. As concerns the biochemical assessment, we considered morning cortisol plasma levels and blood cell counts. Non-parametric Spearman correlations were applied. The statistical threshold was set up at $P \leq .05$.
Results: We found significant negative correlations between cortisol plasma levels measured in the morning and sleep (P=.001) or appetite disturbances (P=.04), as well as total altered mood scores (P=.001). Significant positive correlations emerged between Platelet count and total depression scores (P=.042), appetite disturbances (P=.027), TALS-SR domain 3 score (P=.0069), as well as the anger (P=.006), the anxiety (P=.025) and the total components (P=.015) in the EES. Interestingly, there were significant positive correlations also between Platelets-to-Lymphocytes Ratio and the domains 3 (P=.015) and 4 (P=.025) of TALS-SR questionnaire.
Conclusions: These preliminary correlations suggest that in severe obesity (or, almost, in a subgroup of patients), post-traumatic stress features, mood, sleep and appetite disturbances could be related to a lower basal hypothalamic-pituitary-adrenal axis activity and higher inflammatory parameters, especially those linked to platelet status.

Disclosure of Interest: None Declared

EPV1512

Depressive Symptoms in a Patient with VEXAS Syndrome and Its Relationship with Depression: A Case Study

Á. Esquembre García[1], M. D. L. E. Sánchez Escalonilla-Relea[1], P. Aguirre[1], M. Viaña Pérez[1], C. Herranz Serfaty[1], A. Muñoz San José[1]*, F. S. Mir Biribay[1] and M. F. Bravo Ortiz[1]

[1]Psychiatry, Hospital Universitario La Paz, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2027

Introduction: VEXAS syndrome is a newly recognized multisystem inflammatory disorder characterized by recurrent fevers, skin manifestations, and systemic symptoms, often leading to significant morbidity. While the physical aspects of this syndrome are increasingly documented, the psychiatric implications, particularly depressive symptoms, are less explored. This case study aims to elucidate depressive symptoms in a patient diagnosed with VEXAS syndrome, examine how these symptoms relate to prolonged diagnostic uncertainty, and assess the impact of receiving a definitive diagnosis on the patient's mental health.
Objectives: To evaluate the presence and severity of depressive symptoms in a patient with VEXAS syndrome. To analyze the psychological impact of prolonged diagnostic uncertainty on the patient's mood. To investigate the effect of receiving a definitive diagnosis and a comprehensive treatment plan on the patient's emotional well-being.
Methods: This case report describes a 61-year-old male patient with VEXAS syndrome, admitted for further evaluation of his condition. He presented to the psychiatry service with complaints of low mood and morning asthenia. A thorough psychiatric assessment revealed a history of psychiatric hospitalization 30 years prior and ongoing treatment for an adjustment disorder since 2007. The assessment utilized standardized scales to measure depressive symptoms and documented the patient's emotional state and coping mechanisms throughout his medical journey.
Results: The patient experienced persistent low mood episodes since the onset of organic symptoms in 2019, exacerbated by multiple misdiagnoses and inadequate treatments. After receiving a diagnosis of VEXAS syndrome in July 2023, he reported significant improvements in mood and a reduction in suicidal ideation. He attributed these changes primarily to the clarity provided by the

diagnosis and the development of a new treatment plan, rather than solely to adjustments in his antidepressant medication (sertraline, 100 mg). Although he tolerated the medication well, he emphasized that the sense of being understood significantly enhanced his motivation. Additionally, the patient reported vivid nightmares over the last two weeks but denied current suicidal thoughts.

Conclusions: This case highlights the complex relationship between prolonged diagnostic uncertainty and depressive symptoms in chronic inflammatory diseases like VEXAS syndrome. The findings suggest that a definitive diagnosis and clear treatment strategy are crucial for improving mental health and overall well-being. This underscores the importance of a multidisciplinary approach that prioritizes both physical and psychological needs, enhancing the quality of care for patients navigating such complex conditions.

EPV1513

Probiotics decrease C-reactive protein level in depression depending on basal chronic low-grade inflammation status or antidepressant use – secondary results of the Pro-demet randomized clinical trail

O. Gawlik-Kotelnicka[1]*, A. Wysokiński[2], A. Gajewska[3], K. Czarnecka-Chrebelska[4], K. Kopacz[5], A. Skowrońska[1], E. Pikus[4], E. Brzeziańska-Lasota[4] and D. Strzelecki[1]

[1]Department of Affective and Psychotic Disorders; [2]Department of Old Age Psychiatry and Psychotic Disorders; [3]Faculty of Medicine; [4]Department of Biomedicine and Genetics and [5]"Dynamo Lab" Academic Laboratory of Movement and Human Physical Performance, Medical University of Lodz, Lodz, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2028

Introduction: There is a need to search for new treatment options not only for depression but also its concomitant diseases. Particularly, depression and metabolic-health abnormalities often coexist, while inflammation and microbiota imbalance, may play a part in their pathophysiological overlap. Thus, the trials of interventions on the microbiota may result in establishing a safe adjunctive treatment option.

Objectives: The primary aim of this seconadry analysis was to assess the effect of probiotic formulation on inflammatory parameters in adult patients with depressive disorders. The secondary aim was to assess some possible pretreatment determinants of probiotics action towards inflammation, e.g., dietary habits, inflammatory or metabolic status, severity and dimensions of psychiatric symptoms, medications used.

Methods: The parent trial was a two-arm, 60-day, prospective, randomized, double-blind, controlled design. The probiotic formulation contained Lactobacillus helveticus Rosell®-52 and Bifidobacterium longum Rosell®-175. The change in inflammatory parameters (e.g., C-reactive protein, complete blood count-derived markers, tumor necrosis factor-alpha) after intervention alone and in the context of basal lifestyle, psychometric, metabolic, and inflammatory parameters was assessed.

Results: Probiotics significantly decreased CRP levels compared with placebo by 21.3 % (p = .047) with nearly moderate effect size as measured with Cliff's delta (Δ = .249). Rates of CRP-responders (a minimum 50% decrease in CRP level) were non-significantly higher in the probiotic than placebo group (18.0 % vs. 5.26 %, respectively; $\chi 2(1) = 3.20$, p = .074); but the effect size was shown to be clinically meaningful (OR = 3.95; NNT = 7.85). In two-way ANOVA with interaction analysis, probiotics anti-inflammatory action was shown to be favoured by antidepressant use, and higher basal alanine aminotransferase. But, pretreatment chronic low-grade inflammation status counteracted probiotics anti-inflammatory properties.

There were no significant differences in complete blood count-derived parameters, nor in TNF-α levels.

Conclusions: We have found an anti-inflammatory action of probiotics in patients with depression, as shown in the assessment of CRP levels. Additionally, probiotics were revealed to be more effective for inflammation measured by CRP levels when used by subjects with certain pretreatment features. Further studies should be performed to replicate these results.

Measurements of Vitamin D and inflammation factors in a psychiatric outpatient clinic

S. Kocijancic Azzaoui[1]* and P. Pregelj[2]

[1]Psycho-oncology, Institute of Oncology and [2]Center of mental health, University psychiatric clinic Ljubljana, Ljubljana, Slovenia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2029

Introduction: Vitamin D is a fat-soluble vitamin that together with parathyroid hormone (PTH) regulates blood calcium and phosphorus levels. Vitamin D also has anti-inflammatory, antioxidant, and neurotrophic properties. It acts through the vitamin D receptor (VDR), which has been found throughout the body, including the nervous system. Its deficiency is associated with various diseases, including depression and schizophrenia. It is estimated that approximately 1 billion people worldwide have vitamin D deficiency, while 50% of people worldwide (4 billion people) are thought to have insufficient levels of vitamin D.

Objectives: The retrospective study aimed to determine whether routine laboratory tests in a psychiatric office/outpatient clinic can find a connection between vitamin D levels and inflammatory parameters such as CRP, leukocytes, and the neutrophil-to-lymphocyte ratio (NLR).

Methods: Data was collected from a psychiatric office/outpatient clinic between the years 2020 and 2023. We included the patients (and their basic data, such as gender, age, diagnosis during treatment) whose laboratory results had vitamin D levels as well as a complete blood count (leukocytes, neutrophils, and lymphocytes) and c-reactive protein (CRP). We calculated the ratio of neutrophils to lymphocytes (NLR) and performed Spearman's correlation, where a p-value of <0.05 indicated a statistically significant change.

Results: Between 2020 and 2023, 88 laboratory tests were conducted in the outpatient office, that included vitamin D levels, of these, 67 had all the necessary data. Vitamin D deficiency was present in 65% of patients. We found that CRP was not sensitive enough for our study, as 83% of CRP values were below 8 mg/L. After performing a correlation between vitamin D levels and leukocytes and NLR, we did not find a statistically significant connection.

Conclusions: We did not find statistically significant corelation between the level of vitamin D and NLR and leucocytes. We would recommend further research that uses a larger sample of patients and conduct measurements during acute illness or exacerbation to obtain more reliable conclusions.

Disclosure of Interest: None Declared

EPV1516

The possible role of seasonality and hs-CRP in the evaluation of suicidality risk

G. Longo[1]*, L. Cavallo[1], L. Orsolini[1] and U. Volpe[1]

[1]Department of Neurosciences/Department of Experimental and Clinical Neurosciences (DIMSC), Polytechnic University of Marche, Unit of Clinical Psychiatry, Ancona, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2030

Introduction: Suicidality is a critical concern in individuals with affective disorders, and environmental and biological factors may influence its risk. In recent years, seasonal variations and systemic inflammation, as indicated by high-sensitivity C-reactive protein (hsCRP), have garnered interest as potential contributors.
Objectives: To assess the risk of suicidality in affective disorders among seasonality correlated with hsCRP.
Methods: A naturalistic, observational, cross-sectional study was carried out by retrospectively recruiting 353 adult inpatients affected by severe mental illness (SMI) consecutively hospitalized in the Psychiatry Clinic of the Ospedali Riuniti of Ancona, Italy. Patients affected by inflammatory pathology, alcohol/substance use disorders or treated by anti-inflammatory/immunosuppressive therapy were excluded. Only patients suffering from mood disorders were considered for this analysis (n=246). We administered a checklist for socio-demographic and clinical features (diagnosis, age of onset, disease duration, number of episodes, number of episodes per year, suicidal attempts and comorbidities). Subscale 5 of the Mini International Neuropsychiatric Interview (MINI-5-s) was administered to all the patients involved to assess suicidality risk. To normalize hs-CRP, a logarithmic transformation was performed (log-hsCRP). At the same time, season were codified as dummy variables. T-test for independent groups and multivariate linear regression were conducted.
Results: 47.2% (n=116) of the sample were male. The mean value of hsCRP was 5.7mg/L (SD=15.8). The mean score of MINI-5-s total score was 13.3 (SD=11.6). Patients admitted to our psychiatric ward in meteorological (p=0.013) and astronomical (p=0.049) autumn had a lower log-hsCRP compared to other seasons. A multivariate linear regression was observed between MINI-5-s total score (R^2 =0.74, F=9.639, Durbin-Watson=1.915, p<0.001) and hsCRP (B=0.94, p=0.041) and the meteorological autumn (B=-7.436; p<0.001).
Conclusions: This study highlights a significant association between seasonality, systemic inflammation (as measured by hsCRP), and suicidality risk in patients with mood disorders. Our results focus on the importance of considering biological and environmental factors in assessing and managing suicidality risk in affective disorders. Further studies are essential to link seasonal and inflammatory mechanisms.

Correction of hematopoiesis in alcoholism by the lymphocytes, modulated with a synthetic GABAA-R ligand

E. Markova[1]*, I. Savkin[1], O. Anikeeva[1], M. Knyazheva[1] and I. Orlovskaya[2]

[1]Neuroimmunology Lab and [2]Molecular pathology Lab, State Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2031

Introduction: It is well known that alcohol has a variety of pathologic effects on hematopoiesis. Long term alcohol abuse result in a significant suppression of both the production of blood cells and structural changes in precursors, namely the suppression of their maturation, up to pancytopenia. We first demonstrated the immunomodulatory properties of a synthetic GABAA-R ligand, metachlorobenzhydrylurea (m-CBU). We also showed that splenic lymphocytes modulated *in vitro* by m-CBU after intravenous administration to syngeneic long-term alcoholized recipients have a positive effect, manifested in the editing of behavior characteristic of alcoholism against the background of stimulation neuroplasticity and reduction of neuroinflammation.
Objectives: The purpose of this work was to study bone marrow hematopoiesis and peripheral blood parameters in long-term alcoholized recipients after transplantation of syngeneic lymphocytes modulated in vitro by m-CBU.
Methods: Male (CBAxC57Bl/6)F1 mice with 6-month 10% ethanol exposure were undergoing the transplantation of syngeneic long-term alcoholized mice lymphocytes, pretreated *in vitro* with m-CBU. The number of bone marrow hematopoietic progenitors and cellular composition of the blood were assessed in the recipients.
Results: Long-term alcoholization in mice led to a decrease in the colony-forming activity of hematopoietic precursors, mainly erythroid; in the peripheral blood of mice, a significant decrease in the number of erythrocytes, leukocytes, lymphocytes and platelets was recorded, while the population of segmented neutrophils significantly increased. Lymphocytes, precultured with m-CBU, in syngeneic long-term alcoholized recipients had a corrective effect on a number of hematopoietic parameters (colony-forming activity of erythroid precursors in the bone marrow, the number of erythrocytes, segmented neutrophils and lymphocytes in the peripheral blood) to indicators comparable to those in intact mice of the corresponding with tendency to increase the number of platelets in the peripheral blood.
Conclusions: The data obtained may indicate the effectiveness of m-CBU -modulated lymphocytes transplantation in correcting a number of changes in hematopoiesis provoked by long-term alcohol abuse.

Immunoediting of stress-induced behaviors using cell-based technologies

E. Markova[1]*, M. Knyazheva[1], E. Serenko[1], I. Savkin[1] and O. Anikeeva[1]

[1]Neuroimmunology Lab, State Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2032

Introduction: Negative consequences of acute and chronic stress caused by information overload, environmental problems, natural disasters, man-made disasters, military clashes, and acts of terrorism have become increasingly evident in recent decades. They can lead to a painful "breakdown" of socio-biological adaptation mechanisms, a decrease in adequacy in assessing the environment, and, as a consequence, the formation of disturbances in the psycho-emotional sphere, manifested in the development of behavioral disorders (aggression and depression). Therapy for behavioral disorders does not provide a complete cure, apparently due to the formation of a "vicious circle" that can only be broken by normalizing the regulatory relationship between the central nervous system and the immune system. One way to solve this problem is to develop new methods of therapy based on immunological approaches. The method of choice may obviously be immunotherapy with autologous immune cells with a certain, including in vitro modulated, functional activity.
Objectives: The aim of the study was to investigate the possibility of obtaining a positive psychoneuroimmunomodulatory effect in aggressive and depressive-like animals by transplanting immune cells, the functional activity of which was in vitro modulated by a psychoactive substance (PAS).
Methods: Male (CBAxC57Bl/6)F1 mice aged, in which aggressive or depressive-like states were formed under the influence of long-term social stress, were used as donors and recipients in the experiments. Immune cells for transplantation were obtained from a suspension of donor's splenocytes, cultured in vitro with PAS (chlorpromazine or caffeine, respectively) and then intravenously administered to syngeneic recipients. In the control group of animals, cell preparation and transplantation were carried out under similar conditions, except that the latter were cultured without the presence of PAS. In recipients the parameters of the nervous and immune systems functional activity were recorded.
Results: Transplantation of in vitro PAS-modulated splenocytes to recipients with stress-induced behavior patterns resulted in targeted changes in their motor and exploratory activity in the Open field test, motor activity in the Porsolt test, and decreased anhedonia in recipients with a depressive-like phenotype, recorded against the background of changes in the content of a number of pro- and anti-inflammatory cytokines IL-1β, IL-2, IL-4, IL-6, IL-10, IFNγ, TNFα in pathogenetically significant brain structures. In recipients, a positive change in the parameters of the immune system functional activity were also revealed.
Conclusions: The possibility of immunoediting stress-induced forms of behavior by transplanting in vitro PAS-modulated immune cells, which have a positive psychoneuroimmunomodulatory effect in the body of syngeneic recipients, has been demonstrated.

Differential Diagnosis of Neuropsychiatric Presentations: A Combined Assessment of Psychiatric and Neurological Symptoms

F. S. Mir Biribay[1], M. P. Sanchez Castro[1], H. Rincon Reques[1], M. Velasco[1], C. Serrano[1], A. Huerta[1], C. Delicado[1], M. A. Morillas[1] and M. Bravo[2]*

[1]Psychiatry and [2]HOSPITAL UNIVERSITARIO LA PAZ, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2033

Introduction: Assessing psychiatric and neurological symptoms in emergency settings is crucial for accurate differential diagnosis. Psychosis, seizures, and cognitive impairment often overlap with various medical and psychiatric conditions, making early and precise identification essential for differentiating between potential causes, guiding appropriate treatment, and improving patient outcomes.
Objectives: This report presents a clinical case with initial suspicion of psychotic symptoms accompanied by convulsive features to emphasize the importance of differential diagnosis in neuropsychiatric manifestations.
Methods: This report details a clinical case involving a 26-year-old woman with no prior psychiatric or neurological history, who presented to the emergency department with headaches, insomnia, and unusual behaviors. Three weeks earlier, she had a right parietal focal epileptic seizure and was being treated with lacosamide 100 mg every 12 hours. Post-seizure, she exhibited symptoms such as disorientation, memory lapses, thought blocking, soliloquies, disorganized thinking, and insomnia. Due to suspected psychotic symptoms, the emergency department consulted psychiatry. Both psychiatry and neurology were involved in her evaluation due to the neuropsychiatric nature of her symptoms. The differential diagnosis considered was a first psychotic episode, postictal psychosis, or encephalitis. She was initially prescribed anxiolytics and antipsychotics, including olanzapine 2.5 mg and clonazepam 0.5 mg. Complementary tests, including an EEG, showed right parietal epileptiform discharges and diffuse encephalopathy, but no evidence of status epilepticus. These findings, combined with convulsive symptoms, suggested a neurological origin, leading to her admission to the neurology department.
Results: Further investigation revealed right temporoparietal cortical thickening on brain MRI, indicative of encephalitis, and lumbar puncture results were positive for anti-NMDA receptor antibodies. The patient was then treated with high-dose corticosteroids, later replaced by plasmapheresis every two days. A gynecological consultation was performed to exclude ovarian pathology, and a body CT scan was ordered to rule out tumor-related conditions. Although her condition has stabilized, it is still early to fully assess the effectiveness of the treatment.
Conclusions: This case emphasizes the critical importance of neuropsychiatric differential diagnosis. The overlapping symptoms of psychosis and cognitive impairment can mimic various conditions, making accurate diagnosis challenging. The collaboration between psychiatry and neurology was essential in distinguishing between psychiatric disorders and anti-NMDA receptor encephalitis. Timely and precise diagnosis enabled targeted treatment, demonstrating the need for a multidisciplinary approach in managing complex neuropsychiatric cases.

Assessment of inflammatory markers in late-onset schizophrenia

V. Pochueva[1]*, I. Kolykhalov[1] and L. Androsova[1]

[1]FSBSI Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2034

Introduction: Previous studies have shown that neuroinflammation can play a significant role in the pathogenesis of schizophrenia. The search for inflammatory markers in late-onset schizophrenia are very important for diagnostics.
Objectives: Determination of inflammatory markers in the peripheral blood plasma of patients with late-onset schizophrenia in relation to the clinical characteristics of patients.
Methods: The study included 46 patients with schizophrenia aged 61 [56; 69] years (2 men and 44 women); the age of disease onset was 51 [45; 60] years. The severity of mental disorders was assessed using the PANSS scale, and cognitive impairment was assessed using the MMSE and MoCA scales. The control group consisted of 77 people comparable in age with the patients (p=0.16). A spectrophotometric method was used to determine inflammatory markers (enzymatic activity of leukocyte elastase (LE), functional activity of α1-proteinase inhibitor (α1-PI)). The protease inhibitory index (PII) was calculated - the ratio of LE and α1-PI activity, indicating the direction of the inflammatory process. Comparative data analysis was performed using the Statistica 10.
Results: The 1st cluster (22 patients (47.8%)) was characterized by a significantly increased α1-PI activity (p=0.000), decreased LE activity (p=0.000) compared to the control values, and, accordingly, a low PII value (p=0.000), which is an unfavorable prognostic factor for further development of the disease and response to therapy. A 28-day course of therapy with 1st and 2nd generation neuroleptics didn't change the immunological parameters in patients of this cluster. In this cluster, a positive correlation was found between LE activity and scores on the MMSE (r=0.512, p<0.05) and MoCA (r=507, p<0.05) scales at the start of treatment, i.e. the lower score on the cognitive functioning scales and the more severe the disease correlate with lower the LE activity.
The 2nd cluster (24 patients (52.2%)) was characterized by a significant increase in inflammatory markers, LE and α1-PI activity (p=0.000, p=0.000, respectively) in relation to the control parameters, while the PII value didn't differ from the control. In this group, paranoid and schizotypal personality were significantly less common in the premorbid period (41.6% of cases), and formal thinking disorders were expressed to a lesser extent. No clinical and immunological relationships were revealed. A 28-day course of therapy influenced the change in immunological parameters towards their relative normalization.
Conclusions: The obtained results confirm the involvement of the inflammatory link in the development of late-onset schizophrenia, as well as the heterogeneity of the patient group in terms of clinical and immunological parameters. Evaluation of the spectrum of inflammatory markers allows us to identify patients with an unfavorable course of the disease and resistance to therapy.

Psychotic episode associated with autoimmune limbic encephalitis in a patient treated with checkpoint inhibitors: a case report

P. Sánchez Díez[1]*, C. Blanes Morell[1] and J. Torres Cortés[1]

[1]Psychiatry, Ramón y Cajal Hospital, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2035

Introduction: Immune checkpoint inhibitors are being used in patients with advanced malignancies. Although it can effectively treat tumors, 30–60% of patients could experience immune-related adverse events such as encephalitis with antibodies against the NMDA receptor. We present a case of a 57-years-old man with no prior mental health history who was diagnosed of kidney cancer and received treatment with checkpoint inhibitors. He developed incoherent speech, visual hallucinations, delusional megalomania, disorientation, sleepiness and a low-grade fever of 37.7ºC. He was admitted in Neurology unit and diagnosed of autoimmune limbic encephalitis in a patient treated with checkpoint inhibitors.
Objectives: To describe a case of a psychotic episode associated with autoimmune limbic encephalitis in a patient treated with checkpoint inhibitors.
Methods: Clinical assesment and bibliographic review of pertinent literature.
Results: During his admission in Neurology ward, the patient was suspicious, inattentive, aggressive with healthcare staff and he developed incoherent speech with visual hallucinations.
MRI suggested bilateral limbic encephalitis and the antibody test in cerebrospinal fluid were positive for NMDA receptor.
The psychotic episode was treated with olanzapine up to 20 milligrams and the limbic encephalitis with rituximab with a good response.
Conclusions: The case presented is consistent with other reports of psychotic symptoms and development of encephalitis associated with antibodies against the NMDA receptor.
The diagnosis of anti-NMDAR encephalitis is usually delayed.
The differential diagnosis should be established with primary psychiatric disorders.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2036

Introduction: Major depressive disorder (MDD) is a prevalent neuropsychiatric condition influenced by genetic, environmental, and inflammatory factors. Alterations in T helper (Th) cell subsets, including Th1, Th2, Th17, and regulatory T cells (Tregs), have been implicated in the immune dysregulation observed in MDD, linking the adaptive immune system to depression. However, the link between these T cell subsets, MDD severity and their connection with childhood trauma (CT), a major risk factor for depression, remain incompletely understood.
Objectives: In this project we characterized peripheral blood T cell subsets and their association with CT and MDD.
Methods: In this study, we performed multiparameter flow cytometry analysis on peripheral blood immune cells from a subgroup of the FOR2107 cohort. T cell differentiation is characterized by their phenotypic markers. Age- and gender- matched groups of 46 individuals with depression and 55 healthy controls (HC) were included, both with and without a history of childhood trauma. Depression severity was assessed using the Hamilton Rating Scale for Depression), (HAM-D21), and CT was evaluated via the Childhood Trauma Questionnaire (CTQ). Correlational analyses examined relationships between T cell subtype frequencies, depression severity, and CT subtypes.
Results: The analysis revealed an increased frequency of circulating Th17 cells in patients with MDD compared to healthy controls. In participants with a history of CT, the overall frequency of $CD3^+$ T cells was decreased, while Th2 cells and Treg cell frequencies were reduced when compared to individuals without CT. Frequencies of specific T cell types correlate with CT subtypes, especially in depressive patients. Th1, effector memory T cells (Tem) and central memory T cells (Tcm) showed a positive correlation with physical abuse, while Treg cells correlated with the overall CTQ score and emotional neglect.
Conclusions: Our findings indicate dysregulations of the adaptive immune system in CT and MDD, characterized by alterations in peripheral blood Th17, Th2, and Treg cells. These data highlight the influence of early life adversity on immune function and its potential contribution to the pathophysiology of depression.

Strike three, you're out - when a primary psychosis just doesn't cut it

M. Vasconcelos[1]*, C. Silva[2], M. Bajouco[1], D. Mota[1], S. Batista[2] and A. Mendes[1]
[1]Psychiatry and [2]Neurology, Coimbra Hospital and University Centre, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2037

Introduction: Autoimmune psychosis has gained increased recognition as a distinct entity and is known to mimic variants of primary psychosis, typically presenting with an acute onset of polymorphic psychotic symptoms. We describe a case of probable autoimmune psychosis in a young patient who experienced a severe first psychotic episode.
Objectives: Reflection over the diagnostic challenges of autoimmune psychosis.
Methods: Clinical case report.
Results: A 19-year-old male patient with no relevant medical history was admitted to the psychiatric ward due to a first psychotic episode with a peracute onset. The episode peaked with severe confusion, disorientation, and disorganized behavior, leading to his referral to the emergency room. This episode was characterised by delusional ideation with mystical, self-referential, and persecutory themes, complex auditory-verbal hallucinations, and marked negative and cognitive symptoms (including affective blunting, social withdrawal, apathy, alogia, impaired attention, decreased social cognition, and reduced speed of cognitive processing). The analytical study, substance screening, and brain CT upon admission were normal, leading to the assumption of a primary psychotic disorder. Antipsychotic therapy was initiated with progressive titration (risperidone, cariprazine, and clozapine), yet there was no significant improvement. Given the severe presentation and treatment resistance, a neurological examination was requested, which revealed no focal signs. A comprehensive laboratory workup showed positive ANAs, anti-recoverin antibodies, and hypocomplementaemia (C3 and C4). No significant abnormalities were observed in the brain MRI. CSF analysis revealed slight protein elevation (55 mg/dL) without pleocytosis, oligoclonal bands, or antibodies. EEG indicated mild to moderate encephalopathy with FIRDA bursts and focal paroxysmal activity in the left temporo-parieto-occipital region. Brain PET-FDG showed no significant abnormalities. Serum and CSF neurofilament levels were normal. Full-body CT and PET-FDG scans were also unremarkable. Given the findings, autoimmune psychosis was assumed. Treatment with IV immunoglobulin (30 g) and methylprednisolone (1 g for 5 days) was administered. The case was discussed in a multidisciplinary meeting, and a regimen of daily prednisolone (10 mg) was chosen. At follow-up, the patient showed slight improvement, with mitigation of the positive symptoms.
Conclusions: Psychosis that does not respond to antipsychotic treatment and presents with atypical signs should raise suspicion of secondary immune-mediated schizophreniform psychosis. However, the challenge lies in identifying these patients, selecting appropriate diagnostic tests, and establishing criteria for implementing treatment.

Heterogeneity of juvenile depression with different risks of developing psychosis according to immunological blood parameters

S. A. Zozulya[1]*, T. I. Shishkovskaya[1], I. N. Otman[1], I. V. Oleichik[1], Z. V. Sarmanova[1], P. A. Baranov[1] and L. V. Androsova[1]
[1]FSBSI "Mental Health Research Centre", Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2038

Introduction: One of the mechanisms underlying the pathogenesis of mental disorders, including endogenous depression, is systemic inflammation. It is of interest to study the immunological aspects of the early stages of endogenous disorders and identify subgroups of patients with immunotypes that characterize a high risk of developing the first psychotic episode.
Objectives: Comparative analysis of the spectrum of inflammatory markers in patients with a juvenile depression with high and low risk of developing psychosis.

Methods: The study involved 98 women 16 to 25 years (20.9 ± 5.14 years) with depression within the framework of various nosologies (F31.3-4; F33.0-1; F60.0-9; F21.3-4; F20.01-2; F25.1). Two groups of patients without a history of psychosis were identified: group 1 (n = 47) - without symptoms of psychosis risk, group 2 (n = 51) - with depression associated with psychopathological symptoms of psychosis risk. The control group consisted of 42 healthy women of the corresponding age. The severity of depressive symptoms was assessed using the HDRS-21, the severity of negative and positive symptoms was determined using the SANS and SAPS. In group 2, the severity of attenuated positive symptoms was determined using the SOPS. The activity of the leukocyte elastase (LE) and α1-proteinase inhibitor (α1-PI), as well as the level of autoantibodies (AB) to S100B and MBP, were determined in plasma.
Results: The groups were characterized by a statistically significant increase in both LE and α1-PI ($p<0.05$), and the level of AB compared to the control ($p<0.05$), but no significant differences were found. In group 1, clinical and biological correlations were found between LE activity and the total score on the SANS ($r=0,44$, $p=0.002$). In group 2, a negative correlation was found between LE activity and the age of onset of the disease ($r=-0.3$, $p=0.046$).
The clustering of patients by LE activity and their distribution by immunological groups showed that 29.4% and 27.5% of patients in groups 1 and 2, respectively, were characterized by a high level of inflammatory markers and the absence of an autoimmune component to neuroantigens, which is a sign of a more favorable course of the pathological process. On the contrary, 70.6% and 72.5% of patients in groups 1 and 2, respectively, were characterized by the type of inflammatory response associated with an increase in the level of AB and varying degrees of insufficiency of the functional activity of neutrophils, which is considered an unfavorable factor that aggravates the course of the disease.
Conclusions: Comparison of the spectrum of inflammatory markers in juvenile depression with different risk of developing psychosis indicate their significant immunological heterogeneity. The immunotype characterized by a high level of AB and insufficient LE activity can presumably be considered as a predictor of the risk of developing psychosis.

Disclosure of Interest: None Declared

EPV1525

Quantitative and functional characteristics of monocytes and neutrophils in patients with treatment-resistant schizophrenia

S. Zozulya[1]*, Z. Sarmanova[1], I. Otman[1], V. Kaleda[1] and D. Tikhonov[1]

[1]FSBSI "Mental Health Research Centre", Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2039

Introduction: Despite significant progress in the treatment of schizophrenia, the number of patients with schizophrenia who do not respond to treatment remains constant. Identification of biomarkers of therapeutic resistance in the schizophrenia can help in early prediction of these conditions, as well as in the development of new approaches to treatment. Inflammation is considered as one of the possible mechanisms involved in the development of the pathological process in the formation of resistance to therapy in schizophrenia. The main cells of innate immunity, neutrophils and monocytes, are involved in the implementation of the inflammatory response.
Objectives: To compare the subpopulation composition of monocytes and the level of other inflammatory markers in patients with treatment-resistant schizophrenia and in the control group.
Methods: The study included 17 men with treatment-resistant schizophrenia (TRS) (27.0±8.0 years) and 15 healthy individuals without signs of mental and inflammatory diseases. The relative content of neutrophils and monocytes in the blood, as well as the ratio of monocyte subpopulations, estimated by the expression level of CD14 and CD16 receptors, were determined by flow cytofluorometry. The functional activity of neutrophils was determined spectrophotometrically by the activity of leukocyte elastase in plasma. The level of autoantibodies to S100B in plasma was estimated by ELISA.
Results: A significant increase in the relative content of monocytes ($U=28.0$, $p<0.01$) and a decrease in neutrophils ($U=35.0$, $p=0.036$) were found in TRS patients compared to the controls. An increase in a proportion of the "transitional" CD14+CD16− subpopulation ($U=61.5$, $p=0.04$) and a decrease in the "classical" CD14++CD16− subpopulation ($U=60.5$, $p=0.036$) were accompanied by the proportion of "intermediate" inflammatory CD14++CD16+ and "non-classical" CD14+CD16+ subpopulations that did not differ from controls. A moderate increase in leukocyte elastase activity ($U=34.0$, $p=0.001$) and a high level of S100B autoantibodies ($U = 55.0$, $p = 0.02$) were found in blood plasma of patients. The proportion of "intermediate" CD14++CD16+ monocytes was negatively correlated with the level of autoantibodies to S100B ($r= -0.55$, $p=0.021$). It should be noted that this spectrum of immune parameters differs from the corresponding profile that we identified in patients with schizophrenia who responded to treatment. The main differences concern the proportion of "intermediate" monocytes, the relative content and functional activity of neutrophils.
Conclusions: The identified quantitative and functional characteristics of monocytes and neutrophils in patients with TRS indicate the possible involvement of the cellular component of immunity in the development of resistance to treatment and may be associated with the severity of the disease in a long-term pathological process in the brain.

Distinguishing Obsessive-Compulsive Symptoms in Schizophrenia-Spectrum Disorders and Obsessive-Compulsive Disorder: The Role of Basic Self Disturbances

V. Alves Barata[1]*, J. Bastos[1] and T. Filipe Ferreira[1]

[1]Hospital Prof. Doutor Fernando Fonseca, Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2040

Introduction: Obsessive-compulsive symptoms (OCS) are frequently observed in both obsessive-compulsive disorder (OCD) and schizophrenia-spectrum disorders (SSD), creating significant diagnostic challenges. Historically, Karl Jaspers defined "true obsessions" as a struggle against intrusive ideas that appear nonsensical and "alien" to the personality, demarcating this concept from delusions and overvalued ideas, in which cases the person

would be convinced of the relevance of the content. However, since the 1980s, the concepts of insight and resistance in OCD have been deemphasized in diagnostic criteria, broadening the definition of OCD to include cases with poor or absent insight. The broadening of these criteria has blurred the distinction between OCD and SSD and has narrowed the diagnosis of schizophrenia to primarily delusional and hallucinatory conditions, overlooking obsessive phenomena in this disorder.

Objectives: The primary goal of this review is to differentiate the phenomenological features of OCS in OCD from those in SSD, focusing on the connection between obsessive-compulsive phenomena and disturbances in the basic self in SSD.

Methods: A literature review was conducted using the keywords "obsessive-compulsive symptoms"; "schizophrenia"; "obsessive-compulsive disorder"; "phenomenology" in the Pubmed and Google Scholar databases.

Results: The findings suggest that the underlying nature and subjective experience of OCS may differ substantially between OCD and SSD. An essential component of this differentiation is the exploration of basic self-disturbances, which refer to profound disruptions in an individual's sense of ownership of experience and agency of action - elements often impacted in SSD but less so in OCD. Patients with SSD often experience OCS in a more alien and automatic manner, with intrusive thoughts and compulsions lacking a clear sense of personal ownership or agency. These obsessions are more likely to blend with delusional thinking and other psychotic features, reflecting broader disturbances in the basic self. The lack of insight and the feeling that obsessive thoughts are externally imposed or intruding from outside the self is a hallmark in these cases. As for compulsions, these may serve as maladaptive strategies to manage or compensate for self-disturbances, rather than purely to neutralize distress as seen in OCD.

Conclusions: Accurate differentiation of OCS in SSD from those in OCD requires clinicians to focus on the quality of self-experience, particularly in terms of insight, ownership and agency. Recognizing how certain obsessive phenomena in SSD reflect disturbances in the basic self is crucial for improving diagnostic accuracy and ensuring appropriate treatment.

Progress in the neurolinguistic assessment in schizophrenia (SZ) – the SchizoLang pilot study

X. Ansorena[1]*, S. Mancini[2], J. Díaz[3], A. M. Sánchez-Torres[4] and M. J. Cuesta[3]

[1]Instituto de Investigación Sanitaria de Navarra (IDISNA), Pamplona; [2]Basque Center on Cognition, Brain and Language, San Sebastian; [3]Servicio de Psiquiatría, Hospital Universitario de Navarra and [4]Departamento de Ciencias de la Salud, Universidad Pública de Navarra, Pamplona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2041

Introduction: Individuals with SZ show alterations at all levels of language: discourse, lexical-semantics, comprehension and syntax/ morphology. Linguistic capacities are associated with worse occupational, social and quality of life related outcomes (Ehlen et al. Front Psych 2023; 14). Still, language assessment is probably overseen in the cognitive assessment of individuals with SZ

Objectives:

1. To review the role of language in the cognitive assessment in SZ
2. To introduce the SchizoLang pilot study

Methods: We reviewed the available cognitive assessment tools in SZ to determine whether language is adequately represented. Consequently, we describe the SchizoLang pilot study

Results: Available instruments for the assessment of cognition in SZ do not adequately evaluate language. Importantly, fluency tests are not representative of language. Table 1 shows the major cognitive assessment tools in SZ.

Table 1. Cognition assessment instruments in schizophrenia (adapted from Vita et al. Eur J Psychiat 2022; 65 1-24)

The Schizolang pilot study: bridging neurolinguistics and Psychiatry to characterize language in Schizophrenia

The aims of this pilot study are:

To explore which linguistic domains are altered in people with SZ

To explore the relationship between language and (a) formal thought disorders, (b) psychiatric symptoms, (c) neuropsychological alterations, (d) deficits in psychosocial functioning, and (e) quality of life

ACS.esp

ACs.esp is a digital battery for the assessment language in aphasia based on neurolinguistic research. It shows good preliminary validity and reliability (Ansorena et al. 2022; SSTaal, 95 237–240). ACS.esp includes novel measures (see Table 2): an extensive discourse protocol, tasks for sentence planning, and sentence comprehension and production at the syntactic and grammatical levels.

Table 1. ACS.esp's structure with its factors, subfactors, input, stimuli and tasks. Auditory tasks are colored in blue and visual tasks in brown

Conclusions: Even if language is altered in SZ, it is not adequately assessed. An extensive characterization of language abnormalities in SZ can guide rehabilitation on communication and functioning; and consequently produce a greater well-being and quality of life. The SchizoLang pilot study will allow establishing a clinician-friendly protocol.

EPV1528

Does motivation and effort predict improvement on psychosocial functioning in schizophrenia (SZ)?

X. Ansorena[1]*, E. Rosado[1], J. Chato[1], A. Zarzuela[2], A. Ballesteros[2], J. I. Arrarás[2], F. Gorriz[2], A. M. Sánchez-Torres[3] and M. J. Cuesta[4]

[1]Instituto de Investigación Sanitaria de Navarra (IDISNA); [2]Clínica de Rehabilitación de Salud Mental, Hospital Universitario de Navarra; [3]Departamento de Ciencias de la Salud, Universidad Pública de Navarra and [4]Servicio de Psiquiatría, Hospital Universitario de Navarra, Pamplona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2042

Introduction: Previous research suggests that motivational factors relate to psychosocial functioning in SZ, both concurrently (Tobe et al. Compr Psychiat 2016; 65 103-109) and at follow-up (Fervaha et al. Acta Psychiat Scand 2014; 130 290-299). Importantly, no study has examined the influence of baseline motivation on the *rate of change* in response to rehabilitation

Objectives:

1. To study the relationship between baseline measures of motivation/ effort with psychosocial functioning at follow-up
2. To examine if motivation/ effort predict individual change in psychosocial functioning

Methods: Participants

Table 1 summarizes the sample characteristics

Results: Figures 1 and 2 show individuals slopes for PSP and FAST, with a thick red line representing the average group slopes. For both PSP and FAST, models with only time as the independent variable and random intercepts indicated that time was a significant predictor (**PSP:** t=10.65, p<.0001; **FAST:** t =-6.13, p<.0001).

Baseline motivation/ effort → follow-up psychosocial functioning

No significant correlations were found for neither PSP scores (**QLS:** ρ=-.018, S=2343.3, p=.93, **IMI:** P=.23, t=1.09, p=.28, **effort:** ρ=.001, S=2297.3, p=.99) nor FAST scores (**QLS:** ρ=-.16, S=2674.9, p=.45, **IMI:** P=-.02, t=-0.09, p=.92, **effort:** ρ=.07, S=2128, p=.72).

Motivation → change in psychosocial functioning

For PSP, the interaction model (Table 2) shows that the interaction of effort and timepoint significantly predicts PSP scores

Variable	Frequency	Mean/ percentage	Standard deviation
Age	30	40.97	12.9
Gender	30		
Male	19	63%	
Female	11	37%	
Years of Education	24	11.42	3.06
Diagnosis	30		
… Schizophrenia	23	73%	
… Schizoaffective disorder	7	23%	

Figure 1. Individual slopes for PSP scores
Figure 2. Individual slopes for FAST scores

Image:

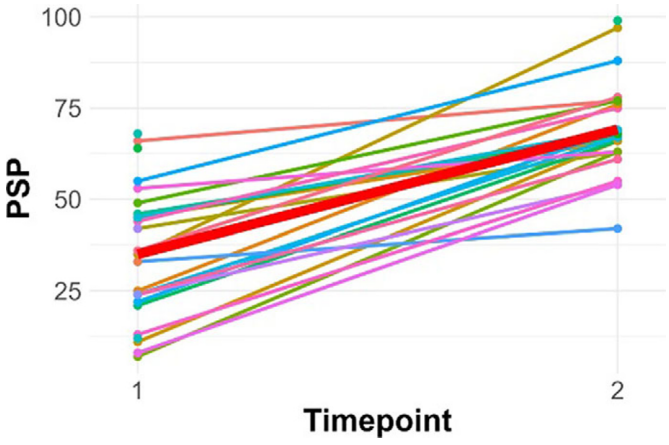

Image 2:

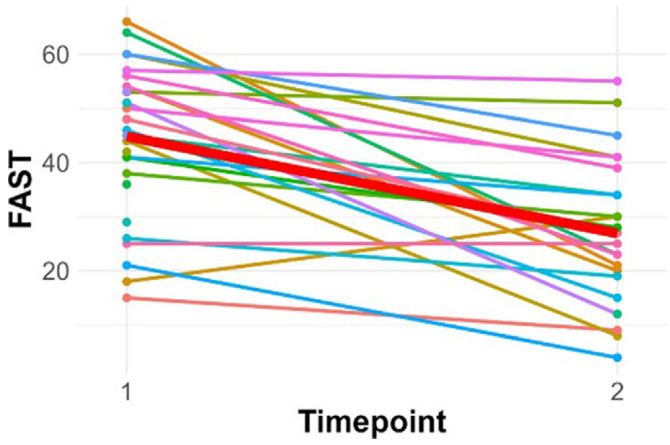

Image 3:

			PSP		
Predictors	*Estimates*	*SE*	*CI*	*T*	*p*
(Intercept)	57.99	13.52	30.69 – 85.29	4.29	**<0.001**
Timepoint	-4.04	16.52	-37.40 – 29.33	-0.24	0.808
Effort	-3.93	2.27	-8.52 – 0.66	-1.73	0.092
Timepoint:Effort	6.38	2.75	0.82 – 11.94	2.32	**0.026**
Random Effects					
σ^2	115.73				
$\tau_{00\ ID}$	101.65				
ICC	0.47				
N_{ID}	27				
Observations	47				
Marginal R^2 / Conditional R^2	0.575 / 0.774				
Deviance	377.202				
AIC	374.354				
log-Likelihood	-181.177				

Conclusions: Patients showed an improvement after rehabilitation. Effort can explain this trend. Finally, unlike previous studies, basal motivation did not predict follow-up psychosocial functioning

EPV1529

Compliance in Patients with Paranoid Schizophrenia and Substance Dependence

M. S. Artemieva[1]*, A. T. M. Mkrtchyan[1], V. P. Sokolov[1] and I. E. Danilin[1]

[1]Psychiatry and medical psychology, RUDN University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2043

Introduction: Schizophrenia is one of the most disabling psychiatric disorders, with about 60% of patients also suffering from substance dependence—a rate significantly higher than in the general population. Mentally ill individuals have a suicide risk four times higher than healthy individuals, which doubles when comorbid mental disorders are present. Compliance with treatment in patients with schizophrenia is generally lower than in those with other psychiatric disorders, often due to a lack of continuity between psychiatric and addiction services.
Objectives: This study aims to assess compliance in patients diagnosed with paranoid schizophrenia and substance dependence syndrome and compare it with compliance in patients diagnosed with paranoid schizophrenia without dependence.
Methods: The study included two groups: 15 patients with paranoid schizophrenia and 20 patients with paranoid schizophrenia and substance dependence. The average hospital stay for patients without substance dependence was 25.8 days, whereas it was 38.4 days for those with dependence.
Results: Prolonged hospitalizations increase the economic burden on healthcare and introduce additional challenges, such as job loss, which heightens stigma and marginalization. The number of hospitalizations was also higher among patients with dependence, averaging 4.75 times over five years compared to 1.06 times in those without. Patients without dependence can often remain functional in society on monotherapy, requiring only one medication—a more convenient regimen. In contrast, patients with dependence typically require a combination of three or more medications, with a less flexible and more demanding dosage schedule. These regimens not only increase economic strain but also can worsen medication tolerance. This increases the risk of selective intake, reduced frequency, or complete discontinuation of medications, which often leads to rehospitalization. Frequent therapy adjustments may further erode patients' adherence to new regimens, undermining their trust in the need to engage with psychiatric care.
Conclusions: As shown, compliance in patients with a "dual diagnosis" is a pressing issue in modern psychiatry. Addressing this complex problem requires multiple steps, including selecting appropriate therapies, addiction treatment, psychoeducation, and fostering a strong doctor-patient relationship in an outpatient setting. These measures collectively aim to reintegrate patients into society, reduce disease burden, improve quality of life, lower suicide risk, and decrease the frequency and length of hospitalizations.

Disclosure of Interest: None Declared

EPV1533

The Double Within: A review of the phenomenology and psychopathology of Autoscopic Phenomena

A. F. Reis[1], T. Cardoso[1]*, C. P. Ramos[1], M. M. Figueiredo[1], J. Marta[1] and M. J. Freire[1]

[1]Psychiatry and Mental Health, Unidade Local de Saúde da Arrábida, Setúbal, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2044

Introduction: Autoscopic Phenomena (APs) are rare perceptual experiences where individuals perceive a visual double or duplicate of their own body. It has been recognized since ancient times, but gained significant attention in the 19th century, both through its depiction in romantic literature and in neuropsychiatric studies; in

the literature, their association with epilepsy and schizophrenia is very extensively documented. Recent research brought new insights into the neurobiology of these phenomena.
Objectives: In this article, we aim to review the phenomenology and psycopathology of APs.
Methods: Narrative literature review.
Results: From a phenomenological perspective, three main conditions can be identified. In Autoscopy, the person sees a double, but does not feel a connection with it, meaning that they can distinguish between themselves and the double. In Out-of-body Experience (OBE), the individual feels as though they have left their body and observe themselves from an external perspective. In Heautoscopy, the boundary between the self and the double is blurred, causing uncertainty about where one's "self" is located, representing a middle ground between autoscopy and OBE.
Current research suggests that APs are linked to dysfunctions in the normal integration of body ownership, self-location, and perspective-taking, caused by lesions in regions responsible for integrating multisensory inputs (visual, proprioceptive and vestibular). All types of APs have in common a dysfunction specifically in the temporo-parietal junction (TPJ), a brain area involved in processing self-location and integrating sensory inputs to create a unified sense of self; other common areas include the insula and cingulate cortex.
Regarding to the different networks of APs, Autoscopy primarily involves abnormalities in the visual processing regions (as the occipital and parietal lobes), causing a visual perception of double; OBEs are caused by dysfunctions in areas responsible for self-location and vestibular processing (such as the medial prefrontal cortex), leading to a sensation of floating outside one's body; lastly, Heautoscopy engages more widespread brain dysfunctions, including the regions involved in self-representation and embodiment, leading to ambiguity in self-location.
Conclusions: APs challenge our understanding of the bodily self and how identity is constructed, raising questions about how the brain creates a unified sense of being in a body and how this can break down under certain pathological conditions. Although much is unknown, one thing is for sure: these phenomena demonstrate that the sense of self is not fixed, and the study of its disruption, by exploring its phenomenology and psychopatology, may contribute to reveal the underlying processes involved in bodily self-consciousness.

Academic procrastination and suicidality: A systematic review

I. Delgado[1]*, A. Criado[1], B. R. Merino[1] and J. Muñoz[1]
[1]Universidad Isabel I, Burgos, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2045

Introduction: Academic procrastination is the deliberate action of postponing the completion of academic tasks that must be completed, despite the harmful effects that not completing them may entail, having a particularly high prevalence in university students. Numerous studies have analyzed the consequences of academic procrastination on mental health. Furthermore, scientific evidence has also found a high prevalence of suicide risk in youth and adolescents. Therefore, it is worth asking if academic procrastination is related to the risk of suicide and self-harming behavior in students. To our knowledge, this is the first systematic review to analyze the relationship between academic procrastination and suicidality.
Objectives: To analyze 1) the relationship between academic procrastination and suicidal tendencies, 2) whether this relationship, if it exists, is influenced by other variables.
Methods: Academic Search Premier, APA PsycArticles, APA PsycInfo, PSICODOC, Psychology and Behavioral Sciences Collection, MEDLINE, E-Journals, ERIC and Scopus were searched during October 2024. An additional search was also conducted using the Google Scholar search engine. The review was carried out following the criteria of the PRISMA 2020 declaration. Observational studies that analyzed the relationship between procrastination and suicidality were included, without language or time restrictions. Single case studies or case series, studies examining procrastination in non-academic settings, and studies using qualitative methodology were excluded. Each study was narratively summarized.
Results: Ninety-three studies were identified; after eliminating duplicates and those works that did not meet the eligibility criteria, four studies were included for review. These studies varied in their origin (two articles from the United States, one from Spain, one from Peru, and one from Jordan) and the secondary variables evaluated. All studies found a positive and significant relationship between suicidality and academic procrastination (with correlation coefficients ranging from 0.19 to 0.51), observing a slightly higher correlation in women compared to men. Self-control was found to mediate the relationship between procrastination and suicidality.
Conclusions: Our findings suggest a strong positive relationship between academic procrastination and suicidality. However, there are still few studies that analyze this topic, so it is necessary to continue researching in this field.

EPV1535

A Complex Case of Feigned Psychosis or Hidden Truths? A Case Report

M. A. Dimitrov[1]* and P. McLaughlin[2]
[1]Psychiatry, St James Hospital and [2]Psychiatry, Central Mental Hospital, National Forensic Mental Health Service, Dublin, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2046

Introduction: Feigning is defined as "to represent falsely; to imitate so as to deceive" (McDermott et al. Int J Law Psychiatry 2013; 36:287-92). Malingering and dissimulation are subtypes of feigning: malingering involves intentionally producing symptoms for incentives (World Health Organization. ICD-11 2022), while dissimulation involves concealing symptoms to appear mentally well (Caruso et al. J Am Acad Psychiatry Law 2003; 31:444-50). The prevalence of feigning illness remains uncertain, and varies with context and incentives. Within the legal context, 17.5% feign incompetence to stand trial and 64.5% to plead not guilty by reason of insanity. Malingering has been reported in up to 56% of general offender samples (McDermott et al. Int J Law Psychiatry 2013; 36:287-92). In the public setting, the malingering prevalence constituted 30% of disability evaluations, 29% of personal injury evaluations, 19% of criminal evaluations and 8% of medical cases (Mittenberg et al. J Clin Exp Neuropsychol). In 2006, malingering resulted in approximately $150 billion in annual expenses for the US insurance industry (Mason et al. Perspect Psychiatr Care 2014; 50: 51-7).

Objectives: To explore the challenges in differentiating psychiatric illness from feigning.
Methods: This case involves analysing the patient's history, collateral information, and diagnostic interviews to distinguish psychiatric pathology from feigned symptoms.
Results: A 31-year-old male with a history of paranoid schizophrenia, whose recent psychiatric admission was prompted by psychosis and charges of serious assault, property damage, and possession of a weapon. The admission raised suspicions of symptom feigning and patient wariness of the psychiatric stigma. Despite four years of engagement with mental health services (MHS), the patient disclosed shortly after admission that he had been feigning his symptoms to obtain an insanity plea, but now hopes to return to prison seeking a more favourable environment and the certainty of a confirmed guilty sentence. Collateral information from the community MHS and family members suggested underlying psychiatric concerns and manipulative tendencies of the patient, complicating the diagnosis and raising the possibility of dissimulation.
Conclusions: The case highlights the challenges of distinguishing genuine psychiatric illness from deceptive behaviour, emphasizing the importance of thorough history-taking, understanding symptom pathology, using diverse interview techniques, gathering collateral information, and conducting psychological assessments. Clinicians must carefully distinguish feigning from true pathology to provide accurate diagnoses, ensure proper treatment, reduce costs, and safeguard public safety.

Rare Psychopathology Associated with Progressive Supranuclear Palsy (PSP) with Frontotemporal Dementia (FTD) Phenotype - A Case Report

S. Garg[1]*, O. Afroz[1] and V. Patil[1]
[1]Psychiatry, All India Institute of Medical Science, New Delhi, India
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2047

Introduction: Progressive supranuclear palsy (PSP) is a neurodegenerative disorder characterised by supranuclear ophthalmoplegia (SNO), parkinsonism, and postural instability. Overlap with frontotemporal dementia (FTD) has been suggested, with PSP-FTD considered a specific phenotype. Common psychiatric symptoms include apathy and depression, while hallucinations and delusions are rare. Hallucinatory palinopsia is the persistence or recurrence of vivid visual images after the stimulus has been removed. It results from aberrant activation of visual memory circuits, and, while uncommon, is typically seen in conditions such as strokes, space-occupying lesions and seizures.
Objectives: To present a case highlighting unique psychopathology in a patient with PSP-FTD phenotype.
Methods: Clinical case description and literature review.
Results: An 80-year-old male with a 6-year history of progressive behavioural changes, memory disturbances, and motor dysfunction presented initially with apathy and social withdrawal. Memory impairment and gait difficulties followed, along with irritability, aggression, and hypersexual behaviours like inappropriate touching or gesturing towards family members or masturbating in public. Asymmetric intention tremors (left > right) and stereotypic hand movements developed over time. In the past year, the patient began experiencing visual hallucinations, particularly hallucinatory palinopsia, where he persistently saw objects like lizards or water bottles that had been removed from view. These occurred in clear consciousness, were not perceived by others, and would typically last for about an hour. By a multidisciplinary approach, the possibility of delirium was ruled out. A diagnosis of PSP with FTD phenotype was made based on clinical evaluation, including SNO, and neuroimaging. The patient was started on Syndopa and Donepezil. Psychiatric evaluation revealed high scores in domains of Apathy, Disinhibition, Agitation, and Hallucinations on the Neuropsychiatric Inventory (NPI). Psychoeducation was provided, and Quetiapine 12.5 mg was initiated, leading to mild improvement in behavioural symptoms. The patient remains under regular follow-up with plans for medication optimization and physiotherapy inclusion.
Conclusions: Behavioural symptoms in PSP are prevalent and challenging to manage. This case highlights the importance of distinguishing between apathy and depression, as misdiagnosis can lead to unnecessary antidepressant use. The patient's presentation, including disinhibition, hypersexuality, and less commonly reported visual hallucinations, emphasises the need for comprehensive evaluation and a multidisciplinary approach to management in PSP-FTD cases.

Disclosure of Interest: None Declared

EPV1537

An unfrecuenty case of Auditory Charles-Bonnet syndrome

E. S. Gisbert[1]* and M. J. A. ABILDUA[1]
[1]PSYCHIATRY/NEUROLOGY, HOSPITAL UNIVERSITARIO INFANTA SOFIA, SAN SEBASTIAN DE LOS REYES, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2048

Introduction: In 1760, Charles Bonnet, a Genoese naturalist and philosopher, described the case of his grandfather, who experienced vivid, elaborate, and recurrent visual hallucinations and who also suffered from visual impairment. Bonnet himself later developed visual impairment and experienced similar symptoms. Since then, there have been multiple reports and cases in the European literature regarding this syndrome.
Objectives: Auditory Charles-Bonnet syndrome describes a rare condition presenting with sensorineural hearing loss, which can result in auditory-musical hallucinations in the absence of an acoustic stimulus. It has been reported in patients with diseases such as psychiatric disorders and organic brain diseases. However, the most common are idiopathic musical hallucinations that occur along with deafness in elderly people. Musical hallucinations that accompany hearing loss may reflect impaired brain function.
Methods: We present the case of a 84-year-old woman with a long-standing history of depression, who also presents mild bilateral pantonal sensorineural hearing loss with associated subjective tinnitus, without other associated somatic and/or psychiatric symptoms. In addition, a CT study of the head was performed which revealed severe fronto-temporal cortical atrophy.
Results: The treatment remains the subject of extensive research. Some authors have reported that hearing aids, antiepileptic drugs, benzodiazepines and antipsychotics can alleviate musical

hallucination, which in the case of our patient was eradicated, so the contribution of this case could enrich the current bibliography.
Conclusions: This is unfrecuently presentation of Charles Bonnet symdrom.

Disclosure of Interest: None Declared

Complexities of the Prodromal Phase of First-Episode Psychosis: A Longitudinal and Phenomenological Diagnostic Approach

A. Guiomar[1]*, C. P. Osório[1], P. M. Martins[1], P. Macedo[1] and M. de Barros[1]

[1]Psychiatry, Unidade Local de Saúde do Tâmega e Sousa, Penafiel, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2049

Introduction: A 26-year-old man presented with his first-episode psychosis (FEP) following a 15-month period marked by a progressive sense of estrangement from his surroundings, ideas of reference, persistent anxiety, difficulty focusing, and social withdrawal. Two years prior, he began stimulant treatment for suspected attention-deficit/hyperactivity disorder (ADHD), though he discontinued the medication shortly after, as he perceived no improvement. Over the past year, he became increasingly distant from friends and eventually resigned from his job. About three months before hospitalization, he began experiencing first-rank symptoms of schizophrenia. This case will serve as a starting point to discuss the complexities of diagnosing the prodromal phase of FEP.
Objectives: This clinical review aims to examine the phenomenology of the prodromal phase of FEP and address the diagnostic challenges posed by symptom similarities between this phase and neurodevelopmental conditions like ADHD.
Methods: A literature review was conducted using the PubMed database, covering studies from the past 20 years. Studies were selected if they included phenomenological descriptions of the prodromal phase in FEP and/ or examined the impact of neurodevelopmental conditions on the emergence of psychosis.
Results: The review identified several key phenomenological markers characterizing the prodromal phase of FEP, which can aid in distinguishing it from other psychiatric conditions. The prodromal phase of FEP is frequently marked by subtle but progressive alterations in cognition, perception, and affect, including experiences such as derealization-depersonalization, ideas of reference, paranoid ideation, and social withdrawal. Evidence suggests that prodromal symptoms intensify over time, evolving from vague unease to specific disruptions in reality testing. Although ADHD and the prodromal phase of a FEP may share some overlapping characteristics - particularly when symptoms are assessed in a cross-sectional manner - ADHD symptoms are generally regarded as stable traits that persist consistently into adulthood.
Conclusions: This case underscores the need for careful differential diagnosis, especially when evaluating individuals in high-risk age groups for psychosis who present with subtle symptoms that do not clearly fit a single diagnostic category. In such cases, clinicians should avoid premature conclusions and instead adopt a longitudinal and comprehensive approach, considering whether genetic, neurodevelopmental, or social risk factors may be contributing to the presentation. A phenomenological perspective can help clinicians detect subtle yet significant shifts in perception, cognition, and affect, enhancing diagnostic accuracy and enabling timely intervention.

EPV1541

A literature review of first-episode psychosis, a perspective on the future

M. C. Herrero Rodriguez[1]*, Z. Martin García[1], C. Vall García[1] and J. M. Martínez Sánchez[1]

[1]Psychiatry, Río Hortega University Hospital, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2050

Introduction: First-episode psychosis is one of the major challenges of mental health research worldwide because it is a traumatic experience for patients and their families. Patients who experience these episodes may experience fear, distress, and isolation.
Objectives: The early phase of psychosis is a critical period when long-term outcome is predictable and biological, psychological and psychosocial influences are developing and display maximal plasticity. This phase presents important opportunities for secondary prevention and delaying treatment may affect the chance of recovery. The main goal is to reduce the duration of untreated psychosis and ensure that, in addition to symptom remission, there is also psychosocial recovery. Currently, the clinical and research focus in psychotic disorders has shifted toward first episode psychosis, early detection of the prodromal phase of psychosis, and an effective integrated treatment model known as "Early Intervention."
Methods: Selective review of the literature on first episode psychosis.
Results: The studies strongly support the efficacy of antipsychotic medication as both acute and maintenance treatment for patients with a first episode of psychosis.
Conclusions: Early intervention may improve outcomes in first episode psychosis. The use of new antipsychotics with greater efficacy and fewer side effects may improve medication adherence and reduce morbidity associated with repeated relapses. However, the optimal duration of maintenance treatment has not been determined and a long duration of untreated psychosis may be associated with a poorer treatment response. Finally, services for Early Intervention should be easily accessible, non-threatening and non-stigmatising.

Does negative voice content enhance strong priors and conditioned hallucinations?

C. Jacquet[1]*, C. Dondé[2,3] and C. Bortolon[1,4,5]

[1]38000, Univ. Grenoble Alpes, Univ. Savoie Mont Blanc, LIP/PC2S; [2]38000, Centre Hospitalier Universitaire Grenoble Alpes, GIN, Grenoble; [3]38120, Centre Hospitalier Alpes Isère, Saint-Egrève; [4]Institut Universitaire de France, Paris and [5]38000, C3R – Réhabilitation psychosociale et remédiation cognitive, Centre Hospitalier Alpes Isère, Grenoble, France

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2051

Introduction: Auditory Hallucinations (AH) can be distressing experiences lived by clinical samples but can also be observed in the general population. Predictive Coding Theories of AH argue that when strong priors are favoured over sensory input, AH would emerge. Powers and collaborators (2017) and Benrimoh et al. (2024) have employed the Conditioned Hallucinations task (CHT) to demonstrate that strong priors were linked to AH. In the CHT, conditioned hallucinations (CH) were created using tones, which neglects the fact that most patients describe AH as verbal and characterised by negative content. Consequently, little is known about the effect of the nature (i.e., verbal) and valence of the AH within the Predictive coding framework of hallucinations. More specifically, the role of emotional voice content in CH has not been explored.
Objectives: Thus, our goal is to replicate and expand these results by manipulating the content valence of voices in the CHT. This will allow us to test a possible interaction effect of voice content and the proneness to AH on the rise of CH.
Methods: We will recruit 400 French participants from the general population presenting different levels of proneness to AH. Participants will undergo an adapted version of the CHT with two different blocs where either negative or neutral voice content will be presented. Following Powers et al. (2017), for both the negative and neutral conditions, participants will undergo a QUEST maximum-likelihood-based procedure to derive individual thresholds. After, they will complete 12 blocs, during which the number of signals present and their volume will decrease. A no-signal condition will also be presented. The speech presented will be French translation of Baumeister et al. (2022) stimuli. They were created to simulate verbal AH. Since some voice content resemble inner dialogue, we will measure the inner dialogue forms of participants through the Forms of Self-Criticizing/Attacking & Self-Reassuring Scale. Hallucination proneness will be measured through the Launay and Slade Hallucination Scale Extended we modified. Our local ethical committee approved this study following the Helsinki and APA principles.
Results: We are currently collecting data and are not able to communicate any results at this time. Data collection should be done by April 2025. Our data will be analyzed through the signal detection theory, a logistic regression on the probability of saying a signal is present and through Hierarchical Gaussian Filter Analysis.
Conclusions: A better understanding of the mechanisms behind AH and the role of emotions will help us improve predictive coding theories of AH that can also used to improve interventions targeting them.

EPV1543

Cognitive control and adaptive responding in patients with Attention Deficit Hyperactivity (ADHD) and Autism Spectrum Disorder (ASD)

B. Kakuszi[1]*, I. Bitter[1] and P. Czobor[1]

[1]Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2052

Introduction: Deficits of cognitive control and performance monitoring play a critical role in the psychopathological manifestations of ADHD and ASD. However, relatively few studies have used a transdiagnostic approach to examine deficits in cognitive control and performance monitoring deficits across diagnostic boundaries.
Objectives: Using a transdiagnostic approach, we examined post-error slowing (PES), a principal measure of cognitive control and adaptive behavior, in subjects with ADHD and ASD compared to typically developing (TD) subjects. We also investigated the signal detection ability in the three study groups using the d-prime index, which characterizes the observer's ability to select the right stimuli while avoiding the wrong ones based on the commission and omission errors.
Methods: Participants included adults (18-65 years) with the DSM-IV diagnosis of ADHD (n=22) or ASD (n=24), as well as TD subjects (n=25). We used pictures from the International Affective Picture System as stimuli, displayed in random sequence. Stimuli were shown centrally every 1400 msec for 800 msec. A total of 243 stimuli were shown in two blocks (negative, positive & neutral pictures with equal probability). Subjects were asked to push a button as soon as possible upon appearance of the stimulus pictures (Go trials); they were, however, asked not to respond if a picture was repeated (NoGo trials). Generalized Linear Model (GENMOD) analysis was used to test post-error slowing (decrease of reaction time after an error) and the d-prime index, applied as dependent variables in the analyses. Study group (ADHD, ASD, TD) was used as independent variable.
Results: The analysis indicated a significant ($p<0.05$) overall group difference in PES among the three study groups. Post-hoc analyses showed that as compared to TD subjects, patients with ADHD manifested a markedly increased PES (˜70msec, $p<0.05$), while subjects with ASD showed no significant change. Additionally, we found a significantly reduced value for the d-prime index in both the ADHD and ASD groups as compared to TD subjects, with no difference between the ADHD and ASD group.
Conclusions: While the reduction of signal detection ability was similar in the ADHD and ASD groups, subjects with ADHD and ASD showed a distinctive profile of post-error adjustment in a behavioral response inhibition task. While patients with ADHD show decreased inhibition and fail to make the adjustment that TD subjects make (as indicated by the decreased PES in ADHD), adults with ASD showed intact behavioral reactions after errors (i.e., with post-error slowing reactions similar to that observed in TD subjects).

The Impact of Parent-Child Relationships on Mental Health in Adulthood

N. Kissa[1]*, A. Korchi[1], N. Ait Bensaid[1], H. El Majdoub[2] and A. Ouanass[2]

[1]University psychiatric hospital Arrazi and [2]University Psychiatric Hospital Arrazi of Salé Faculty of Medicine and Pharmacy – Mohammed V University of Rabat, Salé, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2053

Introduction: Parent-child relationships significantly influence psychological and social development, with lasting effects on mental health. Warm and supportive relationships are linked to higher emotional well-being, while neglectful or strict parenting increases the risk of mental disorders [1]. Even non-abusive but conflictual relationships can raise the risk of psychological issues in adulthood [2][3], and stable family bonds contribute to resilience in facing life challenges [4][5].
Objectives: This study aims to explore and assess the impact of parent-child relationships on mental well-being in adulthood.
Methods: This study uses a Google Forms questionnaire with six sections to assess the impact of parent-child relationships on mental well-being in adulthood. Univariate analysis was conducted in Excel, and multivariate analysis, including a logistic regression model, was performed in R Studio to measure this impact.
Results: Approximately 65% of participants who reported a warm parental relationship exhibit high mental well-being in adulthood. In contrast, 45% of those who experienced frequent parental conflicts report symptoms of psychological disorders. Among participants who experienced neglect in their parental relationships, 55% developed signs of anxiety in adulthood, while 40% show increased resilience to challenges when family relationships during childhood were stable and secure
Conclusions: The parent-child relationship plays a crucial role in mental health in adulthood. Warm and stable relationships are associated with increased emotional well-being and better resilience in facing challenges. In contrast, relationships marked by neglect or conflict increase the risk of long-term psychological disorders. These findings highlight the importance of the family environment for psychological development and the prevention of mental health issues.

Exploring one-year mental health outcomes in a cohort of severe COVID-19 survivors: a focus on depressive and anxiety symptoms

H. Salgado[1,2], S. Martins[2,3]*, L. Fontes[4], A. R. Ferreira[2,3], I. Coimbra[4], A. Braga[4], J. A. Paiva[4,5] and L. Fernandes[1,2,3]

[1]Psychiatry Service, Unidade Local de Saúde São João, Porto.; [2]Department of Clinical Neurosciences and Mental Health, Faculty of Medicine, University of Porto.; [3]Center for Health Technology and Services Research (CINTESIS@RISE), Faculty of Medicine, University of Porto.; [4]Intensive Care Medicine Department, Unidade Local de Saúde São João, Porto and [5]Department of Medicine, Faculty of Medicine, University of Porto, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2054

Introduction: The COVID-19 pandemic has evolved into substantial mortality and morbidity worldwide, with 5-8% of patients requiring intensive care. Years after the emergence of COVID-19, there is a heightened interest about the Long COVID, a heterogeneous condition characterized by persistent or emergent symptoms that last for weeks or months after patient's recovery from acute infection, with a negative impact on physical and mental health. Research indicates that depression and anxiety often co-occur and may serve as predictors for Long COVID. Given the scale of the pandemic, even a small proportion of patients with long-lasting symptoms will create a significant health burden. Therefore, gathering data on the long-term evolution and outcomes of these patients is of utmost importance.
Objectives: To identify depressive and anxiety symptoms in severe COVID-19 survivors 1-year after discharge and to analyse their association with sex, age and fear of recurrence and sequelae of COVID-19.
Methods: The cohort analysed is part of MAPA research project and includes adult patients admitted due to COVID-19, in an Intensive Care Medicine Department of a University Hospital in Portugal. Participants were evaluated 1-year after discharge to home with a comprehensive protocol, which included Patient Health Questionnaire (PHQ-9; depressive symptoms), General Anxiety Disorder scale (GAD-7; anxiety symptoms) and a brief questionnaire about fear of recurrence and sequelae of COVID-19.
Results: The final sample (n=159) had a mean age of 62.2 years and mostly (69%) was male. About 19% and 21% of survivors scored for depressive and anxiety symptoms, respectively. Both symptoms were significantly more prevalent among younger participants ($p=0.031$; $p<0.001$) and were associated with fear of recurrence ($p=0.002$; $p=0.009$) and sequelae ($p=0.001$; $p<0.001$) of COVID-19 1-year after discharge.
Conclusions: Overall, there is a significant prevalence of anxiety and depressive symptoms among COVID-19 survivors 1-year after discharge. These findings emphasize the need for greater attention to these symptoms in this population, since its recognition and treatment can improve quality of life and reduce symptoms in the long term, especially in younger patients.

Exploring Auditory Hallucinations in Congenital Deafness and Subvocal Articulation Hypotheses – a Case Report

R. A. Moreira[1]*, M. Marinho[2] and J. Justo[1]

[1]Psiquiatria, Unidade Local de Saúde do Nordeste, Bragança and [2]Psiquiatria, Unidade Local de Saúde do Santo António, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2055

Introduction: One of the main symptoms of schizophrenia is auditory hallucinations. Although reliable epidemiological data is limited, the prevalence of schizophrenia among the deaf community seems to be about the same as in the general population. Approximately 50% of deaf individuals diagnosed with schizophrenia report 'hearing' voices or experiencing the sensation of communication in the absence of external input. Minimal information is available regarding the perceptual aspects of voice hallucinations in congenitally deaf individuals.
Objectives: With this case report, we aim to describe auditory hallucinations in a patient with congenital deafness and discuss auditory hallucinations in deaf individuals. We will also examine

how these phenomena may fit into explanatory subvocal articulation hypotheses, providing insights into language modality and auditory deprivation.
Methods: Description of a clinical case of a deaf patient with auditory hallucinations in a psychiatric outpatient consultation.
Results: The authors report a case of a 26-year-old male patient with congenital deafness and no prior psychiatric or relevant medical history. He communicated preferably by sign language and also by lip reading. The consultation was realized with the presence of a sign language interpreter. The patient was referred to a psychiatric outpatient appointment due to a 1-year history of bizarre behavior, social isolation, and apparent psychotic symptoms. He lived with his parents and was currently unemployed. According to his mother and brother, he "spoke and laughed alone, like he was talking with someone". In his mental status examination, he presented a religious delusion and likely auditory hallucinations. He had no changes in his physical and neurologic examination. Blood tests, urinalysis, and urine screening for drug abuse were performed, with normal results. Computed tomography of the brain and an electroencephalogram were also performed, with no significant changes. Over time, the patient was diagnosed with schizophrenia and was medicated with paliperidone with remission of his symptoms.
Conclusions: These findings highlight how auditory hallucinations in congenitally deaf individuals offer a unique view of the interplay between sensory perception and the experience of 'voices.' The subvocal articulation hypothesis suggests that auditory hallucinations may arise from disruptions in inner speech mechanisms—subtle, unconscious movements that the brain misinterprets as external voices. In deaf individuals, this experience may manifest through sensory feedback loops adapted to visual modalities, such as the perception of sign language movements, rather than through purely auditory sensations. This shows how language and sensory experiences shape hallucinations, emphasizing the need to consider sensory differences in psychotic symptoms across populations.

doi: 10.1192/j.eurpsy.2025.2056

Introduction: Health Related Quality of Life (HRQOL) is a key outcome in the treatment of patients with psychosis. It is considered Patients should assess their HRQOL through PROMs. This subjective assessment could be combined with other sources of information
Objectives: The aims of the present study are to evaluate HRQOL and other related variables in a sample of Spanish schizophrenia spectrum patients, who start treatment in a Rehabilitation Unit and to evaluate if there are improvements in HRQOL and in these variables after receiving a rehabilitation treatment
Methods: A sample of 127 of schizophrenia or schizoaffective disorders patients were included in the study (Table 1). These patients started a multi-professional treatment in a Rehabilitation Service. Patients have been evaluated twice – at the beginning and treatment end. Patients have assessed their general and specific HRQOL with the EUROQOL-5D-5L and SQLS-R4 scales. Professionals have evaluated main symptoms of psychosis SSPI, general functioning (objective QOL) PSP and basic and instrumental Daily activities VAVDI. Frequencies in the demographic, clinical and questionnaire scores were calculated. Changes in the questionnaires between the two assessments (Wilcoxon and Chi Square tests) (Table 1).
Results: HRQOL scores were moderate in the EQ-5D-5L health and SQLS-R4 factors and total score (M=37.9; ST=20.9) in the first assessment, and high in the EQ-5D-5L value. The PSP score (objective QOL) at the first assessment shows notable difficulties. Significant changes HRQOL improvement were found in the EQ5D5L health, in the SQLS-R4 factors and total score (effect size range between .35-.39 small effect). General functioning (PSP) scores improved (effect size .68, middle effect) and Daily activities (0.34 small effect). A significant reduction in symptoms was observed in the total SSPI score, especially in negative symptoms, and anxiety/depression, with the effect size being particularly large (Table 2).

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2057

Introduction: In the last decades, research has focused on investigating cognition and psychopathological symptoms as variables contributing to functional outcomes. However, in recent years the study of motivation has attracted interest as a research target related to functional outcome (Miley *et al* Psychol Med. 2023;53 (5):2041-2049).

Objectives: We aimed to study the relationship of clinical symptoms, motivation, socio-affective capacity and cognition with functioning in social and occupational areas in patients with a psychotic disorder.

Methods: A sample of 97 patients with a DSM-5 psychotic disorder diagnosis was included. Assessments included the Specific Levels of Functioning Scale (SLOF; Schneider *et al.* Soc Work Res Abstr 1983;19(3):9-21) to assess functioning; the Comprehensive Assessment of Symptoms and History (CASH; Andreasen *et al.* Arch Gen Psychiatry 1992; 49(8):615-23) for clinical symptoms; and the Cognitive Assessment Interview (CAI-Sp; Ventura *et al.* Schizophr Res 2010; 121(1-3): 24-31) and a comprehensive neuropsychological battery to assess cognition. Motivation and socio-affective capacity were assessed by means of the Quality of Life Scale (QLS; Heinrichs *et al.* Schizophr Bull. 1984; 10(3):388-98). Both domains were derived from items of the Intrapsychic Foundations subscale of the QLS. Motivation was derived from items 13, (sense of purpose), 14 (degree of motivation) and 15 (curiosity). Socio-affective capacity comprised items 20 (capacity for empathy) and 21 (capacity for engagement and emotional with the interviewer). Spearman correlations were calculated. Variables which correlated significantly ($p<0.05$) with SLOF scores were included in the regression analyses.

Results: All the clinical, cognitive and related with motivation and socio-affective capacity variables included in the analyses were significantly correlated with SLOF scores (Table 1), except for positive symptoms with SLOF activities and work. However, in the hierarchical analyses most of the variables were not significant. Specifically, regarding SLOF social scores, positive symptoms and motivation explained 51.5% of the variance. Motivation also explained 40.1% and 68% of the variance of the scores of SLOF activities and work, respectively (Table 2).

Image:

Table 1. Non-parametric correlations between SLOF scores and clinical, motivation and cognition scores.

	SLOF social	SLOF activities	SLOF work
Positive symptoms	-.27**	-.12	-.03
Negative symptoms	-.56**	-.57**	-.61**
Disorganized symptoms	-.31**	-.28**	-.26*
Motivation	.66**	.76**	.79**
Socioaffective capacity	.56**	.51**	.51**
CAI patient	-.16	-.23*	-.35**
CAI family	-.39**	-.47**	-.59**
CAI rater	-.38**	-.48**	-.60**
Global cognition index	.31**	.38**	.47**

* p<0.05; ** p<0.001
SLOF: Specific Levels of Functioning; CAI: Cognitive Assessment Interview

Table 2. Hierarchical regression models of functioning.

	Variables in the model	β	t	R^2 adjusted	p
SLOF social	Positive symptoms	-1.17	-2.75	0.515	0.008
	Motivation	0.41	2.19		0.034
SLOF activities	Motivation	0.68	3.03	0.401	0.004
SLOF work	Motivation	0.93	5.15	0.68	<0.001

SLOF: Specific Levels of Functioning

Conclusions: Motivation has a great value as a predictor factor in social, activities and work functioning. Therefore, motivation should be considered as a target related to improving functioning in early intervention programmes for psychotic disorders.

EPV1551

Auditory variant of Charles Bonnet Syndrome: A review of two clinical cases

J. Santilari Planas[1]*, J. Tortajada Valero[1,2,3] and E. García González[1]
[1]Institut Pere Mata; [2]CIBERSAM and [3]Institut d'Investigació Sanitaria Pere Virgili, Reus, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2058

Introduction: Charles Bonnet Syndrome (CBS) is characterized by complex hallucinations in patients with sensory impairment. The World Health Organization in 2018 outlined the diagnostic criteria for CBS as follows: complex visual hallucinations; partial or complete vision loss; and absence of mental disorders (Dhooge Patty et al. AES 2022;7:12). Notably, auditory hallucinations are excluded from this definition, and recent reviews argue that CBS should not encompass sensory or auditory hallucinations (Rojas LC, Gurnani B. StatPearls 2024). Although their frequent association with psychotic disorders, a broad differential diagnosis is crucial given the diverse etiologies. Recently, there has been growing literature of cases of auditory hallucinations which were only explained as a CBS.
Objectives: The work aims to explore and discuss the auditory variant of Charles Bonnet Syndrome (CBSa).
Methods: Based on two clinical cases, we conducted a literature review on this topic using PubMed database.
Results: We describe two patients with severe sensorineural hearing loss and auditory hallucinations. The first patient, a 95-year-old independent in daily activities, presented with sudden-onset external voices. The second, an 81-year-old institutionalized woman, exhibited musical auditory hallucinations that developed over several months. Both patients maintained insight into the unreality of their hallucinations.
Comprehensive evaluations ruled out other potential causes, including neurological, psychiatric, pharmacological, and toxic-metabolic origins. Given the symptoms and and the exclusion of alternative diagnoses, CBSa was determined as the underlying cause.
The course of CBSa is known to be variable; hallucinations may diminish or resolve spontaneously or when the hearing deficit is ameliorated. Therefore, management is directed toward addressing the primary cause. No standardized treatment exists; however, medications such as antipsychotics, antidepressants, or antiepileptics may alleviate symptoms (Perez PA et al. Open Neurol J 2017 Feb 28;11:11-14). In our cases, both patients were treated with risperidone at 1 mg/24h, resulting in good tolerance and complete resolution of symptoms.
Conclusions: Despite the absence of definitive diagnostic criteria for CBS, it is predominantly associated with visual hallucinations without concomitant neurological or psychiatric pathology, excluding auditory manifestations. However, if patients experience hallucinations in non-visual sensory modalities while retaining insight into their unreality, they should not be excluded from a CBS diagnosis. Recent case studies support the existence of such variants.
This paper advocates for the refinement of CBS diagnostic criteria to encompass these additional manifestations. Expanding these criteria could enhance psychiatric epidemiology by addressing the current underestimation of CBS prevalence and improving the recognition and management of this condition.

Self-disorders in schizophrenia spectrum disorders

I. M. M. Soerensen[1]*, J. Nordgaard[1], I.-M. Moelstroem[2], R. Handest[2], A. R. Rasmussen[2], K. E. Sandsten[2] and J. Thalbitzer[2]
[1]Psychiatry Region Zealand, University of Copenhagen, Roskilde and [2]University of Copenhagen, Copenhagen, Denmark
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2059

Introduction: The term *self-disorder* investigated in this study refers to a disorder of the minimal self. It is a disturbance at the basic pre-reflective level typical in schizophrenia spectrum disorder, These disturbances are often present in the prodromal face of schizophrenia.
In 2003 Sass and Parnas proposed the ipseity-disturbance model (*ipseity also sometimes termed minimal self, basic self, experimental self, and for-meness).* Since 2003 Parnas and colleagues have published EASE (Examination of anomalous Self-experience): a semi-structured interview guide to allow for a systematic, qualitative and quantitative assessment of self-disorders.
The EASE-scale consist of a checklist of 57 items divided into 5 domains: 1) Cognition and Stream of Consciousness, 2) Self-Awareness and Presence, 3) Bodily Experiences, 4) Demarcation/Transitivism and 5) Existential Reorientation. The domains serve to structure the interview and to aid the interviewer to navigate and cover all 57 items during the interview.
In the last 20 years, several studies using EASE have supported self-disorders to be a central psychopathological feature of schizophrenia. A systematic review from 2021 showed that self-disorders hyper-aggregate in schizophrenia spectrum disorders but not in other mental disorders. However, self-disorder aggregation and distribution in between schizophrenia spectrum disorders have not been investigated before.
Objectives: The purpose of this study is to compare overall EASE-sums in types of schizophrenia spectrum disorders including subtypes of schizophrenia (ICD10).
We hypothesize that there will not be a significant difference in overall EASE-score, reflecting self-disorder to be a core disturbance in schizophrenia spectrum disorders.
Furthermore, we plan to perform explorative statistical analysis on item-level of the EASE-scale, to investigate whether self-disorders presents differently and characteristically in-between schizophrenia spectrum disorders.
Methods: Data is pooled from 6 different studies, totaling 236 patients.
All patients were examined using the EASE-guide by a professional clinicians who were trained in the semi-structed EASE-interview. The patients were furthermore assessed thoroughly for psychopathology and diagnosed according to ICD10 and DSM-IV or V.
Results: Ongoing
Conclusions: Ongoing

Disclosure of Interest: None Declared

Auditory Verbal Hallucinations in Schizophrenia and Bipolar Disorders

J.-E. Yttri[1,2*], A. Urfer-Parnas[2,3], S. M. Arnfred[1,2] and J. Parnas[2,4,5]

[1]Psychiatry Vest, Mental Health Service Region Zealand, Slagelse; [2]Faculty of health and medical sciences, University of Copenhagen; [3]Psychiatry in the Capital Region of Denmark, Mental Health Centre Amager; [4]Psychiatry in the Capital Region of Denmark, Mental Health Center Glostrup and [5]University of Copenhagen, Center for Subjectivity Research, Copenhagen, Denmark

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2060

Introduction: Auditory verbal hallucinations (AVH) are prevalent in schizophrenia but also occur in bipolar disorder, yet differences in their phenomenology remain poorly understood. This ongoing study aims to fill this gap by comparing the phenomenological characteristics of AVH in schizophrenia and bipolar disorder.

Objectives: The research questions we are interested in are:

- The nature of hallucinations. We hypothesize that hallucinatory experiences in bipolar disorders is connected to the mood, for example mania.
- We hypothesize that auditive verbal hallucinations in bipolar disorders will not have the immanent character as in schizophrenia and won't be experienced in a pathologically altered private space.
- We hypothesize that bipolar patients after a remission from the episode will consider their voices as a sign of disease whereas the patients with schizophrenia will continue to ascribe extraordinary meanings to their hallucinations.

Methods: Building on our prior research in schizophrenia, we are conducting semi-structured, phenomenologically oriented qualitative interviews with patients diagnosed with bipolar disorder who experience AVH. Participants are recruited from outpatient clinics and hospital wards in Denmark. Data will be analyzed using thematic analysis with a bottom-up approach.

Results: Preliminary findings from our ongoing study will be presented.

Conclusions: A deeper understanding of AVH phenomenology in schizophrenia and bipolar disorder can lead to more accurate differential diagnoses, reducing the risk of misdiagnosis and ensuring that patients receive appropriate and timely treatment.

Bariatric Surgery and Its Implications on Pharmacokinetics in Patients with Mental Illness: A Literature Review

O. Alli-Balogun[1*], K. Jafari[1], U. Anyeji[1] and S. Gunturu[1]

[1]Psychiatry, Bronxcare Health System, New York, United States

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2061

Introduction: Obesity has reached epidemic proportions globally, significantly increasing the risk of cardiovascular diseases, diabetes, and various cancers. In the United States, as of 2017-2018, the prevalence of obesity among adults was approximately 42.4% (CDC, 2020). Worldwide, over 650 million adults were obese in 2016 (WHO, 2020).

Bariatric surgery, which includes a variety of procedures aimed at weight loss, While these surgeries primarily aim to induce weight loss and improve metabolic health, they also present challenges for patients taking psychotropic medications, such as antidepressants, antipsychotics, and mood stabilizers.

Objectives: Understanding the Impact of Bariatric Surgery on Psychotropic Medication Management

1. Changes in Pharmacokinetics: Bariatric surgery can significantly alter the absorption, distribution, metabolism, and elimination (Smith et al., 2018).
2. Drug Interactions:Post-surgery changes in gastrointestinal physiology can impact drug interactions and the efficacy of psychotropic medications. (Alvarez et al., 2020).
3. The need for Monitoring and Dosing Adjustments:
4. Understanding Nutrient Deficiencies: can lead to deficiencies in essential nutrients like vitamin B12, vitamin D, iron, and calcium, which can exacerbate psychiatric symptoms or affect the metabolism of psychotropic medications (Courcoulas et al., 2020).

Methods: A thorough literature review was carried out, with emphasis on research done within the the last 5 years.

Results: On thorough reiew of literature, better outcomes resulted from implementing the following

1. Individualized Monitoring: Regular assessment of weight loss, nutritional status, and psychiatric symptoms can inform dosage adjustments to maintain therapeutic efficacy (Zachariah et al., 2015).
2. Consideration of Formulations: Immediate-release formulations may ensure consistent absorption and therapeutic effects due to altered gastrointestinal transit times (Lopez-Nava et al., 2017).
3. Collaborative Care:A multidisciplinary team, including bariatric surgeons, psychiatrists, pharmacists, and dietitians, can optimize medication regimens and address nutrient deficiencies (Smith et al., 2018).

Also considered the Benefits of Long-Acting Injectable (LAI) Psychotropics Post-Bariatric Surgery which improved the following

Conclusions: Post Bariatric surgery,Clinicians must carefully monitor medication efficacy, adjust doses as needed, and manage nutrient deficiencies to ensure optimal mental health outcomes. Ongoing research and multidisciplinary collaboration are essential to refining guidelines and improving the long-term management of these complex patient populations. By integrating personalized care strategies and considering LAI formulations, healthcare providers can optimize treatment outcomes for patients undergoing bariatric surgery.

Comparative study of relapses in Severe Mental Disorder among the different long-acting injectable treatments available on the market

P. Andres-Olivera[1,2*], F. Prieto-Flores[3], J. de la Iglesia[1,2], E. Dominguez-Alvarez[1], C. P. Rodriguez[4], C. Munaiz-Cossio[4], R. K. Gonzalez-Bolaños[4], R. Brito-Rey[4] and C. Marín-Lorenzo[4]

[1]Psichiatry, CAUSA; [2]Medicine; [3]USAL and [4]CAUSA, Salamanca, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2062

Introduction: Schizophrenia affects approximately 1% of the population aIts treatment is mainly based on antipsychotics, although therapeutic non-compliance is common due to lack of illness insight and side effects. Long-acting injectable antipsychotics emerged as an alternative to improve treatment adherence. This study investigates relapses in patients with severe mental illnesses treated with long-acting injectable antipsychotics, originating from the province of Salamanca.
Objectives: To evaluate and compare the efficacy of different long-acting injectable treatments available in the market in preventing relapses in patients with Severe Mental Disorder (SMD), through retrospective analysis of epidemiological, clinical, and treatment data obtained from electronic medical records.
Methods: This is an observational, retrospective, and comparative study using anonymized data extracted from electronic medical records of patients diagnosed with Severe Mental Disorder (SMD) who have been treated with Long-Acting Injectable (LAI) medications. The study period covers from January 2018 to December 2022.
Results: The study contains information from 161 patients, with a uniform distribution by age and sex. The main group presents psychotic disorders (74.5%), followed by bipolar disorder (18%). Monthly Long Acting aripiprazole is the most used injectable antipsychotic (39.8%). Side effects were recorded, such as extrapyramidal symptoms (11.9%) and sexual dysfunction (8.8%). Antipsychotic switching occurred in 19.5% of patients. The absence of relapses was higher for six-month long-acting paliperidone palmitate (80%) and lower for Monthly Long Acting aripiprazole (69.4%), a survival analysis was performed using the Kaplan-Meier method.
Conclusions: The comparative study reflects that, although Abilify Maintena was the most used, no significant differences were found in relapse prevention among different treatments. Survival analysis also did not yield conclusive results. Although the study has some limitations, such as a small sample size and missing data in some medical records, it provides a starting point for future research. Despite the limitations of this study due to the small sample size and lack of statistically significant results regarding the efficacy of injectable antipsychotics, the study provides information on the use of these treatments in patients with Severe Mental Disorder. Although Monthly Long Acting aripiprazole was the most used, side effects do not seem to be related to its efficacy. The results suggest that there are no significant differences between long-acting injectable antipsychotics available in the market. However, it is important to note the significance of this research topic for the future, given its clinical implications.

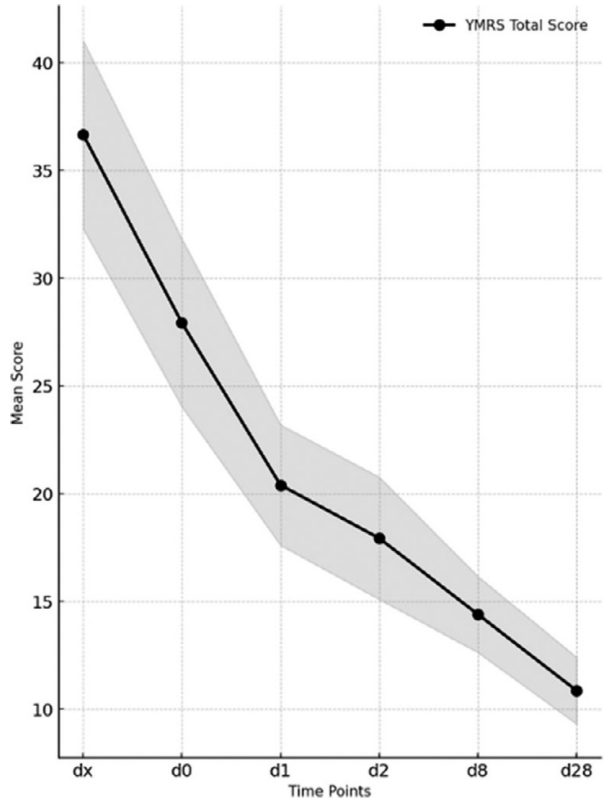
Risperidone ISM Long-Acting as a Possible Treatment for Manic Episodes in Nonadherent Patients with Schizoaffective Disorder

G. Barilla'[1]*, A. Cuomo[2], D. Koukouna[2], C. M. Borgese[1], A. Gallo[1], R. Larcinese[1], C. Venco[1], D. Bussolotti[1] and A. Fagiolini[2]
[1]U.O. Psichiatrica Mantova 1, ASST-Mantova, Mantova and [2]Molecular Medicine, University of Siena, Siena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2063

Introduction: Risperidone In Situ Microimplants (ISM®), a novel long-acting injectable (LAI) antipsychotic, rapidly achieves therapeutic plasma levels, with a significant first plasma peak occurring at 48 hours. This rapid onset of action, without the need for oral supplementation or loading doses, offers a promising new approach for effective management of acute symptoms (Walling et al. Drug Des Dev Ther 2021;15 4371-4382).
Objectives: To evaluate the efficacy and safety of risperidone ISM (R-ISM) in the treatment of acute manic episodes with psychotic symptoms, focusing on symptom change over time.
Methods: This preliminary and retrospective study included 15 inpatients with schizoaffective disorder who were started on R-ISM during a manic episode. RISM was administered after 6 days of oral risperidone. We retrospectively examined the Young Mania Rating Scale (YMRS) scores obtained in routine clinical practice at baseline (Dx), on the day of inpatient admission, on the day of injection (D0) and then 24 hours (D1), 48 hours (D2), 7 days (D8) and 28 days (D28) after the injection.
Results: A statistically significant improvement in the total YMRS score was observed as early as the day of injection, with the median score decreasing from 37 [IQR: 4.5] at baseline to 27 [IQR: 2.5] at D0 and further to 20 [IQR: 4] at 24 hours after the injection 1 (D1) ($p < 0.01$). The improvement remained statistically significant at all assessment time points, reaching 11 [IQR: 1.5] at day 28 (D28) (*see Image 1*).
Single-item analysis showed rapid and significant improvement across all YMRS items, in particular the following symptoms (*see Image 2*):

- *Irritability:* Significantly decreased from a score of 6 [IQR: 0] at baseline to 3 [IQR: 0.5] at D1 and to 1 [IQR: 0.5] at D28 ($p < 0.01$).
- *Disruptive-Aggressive Behavior:* Significantly decreased from a score of 3 [IQR: 2] at baseline to 1 [IQR: 1] at D1 and to 0 [IQR: 1] at D28 ($p < 0.01$).
- *Sleep Disturbances:* Significantly decreased from a score of 3 [IQR: 1] at baseline to 0 [IQR: 0.5] at D28 ($p < 0.01$).
- *Speech (Rate and Amount):* Significantly decreased from a score of 4 [IQR: 1] at baseline to 1 [IQR: 0] at D28 ($p < 0.01$).
- *Content (Delusions; Hallucinations):* Significantly decreased from a score of 6 [IQR: 0.5] at baseline to 3 [IQR: 1] at D28 ($p < 0.01$).
- *Insight:* Significantly decreased from a score of 3 [IQR: 2] at baseline to 2 [IQR: 1] at D28 ($p<0.01$).

Image 1:



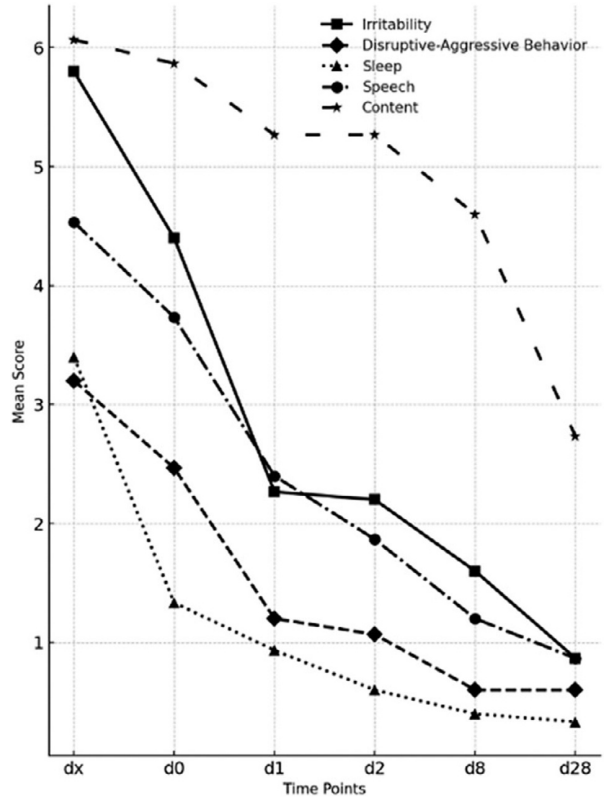


Image 2:

Conclusions: This preliminary and retrospective study suggests the possible efficacy of risperidone ISM (approved for schizophrenia) for acute manic episodes. However, due to the retrospective design of the study, the small sample size, and the presence of concomitant treatments, the results are primarily exploratory and no conclusions can be drawn until prospective, randomized, placebo-controlled trials are conducted.

Pharmacological Interventions in the Management of Antipsychotic-Induced Metabolic Disturbances

J. Barreira[1]* and S. Macedo[1]

[1]Psychiatry and Mental Health, Unidade Local de Saúde do Tâmega e Sousa, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2064

Introduction: Antipsychotic medications, particularly atypical antipsychotics, are commonly associated with metabolic side effects such as weight gain, dyslipidemia, and insulin resistance. These disturbances significantly increase the risk of cardiovascular disease and mortality, especially in patients treated with clozapine and olanzapine. It is not always feasible to discontinue these treatments, as the decision largely depends on the clinical context. Therefore, addressing these metabolic side effects requires specific pharmacological interventions to mitigate their impact.
Objectives: This non-systematic review aims to assess the evidence supporting pharmacological interventions in managing antipsychotic-induced metabolic disturbances.
Methods: Relevant and recent studies or reviews were selected from the PubMed electronic database using search terms related to antipsychotic-induced metabolic disturbances and pharmacological interventions to manage them.
Results: Current evidence suggests the need for early and aggressive pharmacological intervention in patients experiencing antipsychotic-induced weight gain. Non-pharmacological interventions, such as physical activity and dietary changes, are often insufficient to mitigate these iatrogenic effects. Pharmacological interventions to reduce metabolic risk in individuals with severe mental illness may include the introduction of an antipsychotic with a more favourable metabolic profile, modification of antipsychotic therapy (dose adjustment, augmentation with another antipsychotic with a lower metabolic risk or switching to another antipsychotic with a lower metabolic risk) and treatment of medical conditions (through the use of drugs such as metformin, statins, among others). Based on updated scientific evidence, the most effective pharmacological treatments for reducing weight gain associated with second-generation antipsychotics are metformin, GLP-1 receptor agonists, topiramate, zonisamide, and nizatidine. The adjunctive use of aripiprazole also reduces lipid levels and weight and attenuates negative symptoms in patients with schizophrenia and metabolic syndrome. Metformin is considered the best-tolerated intervention, while topiramate is the least tolerated.
Conclusions: Pharmacological interventions, particularly the use of metformin and GLP-1 analogues, offer promising results in managing antipsychotic-induced metabolic disturbances. These interventions improve weight management, glucose levels, and lipid profiles. More large-scale randomized trials are needed to further validate these interventions and assess long-term safety and efficacy.

Use and experience of Italian healthcare professionals with aripiprazole once-monthly 400mg two-injection start initiation regimen in adult patients with schizophrenia

C. Beckham[1]*, M. Yildirim[2], S. Pappa[3], K. Leopold[4,5], W. J. Cottam[6], J. Hickey[6], O. Rogerson[6] and A. Fagiolini[7]

[1]Otsuka Pharmaceutical Europe Ltd., Berkshire, United Kingdom; [2]H. Lundbeck A/S, Valby, Denmark; [3]Division of Psychiatry, Department of Brain Sciences, Imperial College London, London, United Kingdom; [4]Department of Psychiatry, Psychotherapy and Psychosomatics, Vivantes Hospital am Urban and Vivantes Hospital im Friedrichshain, Charite, Universitätsmedizin, Berlin; [5]Department of Psychiatry and Psychotherapy, Carl Gustav Carus University Hospital, Technische Universität Dresden, Dresden, Germany; [6]Real-World Evidence, OPEN Health, London, United Kingdom and [7]Università Di Siena, Siena, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2065

Introduction: Aripiprazole once monthly 400mg (AOM400) is a long-acting injectable (LAI) available as a two-injection start initiation regimen (AOM400-TIS) for the maintenance treatment of adult patients with schizophrenia stabilised with oral aripiprazole.
Objectives: This survey sought to explore HCPs' perspectives and attitudes towards prescribing and/or administering AOM400-TIS according to the European label in clinical practice (including reasons for its use, potential benefits, and common barriers and/or concerns) across Europe.
Methods: HCPs who had prescribed and/or administered the AOM400-TIS regimen to ≥3 patients with schizophrenia were invited to participate in an online survey. The survey was launched in two waves across the target countries (wave 1: Italy, Germany, United Kingdom; wave 2: Denmark, Italy, Sweden). Analysis was descriptive; data was collected between February 1–March 21, 2024 (wave 1) and September 16-October 28 (wave 2). Data from Italian HCPs are presented.
Results: 31 HCPs from the 1st wave and 64 from the 2nd wave completed the survey including psychiatrists (69%), psychiatric nurses (23%), community nurses (4%) and general practitioners/primary care practitioners (1%). HCPs estimated 30.0% (median; IQR: 20.0–50.0) of patients in their caseload were diagnosed with schizophrenia, and of these, 45.0% were treated with LAIs (median; IQR: 25.0–62.5). 47% of HCPs were primarily responsible for prescribing AOM400-TIS, 24% for administering it, and 28% were responsible for both. HCPs estimated that 44% of patients typically spent up to 14 days on oral aripiprazole prior to AOM400-TIS, with HCPs rating the severity of symptoms of patients initiated with AOM400-TIS as mild (22% of HCPs), moderate (68% of HCPs) and severe (40% of HCPs). The most common reasons for initiating AOM400-TIS after transitioning from oral aripiprazole were poor adherence (80%) and patient preference (49%), and the most reported goals for prescribing AOM400-TIS were to improve adherence (75%) and prevent relapses (69%). Common barriers to the use of AOM400-TIS were patient reluctance to receive two injections (39%), concerns about tolerability (24%), safety of administering a high dose in a single day (23%). Prior treatment adherence (54%) and efficacy (46%) were the most cited factors influencing prescribing of AOM400-TIS. Overall, HCPs "agreed", or "strongly agreed", that AOM400-TIS was easy to administer (81%) and that it had a similar safety/tolerability profile to the single injection start regimen (69%), while the majority were satisfied with patient outcomes with AOM400-TIS (83%).
Conclusions: Overall, Italian HCPs with experience of using AOM400-TIS reported that it is easy to administer, well tolerated and improves treatment outcomes, while barriers to its use include patient reluctance and perceived safety concerns.

Esketamine in persistent long COVID with predominant psychiatric manifestations: A case series

I. Bozic[1,2]*, D. Ivkic[1,2], L. Reinfried[1,2], J. Donath[1,2], C. Schmidt[1,2], S. Graf[1,2], P. A. Handschuh[1,2], M. Dold[1,2], D. Winkler[1,2], A. Naderi-Heiden[1,2], N. Praschak-Rieder[1,2], D. Rujescu-Balcu[1,2], A. Weidenauer[1,2] and L. Bartova[1,2]

[1]Psychiatry and Psychotherapeutic Medicine and [2]Comprehensive Center for Clinical Neurosciences and Mental Health, Medical University of Vienna, Vienna, Austria

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.2066

Introduction: The COVID-19 pandemic has led to a significant number of patients presenting with post COVID-19 condition, commonly referred to as long COVID, which can affect any individual exposed to SARS-CoV-2, resulting in diminished quality of life, reduced productivity, increased healthcare expenditures, and broader economic implications. The most prevalent symptoms include neuropsychiatric manifestations such as fatigue, cognitive impairment, anxiety, and depression. Beneficial effects of Silexan, a herbal medicine derived from Lavandula angustifolia, were reported in long COVID patients with subsyndromal psychiatric symptoms (Bartova et al. Eur Neuropsychopharmacology 2023;70:47-48). However, research is lacking regarding psychopharmacotherapy in patients with persistent symptoms. Esketamine, noted for its modulation of NMDA receptors, has also demonstrated immunomodulatory effects, positioning it as a promising intervention for Long

COVID (Johnston et al. Neuropsychopharmacology. 2024; 49(1): 23-40).
Objectives: Our objective was to examine two patient cases to identify patterns, explore potential treatment options, and contribute insights to clinical practice in psychiatry.
Methods: This case series reports the clinical histories, demographic information, diagnostic findings, and treatment details of two long COVID patients who were treated in analogy to the well-established guideline for treatment-resistant depression.
Results: A 33-year-old female patient, who failed to respond to phytotherapy and conventional psychopharmacological treatments, including two trials of antidepressants and augmentation with an atypical antipsychotic agent received 10 intravenous esketamine treatments, administered at doses of up to 50 mg (0,86 mg/kg/hour). She experienced substantial clinical improvement without any adverse effects within 8 weeks. A 34-year-old non-responding female patient received 9 sessions of intranasal esketamine, targeting a dosage of 84 mg, resulting in complete remission without significant adverse effects within 6 weeks.
Conclusions: There is an urgent need for effective and sustainable treatment options that address the debilitating neuropsychiatric symptoms of long COVID. This condition disproportionately affects young women, a group that is frequently underrepresented in research and insufficiently recognized in clinical practice. In this case series, we report on two female patients with severe physical and social impairment from long COVID, who showed significant clinical improvement following add-on esketamine administration.

Is there enough evidence to stop using available and accessible antipsychotics such as haloperidol and promote the use of newer and more expensive drugs? What is the hope for populations that cannot afford them

C. Carreño Glaria[1]*, G. Keane[2], K. Ibragimov[3] and A. LLosa[1]

[1]Médecins Sans Frontières, Barcelona, Spain; [2]Médecins Sans Frontières and [3]Epicentre, Paris, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2067

Introduction: Doctors Without Borders works in humanitarian settings. In these settings, we have observed a notable movement away from first generation medications such as haloperidol towards second-generation antipsychotics, where these medications are available. We began to question whether the evidence clearly justified this and decided to contribute to the evidence.
Objectives: To assess the clinical benefits and harms of haloperidol compared to olanzapine for people with schizophrenia and schizophreniaspectrum disorders.
Methods: Searched the Cochrane Schizophrenia study-based register of trials, screened the references of all included studies. We contacted relevant authors of trials for additional information where clarification was required or where data were incomplete. The register was last searched on 14 January 2023.
Results: We didn't find a statistically significant difference between haloperidol and olanzapine in global state (RR 0.84, 95% CI 0.69 to 1.02), nor in relapse (RR 1.42, 95% CI 1.00 to 2.02). Haloperidol resulted in an increase of extrapyramidal side effects compared to olanzapine (RR 3.38, 95% CI 2.28 to 5.02). For weight gain, there may be a large reduction in the risk with haloperidol compared to olanzapine (RR 0.47, 95% CI 0.35 to 0.61). Haloperidol may result in an increase of leaving the study early compared to olanzapine (RR 1.99, 95% CI 1.60 to 2.47).
Conclusions: Overall, the certainty of the evidence was low to very low for the main outcomes in this review, making it difficult to draw reliable conclusions. There is no clear difference between haloperidol and olanzapine in terms of global state and relapse. Different side effect profiles were noted. These findings should contribute to continue using haloperidol and olanzapine.
Many studies did not use equivalent doses of the two medications when they were compared. Most studies used comparatively higher doses of haloperidol compared to olanzapine.

Depression and Fitness: The Role of Psychopharmacology

D. V. Cotovio[1]*, R. S. Nogueira[1], R. Lousada[1], M. B. Resende[1], F. Agostinho[1], M. M. Melo[1] and M. J. Heitor[1]

[1]Departamento de Psiquiatria e Saúde Mental, Hospital Beatriz Ângelo, Loures, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2068

Introduction: The use of antidepressants is becoming more prevalent among athletes due to the growing awareness of mental health issues in sports. However, the impact of these medications, especially selective serotonin reuptake inhibitors (SSRIs), on physical performance remains uncertain. Studies on psychotropic drugs' effects on athletic capabilities raises concerns about their use in sports, particularly under anti-doping regulations.
Objectives: This review aims to assess the impact of antidepressants on physical exercise performance and muscle metabolism, in order to clarify how they influence physical capabilities.
Methods: A literature search was conducted on PubMed in September 2024 using search terms such as "sports" AND "antidepressants," "physical activity" AND "antidepressants," "exercise" AND "selective serotonin reuptake inhibitors," among others. Only systematic reviews and meta-analyses were included, without restrictions on language or year. Three articles met the scope of this work.

Results: The effects of antidepressants on athletes are inconsistent, with some studies indicating no significant change in performance, while others report reduced endurance. Paroxetine and fluoxetine, commonly prescribed SSRIs, may impair endurance due to increased serotonin levels, which can exacerbate fatigue, known as central fatigue hypothesis. It is also emphasized that SSRIs may reduce athletic performance, especially under thermal stress, by affecting thermoregulation, alongside its interference in serotonin pathways. Potential metabolic impact of these drugs was found, as chronic exposure to SSRIs showed modulation of glucose uptake, mitochondrial respiration, and muscle mass. Furthermore, SSRIs also induced changes in electrical muscle activity.
Conclusions: The evidence on the effects of antidepressants, particularly SSRIs, on physical performance and muscle function remains inconclusive. Athletes and healthcare providers must weigh these risks carefully, considering both the clinical and ethical implications of psychotropic drug use in competitive sports. Therefore, future research should focus on more consistent study protocols and explore the long-term metabolic consequences of SSRIs in physically active populations.

Evolutionary History and Phylogeny of Biochemical Functions of Hypericin and Hyperforin in Hypericum spp

D. J. Cox[1]*, R. Maldonado-Puebla[1] and B. Carr[1]

[1]Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2069

Introduction: Hypericum spp., particularly Hypericum perforatum (such as St. John's Wort), produce hypericin and hyperforin, secondary metabolites that play critical roles in the plant's defense mechanisms. These compounds, characterized by their polycyclic and lipophilic properties, have evolved to deter herbivores and protect against pathogens. Understanding the evolutionary pressures that shaped these compounds enhances our knowledge of their biochemical roles.
Objectives: This review aims to synthesize current knowledge on the evolutionary development of hypericin and hyperforin within the Hypericum genus, focusing on how these metabolites evolved to fulfill defensive ecological functions.
Methods: A comprehensive literature review was conducted, examining phylogenomic studies, structural analyses, and biochemical research related to the biosynthesis of hypericin and hyperforin. We reviewed relevant phylogenetic data to understand the diversification of these compounds across Hypericum spp.
Results: The literature supports that hypericin and hyperforin evolved in response to selective pressures during the Cretaceous-Paleogene boundary, with their complex polycyclic aromatic structures optimized for defense. These structures, which include conjugated π-systems, are central to the compounds' ability to deter herbivores and resist pathogens, reflecting an evolutionary adaptation that is conserved across the genus.
Conclusions: The evolution of hypericin and hyperforin within Hypericum spp. is a prime example of how secondary metabolites serve dual purposes in nature and human use. The phylogenetic and biochemical insights reviewed highlight the importance of these compounds as both ecological defenses and pharmacologically active agents.

Perspectives of the use of Perampanel in Psychiatric Symptoms

J. J. De Frutos Guijarro[1]*, B. Macías Gamo[1], N. E. Chinchurreta De Lora[1], C. Merino Del Villar[1] and B. Romero Salicio[1]

[1]Psychiatry, Hospital Can Misses, Ibiza, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.2070

Introduction: Perampanel is a selective antagonist of the AMPA receptor for glutamate, primarily approved for the treatment of certain types of epilepsy. With the evolving understanding of psychiatric disorders' neurobiology, it's hypothesized that targeting the glutamatergic system could offer substantial therapeutic benefits (Perversi F, Costa C, Labate A, Lattanzi S, Liguori C, Maschio M, et al. The broad-spectrum activity of perampanel: state of the art and future perspective of AMPA antagonism beyond epilepsy. Front Neurol [Internet]. 2023 [cited 2024 Sep 2] ;14:1182304).
Objectives: The purpose of this study is to evaluate the effectiveness of perampanel in managing psychiatric symptoms such as sleep disturbances, depression, anxiety, and irritability.
Methods: A comprehensive review of scientific studies was carried out, centering on clinical trials and observational research that explored the application of perampanel in individuals exhibiting psychiatric symptoms. The review included articles published between 2013 and 2024, utilizing databases like PubMed, Scopus, and PsycINFO for sourcing. The inclusion criteria covered studies that assessed the impact of perampanel on psychiatric conditions, detailing both the clinical results and any side effects.
Results: Findings indicate that perampanel may have beneficial effects in reducing symptoms of insomnia (Abenza-Abildúa MJ, Suárez-Gisbert E, Thuissard-Vasallo IJ, Andreu-Vazquez C. Perampanel in chronic insomnia. Clin Neurol Neurosurg. 2020 May 1;192), depression and anxiety (Scorrano G, Lattanzi S, Salpietro V, Giannini C, Chiarelli F, Matricardi S. The Cognitive and Behavioural Effects of Perampanel in Children with Neurodevelopmental Disorders: A Systematic Review. J Clin Med [Internet]. 2024 Jan 10 [cited 2024 Sep 3];13(2)) in certain patient groups. However, significant adverse effects were also reported, including behavioural changes and increased aggression in some cases, necessitating careful monitoring during treatment.
