Results: 42 subjects (28.8%) were diagnosed with ADHD comorbid with ASD (26 combined type, 16 inattentive, 0 impulsive). Most diagnosed subjects (71.4%) were females, but males scored higher on inattentive and hyperactive-impulsive symptoms. Autistic traits were positively correlated with attentive impulsiveness.

Conclusions: Adults with ASD without intellectual disabilities show a significant prevalence of comorbid ADHD, particularly with inattentive symptoms. Attention difficulties are common in both disorders. Further studies and tailored diagnostic processes are needed to assess sub-threshold symptoms in ASD, ADHD, and other neurodevelopmental conditions.

Network Analysis of Symptom Structures in Autism, Schizophrenia, and Non-Diagnosed Controls

S. Holka[1,2*], D. Sörnyei[1,3], Á. Vass[1] and K. Farkas[1]

[1]Department of Psychiatry and Psychotherapy, Semmelweis University; [2]HUN-REN Institute of Cognitive Neuroscience and Psychology, Research Centre of Natural Sciences and [3]Department of Clinical Psychology, Semmelweis University, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.751

Introduction: Despite differences in the onset and symptomatology, Autism Spectrum Disorder (ASD) and Schizophrenia (SCH) are neurodevelopmental conditions with evolving conceptual links in modern psychiatry. This stems from increasing evidence suggesting overlap in social cognition, attachment and the conceptualization as disorders of the self. A transdiagnostic approach, in which network analysis can play an important role, offers valuable insights into the complex interrelationships between symptoms and key constructs in the psychopathology of them. It may reveal underlying similarities and differences, contributing to more targeted interventions.

Objectives: Our study aims to investigate the symptom structures of ASD, SCH, and neurotypical individuals (NTP) using network analysis. By comparing them, our explorative goal was to identify key constructs and their connections, providing potential intervention targets. We hypothesize that both ASD and SCH networks will significantly differ from the NTP network, and that mentalization and disorganized schizotypy would be the most central nodes in the networks of ASD and SCH.

Methods: In a cross-sectional study, 1694 participants were involved in the analysis (NNTP=1477, NASD=155, NSCH=62). Participants completed self-report questionnaires. Based on theoretical and methodological considerations we included psychological inflexibility, mentalization, insecure attachment, perceived social support, minimal and narrative self, negative and disorganized schizotypy, autistic traits, anxiety in the analysis. Gaussian Graphical Models were used to estimate relationships between constructs, with LASSO regularization, focusing on network centrality and predictability measures. Network Comparison Test was applied to unveil local and global differences.

Results: A comparative representation with node scaling for predictability values are shown in image 1 and image 2. Minimal self was the most predictable node in each case. Central nodes in the ASD network were psychological inflexibility and minimal self, in the SCH network narrative self and insecure attachment, in the NTP network psychological inflexibility and minimal self. Significant differences in global strength were observed between ASD and NTP networks. Details of a relevant pattern are shown on image 3.

Image 1:

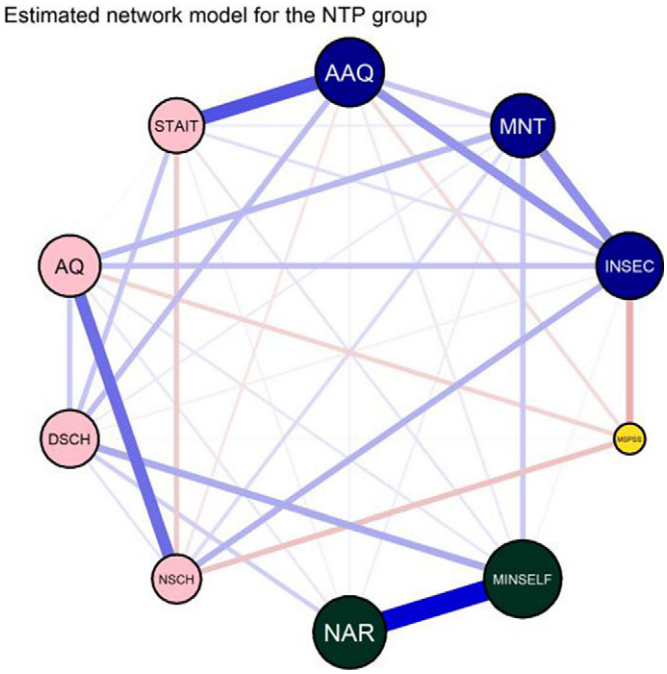

Image 2:

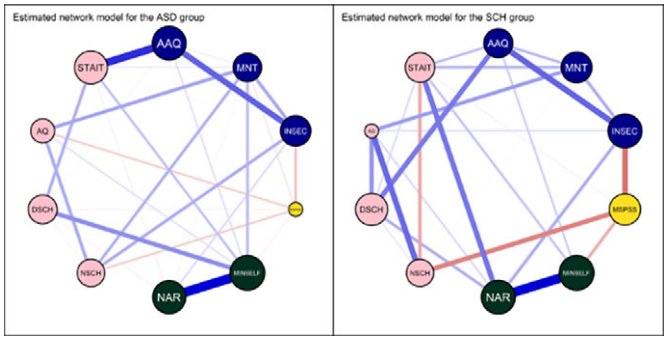

Image 3:

Node1	Node2	NTP	ASD	SCH
mentalization	minimal self	0.1304	0.1467	0
mentalization	narrative self	0.0415	0.0176	0
insecure attachment	minimal self	0.0244	0	0
insecure attachment	narrative self	0	0.0805	0.1712
perceived social support	minimal self	0	-0.0281	-0.1695
perceived social support	narrative self	-0.003	0	0
minimal self	autistic traits	0.0565	0.0700	0
narrative self	autistic traits	0.0516	0	0.0835

Conclusions: Our study highlights distinct symptom networks in ASD and SCH, with distinct centralities emerging. Results suggest interventions targeting psychological inflexibility and self-concept may be effective for ASD, while in SCH, narrative self experience and attachment insecurity may be beneficial. Results show that focusing on isolated constructs may overlook the importance of other constructs. By focusing to the strongest edges and relevant patterns, clinicians may benefit from interventions that simultaneously target the dimensions of the relationships, also considering the most central nodes in the network.

The Phenomenology of Bereavement: Sensory Experiences of the Deceased

A. F. Silva[1]*, A. C. Rodrigues[1], A. C. Matias-Martins[1], F. Santos[1], P. Coelho[1], R. M. Lopes[1], T. Vieira[1] and V. Melo[1]

[1]Psiquiatria, Unidade Local de Saúde do Médio Tejo, Tomar, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.752

Introduction: Many grieving individuals report sensory and phenomenological experiences involving deceased loved ones, such as visual, auditory, or sensed presences. These experiences are common across cultures, with 40-70% of bereaved spouses reporting them. They can provide comfort or cause distress, and can last from brief moments to several years. Despite their prevalence, there is limited empirical research on these occurrences, leaving mental health professionals often unprepared to address them.
Objectives: This study aims to explore the phenomenology of sensory experiences with the deceased, the factors associated with these experiences, and their impact on grieving individuals.
Methods: A bibliographic review was conducted using PubMed, using terms like "Bereavement," "Hallucinations," "Phenomenology," and "Sensory Experiences."
Results: The review indicates that sensory experiences involving deceased loved ones should not automatically be viewed as pathological. Rather, these experiences may function as adaptive responses that help maintain emotional bonds with the deceased, facilitating the grieving process. Research highlights that "sensing a presence" is the most frequently reported phenomenon, followed by visual and auditory encounters. Key factors influencing these experiences include sensory deficits, cognitive difficulties and poor sleep.These phenomena are particularly common among older adults, with women more likely than men to report them. Strong emotional ties, marital satisfaction, and having children with the deceased correlate positively with these sensory experiences. High levels of avoidant coping are significant predictors of experiencing these phenomena, while a more detached coping style appears to help in accepting the finality of the loss. Studies suggest that those who have these experiences often report greater levels of prolonged grief, PTSD, depression, and feelings of emotional loneliness compared to those who do not. However, these experiences do not necessarily result in better or worse clinical outcomes. Mental health professionals must create a supportive environment where individuals can discuss these experiences without fear of judgment or being labeled as mentally ill. Understanding these phenomena as psychologically meaningful and significant to the bereaved can promote healing.
Conclusions: This review emphasizes the need for a nuanced understanding of sensory experiences involving the deceased, moving beyond simplistic interpretations as signs of mental illness. Instead, these experiences should be seen as contextually meaningful and part of the bereaved's relationship with the deceased. For those distressed by these experiences, therapeutic interventions could focus on reshaping their relationship with the deceased or modifying their responses.

Prevalence of personality disorder diagnoses in people referred to specialized gender identity clinics in Finland

M. E. Kaila-Vanhatalo[1,2*], T. Tolmunen[3], A. Mattila[4] and R. Kaltiala[1,5,6]

[1]Faculty of Medicine and Health Technology, Tampere University, Tampere; [2]Department of Adolescent Psychiatry, Oulu University Hospital, Oulu; [3]Department of Adolescent Psychiatry, Institute of Clinical Medicine, University of Eastern Finland, Kuopio; [4]Division of Psychiatry; [5]Department of Adolescent Psychiatry, Tampere University Hospital, Tampere and [6]Vanha Vaasa Hospital, Vaasa, Finland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.753

Introduction: Personality disorders are defined as maladaptive traits of personality and behavior causing severe harm to an individual or people around them. Personality development is closely related to identity development. Higher prevalence on personality disorder diagnoses has been found to be associated with gender dysphoria. However, previous research on this topic has been scarce and methodically varying (Table 1, Image 1&2).
Objectives: The object of this research was to determine the prevalence of personality disorder diagnoses in individuals requesting medical gender reassignment.
Methods: A register-based follow-up study of individuals who contacted the nationally centralized gender identity services in Finland in the period 1996-2019 (n=3,665) and 8:1 age and sex-matched population controls (n=29,292). All their specialist-level psychiatric treatment contacts in 1994-2022 were identified in the National Care Register for Health Care. ICD-10 diagnoses and dates of the contacts were extracted.
Results: Among the gender dysphoria group, 15.0% (551 out of 3,665) had received a diagnosis in the personality disorder group (F60-69 excluding F64.x) in specialized psychiatric health care, while among the control subjects, 2.1% (625 out of 29,292) had received such a diagnosis (Table 2). The most common personality disorder among the gender dysphoria group was borderline personality disorder.

On the 'border-lines' of ADHD: Personality Traits, Diagnostic Overlaps and Clinical Implications

G. Soares[1*], A. Lourenço[1], A. L. Falcão[1], I. Mateus[1], M. Nascimento[1] and C. Oliveira[1]

[1]Clínica 3, Hospital Júlio de Matos - ULS São José, Lisboa, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.754

Introduction: Attention Deficit and Hyperactivity Disorder (ADHD) is a neurodevelopmental condition characterized by persistent patterns of inattention, hyperactivity, and impulsivity. Beyond

these core symptoms, ADHD seems to present complex associations with certain personality traits and to share several clinical features with personality disorders (PDs), particularly those within Cluster B. This overlap of symptomatology may lead to diagnostic challenges and potential misdiagnoses. This paper reviews the literature on the relationship between ADHD and personality traits, highlighting overlaps with personality disorders and exploring their clinical and diagnostic implications.
Objectives: The primary objective of this review is to understand the potential associations between ADHD and specific personality traits, focusing on the extent to which these traits overlap with clinical features of personality disorders.
Methods: A non-systematic literature review was conducted using major databases such as PubMed, Wiley and ScienceDirect targeting peer-reviewed studies published over the last two decades. The search terms included "ADHD," "personality traits," "personality disorders," and "diagnostic overlap." Relevant studies were selected based on their focus on adult ADHD and its association with personality traits and personality disorders. Review articles and cross-sectional studies were included.
Results: The currently available literature reveals significant associations in the clinical presentation of ADHD and specific personality traits (changing accordingly to different models of personality assessment), as well as a relevant diagnostic overlap with Cluster B personality disorders, particularly Borderline Personality Disorder (BPD) and Antisocial Personality Disorder (ASPD). Shared features include impulsivity, emotional dysregulation, and difficulty in maintaining relationships. The presence of ADHD seems to increase the likelihood of personality pathology, with some studies suggesting a high co-occurrence of ADHD with traits of increased neuroticism and novelty-seeking, and decreased conscientious inhibition.
Conclusions: ADHD and personality disorders share multiple overlapping clinical features, making accurate diagnosis challenging and potentially delaying adequate treatment. Thus, as suggested in some of the articles reviewed, an integrative and dimensional approach to such clinical pictures may be more adequate, so to ensure a profound understanding of the difficulties presented by patients, aiming at providing accurate and tailored treatment. Further research is needed to refine diagnostic criteria and strengthen a standardized dimensional thinking to address this diagnostic ambiguity.

The association of salivary biomarkers with self-compassion and perfectionism in medical students exposed to pre-exam stress

P. Boonyalug[1]*, R. Nabhindhakara[1], P. Paradeevisut[1], P. Tayawitid[1], R. Settacomkul[2], T. Prachason[3] and P. Vivithanaporn[2]

[1]Faculty of Medicine Ramathibodi Hospital, Bangkok; [2]Chakri Naruebodindra Medical Institute (CNMI), Faculty of Medicine Ramathibodi Hospital, Samut Prakan and [3]Psychiatry, Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.755

Introduction: Evidence has shown that perfectionism is linked with increased perceived stress, whereas self-compassion might mitigate poor outcomes related to stress. However, how these traits influence stress responses in a naturalistic setting is unclear.
Objectives: The study aims to test the associations of perfectionism and self-compassion traits with stress-related biomarkers, namely C-reactive protein (CRP), alpha-amylase, and cortisol, in medical students exposed to pre-exam stress.
Methods: 61 second-year medical students were enrolled in this study. At baseline, perfectionism and self-compassion were self-rated using the Self-Compassion Scale and the Short-Revised Almost Perfect Scale, respectively. Morning saliva samples were collected at baseline and one week before the exam. The levels of salivary CRP, alpha-amylase, and cortisol were quantified as biomarkers for inflammation, sympathetic activity, and hypothalamus-pituitary-adrenal axis, respectively, using enzyme-linked immunosorbent assay. Multiple linear regression analysis was performed to test the associations between the two traits with pre-exam salivary biomarkers, adjusted for baseline salivary biomarkers, age, sex, and body mass index (BMI). Other potential confounding variables, including acute illness, underlying mood disorder, and lifestyle factors, were also added to the model as sensitivity analyses.
Results: Adjusted for the baseline level of biomarker, age, sex, and BMI, perfectionism traits significantly predicted pre-exam salivary alpha-amylase (B = 0.04, 95% CI 0.01 to 0.07, p = .007), but not CRP (B = -0.03, 95% CI -0.07 to 0.01, p = .177) or cortisol (B = 0.004, 95% CI -0.005 to 0.012, p = .424). No significant associations were found between self-compassion traits and the pre-exam levels of all three salivary biomarkers. The sensitivity analysis, additionally adjusted for other potential confounding factors, confirmed the significant positive association between perfectionism traits and pre-exam salivary alpha-amylase (B = 0.04, 95% CI 0.01 to 0.07, p = .006).
Conclusions: Perfectionism traits could positively predict the level of morning salivary alpha-amylase in naturalistic stress exposure, suggesting a heightened sympathetic activity among those with high perfectionism in response to stress. Replication studies in a larger sample with more diverse populations are warranted.

Impact of Grapefruit Consumption on Plasma Concentrations of Psychiatric Medications through CYP3A4 Inhibition

D. B. Valle[1], D. J. Cox[2]* and B. R. Carr[2]

[1]College of Medicine and [2]Department of Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.756

Introduction: The interaction between grapefruit juice and certain psychiatric medications can lead to significant clinical implications due to the inhibition of the cytochrome P450 3A4 (CYP3A4) enzyme (Fuhr et al. CPT 2023, 114(2), 266-275; Guttman et al. Phytother. Res 2020, 34(5), 1168-1176; Paine et al. Drug Metab. Dispos 2004, 32(10), 1146-1153; Paine et al. J. Pharmacol. Exp. Ther 2005, 312(3), 1151-1160; Schmiedlin-Ren et al. Pharmacol. Ther 1997, 66(2), 234-241). Grapefruit juice contains furanocoumarins, specifically bergamottin and 6',7'-dihydroxybergamottin

(DHB), which irreversibly inhibit CYP3A4, potentially increasing drug plasma concentrations and the risk of adverse effects (Bailey et al. CPT 1998, 64(3) 248-256; de Castro et al. J. Agric. Food Chem 2006, 54(7) 2498-2503; Row et al. J. Med. Chem 2005, 49(20), 6139-6146).
Objectives: This review aims to quantify the impact of grapefruit juice on the plasma concentrations of buspirone, carbamazepine, and diazepam and to understand the duration of these effects to better manage patient safety.
Methods: A comprehensive review of existing pharmacokinetic studies (Furukori et al. BJCP 2003, 55(3), 307-311; Lane et al. Psychopharm 2001, 155(3), 356-359; Tanaka et al. Clin. Pharm 2013, 52(5), 397-420; Wang et al. CPT 1993, 65(3), 314-321; Yasui et al. Psychopharm, 145(1), 84-87) was conducted to gather data on the effects of grapefruit juice on CYP3A4 substrate psychiatric medications. Quantitative increases in plasma concentration metrics (AUC and Cmax) were extracted, and the duration of the inhibition effect was analyzed.
Results: Buspirone plasma concentrations increased by 4.3-fold, with effects lasting 24 hours. Carbamazepine showed a 1.4-fold increase in AUC and a 1.2-fold increase in Cmax, with effects persisting up to 24 hours. Diazepam concentrations increased by 3-fold in AUC and 2-fold in Cmax, with an effect duration of 24 hours. No significant interaction was observed for clozapine and haloperidol.
Conclusions: Grapefruit juice significantly increases the plasma concentrations of buspirone, carbamazepine, and diazepam by inhibiting CYP3A4, with effects lasting up to 24 hours. Clinicians should educate patients on avoiding grapefruit consumption while on these medications and monitor for potential toxicity. Further research is needed to develop guidelines for managing these interactions and to explore genetic variations in response to grapefruit consumption.

Immune4Plasticity: do non-pharmacological interventions modulate the inflammatory pattern of major depressive disorder? A study protocol

M. Di Vincenzo[1]*, B. Della Rocca[1], C. Toni[1], I. Branchi[2], F. Cirulli[3], S. Poletti[4], S. Poggini[2], A. Viglione[2], C. Delli Colli[2], C. Musillo[2], M. Luciano[1], G. Sampogna[1] and A. Fiorillo[1]

[1]Department of Psychiatry, University of Campania "Luigi Vanvitelli", Naples; [2]Center for Behavioral Sciences and Mental Health; [3]Section of Behavioral Neuroscience, Department of Cell Biology and Neurosciences, Istituto Superiore di Sanità, Rome and [4]Psychiatry and Clinical Psychobiology, Division of Neuroscience, Vita-Salute San Raffaele University, Milan, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.757

Introduction: Major depressive disorder (MDD) is a severe mental disorder with a prevalence rate of 10%. Approximately 30-40% of patients suffering from MDD show higher levels of proinflammatory cytokines, associated to low response to pharmacotherapy. Thus, modulation of immune system might have a key role in the management of MDD.
Objectives: This study is aimed to: 1) assess the interrelation between immune hyperactivation and neuronal plasticity; 2) assess how non-pharmacological treatments impact on the immune hyperactivity in patients suffering from MDD; 3) identify biological makers able to predict the course of MDD and the effectiveness of treatments.
Methods: Immune4Plasticity is a longitudinal, multisite trial funded by Italian Ministry of Health. Preclinical analyses aimed at investigating the interrelation between immune hyperactivation and neuroplasticity as well as the identification of biological markers of MDD will be carried out at National Institute of Health in Rome. Clinical part of the study will be performed at the Department of Psychiatry of University of Campania, Naples, and at the Vita-Salute San Raffaele University, Milan. Seventy patients aging 18-65, with a diagnosis of MDD according to the DMS-5 criteria without psychotic symptoms, scoring more than 14 at the 17-item Hamilton Depression Rating Scale and able to release informed consent will be included. Thirty-five participants will attend a lifestyle psychosocial intervention in Naples; thirty-five will undergo light-therapy sessions in Milan. Assessments of both groups will be performed at recruitment (T0), after 3 months (T1) and after 6 months (T2), by using standardized psychometric tools and blood samples. The project will be carried out for 24 months.
Results: This multidisciplinary, translational study will shed more light on the complex interrelationship between MDD, immune system and neuroplasticity by investigating the role of psychosocial intervention and light therapy as 'modulators'. This will make it possible to develop innovative therapeutic strategies by integrating non-pharmacological approaches with anti-inflammatory drugs and to identify new peripheral markers to assess the response to treatment of patients with MDD.
Conclusions: MDD is a complex mental disorder associated with higher expression of inflammation. Sometimes, it is not adequately responsive to pharmacotherapy. Understanding the effect of non-pharmacological treatments as "modulators" of the inflammatory pattern of MDD may be an important strategy to optimize clinical management of this disorder.

Lipopolysaccharide induced acute inflammation leads to a higher systemic and brain exposure to olanzapine in mice

J. Hubenak[1,2]*, J. Chladek[3], J. Masopust[1,2], M. Mzik[4], D. Bayer[1,2], C. Andrys[2,5] and S. Micuda[3]

[1]Department of psychiatry, University Hospital Hradec Kralove; [2]Faculty of medicine in Hradec Kralove; [3]Faculty of medicine in Hradec Kralove, Department of Pharmacology, Charles University; [4]Department of clinical biochemistry and diagnostics and [5]Department of clinical immunology and allergology, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.758

Introduction: Pro-inflammatory mediators inhibit drug metabolism and transport. Detailed knowledge is lacking on the mechanism and extent of alterations in olanzapine pharmacokinetics during acute inflammatory states accompanying infections.
Objectives: To quantify the extent of systemic and brain exposure to olanzapine in a murine model of endotoxemia compared to a non-endotoxemia model.

Methods: Acute endotoxemia model was established in C57BL/6N mice intraperitonealy injected with 5 mg/kg *Escherichia coli* lipopolysaccharide (LPS). On Day 2 following LPS administration, LPS-injected mice and saline-treated controls were given single doses of olanzapine orally (p.o.) or intravenously (i.v.) or desmethylolanzapine (DMO) i.v. Concentrations and unbound fractions of olanzapine and DMO were measured in plasma samples and brain homogenates. Moreover, plasma biochemistry parameters and mRNA expression patterns were evaluated of pro-inflammatory cytokines, selected phase I and II drug-metabolizing enzymes and transporters in the liver, ileum and brain.
Results: Following p.o. olanzapine, the areas under the concentration-time curve (AUC) for olanzapine and DMO in the plasma were increased 3.8-fold and 2.6-fold ($P<0.05$) in LPS-injected mice vs. controls. The AUC for olanzapine in the brain homogenate was 5.2-fold higher ($P<0.05$). Brain DMO was hardly detectable in both groups. The penetration ratios ($K_{p,brain}$) of 8.5 and 6.3 confirmed that LPS increased the passage of olanzapine into the brain. Expression of mRNAs was decreased in the liver of CYP1A2 and UGT1a1/1a5 enzymes and Abcb1a, Bsep and Ntcp transporters and of ileal Abcb1a, whereas Abcb1a and Abcb1b in the brain and inflammatory cytokines and chemokines mRNAs in the liver were upregulated.
Conclusions: Investigation of olanzapine pharmacokinetics in endotoxemia mice clearly indicates a considerable increase in systemic and brain concentrations of the drug after oral administration. Further studies should clarify whether or not the inflammation-induced inhibition of metabolism and efflux transport results in brain overexposure to the drug and adverse effects in accutely infected patients treated with oral olanzapine.

doi: 10.1192/j.eurpsy.2025.759

Introduction: Accumulating research has suggested a possible role of the immune/inflammatory response system in the pathophysiology of suicidal behavior, more specifically of specifically high-lethality suicide attempts (SA). To count with reliable and affordable biological markers of high-lethality SA to complement clinical assessment for early detection of individuals at a high risk of committing suicide is thus mandatory.
Objectives: To assess if immune/inflammatory parameters may differ between suicide attempters with and without SA, taking into account the type of suicide method. The odds of repeating a high-lethality SA in the future will also be explored.
Methods: In this retrospective observational single center study, medical records of suicide attempters admitted to the Emergency Department at Vall d'Hebron University Hospital (Barcelona, Spain) between 2017-2021, will be reviewed. The following immune/inflammatory parameters (i.e., total and differential white blood cell count, platelet counts, C-reactive protein levels) will be extracted for comparisons between subjects without a history of previous suicide attempt (SA), and those with a history of previous SA. Additionally, the following ratios/indexes will be calculated as a proxy of subject's inflammatory status: neutrophil-to-lymphocyte ratio (NLR), basophil-to-lymphocyte-ratio (BLR), monocyte-to-lymphocyte ratio (MLR), platelet-to-lymphocyte ratio (PLR), systemic inflammatory response index (SIRI). Analyses will be controlled for clinical and sociodemographic variables, such as age, gender and/or primary psychiatric diagnosis. Analyses will be also stratified according to the attempt method. Moreover, the capability of the previously mentioned parameters to predict a high lethality SA or to commit suicide in the coming two years will also be evaluated.
Results: Results from the interim analysis will be presented at the congress.
Conclusions: Peripheral immune/inflammatory parameters may allow us to discriminate subjects at risk of committing suicide. In case of positive findings, immune/inflammatory parameters could be incorporated in the comprehensive evaluation of high-lethality SA in individuals admitted to the emergency setting, contributing to improve early detection of suicide risk.

Optimizing Pulse Frequency in Electroconvulsive Therapy

J. C. Hall[1*], R. Grace[1] and B. Carr[2]

[1]College of Medicine and [2]Department of Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.760

Introduction: Effective seizure induction with minimal adverse effects in Electroconvulsive Therapy (ECT) are influenced by administered electrical pulse frequency. Optimized pulse frequency is key to ensure therapeutic efficacy and reduce side effects.
Objectives: This study examines electrical pulse frequency impact on neuronal excitability and seizure quality in ECT, guided by chronaxie and refractory periods.
Methods: A comprehensive literature review was conducted to assess neurophysiological properties affected by ECT and how different frequencies influence treatment outcomes.
Results: Neurons fire action potentials when membrane potentials reach a -55 mV threshold. Lower frequencies (20-32 Hz) balance depolarization and repolarization to trigger seizures without excessive neuronal firing. The neuronal absolute refractory period is 1-2 msec,

and the relative refractory period is 2-4 msec. Lower frequencies optimize repolarization recovery.
ECT is clinically administered at 20-70 Hz. Studies show 20-32 Hz is effective at triggering seizures with optimal treatment outcomes. Lower Hz also minimizes tissue damage from reduced power. The total charge delivered is affected by current amplitude, pulse width, frequency, and train duration. Shorter pulse widths (0.3 ms) reduce total energy and minimize tissue heating.
The neuronal soma is sensitive to electrical stimulation. Chronaxie is the minimum time that an electric current is applied to stimulate a neuron. Chronaxie is 0.2-0.3 msec. Aligning pulse frequencies with these values ensures stimulation with reduced adverse effects. The soma exhibits a lower spike threshold and shorter refractory period when facing prolonged steady depolarization, making it highly sensitive to pulse frequencies that align with its chronaxie values.
In contrast, axons have a higher density of voltage-gated Na+ channels that allow quicker recovery and shorter refractory periods. This high density enables axons to rapidly transmit action potentials, facilitating efficient neuronal signal propagation. Shorter axonal refractory period means they handle higher frequencies more effectively, but optimizing the overall frequency for ECT must balance the excitability of both the soma and axons.
Studies indicate that frequencies around 20-32 Hz are effective in initiating convulsive activity, aligning well with the end of the stimulus train. Frequencies over 50 Hz may suppress ictal activity and be inefficient in seizure induction due to "stimulus crowding," with neurons stimulated during their absolute refractory period.
Conclusions: Optimizing ECT pulse frequency is vital to balance therapeutic efficacy and safety. Fine-tuning ECT's electrical parameters enhances patient outcomes. Lower frequencies (20-32 Hz) are more effective to induce seizures and minimize adverse effects. 20-70 Hz in ECT is most clinically used, and lower end Hz could optimize results. Further frequency range research could lead to improved ECT protocols.

A Randomized Controlled Trial Comparing the Efficacy of High-Frequency rTMS and Intermittent Theta-Burst Stimulation on Depressive and Anxiety Symptoms in Depressive Disorder

J. Opelka[1,2*], J. Albrecht[2,3] and O. Bezdíček[1]

[1]Department of Neurology and Centre of Clinical Neuroscience, First Faculty of Medicine and General University Hospital in Prague, Charles University, Prague; [2]Department of Psychiatry, Most Hospital, Krajská zdravotní a.s., Most and [3]Psychiatric Clinic of the Faculty of Health Studies, Jan Evangelista Purkyně University and Masaryk Hospital in Ústí nad Labem, Krajská zdravotní a.s., Ústí nad Labem, Czech Republic
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.761

Introduction: Depressive disorder is one of the most prevalent neuropsychiatric conditions in the world, significantly affecting both individuals and society. Despite numerous therapeutic options, many patients do not respond adequately to treatment, highlighting the need for novel approaches, in the case of this study repetitive transcranial magnetic stimulation (rTMS).
Objectives: The main objective of this study was to compare the therapeutic efficacy of high-frequency rTMS (HF-rTMS) and intermittent theta-burst stimulation (iTBS) in reducing depressive and anxiety symptoms in patients with depressive disorder.
Methods: This double-blind, randomized controlled trial was conducted at the psychiatric ward of Most Hospital. Patients (N=97) diagnosed with depressive disorder were randomly assigned to receive either HF-rTMS or iTBS both aimed at left dorsolateral prefrontal cortex. Data were collected using both self-assessment and clinician-rated questionnaires, such as the Zung Self-Rating Depression Scale (ZSDS), Beck Anxiety Inventory (BAI), Hamilton Depression Rating Scale (HAMD), and Hamilton Anxiety Rating Scale (HAMA), before and after 10 stimulation sessions.
Results: The analysis showed a significant reduction in depressive and anxiety symptoms after ten stimulation sessions using both HF-rTMS and iTBS across all applied questionnaires. Specifically, the ANOVA results for the ZSDS demonstrated a significant decrease in symptoms over time ($F=414$, $p<.001$), with a mean reduction of 6.54 points (95% CI=4.64–8.43). Similarly, the HAMD scores showed a significant reduction ($F=299.72$, $p<.001$), with a mean reduction of 7.83 points (95% CI=5.79–9.87). For anxiety symptoms, the BAI revealed a significant decrease ($F=389.26$, $p<.001$), with a mean reduction of 5.72 points (95% CI=4.45–6.99) and the HAMA showed a similar trend ($F=656.15$, $p<.001$), with a mean reduction of 7.39 points (95% CI=5.58–9.20).
No significant difference in efficacy was found between the two stimulation protocols across all measures: ZSDS ($F=0.142$, $p=0.237$), HAMD ($F=0.431$, $p=0.376$), BAI ($F=0.269$, $p=0.365$), and HAMA ($F=0.813$, $p=0.370$).
Conclusions: This study confirms that both HF-rTMS and iTBS are effective in reducing depressive and anxiety symptoms, with no significant difference in their efficacy across all measured outcomes after ten stimulations. However, iTBS offers distinct advantages over HF-rTMS, including a shorter stimulation duration and a lower incidence of side effects.

This study was supported by an Internal grant agency: IGA-KZ-2022-1-4 (417119001).

Individual selection of augmentative and alternative communication for people with mental disabilities

A. L. Bitova[1*], A. A. Portnova[1], O. V. Karanevskaya[1] and M. E. Sisneva[1]

[1]Center for Curative Pedagogics, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.762

Introduction: More than 150,000 adults with mental disabilities live in social shelters in Russia and almost 50% of them do not use speech for communication and can't communicate at all. Social institutions lack a system for training those in need of Augmentative and alternative communication (AAC).
Objectives: Development and testing of an algorithm for selecting AAC method for adults with mental disorders and severe speech communication disorders.
Methods: A questionnaire for people with mental disabilities who do not use speech for communication was developed and tested. It included questions accompanied by illustrations, photographs

and graphic symbols. A survey was conducted among 50 people of both sexes, aged 17-58 living in social welfare institutions. 56% of them had a diagnosis of intellectual disability, 18% - Autism, 26% - Schizophrenia. An algorithm for preparing and including respondents in the study was developed, consisting of several components (Establishing primary contact, Determining the preferred means of communication, Determining the ability to understand and use oral speech, Determining the ability to understand and use gestures, images and symbols, written speech).
Results: 92% of people completed the full study. 4 respondents withdrew from the experiment due to their mental state (psychosis, passivity, profound intellectual disability, fatigue). Despite successfully completing the preparatory stage, 74% managed to obtain full results.
Conclusions: The study made it possible to identify potential opportunities for using communication tools, analyze barriers in communication with others, and develop personal recommendations for using AAC, which will undoubtedly improve the quality of life of a person with mental disabilities.

Clients Mixed Experiences of Receiving Job Support and Getting a Job When Participating in Individual Placement and Support in Norway

L. G. Kinn[1]*, L. Davidson[2], K. J. Oedegaard[3] and E. Langeland[4]

[1]Department of Welfare and Participation, Western Norway University of Applied Sciences, Bergen, Norway; [2]School of Medicine, Yale University, New Haven, United States; [3]Department of Clinical Medicine, University of Bergen and [4]Department of Health and Caring Sciences, Western Norway University of Applied Sciences, Bergen, Norway
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.763

Introduction: People with severe mental illness (SMI) view employment as central to their recovery process, principally when work task is experienced as meaningful, manageable, and comprehensible. However, unemployment rates remain extremely high among people with SMI, especially those diagnosed with schizophrenia. The costs are high: significant numbers of people are at risk of loss of life's purpose, social isolation, poverty, and even suicide. Internationally, there is a knowledge gap of lived experience of receiving IPS in a job development and working phase. We need to know more about those who do not get or stay in a job. Correspondingly, in a national context more knowledge is needed about mainstream ESs' practices from an IPS client's perspective.
Objectives: Thus, the aim of this study was to explore clients' experiences of receiving job support from employment specialists (ESs) working with individual placement and support (IPS) in Norway. IPS is developed to help people with severe mental illness (SMI) into competitive employment as an integral component of mental health services.
Methods: Using a hermeneutic phenomenological methodology, this study comprises individual semi-structured interviews with ten participants engaged in IPS at two districts psychiatric centers. Data analysis was conducted according to systematic text condensation.
Results: Three themes emerged: (1) ES—a door opener? (2) Striving to sidestep a "spider web" of triggers at and away from work; and (3) Calling for a safer route.
Conclusions: This study highlights the importance of ESs offering IPS clients' opportunities to try out diverse jobs and focusing more on assessing the work environment in the jobs they place people into. Our findings imply that ESs should spend more time on building a good working alliance with both clients and employers, and pay more attention on understanding individuals' vocational capacities and support needs at the worksite. The ES training should focus not simply on the technical processes of job development and placement, but more directly on empowering clients to stay focused on their vocational ambitions and prospects. The salutogenic model of health can help ESs to analyze whether clients experience workplaces as meaningful, manageable, and comprehensible.

Study of a group of infants with risks of hearing impairment and mental difficulties

Y. Sidneva[1,2]*, O. Lipatova[3] and A. Zakrepina[1,3]

[1]rehabilitation, Clinical and Research Institute of Emergency Pediatric Surgery and Traumatology (CIEPST); [2]neuropsychiatry, National Medical Research Center of Neurosurgery named after N.N. Burdenko and [3]defectology, Federal State Budgetary Scientific Institution Institute of Correctional Pedagogics /FGBNU ICP/, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.764

Introduction: One of the little-studied nosologies with severe delay in psychomotor development in the first year of life is children with risks of damage to the auditory analyzer, which requires the development of an adapted method for diagnosing impaired auditory function and taking into account some external factors that do not depend on the state of the child's auditory function.
Objectives: to study the characteristics of the auditory function in infants at risk for hearing impairment with delayed psychomotor development.
Methods: 60 children (4-11 months) with suspected hearing loss were examined (Federal State Budgetary Scientific Institution "Institute of Correctional Pedagogics"); interview with parents; psychiatric and pedagogical examination.
Results: Three groups of children were identified depending on the level of psychomotor development (a level close to the norm, with a slight delay of 1-3 months, with a significant delay - from 4 months):
The first group (34%) included children admitted with suspected hearing loss, with a level of psychomotor development close to the norm, without concomitant developmental disorders. All children in this group were found to have significant and minor hearing loss. In two children, the hearing condition (according to the better hearing ear) was assessed as normal with atresia of the auditory canal on one side.
The second group (50%) consisted of children with suspected hearing loss, whose psychomotor development was delayed by 1-3 months. Most of them had significant hearing loss. In two children, the suspicion of hearing loss was not confirmed.
The third group (16%) included children with suspected hearing loss with a significant delay in psychomotor development for more

than 4 months. Half of them (8%) had disharmonious development. Most had significant hearing loss.
Conclusions: given that each group included children with significant hearing loss and deafness, it became obvious that their psychomotor development level is independent of their hearing status. The identified risks of sensory impairments combined with a pronounced delay in psychomotor development in the first year of life necessitate a search for markers of these disorders, and above all, factors and conditions that affect their manifestation and the dynamics of psychomotor development in children in the first year of life; presumably, this may be the child's social environment.

A program to reduce self-stigma in patients with endogenous psychiatric disorders

V. Mitikhin[1]*, P. Orekhova[1] and L. Alieva[1]
[1]Mental Health Research Centre, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.765

Introduction: Stigmatization and self-stigmatization remains an actual problem for patients with endogenous mental illnesses, as it is an obstacle to seeking psychiatric help. Taking this into account, it is necessary to develop effective psychosocial interventions aimed at reducing self-stigmatization and improving patients' integration into society.
Objectives: To identify the features of self-stigmatization in patients with schizophrenic spectrum disorders and, taking into account these features, to develop a program to reduce it.
Methods: 30 patients with schizophrenic spectrum disorders (F20, F23, F25 according to ICD-10) were included in the study. The average duration of the disease was 13.5±3.2 years. Among them, 14 were males, 16 were females, and the median age of the patients was 42.21±10.36 years. To assess the severity of self-stigmatization and to determine its components, the "Questionnaire for assessing the phenomenon of self-stigmatization in psychiatric patients" (Yastrebov V.S., Mikhailova I.I., Yenikolopov S.N. et al., 2005) was used.
Results: A rather high general level of self-stigmatization (1.20 ±0.57 points) was revealed in the studied patients, exceeding the average indices according to the mentioned questionnaire. The most pronounced were the indicators on the following scales: "Overestimation of inner activity" (1,61±0,67 points); "Overestimation of self-actualization" (1,48±0,78 points); "Willingness to distance from mentally ill patients in the social sphere" (1,44±0,72 points); "Violation of self-identity" (1,17±0,59 points). Taking into account the identified disorders, a program including psychoeducation, as well as art-therapeutic training based on the approach of Z. Russinova et al. "Anti-stigma photovoice Intervention" (2014) was developed and adapted for the Russian population. The psychoeducation included three sessions where the manifestations of mental disorders, their treatment, forms of psychiatric care, issues of stigmatization and its overcoming were discussed. The training included six sessions discussing the following topics: "My daily life", "Health and illness", "Me and others", "Accepting help and giving help", "My achievements and my possibilities", and "The next chapter of my life". Participants provided pictures according to the session topic and discussed personal experiences, their emotions and feelings. The sessions were held in a closed group, the number of participants from 8 to 12 people, and the duration of the session was 90 minutes.
Conclusions: The developed program contributed to the identification of resources that help in overcoming the disease and reducing self-stigma. The program can be used for patients in the initial stages of the disease and with a long-term course of the disease.

The association of familial factors with drug treatment compliance in psychotic disorders in adolescents and young adults: a follow-up study of former adolescent inpatients

S. Eskelinen[1,2]
[1]Research Unit of Clinical Medicine, Psychiatry, University of Oulu and [2]Oulu university hospital, Oulu, Finland
doi: 10.1192/j.eurpsy.2025.766

Introduction: Schizophrenia and other psychotic disorders have a high social and economic cost. Antipsychotic drugs are the main approach to schizophrenia treatment. Drug adherence can be assessed with the Medication Possession Ratio (MPR), which means the days covered by the drugs purchased / 1 year.
Objectives: The aim of this study was to investigate the effect of primary family factors and adverse childhood experiences (ACEs) on antipsychotic MPR among patients with schizophrenia spectrum disorder (SSD). Furthermore, we analyzed long-acting injectable antipsychotics (LAIs) and mood stabilizers separately.
Methods: We had access to a database of former adolescent psychiatric inpatients (n=508) treated during the years 2001-2006 in Oulu university hospital, Finland. Participants were followed for SSD diagnosis via National care register for healthcare (CRHC) and physician-prescribed antipsychotic drug purchases via Social Insurance Institute (SII) register up to June 2023.
Results: The participants using clozapine (OR 5.26, 95%CI 1.79-15.39) or mood stabilizers (OR 5.34, 95%CI 1.37-20.83) were significantly more likely to have MPR > 80% compared to participants using other antipsychotics. Sibling position, the size of primary family or ACEs did not associate with MPR.
Conclusions: Clozapine and mood stabilizers increased the likelihood of higher antipsychotic MPRs among former adolescent psychiatric inpatients having SSD.

Disclosure of Interest: None Declared

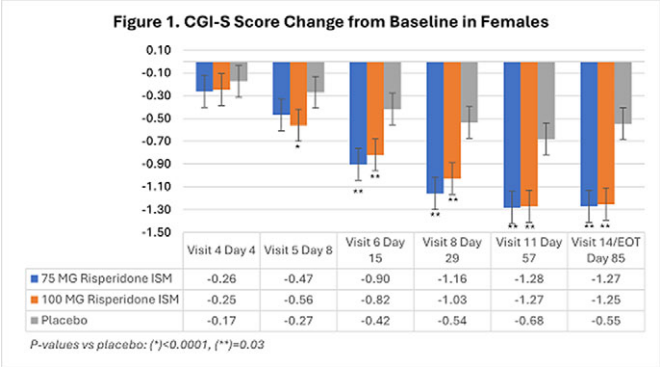
No sex-related differences in CGI-S score reductions in adult patients with acutely exacerbated schizophrenia treated with Risperidone ISM

C. Sherifi[1], J. Martínez González[2]*, L. Anta Carabias[2], M. Almendros Gimenez[2], C. Salazar García[2] and C. U. Correll[3,4,5,6,7]

[1]Medical Affairs, ROVI Biotech Ltd., Croydon, United Kingdom; [2]Medical Department, Laboratorios Farmaceuticos ROVI S.A., Madrid, Spain; [3]Department of Psychiatry and Molecular Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [4]Department of Psychiatry Research, The Zucker Hillside Hospital, Glen Oaks, NY, United States; [5]Department of Child and Adolescent Psychiatry, Charité Universitätsmedizin Berlin, Berlin, Germany; [6]Center for Psychiatric Neuroscience, The Feinstein Institute for Medical Research, New Hyde Park, NY, United States and [7]German Center for Mental Health, Partner Site Berlin, DZPG, Berlin, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.767

Introduction: There is an increasing emphasis on incorporating sex differences into mental health research [Galbally *et al.* CNS Drugs 2024; 38(7):559-570; Ercis *et al.* J Affect Disord. 2024; 352:171-192]. Reports on evaluating sex-related differences in risperidone efficacy are limited [Galbally *et al.* CNS Drugs 2024; 38(7):559-570]. Recently, Risperidone ISM (Risp-ISM), a monthly long-acting injectable (LAI) formulation has been authorised in Europe, USA and some other countries.
Objectives: To assess potential sex-related differences in the short-term efficacy of Risp-ISM LAI in adults with schizophrenia [Correll *et al.* NPJ Schizophr. 2020; 6(1):37].
Methods: Post-hoc analysis of a double-blind (DB), randomised, placebo-controlled, 12-week study conducted in participants with acutely exacerbated schizophrenia (NCT03160521). Data from the Clinical Global Impressions-Severity (CGI-S) rating scale were analysed by sex to reveal potential differences in efficacy versus placebo. The data were analysed within three separate study groups: 75 mg Risp-ISM, 100 mg Risp-ISM and placebo using a mixed effect with repeated measures model (MMRM). Herein, CGI-S scores changes from baseline (the key secondary efficacy endpoint) are shown.
Results: In the double-blind phase, 437 eligible participants were randomly assigned 1:1:1 to receive Risp-ISM 75 mg, 100 mg or placebo every 28 days. 144 (33%) were female and 293 (67%) male. Analysis showed no sex-related differences on CGI-S scores. Decreases from baseline (Figures 1 and 2) were significantly greater versus placebo at Day 8 (after first injection) and beyond in both male and female subgroups at the 100 mg Risp-ISM dose; likewise, at Day 15 and beyond for the 75 mg Risp-ISM dose.

Image 1:



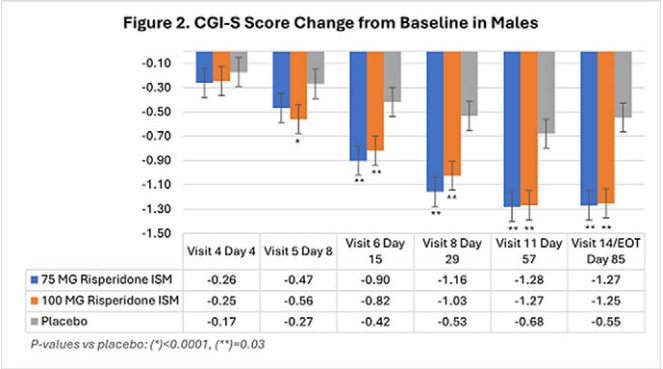


Image 2:

Conclusions: There were no statistically significant differences in efficacy, measured as CGI-S score change from baseline, for male or female participants versus placebo with Risp-ISM 75 mg or 100 mg. Risp-ISM, using monthly intramuscular doses of 75 mg or 100 mg provided significant reduction in severity of the disease as early as 8 days after the first dose in acutely exacerbated patients with schizophrenia regardless of their sex.

Beck Institute, Rome; [5]Unit for Treatment Resistant Psychoses, Section of Psychiatry, Department of Neuroscience; [6]Department of Translational Medical Sciences and [7]Staff of UNESCO Chair on Health Education and Sustainable Development, University of Naples "Federico II", Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.768

Introduction: The corpus callosum (CC) is essential for interhemispheric communication, and its abnormal integration is central to the neurobiology of schizophrenia (SCZ). SCZ patients have a 10-fold higher risk of cannabis use disorder (CUD) and about 20-35% show a lack or poor response to antipsychotics and are defined as treatment-resistant schizophrenia (TRS) Until now, no study has analyzed the morphology of the CC in TRS compared to healthy controls (HC) and non-TRS patients with and without CUD.
Objectives: The aim of the study is to assess whether the diagnosis of psychosis, the response to antipsychotic treatment, and CUD can influence the volume of the CC. To achieve this, we used an innovative artificial intelligence program applied to MRI, which provides structural information on a single subject.
Methods: We included 20 HC and 48 SCZ patients, of whom 14 were affected by TRS and 34 were non-TRS. Among the non-TRS group, 20 had CUD comorbidity (non-TRS-CUD^{+}) and 14 did not have CUD (non-TRS-CUD^{-}). All were assessed cross-sectionally through the Neurological Evaluation Scale, the Brief Assessment of Cognition in Schizophrenia, the Positive And Negative Syndrome Scale. We assessed them cross-sectionally using psychometric tools, cognitive tests. All patients underwent a brain MRI 1.5 T, for white matter volume group analysis, and MRI applied to Artificial Intelligence (MRI-AI-Pixyl.Neuro) for single-subjects analysis.
Results: TRS was associated with higher PANSS total score (fig. 1) and neurological soft signs (fig. 2) and lower negative symptoms (trend) than non-TRS groups. The TRS group performs worse in the Tower of London task compared to non-TRS and HC groups. Only the condition of TRS is associated with a significantly smaller CC volume (64.28%) compared to HCs and non-TRS patients (Fig. 3). Only one patient from the non-TRS-CUD^{-} group showed a reduction in the volume of the CC like TRS patients.

Image 1:

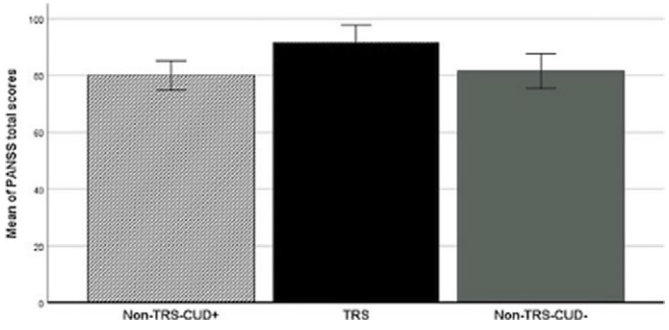

Image 2:

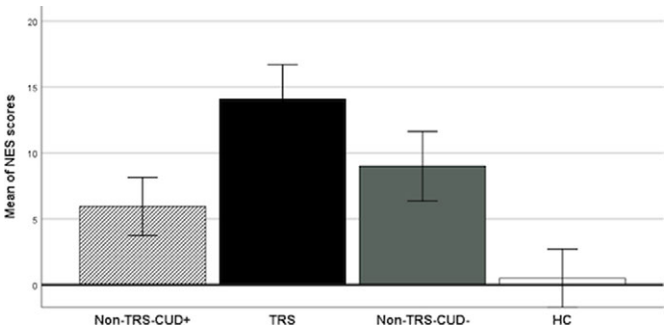

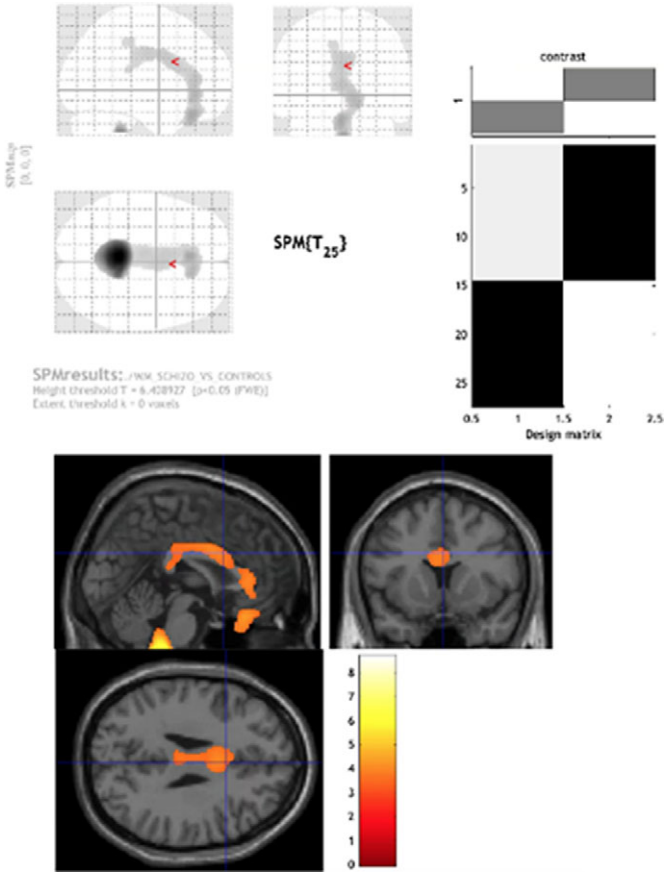

Image 3:

Conclusions: TRS is associated with more severe general and negative symptoms, NSS, and cognitive dysfunctions and with a significantly smaller CC volume, demonstrating the role of this structure in the pathogenesis of TRS and probably in executive function impairment. Is conceivable that TRS has unique evolution and course characteristics, and that continuous cannabis use for 6.95 years is probably not sufficient to cause the structural alterations typical of TRS.

The MRI-AI applied to a single subject has shown reliable results, confirmed by classical group analysis, and represents a revolutionary tool for identifying potential neuroradiological biomarkers of disease, enabling quick TRS diagnosis in clinical practice, faster clozapine treatment following TRIPP guidelines, and easy application using only a standard volumetric sequence without post-scan analysis.

EPP520

Exploring the association between schizophrenia and multiple sclerosis: a case report

T. Pessoa[1]*, B. Silva[1], Â. Pinto[1] and Â. Venâncio[1]

[1]Psychiatry, ULSGE, Vila Nova de Gaia, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.769

Introduction: Schizophrenia (SCZ) is a chronic psychiatric disorder affecting cognition, perception, and behavior, while multiple sclerosis (MS) is a neurological disorder impacting the central nervous system. Despite unclear etiologies, both share commonalities such as immune-inflammatory pathways, neurocognitive impairment, and sleep disturbances (Misiak et al., 2023). Psychotic symptoms in MS typically follow neurological onset. This case report presents a patient diagnosed with SCZ a decade before developing neurological symptoms consistent with MS. His psychotic relapses coinciding with MS onset suggest potential interactions between the two disorders, raising questions about their connection.
Objectives: To investigate the potential link between SCZ and MS through a case report of a patient with SCZ who developed MS a decade later. This study aims to explore the relationship between MS onset and psychotic relapses, focusing on shared neuroinflammatory mechanisms and their implications for co-occurring SCZ and MS.
Methods: We present a case report and a non-systematic review on the subject.
Results: Male patient, 33 years old, diagnosed with SCZ at the age of 23. No previous hospitalisations. No other comorbidities. Stabilised with aripiprazole 10mg for several years. In April 2023, the patient presented to the emergency department with binocular oblique diplopia on levoversion, which had progressed for 4 days due to ophthalmoparesis. Initial diagnostic tests, including an analytical study and a CT scan, showed no abnormalities. He was referred to neurology for further investigation. He underwent an electromyography with repetitive nerve stimulation, which was normal, and an MRI-CE which revealed multiple focal hyperintense areas in T2 and T2-FLAIR in the white matter suggestive of inflammatory demyelinating lesions, consistent with MS. In December 2023, the patient was hospitalized due to psychotic decompensation. He was discharged in January 2024 stabilised with aripiprazole 30mg. However, in March 2024 he was re-hospitalized with another psychotic decompensation attributed to non-compliance with medication. Aripiprazole was reintroduced and transitioned to a long-acting injectable formulation, and the patient was discharged.
Conclusions: This case highlights important aspects of the relationship between SCZ and MS. The patient's decade-long stable psychiatric history before MS onset suggests that neuroinflammation from MS may have triggered or worsened psychotic symptoms. The neuroinflammatory processes and immune-mediated mechanisms, common to both SCZ and MS, potentially explain their co-occurrence. The timeline of neurological symptoms preceding psychiatric relapse strengthens this connection. Further research is needed to clarify the shared pathophysiology between these disorders and guide effective treatments for individuals affected by both conditions.

Clozapine: prevalence and modalities of associations with antipsychotics and mood stabilizer in French psychiatric hospitals. Multicenter survey on a given day

M. Bordes[1]*, R. Klein[1] and E. Queuille[2,3]

[1]Haute-Garonne, Ferrepsy, Toulouse; [2]Gironde, CH Charles Perrens, Bordeaux and [3]Nord, Association du réseau PIC, Armentieres, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.770

Introduction: Clozapine is indicated for resistant schizophrenia as monotherapy. However, the response is inadequate in 40-70% of patients. In this context, the combination of clozapine with a second antipsychotic or a mood stabilizer is a strategy frequently used to potentiate its effects (**Barlatier, A. (2014)** *Human Medicine and Pathology*. [Doctoral thesis, University]). However, the level of evidence for these practices remains low, and data on the prevalence of such combinations in France are limited. Against this backdrop, collaboration between a national multi-professional network operating in various public and private mental health establishments (the PIC network) and a regional psychiatric research federation (FERREPSY Occitanie) enabled the study of the prevalence and modalities of these associations in a large panel of French psychiatric establishments.
Objectives: Estimate the prevalence of co-prescriptions of antipsychotics and mood stabilizer with clozapine for patients hospitalized in full-time psychiatry.
Methods: Observational cross-sectional study conducted on a given day in December 2023 in 30 participating centers that are members of the PIC network and/or FERREPSY.
Results: The computerized records of 795 patients were analyzed by the referring pharmacists at the participating centers. 78.4% of patients had at least one antipsychotic in association with clozapine. 64.5% of antipsychotics associated with clozapine were conventional antipsychotics. Among atypical antipsychotics, aripiprazole was combined with clozapine in 9.9% of patients, amisulpride in 10.7%, risperidone in 8.2%, olanzapine in 4.3% and quetiapine in 3%. For mood stabilizer, the combination of clozapine with valproate was the most commonly used combination (23.64% of patients), ahead of lithium salts (15.6% of patients) and lamotrigine (10.1% of patients).
Conclusions: The combination of psychotropic drugs with clozapine remains a majority practice, which seems to have little connection with existing literature data.

Evaluating Cognitive Bias in Psychosis: A Novel Approach Using Large Language Models on Spanish Speech Data

E. Gutierrez Alvarez[1,2], A. Barajas[3,4]* and R. Ayesa[5,6]

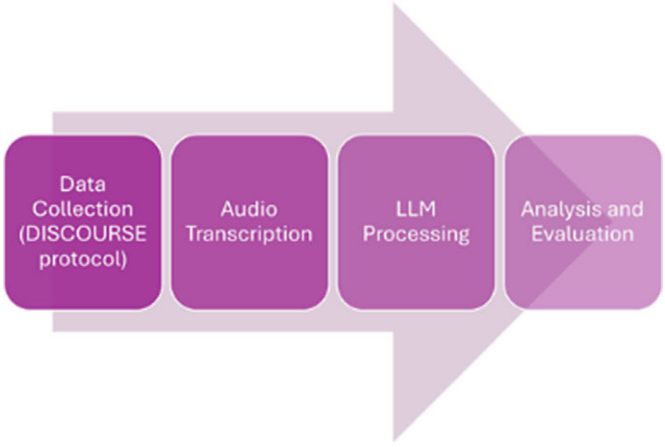
[1]Universidad Politécnica de Madrid, NEBULA group, Madrid, Spain; [2]MIT linQ - Massachusetts Institute of Technology, Cambridge, United States; [3]Department of Clinical and Health Psychology, Autonomous University of Barcelona; [4]Government of Catalonia, Serra Húnter Programme, Barcelona; [5]Mental Illness Research Group, Valdecilla Biomedical Research Institute (IDIVAL), Santander and [6]Biomedical Research Center in Mental Health Network (CIBERSAM), Health Institute Carlos III, Madrid, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.771

Introduction: Jumping to conclusions (JTC) is a cognitive bias strongly involved in the genesis of psychotic symptoms. Accurate evaluation of JTC is crucial for early intervention and treatment planning. However, traditional assessment methods are time-consuming and subject to human error. This study leverages state-of-the-art Large Language Models (LLMs) to evaluate JTC in a unique Spanish population database collected through the DISCOURSE protocol at the Instituto de Investigación Marqués de Valdecilla (IDIVAL).

Objectives: Our primary objectives were to:



1. Assess the efficacy of LLMs in evaluating JTC bias from transcribed speech.
2. Compare different LLM models and prompting techniques for optimal performance.
3. Explore the potential of AI-assisted cognitive bias evaluation in clinical settings.

Methods: We utilized a database of approximately 170 participants, including patients, controls, and relatives, collected through the DISCOURSE protocol. This protocol is particularly valuable as it includes tasks designed to elicit JTC behaviors, such as ambiguous picture interpretation. Audio recordings were automatically transcribed using two speech-to-text algorithms and manually revised for accuracy.

We investigated various LLM models ("gpt4o", "claude-sonnet-3.5", "llama3", "gemini pro") and experimented with different prompting techniques, including instruction combinations and reasoning scratchpads (Chain of Thoughts).

Results: Our evaluation has provided valuable insights into the potential of LLMs for assessing Jumping to Conclusions (JTC) bias. We observed varying degrees of effectiveness across different LLM models in identifying JTC behaviors from transcribed speech, with some showing promise in capturing subtle linguistic cues. Prompting techniques, particularly Chain of Thought reasoning, demonstrated potential in enhancing the models' analytical capabilities. Given our Spanish-language database, we gained important insights into LLM performance in non-English contexts. Error analysis identified common limitations, informing future refinements. Preliminary findings suggested performance variations across demographic subgroups, highlighting areas for further investigation.

Image 1:

Conclusions: This study represents a step towards integrating AI and automation into clinical workflows for psychosis evaluation and treatment. The understanding of the ability of LLMs to assess JTC from speech samples could significantly enhance the objectivity of cognitive bias evaluations. These findings lay the groundwork for future research exploring the integration of AI in psychosocial interventions for psychosis, including potential applications in cognitive remediation, metacognitive training, and personalized treatment planning.

Pathways to care for patients with schizophrenia and severe social impairment

I.-M. Mølstrøm

Psychiatry East, Region Sealand Psychiatry, Research Unit for Early Detection and Psychopathology, Roskilde, Denmark

doi: 10.1192/j.eurpsy.2025.772

Introduction: This presentation sheds light on a group of patients with schizophrenia that are often overlooked. These minority groups include homeless patients and patients with very poor social functioning. Homeless patients with schizophrenia often have complex problems and are difficult to diagnose and treat. While many resources are allocated to early detection and prevention of psychosis programs, few resources are spent on treating the patients who have fallen through the cracks of society and various support systems. These patients are undeniably among the most severely ill psychiatric patients of our time. Patients who are not homeless (domiciled patients) with schizophrenia and very poor social functioning are also often challenging to treat, and they often end up living an isolated existence in their own homes.

Objectives: This presentation will examine the pathways and barriers to care for patients with schizophrenia who are homeless or have serious social function impairment.
Methods: The presentation is based on results from an explorative, cross-sectional study of 85 patients with schizophrenia spectrum diagnosis and severely impaired social function, who either were homeless or domiciled but in need of an outreach team to secure continuous treatment. The study was conducted in Copenhagen in 2020-2024.
Results: We found striking delays in both groups, but most severe in the homeless group. We found a duration of untreated psychosis of ten years and a service delay (period from first contact to psychiatry until a schizophrenia spectrum diagnosis) of four years. Possible reasons for the alarming delays will be discussed, including diagnostic overshadowing and the difficult-to-recognize presentations of schizophrenia. Potential solutions for moving forward will also be highlighted, such as rekindling the diagnostic process.
Conclusions: The overall results from this presentation indicate that there are highly vulnerable minority groups of patients with schizophrenia who have not benefited from the improvements in diagnosis and treatment that we have witnessed in psychiatry in the last 100 years. Acquiring a better understanding of these patients' conditions, symptom presentations, and barriers to timely diagnosis is highly warranted.

Enhancing men's engagement in suicide prevention: Integrating masculine norms and personal narratives

C.-E. Notredame[1,2]*, T. Delbarre[3], N. Pauwels[4], L. Rougegrez[5], G. Metz[6] and M. Morgiève[1,7]

[1]3114 National coordination center, CHU Lille; [2]Lille Neuroscience & Cognition, Univ. Lille, Lille; [3]3114 National coordination center; [4]Papageno program, F2RSMPsy, St André; [5]3114 Lille regional center, CHU Lille, Lille, France; [6]Department of Health Promotion, Maastricht University, Maastricht, Netherlands and [7]Cermes3, Paris, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.774

Introduction: In Western countries, men die by suicide three to four times more often than women, a disparity driven by masculine norms that emphasize stoicism and self-reliance. These cultural expectations often discourage men from seeking help, leading them to face their struggles in isolation. Reluctance to seek support significantly reduces access to the social connections that are vital for suicide prevention. Remote services, such as France's national suicide prevention helpline 3114, offer a discreet and accessible way for men to bypass these barriers and receive the support they need.
Objectives: The national coordination center of the 3114-helpline set out to enhance men's engagement with its services by developing a strategy that accounts for the impact of masculine norms on their willingness to seek and accept help. To ensure the strategy is relevant and effectively addresses the specific needs of men, it aimed to incorporate insights from those who had been directly affected by suicide.
Methods: A Cyclical Evaluation Process was employed to design and assess this digital public health intervention, comprising three key phases: (1) conducting interviews with men who had contacted the 3114 helpline; (2) developing narratives based on their testimonies; and (3) distributing these narratives through social media and the 3114 website. The stories were specifically crafted to boost readers' self-efficacy and encourage help-seeking behaviours. This approach triangulates data to evaluate the narratives' impact on men's attitudes and behaviours concerning suicide prevention.
Results: Phase 1 involved interviews with five men aged 35 to 51, revealing that hegemonic masculine norms, such as stoicism, significantly impede help-seeking behaviors. In Phase 2, a multidisciplinary team transformed the participants' testimonies into compelling narratives, which were published between April and May 2024. Phase 3 saw these narratives garner 2,264 website visits and 49,782 social media impressions, indicating strong public engagement. The anonymity provided by telephone helplines facilitated emotional expression, helping to redefine traditional notions of masculinity. The stories played a significant role in raising awareness, normalizing help-seeking among men, and actively dismantling harmful gender stereotypes.
Conclusions: Incorporating the narratives of individuals who have experienced suicidal episodes offers a deeper, more nuanced understanding of this complex issue. When shared through empathetic and respectful approaches, testimonies significantly enhance prevention strategies. Co-constructing knowledge with those directly affected leads to interventions that are more relevant, tailored, and responsive to their actual needs. This approach underscores the ethical imperative of amplifying the voices of vulnerable individuals to develop more equitable and inclusive solutions.

The Role of Dark and Vulnerable Personality Traits in Self-Harm, Suicide, and Risky Behaviors Among Young Adults in Tehran

K. Qaderi Bagajan[1,2]

[1]Department of Clinical and Health Psychology, Shahid Beheshti University, Tehran, Iran, Islamic Republic Of and [2]Psychological Diagnostics group, Department of Psychology, Humboldt-Universität zu Berlin, Berlin, Germany
doi: 10.1192/j.eurpsy.2025.775

Introduction: Suicidal behaviors, non-suicidal self-injury, and risky behaviors are significant concerns in young adulthood.
Objectives: This study investigates the causal relationships between dark and vulnerable personality traits, guilt and shame proneness, and these behaviors among young adults (ages 18-40) in Tehran. Adopting a dimensional and dynamic perspective on personality, the study aims to develop a comprehensive model that incorporates proposed pathological personality traits from DSM-5 (PID-5).
Methods: Using a cross-sectional design and structural equation modeling, the study analyzed data from a large sample of 1,876 participants, including both a general population sample (n=1,696) and a clinical population (n=180) with suicidal/self-harm behaviors or personality disorders. Data were collected using the Short Dark Tetrad (SD4), Triple Scales of Vulnerable Dark Personality Traits,

Guilt and Shame Proneness Scale (GASP), Domain-Specific Risk-Taking (DOSPERT), Self-Harm Inventory (SHI), and Suicidal Behaviors Questionnaire-Revised (SBQ-R).
Results: The study evaluated three main models and nine sub-models. Findings from the comprehensive research model indicated that the proposed causal model, incorporating dark and vulnerable personality traits and guilt and shame proneness, effectively explains self-harm, suicidal, and risky behaviors in both young adults and those with diagnosed personality disorders. Key findings include:
A spectrum of dark and vulnerable personality traits significantly influences self-harm, suicidal, and risky behaviors. Pathological shame proneness, particularly when accompanied by detachment, increases suicidal tendencies. The absence of healthy guilt and shame proneness is associated with higher levels of risky behaviors and non-suicidal self-injury. All dimensions of the dark and vulnerable personality spectrum predict lower healthy guilt and shame proneness and higher pathological shame proneness.
Finally, Healthy guilt and shame proneness plays a mediating and protective role, reducing the likelihood of self-harm and risky behaviors.
Conclusions: This study contributes to the conceptualization of self-harm, suicidal, and risky behaviors within a dimensional and spectrum-oriented framework, considering personality traits, moral emotions, and behavioral consequences. Practical and research implications are discussed.
Keywords: Dark Personality Traits, Risky Behaviors, Self-Harm Behaviors, Suicide, Guilt and Shame Proneness, Vulnerable Personality Traits, Young Adults.

The Effect of Cognitive Behavioral Intervention on Cognitive Situation, Quality of Life, Depression, Anxiety and Stress Levels of Menopausal Women: Mixed Method Study

F. Atkan[1] and F. Oflaz[2]*

[1]Istinye University, Faculty of Health Sciences and [2]Koç University, School of Nursing, İstanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.776

Introduction: Menopause causes physiological, cognitive, and psychological changes in women and negatively affects women's quality of life.
Objectives: This study aimed to examine the effects of cognitive behavioral approach-based intervention on the cognitive situation, quality of life, anxiety, depression, and stress levels experienced by women after menopause with mixed-method research.
Methods: The research was carried out between March 2022 and August 2023 as a mixed-method research consisting of three phases (quantitative, qualitative, and intervention). Eighty women (experiment=27, control=53) attended in the quantitative phase. Quantitative data were collected before & after intervention by The Sociodemographic Data Form, The Montreal Cognitive Assessment Test, The Menopause-Specific Quality of Life Scale, and The Depression Anxiety Stress Scale. In the intervention phase, a six-session, cognitive behavioral approach-based nursing intervention was conducted with five groups using online Zoom. Hermeneutic phenomenology design was used in the qualitative phase. Qualitative data were collected online, via Zoom platform, and through three focus group interviews. Qualitative data were evaluated by the Thematic Analysis method. In the analysis of quantitative data, descriptive statistics, Independent Samples Groups t-test, Mann-Whitney U Test, and Wilcoxon Test were used.
Results: There was no statistically significant difference between intervention and control groups in terms of sociodemographic characteristics, age, age of onset of menstruation, and menopause. Post-intervention cognitive scores (Z=-3.936, p=0.001) and psychosocial quality of life scores (Z=-2.771, p=0.006) of women who were in the intervention were higher than their pretest scores. There was no statistically significant difference in the post-intervention mean scores between groups in terms of other variables (p>0.05). The themes were loss, stigma, loneliness, not being understood, aging, loss of health, sexuality, acceptance, self-awareness, and coping ability. Women's perceptions of menopause changed mostly functionally after the intervention study.
Conclusions: The research findings showed that Cognitive Behavioral Intervention had some curative effects on women's cognitive changes and psychosocial changes they experienced during menopause. Nurses working with menopausal women can use Cognitive Behavioral approaches to manage the changes brought about by menopause effectively.

Navigating Grief: Understanding the Impact of Pregnancy Loss on Parental Attachment to the Second Child

C. M. Grego[1]* and A. Tarelho[1]

[1]Psychiatry and Mental Health Department, Local Health Unit of Aveiro Region, Aveiro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.777

Introduction: Pregnancy loss is a significant emotional experience that can shape subsequent parenting dynamics, particularly the attachment process to the next-born child. While attachment theory provides a framework for understanding how parents bond with their children, the effects of pregnancy loss on attachment to a subsequent child remain complex and understudied. This review aims to synthesize current research on the relationship between pregnancy loss and parental attachment to the next-born child, considering factors such as grief, coping mechanisms, and emotional healing.
Objectives: The primary objective of this review is to examine existing literature to determine: (1) How pregnancy loss impacts parental attachment to a subsequent child; (2) The emotional, psychological, and contextual factors that influence the attachment process post-loss; (3) Gaps in the research and potential areas for future investigation.
Methods: This review study systematically examines peer-reviewed articles, empirical studies, and theoretical papers published between 2000 and 2024 on the topic of pregnancy loss and subsequent child attachment. The databases used include PubMed and

Google Scholar. Studies were included if they explored parental attachment post-loss, considered factors like grief and coping, and employed qualitative or quantitative measures of attachment. The literature was evaluated for methodological rigor and relevance to the study's objectives.
Results: The review identified consistent evidence that pregnancy loss can significantly affect attachment to the second child. Factors such as unresolved grief, heightened anxiety, and fear of loss contributed to difficulties in forming secure attachments. However, some parents demonstrated increased emotional investment in the second child as part of their healing process. The role of external support systems, such as counseling and social support, was identified as critical in mitigating attachment challenges. Additionally, research showed that fathers and mothers might experience attachment differently after loss, with cultural and individual factors influencing outcomes.
Conclusions: This review underscores the complex and nuanced relationship between pregnancy loss and attachment to a subsequent child. While many parents experience heightened emotional challenges, supportive interventions can facilitate healthier attachment processes. Further research is needed to explore the long-term implications of these attachments and to develop targeted therapeutic strategies for parents navigating pregnancy after loss. The findings have significant implications for healthcare providers, offering guidance on how to support families during this critical period.

Disclosure of Interest: None Declared

A Mental Health Hospitalization at Home program as a novel healthcare delivery model on the postpartum period

O. Marco Estrada[1]*, I. Agasi[2], N. Cabrera[2], I. Pacchiarotti[2], I. Pereta[2], D. N. Ocejo[2], E. Solé[2], A. Roca[2], L. Navarro[2] and M. Garriga[2]

[1]Psychiatry and [2]Hospital Clínic de Barcelona, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.778

Introduction: The early postnatal period is at high risk for new and recurrent episodes of severe mental illness, with around one to two women in 1,000 requiring admission in the first few months after birth.
Home visits by midwives/obstetricians/paediatricians have been tested on preventing mental health problems on the postpartum with no home specific treatment when mental ill relapse appears. Indeed, scarce literature is found on acute relapses on mental health on the postpartum in terms of home visiting programs.
Objectives: Authors aim to explore the role of a Mental Health Hospitalization at Home (MH-HaH) program on acute mental health status on the postpartum period.
Methods: A descriptive study on women attended in a HaH-MH program due to an acute mental health crisis on the postpartum period has been conducted.
Results: Ten mother-baby dyad were attended: 7 were on an avoidance admission regimen (two directly referred from the obstetric ward) and 3 were early discharged from a psychiatric inpatient unit. Three patients were admitted due to psychotic symptoms, 6 due a depression features and one due to manic symptoms. All of them were discharged to a minor intensity setting and none required of hospital admission after a month of the MH-HaH. At a year of follow-up, only one patient required a new hospital admission due to a relapse.
Conclusions: MH-HaH programs could be a safe and respectful alternative to psychiatric admissions with a low relapse rate. However, the need of personalized approach of the dyad and the family as well as collaboration with the Perinatal Mental Health Units is required.

EPP537

Characterization of a transgender population in Portugal and the portuguese outlook on transgender health care

C. P. Desport[1]*, I. G. Carvalho[1], Z. Figueiredo[1] and S. Viveiros[1]

[1]Mental Health, Unidade Local de Saúde de Santo António, Oporto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.779

Introduction: Gender incongruence (GI) and gender dysphoria (GD) represent a health condition in which the individual's gender identity does not correspond to their assigned gender at birth, when dysphoria is present it means there is significant distress. This population needs specific healthcare from a multidisciplinary team involving psychiatry, psychology, endocrinology, urology and/or gynecology, otorhinolaryngology and plastic surgery. In Santo Antonio Hospital, currently, Unidade Local de Saúde de Santo António (ULSSA), there is a sex and gender unit (USEG – Unidade de Sexo e Género), with the previous described specialties, that evaluates and follows transgender individuals through their transition process. A mental health assessment is a major part of this process since, in Portugal, it is required an evaluation, from a mental health professional with clinical experience in this field, to have hormonal treatment, and two to have surgical procedures done.
Objectives: Characterization of a population of transgender individuals in Portugal, framing the results in the current Portuguese panorama of transgender health care.
Methods: Retrospective study of individuals that attended sexology/psychiatry consultation from USEG. Age, type of treatments they have made so far and expectations, type of transition – male to female (MtF) or female to male (FtM) or non-binary (NB), occupation and education, relationship status, city of origin and comorbidities were analyzed.
Results: 143 people were assessed and/or followed for gender incongruence and/or dysphoria, with a minimum age of 17 and a maximum of 61 at the time of their first consultation, mean age of 24,4 years. Of these 49,65% had FtM GI/GD, 38,46 % MtF and 11,89% identified as NB. Several individuals had concomitant medical conditions, and there were high rates of psychiatric comorbidity like anxiety and depression but also neurodevelopmental disorders. The majority of the individuals intended to start hormonal treatment with many expressing fear and anxiety related to the surgical

procedures but with a still high proportion looking forward to them in the future. Many of our patients lived in places far from our hospital.
Conclusions: We found a higher prevalence of FtM than MtF, which is in contrast with most studies in the field but similar to another Portuguese study. The high percentage of medical, specifically psychiatric comorbidities, enhances the importance of a mental health assessment and follow up in this population. A significant percentage of our patients came from cities far away reflecting the scarcity of specialized trans health care in our country. GD and GI diagnosis is increasing worldwide and the transition process is long and highly complex requiring a multidisciplinary team that can collaborate on a unique individual's care in a coordinated and safe way.

Autism and Sexuality: Breaking Taboos and Embracing Desires

A. D. S. Moreira[1]* and R. Malta[1]

[1]Serviço de Psiquiatria, Unidade Local de Saúde de São João, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.780

Introduction: Autism spectrum disorders (ASD) are a group of neurodevelopmental conditions characterized by impairments in social interaction, communication (both verbal and non-verbal), and repetitive behaviors. The global prevalence of ASD has increased significantly, with an estimated 28.3 million cases worldwide. Although many individuals with ASD have normal cognitive and language skills, difficulties with social interactions and understanding nonverbal cues can interfere with their ability to form romantic and sexual relationships, potentially leading to inappropriate behaviors and a distorted experience of sexuality.
Objectives: This paper aims to review the literature on sexuality in individuals with ASD, focusing on typical sexual behaviors, sexual preferences, as well as hypersexuality and paraphilic fantasies and behaviors within this population.
Methods: A non-systematic literature review was conducted, with article selection from PubMed using the keywords: "autism spectrum disorders", "sexuality", "hypersexuality" and "paraphilia".
Results: Studies have shown that adolescents with ASD experience higher rates of inappropriate sexual behaviors and gender dysphoria compared to neurotypical peers. Variants in sexual orientation, including homosexuality, asexuality, and bisexuality, are more prevalent in this population. Recent research indicates that sexual experiences, both alone and with others, are common among individuals with high-functioning ASD, with one study revealing that 47% expressed interest in having a romantic partner. Despite this, adults with ASD, especially men, are generally less likely to be in romantic relationships. They also exhibit more hypersexual and paraphilic fantasies and behaviors than neurotypical individuals. Hypersexual behaviors are predominantly observed among male ASD individuals, while paraphilias, such as voyeurism and fetishism, are frequently reported among both ASD men and women. Sadistic and masochistic fantasies and behaviors are also common in this group.
Conclusions: The results indicate that individuals with ASD have a higher prevalence of sexual orientation variants and inappropriate behaviors compared to their peers. Although they have sexual interests and desires for relationships, their ability to express sexuality in a healthy way is hindered by communication deficits, social interaction challenges, and an unsupportive environment, exacerbated by inadequate sexual education. These challenges prevent many from fully embracing their sexuality. Specialized, evidence-based sexual education addressing the unique needs of individuals with ASD is essential for promoting healthier sexual behaviors and improving psychosocial well-being.

How elevated testosterone levels are responsible for frequent hospitalizations in female patients

S. Vuk Pisk[1,2]*, K. Laskarin[1], E. Ivezic[1,2], E. Gudelj[1], S. Belcic[1], N. Ruljancic[1], K. Matic[1], V. Grosic[1,2] and I. Filipcic[1,2,3]

[1]University Psychiatric Hospital Sveti Ivan, Zagreb; [2]Faculty of Dental Medicine and health Osijek, Osijek and [3]School of Medicine University of Zagreb, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.781

Introduction: Studies that have investigated the relationship between testosterone and psychiatric disorders in women report inconsistent results. Some studies suggesting that female depression patients have lower serum testosterone levels than healthy controls while others report higher serum testosterone levels in female depression patients. Testosterone has also been found to modulate depression and anxiety symptoms. Social research suggests high androgen levels cause aggressive behavior in men and women and as a consequence may cause depression and possible results with more often hospitalization.
Objectives: The purpose of this study was to determine whether there is a link between the intensity of psychological symptoms that required hospital psychiatric treatment and the level of testosterone in the blood.
Methods: The research is prospective and includes female patients with established diagnoses of depressive disorder, anxiety-depressive disorder, bipolar disorder (depressive episode) aged 18-65. The patients had their laboratory parameters determined, including sex hormones (testosteron, estrogen, progesterone, FSH, LH and prolactin), filled out a demographic questionnaire and questionnaires: The Suicide Behaviors Questionnaire-Revised (SBQ-R), Generalised Anxiety Disorder Assessment (GAD-7), Patient Health Questionnaire (PHQ-9), Beck Depression Inventory (BDI-II), Beck Anxiety Inventory (BAI), Matthey Generic Mood Question, Montgomery-Asberg Depression Rating Scale (MADRS), Hamilton Anxiety Rating Scale (HAMA) i Hamilton Depression Rating Scale (HAMD).
Results: The preliminary data of the prospective study showed that there was a statistically significant proportion of patients in whom

higher testosterone levels are linked with higher number of hospitalizations (rho=0.511, p=0.036).
Conclusions: Preliminary results show an association between testosterone levels and frequent psychiatric hospitalizations.

Social Media and E-Cigarette Use Among Adolescents and Young Adults: A Systematic Review of the Role of Influencers and Platforms in Promoting Vaping Culture

K. Jafari[1]*, N. Joshaghani[1], A. Wascher[2] and S. Gunturu[1]
[1]Psychiatry, BronxCare, New York and [2]American University of the Caribbean, Miramar, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.782

Introduction: The widespread use of electronic cigarettes (e-cigarettes) among adolescents and young adults has become a significant public health concern. With the rise of social media, exposure to content promoting e-cigarette use, including endorsements by influencers, has become increasingly pervasive. This overlap between social media and vaping culture may contribute to the normalization and growing use of e-cigarettes among this vulnerable population.
Objectives: This article aims to systematically examine the influence of social media use and endorsements by influencers on e-cigarette use among adolescents and young adults, identifying patterns of exposure and consumption across various platforms and providing insights for future prevention and intervention strategies.
Methods: This systematic review aims to explore the impact of social media use and influencers on e-cigarette use among adolescents and young adults. A PRISMA model review was conducted across four databases: PubMed, Science Direct, Google Scholar, and Scopus. Medical Subject Heading (MeSH) terms and keywords (vape, e-cigarette, smoking, social media, influencer, adolescent) were used to search for full-text studies published in English from the last five years. The studies included focused on human subjects aged 10-21 and met predefined eligibility criteria.
Of the 1,064 articles initially identified, 37 were included after screening and removing duplicates.
Results: Thirty-seven articles met the eligibility criteria. The analysis focused on five key social media platforms: TikTok, Instagram, YouTube, Twitter, and Facebook. However, significant methodological limitations were noted in the studies.
Conclusions: The research highlights a strong link between social media use and youth e-cigarette consumption. Exposure to vaping content, ads, and peer influence on social media increases the risk, particularly among younger and vulnerable groups. Social media enables both direct marketing and peer-to-peer promotion. Stricter regulations on online ads and enhanced parental controls are necessary to mitigate these risks and reduce youth vaping rates.

Predicting return to use for people with substance abuse disorders

L. Mehl-Madrona[1,2]*, B. Mainguy[3], B. Lamboy[4] and J. Lamboy[4]
[1]Native Studies, University of Maine, Orono; [2]Psychiatry Residency, Northern Light Acadia; [3]Wabanaki Health and Wellness, Bangor and [4]Research, Coyote Institute, Orono, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.783

Introduction: Substance Use can be a lifelong issue. Recovery is not necessarily easy and not necessarily predictable. Treatment can be expensive and is potentially offset by other influences.
Objectives: We wanted to predict the likelihood of returning to use for Indigenous clients being treated for Substance Use Disorders in the United States.
Methods: We interviewed 35 people who had been diagnosed with a Substance Use Disorder and had been treated in a conventional detox program followed by 30 to 120 days of residential treatment. The participants were obtained by word of mouth referrals, posters and flyers announcing the studiekeeeeeeWe gathered their life stories using a modification of the Northwestern University Life Story Interview which we called the Maine Life Story Interview. We correlated elements from the life story with the likelihood of return to use. By virtue of where the authors worked (Clinics providing services to Indigenous people), all the clients were Indigenous, though we did not aim for that at the outset. Logistic regression methods were used to predict return to use.
Results: The combination of an ACE Score of 5 or greater, a history of substance use for 4 or more years, couipled with returning to the environment of the original substance abuse (physical and/or human) was associated with a 100% probability of return to use regardless of substance used and despite treatment received., With an ACE score of less than 5, the probability of return to use dropped to 80%. The length of treatment before returning to community did not matter. Adverse Childhood Events were measured using the ACE score and resiilience was assessed using a qualitative rating that has been shown to be reliable. Logistic regression confirmed the above – that the most powerful predictors were returning to the community in which the abuse began and returning to the same social network of people who abused. These variables predicted 84% of the variance. Treatment type or duration did not emerge as significant.
Conclusions: For Indigenous clients, returning to the environment of substance abuse and to the people with whom substance have been used is a powerful factor that overrides the effects of treatment. The higher the ACE score, the more likely the return to use. The length of treatment (ranging from 10 to 130 days) did not seem to matter. Based upon this data, one could argue that tretment should take place in the community from which the person came and be oriented toward changing social networks and eliminating environmental cues. If this is not possible, returning to community appears frought with peril, though inevitable for Indigenous people who need to come home again. Resilience was not a predictive factor once one had returned to the social and environmental locale of the original substance use.

Examination of Theory of Mind, Cognitive Functions and Acute Period Clinical Features in Patients Diagnosed With Substance Use-Related Psychotic Disorder

C. Yildirim[1]*, N. Zorlu[1], B. Bagci[1] and A. Bilge Bektas[2]

[1]Psychiatry, Izmir Katip Celebi University Ataturk Education and Research Hospital and [2]Psychiatry, Izmir City Hospital, Izmir, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.784

Introduction: There are recent studies examining the cognitive functions, depressive symptoms, social cognitive characteristics (Terms of Theory of Mind) and acute symptoms of patients with substance-induced psychosis, as well as varying effects of different substances on development of psychosis (Beckmann et al. Child Adolesc Psychiatr CNA.2020;131-143).
Objectives: It was aimed to examine sociodemographic characteristics, clinical symptoms in acute psychotic period, cognitive functions, social cognition characteristics of hospitalized patients diagnosed with substance related psychosis; compare the severity of clinical symptoms, improvement in acute period symptoms with treatment, cognitive functions and social cognitions according to substance (methamphetamine, cannabis, polydrug).
Methods: 34 hospitalized patients in acute psychotic episode diagnosed with Substance-Induced Psychosis according to DSM-5 were included in study. Socidemographic Data Form, Reading the Mind in the Eyes Test, Stroop Test, Calgary Schizophrenia Depression Scale and every 3 days during the treatment PANSS (Positive Negative Syndrome Scale) were administered.
Statistical analyses done with R program. Kruskal-Wallis test was used to compare numerical variables between groups. For the significant differences between groups, Bonferroni correction was applied in post hoc analyses. P-value of less than 0.05 was considered statistically significant for all analyses. Chi-square test was used to analyze categorical variables.
Results: It was determined that drug-induced psychosis patients were mostly male, unemployed, young adults, started using drugs before the age of 18, lived in irregular urban areas. Methamphetamine, cannabis and polydrug-related psychosis were compared; There was no difference in cognitive functions and social cognition characteristics between all groups. At the end of treatment, it was observed that the rate of improvement in positive and negative symptoms and the decrease in PANSS scores were greatest in methamphetamine group, there was no difference between cannabis and polydrug groups. We found that PANSS and negative symptom severity before starting treatment were not different between methamphetamine and cannabis, and initial positive symptoms were more severe in methamphetamine than cannabis.
Conclusions: Methamphetamine group showed greater improvements in positive and negative symptoms and total PANSS scores compared to cannabis and polydrug. The fact that there was less improvement in cannabis group than in methamphetamine group supports the data in the literature identifying the relationship between cannabis and chronic psychosis (D'Souza et al, The World Journal of BP, 2022, 719–742).
No difference was found between social cognitions and cognitive functions of 3 groups.

Keywords: Drug Induced Psychosis, Methamphetamine, Cannabis, Theory of Mind.

Pregnancy and reproductive health in women with bipolar disorder at the Arrazi Psychiatric University Hospital in Salé

N. Ait Bensaid[1]*, M. Sabir[1,2] and F. El Omari[2]

[1]arrazi psychiatric hospital, Sale, Morocco and [2]HAS, arrazi psychiatric hospital, Sale, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.785

Introduction: Bipolar disorder, like other severe mental illnesses, is considered to be a condition with an increased risk of unsafe sexual practices [1]. Unsafe sex in bipolar disorder has been empirically linked to manic episodes due to symptoms of hypersexuality, cognitive impairment and substance and alcohol abuse.
Unprotected sex poses health risks for both sexes in terms of sexually transmitted diseases, but for women it also means a risk of unplanned pregnancy. Unplanned pregnancies can have negative consequences for the health, social and psychological lives of women and children [2].
Translated with DeepL.com (free version)
Objectives: To assess reproductive health and unplanned pregnancies in patients with bipolar disorder followed and hospitalised at the Arrazi psychiatric hospital in Salé.
Methods: This was a descriptive cross-sectional study using a questionnaire including sociodemographic and clinical criteria as well as questions on the sex life of patients with bipolar disorder type I or II, questions on contraception, and on pregnancies and their outcomes.
Inclusion criteria: women with bipolar disorder type I or II.
Exclusion criteria: psychosis, intellectual disability.
Results: The average age of the participants was 33 years. 68% were married and 57% had children. The majority were unemployed (87%). 85% had a substance use disorder. 61% had type I bipolar disorder and 44% were hospitalised, with the remainder receiving outpatient treatment. Almost all the patients were sexually active at the time of the study, and 88% had only one sexual partner. 77% were using contraception, mainly the pill. The average age of first pregnancy was 22 years. 66% of pregnancies were unplanned. 89% gave birth and 11% had abortions.
Conclusions: Bipolar disorder, like other serious mental illnesses, is considered to be a condition with an increased risk of unsafe sexual practices. Female patients with bipolar disorder have an early age of onset of sexual activity. This leads to frequent unplanned pregnancies. These unplanned pregnancies can have negative consequences for the health, social and psychological life of women and children. Clinicians must be aware of reproductive health and take steps to improve access to family planning when treating young women with bipolar disorder, in order to avoid negative consequences.

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.786

Introduction: Bipolar Disorder (BD) is a severe and chronic psychiatric condition, with complicated course and substantially reduce psychosocial functioning. Alterations in immune response are considered to be one of the major factors underlying the etiopathogenesis of BD, causing alterations in neurotransmitter systems, neuroendocrine systems, neurotrophic factors, and producing oxidative stress. Inflammatory cytokines have potential value for the clinical diagnosis and prognosis of BD.

Objectives: The primary aim of the study was to assess the effect of disease course and clinical-characteristics on alterations of transforming growth factor-beta (TGF-beta), in BD.

Methods: This cross-sectional study included 82 patients with BD in remission. Multivariate linear regression with TGF-beta value as an outcome, and duration of illness, number of hospitalizations, residual symptoms estimated as Brief Psychiatric Rating Scale (BPRS) score, gender, and age, was used to produce the model.

Results: The explored linear regression model was significant, explaining 39.4% of the variance ($p<0.001$). Higher TGF-beta was predicted by less previous hospitalizations ($p<0.001$) and lower BPRS score (0.034), while longer duration of illness was almost significant predictor ($p=0.054$). Age and gender showed no predictive effect in the model.

Conclusions: The study points out to the better course of BD characterized by less episodes and less residual symptoms in determining the TGF-beta levels, potentially creating a more favorable immunological state. The importance of neuroprotective and neurodegenerative balance of immune mediators, their interplay and relation to chronicity and severity of BD should be further explored.

The Evolution and Impact of Mixed Mood States: From Ancient Observations to Modern Understanding

V. I. Grasso[1], D. G. Sotelo[2], M. Cetkovich[3], M. Dines[3], B. Hofmann[4] and G. Vazquez[5*]

[1]psychiatry, CIPCO; [2]psychiatry, private practice, Cordoba; [3]psychiatry, INECO, Buenos aires, Argentina; [4]psychiatry, private practice, Palma de mallorca, Spain and [5]psychiatry, Providance Care Hospital, kingston, Canada

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.787

Introduction: Mood disorders with mixed features, characterized by the concurrent presence of manic and depressive symptoms, represent a complex and significant area in psychiatric research. Historically, the recognition of such mixed states traces back to ancient Greek scholars, with evolving understanding through the 19th century. This evolution reflects substantial contributions from early thinkers to modern psychiatric frameworks.

Objectives:

1. To trace the historical development of the concept of mixed mood states from ancient Greece to the 19th century.
2. To analyze the contributions of key figures such as Areteo of Cappadocia, Wilhelm Griesinger, Jean-Pierre Falret, Emil Kraepelin, and Wilhelm Weygandt in shaping the understanding of mixed states.
3. To evaluate the impact of Kraepelin's and Weygandt's work on contemporary classifications of mood disorders.

Methods: A historical review of primary and secondary sources, including classical texts and psychiatric literature, was conducted. The analysis focused on the contributions of significant historical figures, examining their theories and classifications of mood disorders. Key publications, such as Kraepelin's treatises and Weygandt's monographs, were scrutinized to assess their influence on modern psychiatric nomenclature.

Results: The study highlights the foundational observations of mixed mood states by ancient Greek scholars, particularly Areteo, who first proposed that mania and melancholia were facets of the same condition. The 19th-century revival of interest in these states saw important contributions from Griesinger and Falret, with Kraepelin's systematic framework in his 1899 treatise integrating mixed states into a unified concept of manic-depressive insanity. Weygandt's 1899 monograph further refined the understanding of mixed states, reflecting a collaborative intellectual effort with Kraepelin.

Conclusions: The historical evolution of mixed mood states demonstrates a significant advancement in psychiatric theory. Kraepelin's comprehensive framework, supported by Weygandt's detailed analysis, laid the groundwork for contemporary classifications of mood disorders. Recognizing the collaborative nature of these developments underscores the importance of shared intellectual contributions in the advancement of psychiatric science.

The Syndrome of Irreversible Lithium-Effectuated Neurotoxicity: A Report of Two Cases

G. Ozmen[1*], V. Kolcu[1], E. Sipahi[1] and B. Yıldırım Cinek[1]

[1]Health Sciences University, Erenkoy Mental Health and Neurological Diseases, Training and Research Hospital, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.788

Introduction: Lithium is a widely used treatment for mood disorders, particularly bipolar disorder, but its narrow therapeutic range often leads to toxicity. A major complication is lithium-induced neurotoxicity, which is generally reversible with dose adjustment or discontinuation. However, symptoms persisting beyond two months after cessation are deemed irreversible and may result in permanent neurological damage(Verdoux *et al.* Encephale 1991;17:221-4).

The permanent sequelae, first recognized in the 1980s, are known as "Syndrome of Irreversible Lithium-Effectuated Neurotoxicity" (SILENT). SILENT is marked by irreversible neurological damage, including cerebellar dysfunction, dementia, parkinsonian syndromes, choreoathetosis, brainstem syndromes and peripheral neuropathies (Farouji et al. Cureus 2023;15).

Objectives: This case report aims to highlight the rare SILENT syndrome and underscore the importance of early diagnosis and management of lithium-induced neurotoxicity.

Methods: Case 1: A 61-year-old male with a long-standing diagnosis of bipolar disorder, managed since age 18, presented in 2022 with speech and gait disturbances while on lithium therapy. His lithium level was elevated (2.31 mmol/L), and he underwent emergency hemodialysis after the suspected interaction of NSAIDs with lithium. Despite normal brain imaging, the patient experienced persistent symptoms of postural instability, ataxic gait, dysarthria and tremor over two years. Subsequent imaging revealed cerebral atrophy and ischemic white matter changes. Neuropsychological testing showed frontal-type memory deficits, leading to a diagnosis of Syndrome of Irreversible Lithium-Effectuated Neurotoxicity.

Case 2: A 71-year-old male with a 40-year history of bipolar disorder presented with tremors, bradykinesia, dysarthria and anorexia. Blood tests showed renal impairment (creatinine 2.3 mg/dL) and elevated lithium levels (1.7 mmol/L), likely secondary to chronic kidney disease. Lithium was discontinued, and valproate was initiated. Nine weeks later, he returned with increased energy, insomnia, impulsivity, auditory hallucinations, temporal disorientation, perseverative speech, and gait instability. Examination revealed agitation, a blank stare, mild dysarthria and gait imbalance despite normal routine blood tests.

Results: Lithium poisoning is a common clinical issue. Elevated lithium levels can result from excessive intake, impaired excretion or drug interactions. SILENT syndrome, a rare complication of lithium therapy, leads to permanent neurological damage, including cerebellar dysfunction, ataxia, dysarthria and tremor (Konieczny *et al.* Alpha Psychiatry 2024; Mar.).

Conclusions: This emphasizes the importance of monitoring for drug interactions and conducting regular neurological assessments to detect and manage lithium-related complications early. The case underscores the need for heightened clinical awareness to prevent permanent lithium neurotoxicity.

People with severe mental illness are not adequately screened for non-communicable diseases: Findings of a multi-country cross-sectional study in South Asia

K. K. Appuhamy[1]*, F. Wiggins[1], A. Mitchell[1], H. U. Ahmed[2], M. Ashworth[3], F. Aslam[4], J. R. Boehnke[5], O. P. Garcia[6], R. I. Holt[7], R. Huque[8], K. P. Muliyala[9], P. Murthy[9], B. Perry[10], D. Shiers[11], N. Siddiqi[1], K. Siddiqi[1], A. Tamizuddin[4] and G. A. Zavala[1]

[1]Health Sciences, University of York, York, United Kingdom; [2]National Institute of Mental Health, Dhaka, Bangladesh; [3]School of Life Course and Population Sciences, King's College London, London, United Kingdom; [4]Institute of Psychiatry, Rawalpindi Medical University, Rawalpindi, Pakistan; [5]School of Health Sciences, University of Dundee, Dundee, United Kingdom; [6]Facultad de Ciencias Naturales, Universidad Autonoma de Queretaro, Santiago de Querétaro, Mexico; [7]Human Development and Health, Faculty of Medicine, University of Southampton, Southampton, United Kingdom; [8]ARK Foundation, Dhaka, Bangladesh; [9]National Institute of Mental Health and Neurosciences, Bangalore, India; [10]School of Psychology, University of Birmingham, Birmingham and [11]Psychosis Research Unit, Greater Manchester Mental Health NHS Trust, Manchester, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.789

Introduction: People with severe mental illness die 10-20 years earlier than the general population. This is largely due to non-communicable diseases (NCDs) such as hypertension, diabetes and hypercholesterolaemia increasing the risk of cardiovascular disease, which is the greatest contributor to the excess mortality seen. The effect of these NCDs is likely to be greater in low-and middle-income countries such as Bangladesh, India and Pakistan due to additional barriers to health care access, lack of resources and other sociodemographic variables.

Objectives: Our study aimed to estimate the proportion of individuals with SMI in Bangladesh, India, and Pakistan who were screened for NCDs and offered health risk modification advice. Furthermore, we also explored socio-demographic factors associated with the likelihood of being screened for NCDs within this demographic.

Methods: This cross-sectional study gathered data from three national mental health institutions in South Asia. Participants aged ≥18 years diagnosed with SMI were included. Data collection involved face-to-face interviews based on the World Health Organisation Stepwise (WHO-STEPS) approach to NCD risk factor surveillance, supplemented by anthropometric measurements and blood tests to confirm NCDs. The prevalence of screening, diagnosis, health risk modification advice, and treatment for diabetes, hypertension, and high cholesterol was assessed. A logistic regression model assessed the associations of sociodemographic characteristics with NCD screening.

Results: 3,989 participants were recruited. Screening prevalence varied by country and disease, with hypertension being the most commonly screened NCD (Bangladesh = 52.5% [50.0-55.1], India = 43.1% [40.3-45.9], Pakistan = 60.9% [58.2-63.5]), and cholesterol was the least common (Bangladesh = 4.1% [3.2-5.2], India = 14.8% [12.9-17.0], Pakistan = 9.6% [8.1-11.3]). Characteristics such as BMI, age and education level were positively associated with screening, and females were more likely to be screened than males. The provision of health risk modification advice was most common in India (diet = 66.7% [62.1-71.1], physical activity = 71.5% [67.0-75.6], smoking = 17.1% [13.8-21.0]), and least common in Bangladesh (diet = 17.8% [15.8-20.0], physical activity = 12.0% [10.3-13.8], smoking = 9.8% [8.3-11.5]).

Conclusions: There is a consistent gap in the screening of NCDs among individuals with SMI in South Asia, with marked sociodemographic disparities. There is a pressing need for standardised screening protocols and health risk modification interventions tailored to South Asian populations. Improving health literacy and implementing culturally sensitive, cost-effective prevention strategies could mitigate the increased risk of NCDs in South Asian individuals with SMI.

The Relationship Between Attention Deficit Hyperactivity Disorder and Major Depressive Disorder in Young Adults: Mediating Role of Mood and Anxiety Disorder Symptoms

D. U. Erarslan[1]*, H. Yapıcı Eser[1], S. Hun Şenol[1] and A. Ercan Doğan[1]

[1]Psychiatry, Koc University Faculty of Medicine, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.790

Introduction: Attention Deficit Hyperactivity Disorder (ADHD) is a lifetime co-diagnosis of one or more psychiatric disorders in 70-80% of cases. In adults, ADHD is associated with anxiety, MDD, bipolar disorder and substance use disorder. (Faraone, S.V. *et al., Nature Reviews Disease Primers* (2024)). The aim of this study was to examine the relationship between ADHD and MDD symptoms in young adults and the mediation of mood and anxiety disorder symptoms on this relationship.
Objectives: In this study, we examined the explainability of the relationship between ADHD and MDD symptoms in young adults through mood and generalized anxiety disorder scales. The aim was to reveal the relationships between different psychiatric dimensions in young adults presenting with these symptoms and to present the necessary treatment approaches.
Methods: Between September 2019 and September 2022, 935 students who applied to Koç University Psychological Counseling and Psychotherapy Center were examined. Sociodemographic information and data were collected using the Adult ADHD Self-Report Scale (ASRS-v1.1), Patient Health Questionnaire-9 (PHQ-9), Generalized Anxiety Disorder-7 (GAD-7) and Mood Disorder Questionnaire (MDQ). Data were evaluated with descriptive statistics and Pearson correlation analysis. The effect of ASRS on PHQ-9 and the mediating effect of GAD-7 and DSQ scores were analyzed with Process macro model 4. The study was approved by Koç University Ethics Committee (Protocol No: 2024.291.IRB2.124).
Results: 82.8% of the students were classified as ADHD positive according to the ASRS 24 cut-off score. According to PHQ-9, the rate of depression was 78.1%. The rate of ADHD and depression positives was 70% according to ASRS24, 57.6% according to ASRS30 and 22.8% according to ASRS44. In the mediation analysis in which ASRS, PHQ9, GAD7 and MDQ scales were evaluated, the model explained 52% of the variance ($p<0.00001$). The direct effect of ASRS on PHQ9 (β: 0.35; $p<0.00001$; 95% CI: 0.29-0.39) was higher than the indirect effects via GAD7 (β: 0.21; 95% CI: 0.175-0.245) and DBQ (β: 0.025; 95% CI: 0.0027-0.048); the effect of MDQ was minimal.
Conclusions: The study shows that ADHD symptoms are frequently associated with depression and that anxiety and mood disorder symptoms may strengthen this association. The possible bidirectional relationship between disorders should be considered in young adulthood assessment and should be followed up with longitudinal studies. The strengths of the study are its large sample size and focus on a significant age range; limitations are its cross-sectional nature and reliance on self-report scales.

Crossing Boundaries: Unraveling the Link Between Gender Dysphoria and Autism

C. M. Grego[1]*, A. I. Gomes[1], G. Simões[1] and A. Tarelho[1]

[1]Psychiatry and Mental Health Department, Local Health Unit of Aveiro Region, Aveiro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.791

Introduction: Gender dysphoria (GD) and Autism Spectrum Disorder (ASD) are two complex conditions that can significantly impact an individual's identity and well-being. Emerging research suggests a notable overlap between these two conditions, yet the nature and implications of this relationship remain underexplored. This paper aims to investigate the intersection of gender dysphoria and autism, considering both psychological and social dimensions.
Objectives: The primary objectives of this study are to: (1) analyze the prevalence of gender dysphoria among individuals with autism, (2) explore the psychosocial factors contributing to the co-occurrence of GD and ASD, and (3) examine the implications for treatment and support strategies.
Methods: A comprehensive literature search was conducted across multiple databases, including PubMed and Google Scholar, focusing on studies published between 2000 and 2024. Inclusion criteria centered on peer-reviewed articles that discuss the relationship between GD and ASD. Data were extracted and analyzed to identify common themes, prevalence rates, and psychosocial factors.
Results: Preliminary findings indicate that individuals with ASD may experience higher rates of gender dysphoria compared to the general population. Factors such as social communication difficulties, rigid thinking patterns, and heightened sensitivity to social norms appear to influence the experience of gender identity. Qualitative data reveal that many individuals navigate significant challenges in accessing appropriate support and validation, often feeling marginalized within both the autistic and gender-diverse communities.
Conclusions: This study highlights a critical intersection between gender dysphoria and autism, emphasizing the need for tailored support systems that acknowledge the unique experiences of individuals at this intersection. Increased awareness and understanding among healthcare providers can lead to more effective interventions and improved outcomes for those navigating both gender identity and autism. Future research should continue to explore this relationship to inform policy and practice, ultimately fostering a more inclusive environment for all individuals.

Methylphenidate for Emotional Dysregulation in patients with Comorbid ADHD and Borderline Personality Disorder

S. Pardossi[1]*, A. Fagiolini[1], D. Koukouna[1], B. Firenzuoli[1], P. Carmellini[1], C. Pierini[1], M. Pinzi[1], V. Centi[1], F. Torrigiani[1] and A. Cuomo[1]

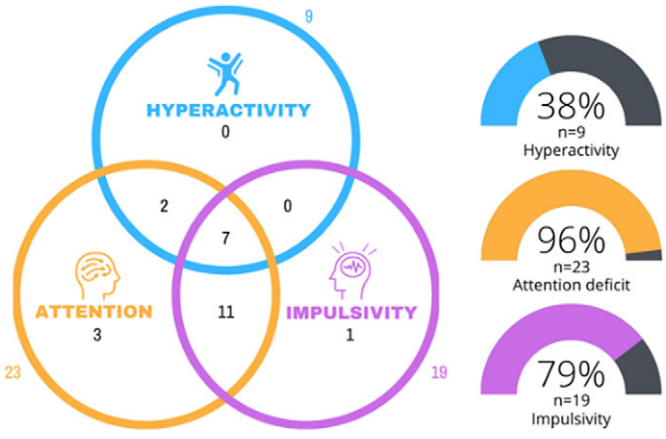
[1]Molecular Medicine, University of Siena, Siena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.792

Introduction: Emotional dysregulation (ED) is highly heterogeneous in its definition, presentation, and classification. It manifests in a variety of ways, including emotional impulsivity, heightened emotional intensity (both positive and negative), and emotional lability. This pattern of emotional experience and expression is seen in several psychiatric disorders, such as Attention-Deficit Hyperactivity Disorder (ADHD) and Borderline Personality Disorder (BPD). Methylphenidate (MTH) has been extensively studied for its efficacy in treating ED in patients with ADHD, but it has been less studied for specific dimensions of BPD, such as impulsivity and executive dysfunction, and even less studied for ED in patients with comorbid ADHD and BPD.
Objectives: This retrospective observational study evaluates the efficacy of MTH in reducing ED in patients with a dual diagnosis of BPD and ADHD. Specifically, we report the efficacy of MTH on emotional impulsivity, emotional lability, and emotional intensity (both positive and negative).
Methods: Patients with a dual diagnosis of ADHD and BPD treated with MTH were evaluated. Descriptive statistics were used to assess the presentation of the comorbidity. The Negative Emotion Dysregulation (NED) subscale of the Reactivity, Intensity, Polarity, and Stability Questionnaire (RIPoSt-40) was used to measure emotional lability and emotional intensity (both positive and negative). In addition, the C-T-Score representing 'Impulsivity/Emotional Lability' from the Conners' Adult ADHD Rating Scales-Self Report: Short Version (CAARS-S:S), was assessed at baseline, week 2, and week 4. A repeated measures ANOVA test was used to assess mean differences.
Results: Of the 24 patients (37.5% female, median age = 24, IQR: 21-37), 23 participants (96%) in the cohort had attention deficits, 9 participants (38%) had hyperactivity, and 19 participants (79%) had impulsivity. Most participants had overlapping symptom profiles (Figure 1). The median dose of MTH was 20 mg [10-30 mg], and the median duration of treatment was 4 months [3-10 months]. Statistically significant reductions in both NED and C-T-Score were observed from baseline to week 2 and from week 2 to week 4 (Table 1, Figure 2).

Table 1

	BASELINE mean (sd)	WEEK 2 mean (sd)	WEEK 4 mean (sd)	p-value
NED	122 (2.43)	105.92 (5.94)	91.83 (8.46)	0.0001
C-T-Score	74.54 (5.27)	66.92 (5.85)	62.88 (5.76)	0.0001

Image 1:



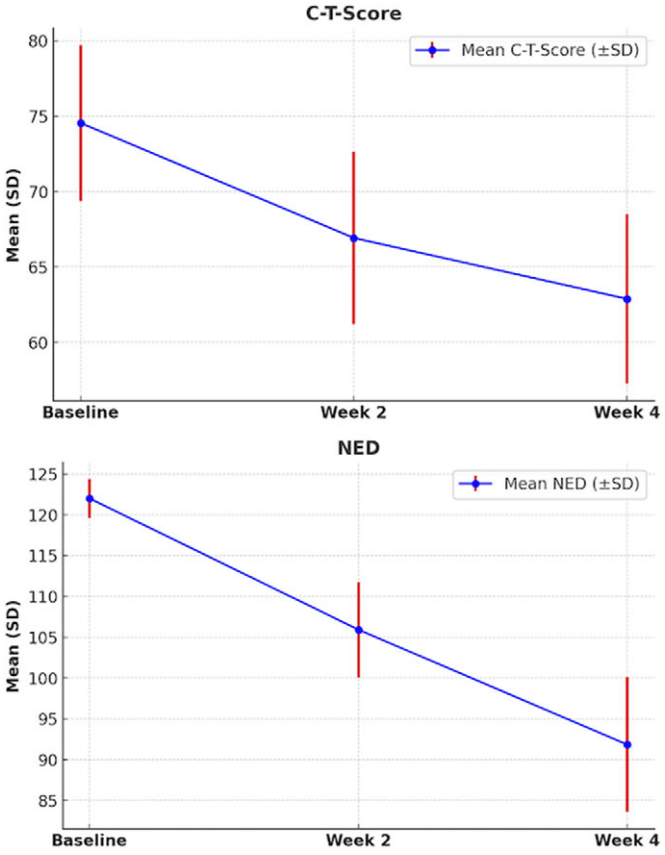


Image 2:

Conclusions: ED is a core symptom of BPD and an important aspect of ADHD psychopathology. Targeting this pattern is complex because it encompasses multiple dimensions such as emotional impulsivity, lability, and intensity. In our study, MTH demonstrated efficacy in reducing these aspects in a real-world population with a dual diagnosis of ADHD and BPD, suggesting a possible role in improving ED, but further controlled studies are needed to confirm these findings.

The clinical utility of biomarkers in diagnosing Major Depressive Disorder in adults: A Systematic Review of literature from 2013 to 2023

S. H. Ang[1]*, R. Ho Chun Man[2,3], R. S. McIntyre[4,5], S. K. Chiang[2], K. M. Teopiz[6], Z. Zhang[7] and C. Ho Su Hui[2,3]

[1]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [2]Department of Psychological Medicine, Yong Loo Lin School of Medicine, National University of Singapore; [3]Department of Psychological Medicine, National University Hospital, Singapore, Singapore; [4]Department of Psychiatry, University of Toronto; [5]Mood Disorders Psychopharmacology Unit, Univesity Health Network; [6]Brain and Cognitive Discovery Foundation, Toronto, Canada and [7]Anhui Engineering Research Center for Intelligent Computing and Application on Cognitive Behavior, Anhui, China

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.793

Introduction: The variety and efficacy of biomarkers available that may be used objectively to diagnose Major Depressive Disorder (MDD) in adults are unclear. This systematic review aims to identify and evaluate the variety of objective markers used to diagnose MDD in adults.
Objectives: This systematic review aims to identify and evaluate the variety of objective markers used to diagnose MDD in adults.
Methods: The search strategy was applied via PubMed and PsycINFO over the past 10 years (2013-2023) to capture the latest available evidence supporting the use of biomarkers to diagnose MDD. Papers were excluded if they were published in a non-peer-reviewed journal and/or not published in English; featured non-primary study designs (e.g. systematic review, meta-analysis, literature review); included children or adolescents in the study population; featured participants without a clinical diagnosis of MDD; featured participants with a diagnosis of other forms of MDD such as treatment resistant depression, vascular depression, remitted depression. Data was reported through narrative synthesis.
Results: 42 studies were included in the review. Findings were synthesised based on the following measures: blood, neuroimaging/neurophysiology, urine, dermatological, auditory, vocal, cerebrospinal fluid and combinatory – and evaluated based on its sensitivity/specificity and area under the curve (AUC) values. The best predictors of blood (MYT1 gene), neuroimaging/neurophysiological (5-HT1A auto-receptor binding in the dorsal and median raphe), urinary (combined albumin, AMBP, HSPB, APOA1), cerebrospinal fluid-based (neuron specific enolase, microRNA) biomarkers were found to be closely linked to the pathophysiology of MDD.
Conclusions: A large variety of biomarkers were available to diagnose MDD, with the best performing biomarkers intrinsically related to the pathophysiology of MDD. Potential for future research lies in investigating the joint sensitivity of the best performing biomarkers identified via machine learning methods and establishing the causal effect between these biomarkers and MDD.

Intermittent white light at 60Hz, a novel non invasive brain stimulation (NIBS), modulates neuroplasticity and ameliorates depressive-like symptoms in animal models - preliminary preclinical and in human data

M. T. Ferretti[1]*, A. Venturino[2], M. Alamalhoda[1], S. Gorkiewicz[2], M. Muhia[2] and S. Siegert[2]

[1]Syntropic Medical and [2]ISTA, Klosterneuburg, Austria
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.794

Introduction: Non-invasive brain stimulation (NIBS) is emerging as a promising option for the treatment of psychiatric diseases, including major depressive disorder (MDD). In this context intermittent white light at a specified frequency holds high promise. We have previously shown that 60Hz stimulation in mice induces selective brain entrainment associated with microglia-mediated remodeling of the perineuronal nets (Venturino et al., Cell Reports 2021).
Objectives: Here, we extend our previous findings with 60Hz stimulation to assess behavioral effects in mice and EEG response in healthy volunteers.
Methods: For the preclinical data, we exposed C57Bl6/J mice to a battery of behavioral tests to assess anxiety level, learning capability, and response to various stress paradigms after 60Hz light (2h per day/5 days) compared to constant light. Weight change, water and food intake were recorded. For human studies, a cohort of 12 healthy volunteers (6M, 6F) was recruited; their EEG response was investigated with an 8-channel EEG setup following acute (same day), short (5 days), and intermediate (3 weeks) stimulation with 60Hz entrainment (n=6) or sham light (n=6).
Results: Preliminary data from the preclinical behavior studies indicate that 60Hz treatment improves the social interaction of socially defeated mice compared to sham light stimulation. Furthermore, the animals showed less anxiety-related behavior when exposed to the elevated plus maze. No differences were noticed in weight change, water and food intake following 60Hz stimulation.
In healthy volunteers, we observed robust and widespread entrainment at 60Hz after acute 60Hz stimulation; the entrainment spread beyond the visual cortex and reached the frontal cortex. The normalized power of the 60Hz component slightly declined over time but remained significant as compared to sham stimulation at three weeks, indicating sustained EEG response. The stimulation was very well tolerated overall, without major side effects.
Conclusions: 60Hz intermittent light induces strong and sustained neuronal response in mice and humans, is well tolerated, and ameliorates depressive-like symptoms in the social defeat model in mice. 60Hz might represent a novel NIBS for the treatment of psychiatric disorders, including MMD.

Effectiveness of Psychotherapy vs Antidepressants for Depression in Primary Care in India: A Randomized Pilot Trial

J. R Pozuelo[1]*, A. Lahiri[2], R. Singh[2], S. D. Hollon[3], N. Dongare[2], A. Khan[2], A. Shukla[2], M. Ghosh[2], A. Kushwah[2], A. Bhan[2], Y. Parashar[4] and V. Patel[4]

[1]Global Health and Social Medicine, Harvard University, Boston, United States; [2]Sangath, Bhopal, India; [3]Vanderbilt University, Nashville and [4]Harvard University, Boston, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.795

Introduction: Depression is commonly treated with psychotherapy or antidepressants, but predicting which intervention will work best for a given patient remains a challenge. This pilot trial compared the feasibility, acceptability, and effectiveness of psychotherapy based on behavioral activation (Healthy Activity Program, HAP) and antidepressant medication (fluoxetine) in a primary care setting in India.

Objectives: The trial had three key objectives: (1) assess the feasibility and acceptability of a randomized pilot trial comparing HAP and fluoxetine; (2) collect outcome data to refine study instruments and the baseline assessment; and (3) evaluate the preliminary comparative effectiveness of psychotherapy versus medication.
Methods: The pilot trial was conducted at eight primary health care centres in Madhya Pradesh (India) from August 2023 to February 2024. Eligible participants (aged 18+, PHQ-9 score ≥10) with moderate to severe depression were randomized to receive either HAP or fluoxetine. Feasibility was assessed by recruitment, retention, and adherence to study procedures. Acceptability was measured by adherence to interventions. Preliminary efficacy, as a secondary outcome, was assessed through changes in depressive symptoms (PHQ-9) from baseline to the 3-month follow-up.
Results: 76 participants were randomized, with primary endpoint data available for 63 (83%). Retention rates and study assessment completion were acceptable across both arms. Intervention adherence was high, with 79% (30/38 in HAP and ADM groups) completing the treatment per protocol (≥6 HAP sessions or 70% medication adherence). PHQ-9 scores improved significantly, with an average reduction from 15.02 at baseline to 6.73 at the 3-month follow-up, with no statistically significant differences between treatments. Full remission (PHQ-9 < 5) was achieved by 45.16% (28/62) of participants. Additionally, the pilot study identified logistical challenges and facilitators that will help refine the protocol for the larger trial.
Conclusions: This pilot trial successfully demonstrated the feasibility and acceptability of the study design, procedures, and interventions. The preliminary data suggest that both HAP and Fluoxetine are viable treatments for moderate to severe depression in primary care settings in India. The findings will be instrumental in informing the design and implementation of a larger precision trial.

Effect of antidepressants on neurodegeneration and neuroplasticity in patients with depression: A comparison between SSRI and SNRI

D. Sharma[1]*, S. C. Sarangi[1], S. Bhargava[1], B. N. Patra[2], R. Sagar[2], P. Pankaj[3] and S. Kumaran[3]

[1]Pharmacology; [2]Psychiatry and [3]Department of Nuclear Magnetic Resonance, All India Institute of Medical Sciences, New Delhi, India
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.796

Introduction: Depression affects 57 million people in India and is often linked to neurodegeneration (10-90% of cases). However, there's insufficient evidence comparing the effectiveness of SSRIs and SNRIs in managing neurodegeneration symptoms.
Objectives: This prospective observational study aims to compare the effects of SSRI and SNRI monotherapy on neurodegeneration, neuroplasticity, and social cognition.
Methods: This prospective observational study aims to compare the effects of SSRI and SNRI monotherapy on neurodegeneration, neuroplasticity, and social cognition.
Treatment-naïve patients with unipolar depression were evaluated for treatment response using the Hamilton Depression Rating Scale (HDRS) and neurodegeneration parameters at enrollment and after six weeks of antidepressant treatment. Neurodegenerative serum biomarkers [indoleamine-2,3-dioxygenase (IDO), neurofilament light chain protein (NLCP), brain derived neurotrophic factor (BDNF)] were assessed using ELISA. Social cognition was assessed using Social Cognition Rating tools in Indian setting (SOCRATIS). Neuroplasticity was assessed by resting state MRI.
Results: A total of 150 patients of unipolar depression were enrolled, out of these n=126 patients were prescribed SSRI and 24 patients were prescribed SNRI. Both SSRI and SNRI group have significant reduction in HDRS score at 6-week compared to baseline (both $p<0.001$), but no intergroup difference. Overall treatment responder rate (HDRS score reduction >50%) was 11.33%, but SSRI group has more responder (12.69%) compared to SNRI (4.16%). After 6 weeks of follow-up, serum IDO in SSRI group and NLCP levels in both groups were significantly decreased when compared to baseline ($p<0.001$) and BDNF levels were significantly increased in SSRI group when compared to baseline ($p<0.01$). As per SOCRATIS, after 6 weeks treatment, SSRI and SNRI didn't show any significant difference. fMRI assessment of depression patients showed significant decrease in cortical thickness of inferiortemporal, parsopercularis and precuneus regions of brain ($p<0.05$) in comparison with healthy controls. But there was no significant difference/increase in cortical thickness after 6 weeks of follow-up when compared to baseline.
Conclusions: After six weeks of antidepressant treatment, the treatment responder rate among all depression patients was 11.33%, with better outcomes observed in the SSRI group compared to the SNRI group. Likewise, in the assessment of social cognition and neurodegeneration-related biomarkers, the SSRI group showed superior performance over the SNRI group.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.797

Introduction: Social media is now known as a vital aspect of the younger generation's existence, significantly impacting their emotional and psychological growth. In contrast to prior generations, Generation Z has been raised in an environment of continuous digital connectivity, which poses distinct issues with body image, emotional health, and sleep quality. Platforms such as Instagram, TikTok, and Snapchat have been increasingly associated with mental health conditions, including eating disorders, anxiety, depression, and insomnia. Considering the ubiquity of these platforms, it is imperative for psychiatrists, public health practitioners, and educators to comprehend the mental health ramifications associated with social media participation.
Objectives: This study attempts to examine the relationship between social media exposure and mental health disorders in Generation Z, specifically emphasizing eating disorders, anxiety, depression, and sleep disturbances.
Methods: Relevant studies and existing research on social media usage patterns and their effects on mental health in Gen Z were reviewed. Attention was given to how different platforms contribute to the development of body dissatisfaction, social comparison, and sleep difficulties. The analysis included an exploration of platform-specific features and user behavior, focusing on Instagram's image-centric nature, TikTok's short-form, high-stimulation content, and Snapchat's emphasis on transient communication.
Results: The analysis indicated that Instagram, being predominantly a visual medium, exacerbates body dissatisfaction and increases the likelihood of eating disorders by consistently advocating unattainable beauty ideals and trends such as "thinspiration" and "fitspiration." TikTok, although promoting mental health awareness, may also induce anxiety and attention deficits because to its intensely stimulating, rapid content. Snapchat's design, that encourages continuous monitoring of temporary content, seems to exacerbate anxiety stemming from the fear of missing out (FOMO). Cyberbullying has surfaced as a substantial factor exacerbating mental health conditions across all platforms, particularly with anxiety and desperation, along with severe instances associated with suicidal ideation.
Conclusions: Social media has a complex influence on the mental health of Generation Z, with each platform uniquely affecting conditions such as eating disorders, anxiety, depression, and insomnia. Instagram's emphasis on aesthetics, TikTok's rapid content consumption, and Snapchat's addictive interaction present unique mental health issues. These findings underscore the necessity for medical professionals to integrate social media practices into their evaluations and therapies for Generation Z, while public health professionals and educators are encouraged to work together to promote better online habits.

Transforming Mental Health Care in Moldova through Telemedicine

M. Bivol[1]* and C. Radislav[1]

[1]Department of Mental Health, Medical Psychology and Psychotherapy, Nicolae Testemitanu State University of Medicine and Pharmacy of the Republic of Moldova, Chisinau, Moldova, Republic of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.798

Introduction: In Moldova, telemedicine has emerged as a pivotal intervention in addressing the persistent disparities in mental health care. Geographic isolation, coupled with socio-economic constraints, severely limits access to essential mental health services. The prevalence of mental health disorders is alarming, with approximately 17.34% of the population affected, particularly by anxiety and depression among vulnerable populations. This underscores the urgent need for innovative, scalable solutions. Telemedicine harnesses advanced technology to enhance the availability and continuity of mental health support, particularly in rural areas where traditional services are often inaccessible.
Objectives: This study investigates the transformative potential of telemedicine in tackling the unique mental health challenges faced by the Moldovan population. It specifically examines how high rates of anxiety and depression, exacerbated by socio-political factors and historical trauma, can be addressed through telemedicine strategies tailored to the local context.
Methods: A comprehensive literature review was conducted utilizing PubMed, focusing on studies and systematic reviews published since 2020. This analysis aimed to identify global best practices in telemedicine and evaluate their applicability within Moldova's socio-cultural and economic landscape. The synthesis of these findings will inform future telemedicine initiatives aimed at improving mental health outcomes.
Results: The findings indicate that telemedicine has significantly enhanced access to mental health services, facilitating timely interventions while reducing the stigma often associated with seeking help. The implementation of remote consultations during the COVID-19 pandemic has been particularly illuminating, demonstrating the effectiveness of telemedicine in maintaining continuity of care for individuals in remote areas who struggle to access traditional mental health services. Furthermore, telemedicine has led to significant reductions in treatment costs, thereby making mental health support more accessible to at-risk populations.
Conclusions: As telemedicine solidifies its role within Moldova's mental health framework, it promises to enhance public health outcomes and promote a more equitable healthcare environment. Future policy initiatives must prioritize the integration of telemedicine into routine mental health practices. This includes fostering partnerships between healthcare providers, policymakers, and community organizations to ensure that telemedicine solutions are both sustainable and tailored to meet the diverse needs of all patients, particularly those in underserved regions.

EPP565

Exploring Digital Solutions: A Pilot Study on the Intersection of Autistic Traits and Mental Health

D. Sönmez[1]*, E. B. Yıldız[2] and T. R. Jordan[1]

[1]Psychology, Ibn Haldun University and [2]Psychology, İstanbul Bilgi University, İstanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.799

Introduction: Digital interventions are increasingly popular in addressing various issues, including mental health problems, executive functions, and social cognitive skills in clinical and non-clinical populations. Previous studies have revealed that neurotypical individuals with elevated autistic traits may be more susceptible to other mental health conditions such as anxiety disorders, mood disorders, internet addiction, substance abuse, and suicidal risk. While there is no definitive explanation for this susceptibility, social and cognitive impairments may be contributing factors, including problems with executive functions and social cognitive skills.
Objectives: The main goal of this research is to develop an online social cognitive training program and conduct a pilot study to assess its feasibility within the current sample.
Methods: 36 participants (randomly assigned to 16 for the experimental group and 20 for the control group) were recruited for the pilot study and the experimental group completed 6 weeks of an online intervention program, while the control group was assigned to the waiting list. Autism Quotient, Depression Anxiety Stress -21, Patient Health Questionnaire -9, and Generalized Anxiety Questionnaire– 7 were used to assess mental health symptoms. Executive functions were evaluated using the Wisconsin Card Sorting Task, N-back Task, and Go/No-Go task. At the same time, social cognition was assessed through the Interpersonal Reactivity Index, The Eyes test, and the Self-Assessment Manikin.
Results: 2 x 2 mixed repeated measure ANOVA was conducted. The main effect of time and group was significant for mental health symptoms and working memory ($p < 0.5$). However, the interaction of time and group was not significant ($p > .05$). Communication and attention switching (two components of autistic traits) have significant impacts on the scores ($p < 0.5$).
Conclusions: This pilot study demonstrated significant improvements in mental health scores, laying a solid foundation for further development and efficacy testing of the digital intervention program. This suggests that the intervention holds promise, particularly in targeting mental health improvements. Attention switching and communication contribute to the overall main effects highlighting the program's potential in addressing key aspects of mental health.

Substance use and adolescents' activities in digital space

L. Csémy[1]*, L. Kážmér[1] and P. Baďura[2]

[1]National Institute of Mental Health, Klecany and [2]Palacký University, Olomouc, Czech Republic
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.800

Introduction: Representative surveys have shown a decline in alcohol and tobacco use among adolescents over the last years. The rapid spread of adolescents' activities in digital space may have contributed to these changes. However, there is still considerable scope for examining the relationship between activities in digital space and substance use behaviour of adolescents.
Objectives: The study aims to assess the association between adolescents' alcohol use, cigarette smoking and their activities in digital space. The respective associations are controlled for adolescents' subjective well-being as a putative confounder related to both substance use and digital activities.
Methods: Data from the 2022 Czech part of the *Health Behaviour in School-aged Children* study were used. Only 15-year-old respondents were analysed (N=4263, 50.7% boys). To measure substance use, data on the frequency of alcohol use and cigarette smoking in the past 30 days were used. Digital activities were measured by data on typical daily free time spent on social media and computer gaming. To control for subjective well-being the WHO-5 scale was used. Pairwise associations between substance use, social media use, and computer gaming were examined using Spearman rank correlation coefficients (*rho*). Ordinal logistic regression models were used to adjust the respective associations for gender and psychological well-being.
Results: Significant pairwise associations were found between time spent on social media and both frequency of alcohol use (*rho* = 0.181, P<0.05) and cigarette smoking (*rho* = 0.191, P<0.05). In contrast, computer gaming was not significantly correlated with either alcohol use or cigarette smoking (*rho* = -0.015 and *rho* = -0.014, respectively; P>0.30). Poor subjective well-being was a significant risk factor for substance use and time spent on social media. Controlling for adolescents' well-being did not significantly attenuate the former relationship between the substance use and social media use.
Conclusions: The results suggest that among adolescents, different forms of digital activity have markedly different associations with substance use. While increased time spent on social media was significantly associated with higher frequency of substance use, no such association was found for computer gaming. Future research will focus on whether the relationship between specific digital activities and substance use can be explained by other factors related to mental health.
Funding: The study was supported by the OP Johannes Amos Comenius (CZ.02.01.01/00/22_008/0004583).

Analysis of adolescent psychiatry hospitalization in integral beds in a city in northeast Brazil

J. L. Da Silva[1]*, F. F. D. C. Passos[2], J. E. D. L. Sobrinho[1] and M. D. D. S. Leal[1]

[1]HEBIATRIA, UPE, RECIFE and [2]FURG, Rio Grande do Sul, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.801

Introduction: Psychiatric hospitalization of adolescents can have biological, psychological and social impacts on these patients with psychiatric illness if not managed correctly. To achieve this, the aim is to keep the hospitalization time as short as possible and to have a clear goal of the intervention (i.e., to diagnose, monitor risks, and stabilize comorbidities). This care is important because the effectiveness of the hospitalization process and its articulations after discharge are related to the chances of these patients being readmitted.
Objectives: To describe the general aspects related to the hospitalization of adolescents with psychiatric illnesses who require hospitalization in a general hospital in northeastern Brazil.
Methods: This is a longitudinal study carried out in a general hospital in the state of Pernambuco, in the northeastern region of Brazil Medical records of hospitalizations that occurred between January 2018 and January 2023 were analyzed. The medical records of patients aged 12 to 17 years and 11 months were included in the study. Sociodemographic and clinical data were collected from the medical records to be submitted to statistical analysis. This study was approved by the local ethics committee (number 6.880.316).
Results: Five hundred and nineteen adolescents were admitted to the general hospital under study for mental reasons throughout that time. After evaluating the data for consistency, 484 medical records were included in this study. It was observed that approximately 53.7% of hospitalized patients were male. The median age was 16 years (IQR 14-17 years). Regarding the clinical profile of hospitalizations, 39 different diagnoses of psychiatric illnesses were listed throughout the period. Following the ICD-10 classification, the three main reasons for hospitalization are: F23 - acute and transient psychotic disorders (13%); F19 - mental and behavioral disorders due to multiple drug use and use of other psychoactive substances (12.4%), and F32 - depressive episodes (11.4%). Notably, during the study period, 63 individuals were hospitalized more than one time.
Conclusions: The primary mental health diagnoses of teenagers who were hospitalized to a northern Brazilian general hospital were described. From the standpoint of public health, the existence of patient readmissions highlights the deficiency of proper care provided to the adolescents after being discharged from the facility. Nevertheless, the examination of the variables associated with the hospitalization of adolescents was made difficult by the lack of uniformity and precision in medical records.

EPP569

Population models for the main indicators of mental health of the Russian population in the period 1992-2022

V. Mitikhin[1]*, T. Solokhina[1] and D. Oshevsky[1]

[1]Mental Health Research Centre, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.802

Introduction: The mental health of the population at the level of the psychiatric service has a number of main indicators: the levels of general morbidity (prevalence) and primary morbidity (incidence) of mental disorders. Population models allow you to demonstrate the scale of problems and assess the resources to solve them.
Objectives: Building population-based epidemiological models of mental health of the Russian population to analyze the relationship between indicators of mental disorders and the human resource of psychiatric care, as well as demographic, socio-economic factors in the period 1992-2022.
Methods: The work uses data from Russian socio-economic statistics, materials from medical and research institutions and results published in scientific periodicals (see, [1] and references). In the formation of population models, the methods of systematic data analysis presented in the work [1] and statistical analysis in the framework of MS Excel were used.
Results: At the first stage, correlation analysis was used to select demographic, socio-economic factors and the factor of the personnel resource of psychiatric care, which significantly affect the indicators of general and primary morbidity of mental disorders. It turned out that the most significant factors are: population size, life expectancy at birth, unemployment rate, number of psychiatrists and psychotherapists. The correlation coefficients between these factors and the indicators of general and primary morbidity of mental disorders are (in absolute value) in the range of 0.65-0.93 with a reliability level of 95%. At the second stage, linear regression (one-factor, two-factor) and nonlinear (logistic) models were obtained, linking the incidence of mental disorders with the selected factors. The obtained regression models are characterized by high reliability with a coefficient of determination R^2 in the range 0.81-0.92 for single-factor and, respectively, 0.90-0.98 for two-factor models. The obtained nonlinear logistic model for the indicator of general morbidity allowed us to obtain a maximum morbidity value for the Russian population equal to 34.4% of the population. This result practically coincides with the result obtained in the well-known work [2]. In this epidemiological study on the European continent, it was found that 38.2% of European residents suffer from mental disorders.
Conclusions: The obtained models make it possible to quickly monitor the impact of medical, demographic, socio-economic factors and changes in the personnel resource of psychiatric care on the morbidity rates of the Russian population. 1. Mitikhin V., Yastrebov V. et al. *Neuroscience and Behavioral Physiology*. 2019; 49(2): 233-239. doi: 10.1007/s11055-019-00720-4. 2. Wittchen, H. U., Jacobi, F., Rehm, J., et al. *European Neuropsychopharmacology*. 2011; 21: 655-679. doi:10.1016/j.euroneuro.2011.07.018

Is Long-term mental health care in Portugal ensuring psychosocial rehabilitation? – analysis of the discharge destinations

F. Santos Martins[1,2,3]*, R. Malta[1] and J. V. Santos[2,4,5]

[1]Psychiatry, 'S. João' Local Health Unit (ULS S. João); [2]CINTESIS; [3]Neurosciences and Mental Health; [4]MEDCIDS, Faculty of Medicine, University of Porto (FMUP) and [5]Public Health Unit, 'Santo António' Local Health Unit, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.803

Introduction: Since 2017, the reform of mental health services implemented in Portugal has included the establishment of a national network of long-term mental health care (MH-LTC) to promote the psychosocial rehabilitation of people with mental

illness. Different facilities are available according to the degree of psychosocial disability, functionality and family and social support network. Thus, residential structures, home support teams, and socio-occupational units are available to reintegrate these users into society and their families.
Objectives: To assess discharge destinations according to the MH-LTC typology (home care teams, residential structures and socio-occupational units).
Methods: We conducted a national retrospective observational study to analyse the MH-LTC discharge destinations using secondary data publicly available. The following discharge destination categories were considered in the analysis: home (with or without support), social facilities, nursing home, other typologies from the long-term care network (LTC), and others. The analysis included the discharge destinations between May 2018 and March 2024.
Results: A total of 119 discharges were recorded, with 50 patients (42.0 %) going home, four (3.3%) to social facilities, 46 (38.7%) to other LTC typologies and 19 (16.0%) to unspecified destinations. Regarding discharge to home, 27 (54.0%) came from home care teams, 14 (28.0%) from socio-occupational units and 9 (18.0%) from residential facilities. The remaining discharge destinations included 34 (49.3%) from home care teams, 13 (18.8%) from socio-occupational units and 22 (31.9%) from residential facilities.
Conclusions: Although these results do not allow us to gauge the level of disability before and after joining the MH-LTC, they raise some questions. Firstly, the number of discharges is small considering the span of more than five years. In addition, non-residential facilities have the highest number of discharges compared to residential facilities. On the other hand, less than half of the discharge destinations are to the patient's homes, which may lead us to question whether the MH-LTC fulfils its purpose of psychosocial rehabilitation or whether it is a transitional structure aimed at responding to social issues.

"Hidden" Voices
Marginalised community perspectives on policing and community safety; an international scoping systematic review

L. Jordan[1]*, G. Gulati[2], C. Dunne[3], B. Kelly[4] and M. Donnelly[2]

[1]School of Medicine; [2]School of Law, University College Cork, Cork; [3]School of Medicine, University of Limeirck, Limerick and [4]School of Medicine, Trinity College Dublin, Dublin, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.804

Introduction: Community safety is about everyone having the right to be and feel safe in their community. People from marginalised communities (including people with mental illness, intellectual disability, migrants, and homeless) are over-represented in policing contacts. Yet, little is known about the real world perspectives of these marginalised groups in respect of perceived safety and interventions that work to improve this.
Objectives: To systematically review the published literature concerning the experiences of people from marginalised communities on policing and community safety.
Methods: Research database SCOPUS (inception to 1 January 2024) was searched for English-language publications using key words. The electronic search was augmented by manual searching through reference lists and websites of governmental and non-governmental organisations. Published studies with information about the experiences of persons from marginalised communities on policing and community safety were included. Opinion articles or reviews that did not contain qualitative data were excluded, as were studies that focused on law enforcement professionals views.
Results: Of the 857 papers identified, 17 studies met eligibility criteria with a total of 1254 participants from 5 countries. A recurring theme from different marginalised communities was "greater fear" and "less trust" of police and a reluctance to report crime. Those with physical disabilities were less likely to use public transport. Latin migrants feared speaking Spanish in America. African refugees in Australia felt targeted by the police because of their ethnicity. Muslims in England reported they were under increased police surveillance. Homeless youths in Canada with early negative experiences with law enforcement personnel were less likely to seek police involvement if needed in future. Conversely both Mexican-origin residents and Chinese immigrants living in America identified police as having a critical role in making them feel safe.
Conclusions: This study scoped the experiences of people from marginalised communities in respect of policing and community safety. To the author's knowledge, this is the largest scoping study of this type, to date. It is evident from this review that there are voices, sometimes "hidden voices", from marginalised communities that perceive policing approaches differently. This guides not only their future interactions with police but also their social outlook. Working closely and proactively with individuals within these marginalised communities will help find the balance between "over policing" and "under policing" to help contribute to the overall community safety. A key recommendation from this review would be for authorities to meaningfully incorporate these voices when developing or reviewing policies relating to community safety.

Exploring the link between exposure to sexual interpersonal violence and subsequent child sexual offending: Insights from a Danish Study

F. M. Monshizadeh Tehrani[1,2]*, E. Kristensen[3], A. Giraldi[3,4] and S. Bengtson[3]

[1]Child and Adolescent Mental Health Center, Mental Health Services in the Capital Region of Denmark, Copenhagen, Denmark; [2]Forensic Psychiatry Working Group, European Federation of Psychiatric Trainees, Brussels, Belgium; [3]Sexological Clinic, Mental Health Services in the Capital Region of Denmark and [4]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.805

Introduction: Child sexual offending is a significant societal concern with profound consequences. While some individuals with a history of childhood sexual abuse (CSA) may reenact their traumatic experiences later in life, the link between CSA and subsequent offending patterns among individuals convicted of child sexual offending (ICSOs) remains complex and under-researched.
Objectives: This study aimed to investigate the prevalence of self-reported physical and sexual violence among ICSOs and explore the link between self-experienced CSA and offending behavior, particularly focusing on the age and relationship with their victims. We hypothesized that ICSOs would replicate their own victimization experiences when perpetrating CSA.
Methods: A cohort of 78 male ICSOs referred to the Danish Sexual Offender Treatment and Research Program (DASOP) between October 1, 1997, and October 1, 2001, for court-ordered pre/post-trial evaluations was analyzed. Data on self-reported experiences of CSA, physical violence, and characteristics of their victims were collected and examined for patterns.
Results: Of the 31% of ICSOs who reported CSA exposure, 82% of those abused before age 11 targeted victims under 11, while 71% of those abused at 11 or older offended against victims in the same age group, indicating a significant association (p=0.004) between offenders' age at the time of abuse and the age of their victims. Additionally, 86% of those who reported CSA by family members, predominantly targeted children within their households, suggesting a link between family-based CSA and intra-familial offending (86% vs. 48%, p-value= 0.059). Furthermore, among the 55% exposed to physical violence, more used physical force on their victims than those who did not report such adverse experiences (75% vs. 25%, p-value 0.401).
Conclusions: The findings indicate a potential link between offenders' own CSA experiences and their subsequent victim selection, supporting the hypothesis that reenactment of trauma may play a role in offending behavior (Garbutt et al., 2023). These results emphasize the importance of understanding the influence of early trauma to inform prevention and intervention strategies aimed at reducing CSA perpetrated by both children and adults with prior victimization histories. However, most victims of such trauma do not reenact their trauma.

Analysis of the therapeutic effect of the long-acting injectable form of aripiprazole in incarcerated adult males in Greece

E. L. Pasparakis[1,2*], I. Mouzas[1,2], G. I. Detorakis[1] and E. I. Koiliari[1,2,3]

[1]Department of Psychiatry, General Hospital of Agios Nikolaos of Lasithi, Agios Nikolaos of Lasithi; [2]Department of Pathology, Laboratory of Alcohology of the Medical School of the University of Crete and [3]Department of Pathology, University General Hospital of Herakleion (PAGNI), Herakleion, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.806

Introduction: The World Health Organization (WHO) estimates that in Western societies the incidence of psychiatric disorders is up to seven times higher in the prison population. Drug dependence is also a major destabilizing factor in this population. Our study is the first one in Greece with a focus group of incarcerated males which have comorbidity of emotional psychosis and Substance Use Disorder.
Objectives: Hypothesis testing: "Aripiprazole LAI antipsychotic treatment is associated with improved quality of life and functionality in incarcerated patients with comorbidity of Bipolar disease - I (BD-I) and Substance Use Disorder (SUD)".
Methods: 30 patients with BD I were prisoners at the Penitentiary of Neapolis of Lasithi of Crete (Greece). Median age was 36 years (all men). 76.67 % had comorbidity of bipolar disorder type I (BD-I) and alcohol use disorders. 80% had comorbidity of BD-I and cocaine use disorders. 93.3% had comorbidity of BD – I and Cannabis Use Disorder. All were medicated in prison by aripiprazole LAI 400mg/month. For the evaluation of our hypotheses the instruments WHOQOL-BREF questionnaire and the CGI-S scale were used. The quality of life and the functionality were compared in each patient, before the initiation of the LAI medication and during the active treatment period. The minimum of follow-up period was 6 months. Five cases of patients, who remained compliant with LAIs treatment after release from prison for a period of at least 6 months maintained a very good quality of life without ever getting into trouble with the law again.
Results: In all 30 patients (imprisoned) of our sample, the CGI-S score with depot aripiprazole therapy administrated at least for 6 months decreased statistically significantly from 5.72 ±0.88 to 2.94±1.33 (Paired Samples Wilcoxon Signed Rank Test p-value<0.001). Additional, the quality-of-life scale score of these patients increased statistically significantly from 0.7 ±0.53 to 3.6±0.67 (Paired Samples Wilcoxon Signed Rank Test p-value<0.001) with depot aripiprazole therapy administrated at least for 6 months too.
Conclusions: Aripiprazole LAI significantly improves the quality of life and functionality of patients with dual diagnosis of emotional psychosis and SUD in prison. Our study highlights that ensuring medication compliance, during the incarceration and after the release from prison, delays the time to reincarceration for this specific population or diminishes importantly the probability of the reincarceration.

Ways to Support Mental Health and Mental Well-being of Racialized and Immigrant Communities: A Concept Mapping Study

F. Ahmad[1*], L. Culley[1], N. Baldeo[1], K. A. Haque[1] and A. Suleman[2]

[1]York University and [2]Social Services Network, Toronto, Canada
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.807

Introduction: Although there is recent growing attention on mental health and mental well-being across the globe, supports in this area of healthcare can be a challenge for immigrant and racialized groups with frequent experiences of hardship.
Objectives: This study aimed to gather perspectives of immigrants and racialized community members on strategies central to support their mental health and well-being, with the aim of addressing research-to-practice gaps.
Methods: The study was co-designed in collaboration with a Community Action Table in Markham, Ontario, a setting with 93% of residents self-identifying as Canadian visible minorities (i.e., non-Caucasian descent). A mixed method Concept Mapping methodology was used to engage residents, service providers, and policy-makers (n = 68) through three phases of data collection and interpretation.
Results: Participants first brainstormed ways to support their mental health and well-being, generating 283 statements in three group sessions. A consolidated list of 68 statements was then prepared by removing duplicates and merging similar ideas. This list was shared with participants in three group sessions for the sorting and rating actvities: each participant made groups of statements based on a shared meaning and labelled the groups; and rated each statement on a scale of 1-5 for its importance and feasibility to act in next six-months to support the mental health and well-being of their community. The sorted and rated data was then analyzed statistically through techniques of similarity index and hierarchical cluster analysis to produce visual maps, which were shared with participants in the interpretation session for review and naming of clusters followed by open discussion. This led to a 9-cluster concept map comprising of Family Wellness, Awareness & Education, Cultural Sensitivity, Social Service Access, Community Building, Socioeconomic, Food Security, Healthcare Access, and Housing Stability. The rating data showed the clusters of Family Wellness, Housing Stability, Healthcare Access, and Awareness & Education were ranked high for the dimension of importance. In terms of feasibility to act in next six-months, the clusters of Awareness & Education and Family Wellness remained among the top three while the clusters of Housing Stability and Healthcare Access scored low – which was discussed by participants as requiring a multi-year action plan with short- and long-term goals.
Conclusions: Overall, participants viewed mental health and well-being as being closely tied to their living and working conditions while also focusing on family wellness and intergenerational dynamics. The gained insights emphasize a need for multi-sectoral response to support the mental health and well-being supports of immigrant and racialized communities.

Factors Influencing Mental Health of an Afghan Refugee Community in the U.S.

A. Garcia Keeme-Sayre[1]*, K. A. Chesky[1], A. Pathak[1], E. Mani[2], S. Essa[3], I. H. Hanif[4] and S. Banu[5]

[1]Baylor College of Medicine, Houston; [2]Harvard College, Boston; [3]Psychology, University of Houston; [4]Texas A&M and [5]Psychiatry, Baylor College of Medicine, Houston, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.808

Introduction: Rates of mental health disorders in resettled refugees surpass those of the host population (Hameed et al, KJM 2018;11 20-23). However, most studies suggest heterogenicity between populations, suggesting a need for a non-generalized approach to resettled-refugee mental health (Silove et al, World Psychiatry 2017;16 130-139). Since the Taliban assumed control in August 2021, the United States has taken in about 90,000 Afghan refugees (Green, Wilson Center 2023), 15,000 have settled in Houston, Texas (Schneider, Texas Standard 2023).
Objectives: This study investigates factors that may predict higher rates of distress and symptoms of PTSD and depression within an Afghan refugee community resettled in Houston, Texas.
Methods: Seventy-four Afghan refugees located in Houston, Texas were surveyed for demographic information and physical or emotional symptoms as directed by the Refugee Health Screener-15 (RHS-15). An average score of ≥ 12 on the RHS-15 or a self-reported distress score ≥5 indicated a positive result on the screening tool. Mann-Whitney and Fisher's exact tests were used to compare differences in patient baseline characteristics and responses stratified by a positive RHS-15 or distress screen. Spearman's Rank Correlation Coefficient was used to assess the correlation between selected response variables and outcomes as well as between the RHS-15 and distress scores.
Results: 40% of subjects scored ≥12 on the RHS-15 and 35% indicated a distress score ≥ 5. Income differed significantly between the RHS <12 group and the RHS ≥12 group (p=.02). The RHS <12 group had a higher proportion of individuals in the lowest income bracket, < $10,000, and a greater proportion in the $20,000-$30,000 bracket. Meanwhile, the RHS ≥12 group had a higher proportion in the $10,000-20,000 income bracket. There was a negative correlation between self-reported health scores with both RHS-15 score (ρ=-.508, p<.001) and distress score (ρ=-.423, p=.001) as well as between neighborhood support levels and distress scores(ρ=-.314, p=.018).
Conclusions: This Afghan refugee cohort shows theoretical rates of PTSD and MDD higher than the average American (40.3% RHS-15 score vs. 3.6% PTSD and 8.3% MDD) (NIH 2023). The increased risk of mental disorder may be attributed to lower perceived community support, poor physical health, and low socioeconomic status. If income growth is a function of increased time spent in the United States, the unique pattern in income between the two RHS groups may reflect a "honeymoon period" that has previously been demonstrated in studies on migrants and culture shock (Maillet et al, APMH 2023; 50 563–575). Following this honeymoon period, however, lower income may predict worsened mental health in resettled refugees. These results support multi-factorial initiatives to support resettled refugees especially in areas of community interconnectedness, health and economic support.

Dismantling task-sharing psychosocial interventions to personalize care for people affected by common mental disorders in poor resource settings

D. Papola[1,2]*, V. Patel[2] and C. Barbui[1]

[1]University of Verona, Verona, Italy and [2]Harvard Medical School, Boston, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.809

Introduction: The global burden of common mental disorders is high, particularly for migrants and people living in low-resource settings. Although psychosocial interventions delivered by locally available lay or community health workers are effective, the mechanisms of intervention response are poorly understood. One of the major barriers is that psychosocial interventions are delivered as complex, multi-component 'packages of care'.
Objectives: The aim of the project is to systematically review all randomized controlled trials (RCTs) that have tested the efficacy of task-sharing psychosocial interventions for the treatment of people suffering from common mental disorders (depression, anxiety, and related somatic complaints), to dismantle the intervention protocols, to create a taxonomy of active intervention components, and to re-evaluate their efficacy.
Methods: This project uses a mixed methods approach. In the first phase (qualitative), intervention manuals are reviewed and components are extracted to create a component taxonomy. The components and manual files were transferred to Dedoose, a qualitative data analysis computer software package. An initial two manuals were reviewed by two coders who piloted the entire codebook and assessed inter-rater reliability; any code discrepancies were discussed with a senior author. The two coders independently coded the same manual and repeated until an 80% IRR was achieved. The two coders then divided 12 manuals and coded them separately. In the second phase (quantitative analysis), we will use component network meta-analysis (cNMA) methodology. The main advantage of cNMA is the ability to disentangle intervention components and examine their effectiveness separately or in different combinations. According to the additive cNMA model which we will implement, adding a component "c" to a composite intervention "X" will lead to an increase (or decrease) of the effect size by an amount only dependent on "c", and not on "X". We will denote the corresponding component specific incremental standard mean difference (iSMD) so that iSMDc = SMD(X+c) v. (X). Combining these component-specific iSMDs will allow the estimation of SMD between any two composite interventions.
Results: The component taxonomy will be presented at the conference, along with a network of comparisons and a hierarchy of all intervention components expressed as iSMD, indicating the added benefit of adding a component to an intervention.
Conclusions: By selecting the most effective components, it will be possible to outline a novel task-shifting psychosocial intervention to be tested in future RCTs for the benefit of people with common mental disorders living in low-resource settings. These findings will form the basis for further investigations in the field of precision medicine.

Evaluating the Prevalence and correlates of high stress and low resilience among Educators

A. Belinda[1]*, R. D. L. Dias[2], Y. Wei[1] and V. I. O. Agyapong[1,2]

[1]University of Alberta, Edmonton and [2]Dalhousie University, Halifax, Canada

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.810

Introduction: High-stress levels can be problematic for teachers and indirectly affect students. Knowledge about the prevalence and predictors of high-stress and low resilience will provide information about the extent of the problem among teachers in Canada.
Objectives: To examine the prevalence and correlates of perceived stress and low resilience among Alberta, Nova Scotia, Newfoundland and Labrador teachers.
Methods: This is a cross-sectional study. Participants self-subscribed to the Wellness4Teachers text-messaging program and completed the online survey on enrollment. Data collection occurred from September 2022 to August 2023. Resilience and stress were respectively assessed using the Brief Resilience Scale (BRS) and the Perceived Stress Scale (PSS-10). Data was analyzed with SPSS version 28.
Results: A total of 1912 teachers subscribed to the Wellness4Teachers program, and 810 completed the baseline survey, yielding a response rate of 42.40%. The prevalence of high stress and low resilience were respectively 26.3%, and 40.1%. Participants with low resilience were 3.10 times more likely to experience high-stress symptoms than those with normal to high resilience (OR = 3.10; 95% CI: 2.18–4.41). Conversely, participants who reported high stress were 3.13 times more likely to have low resilience than those with low to moderate stress (OR = 3.13; 95% CI: 2.20–4.44).
Conclusions: Our study findings infer there's an incidence of high levels of stress and low resilience among teachers in the three Canadian provinces. Governments and policymakers in the education field should integrate stress management and resilient building strategies into teachers' ongoing professional development programs to help prevent and address high stress.

Postnatal depression and bonding disorder: A tautology or two overlaping phenomena?

G. Hernández-Santillán[1]*, M. Gurpegui[2], M. Alcamí-Pertejo[1], G. Lahera[3,4] and M. F. Bravo-Ortiz[1]

[1]Psychiatry, Hospital Universitario La Paz, Madrid; [2]Granada Centre for Psychiatric Studies, Granada; [3]Psychiatry, Hospital Universitario Príncipe de Asturias and [4]Psychiatry, Universidad de Alcalá, Madrid, Spain

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.811

Introduction: Perinatal disorders occur in 25% of childbearing women. Postnatal depressive symptoms (PDS) have been widely studied, whilst PDS usually overshadows bonding disorder (BD) in clinical practice and research. BD includes mild disorders, such as delay, ambivalence or loss of maternal emotional response, and severe disorders, such as pathological anger or rejection of the child (Brockington et al., Arch Womens Ment Health 2006; 9 (5) 243-251).
Objectives: To estimate the prevalences of PDS and BD in mothers during the six months after birth.

Methods: Women and their male partners aged ≥ 18, without delivery and neonatal complications, were recruited at the Maternity Ward in a public hospital in Madrid, during 2021-2022. Data was collected at immediate puerperium (T0), sixth week (T1), fourth month (T2), and sixth month (T3). The last observation carried forward (LOCF) was used. An Ad hoc Socio-Demographic questionnaire was used. To determine the presence of PDS and BD, respectively, there were used the Edinburgh Postnatal Depression Scale (EPDS), cut off ≥ 11 (Ascaso-Terrén et al., Med Clin (Barc) 2003; 120(9) 326-329) and Postpartum Bonding Questionnaire (PBQ), cut off ≥ 13 for BD, and ≥ 18 for severe BD (Torres-Giménez et al., Span J Psychol. 2021; 24, e47, 1-9).
Results: 1502 couples were recruited at T0. The main characteristics of female participants were: mean age 34.1 years, 53.9% married, 54.1% primiparous, 27.8% migrants, 67.3% university degree or higher, 83.2% employed, 14.8% financial difficulties, 4.9% smoking during pregnancy and, 21.7% c-section. At T0, the prevalences of PDS were 13.0% of mothers, 10.5% of fathers, and 3.5% of both parents. Applying LOCF, 874 women responded to the questionnaires at some timing during the follow-up. The results were divided into two groups (see Table 1 and Table 2) depending on whether they presented PDS at T0. In mothers with PDS at T0, PDS and BD rates eventually decrease at T3. In the other group, while BD rates decrease at T3, a slight increase in PDS presentation at T3 is observed.

Table 1. LOCF of mothers with PDS at T0

N	Follow-up	No-PDS	BD	Severe BD
106	T1	53/87 (60.9%)	49/87 (53.3%)	32/87 (36.78%)
PDS at T0	T2	47/74 (63.5%)	33/74 (44.6%)	19/74 (25.7%)
	T3	44/73 (60.3%)	30/73 (41.1%)	14/73 (19.2%)

Table 2. LOCF of mothers without PDS at T0

N	Follow-up	PDS	BD	Severe BD
768	T1	46/638 (7.2%)	225/638 (35.3%)	106/638 (16.6%)
No-PDS at T0	T2	47/575 (8.2%)	147/575 (25.6%)	66/575 (11.5%)
	T3	45/525 (8.6%)	122/525 (23.2%)	57/525 (10.9%)

Conclusions: Depressive symptoms and impaired bonding could have different severity and timing during the postnatal period. More research on bonding disorder is needed to clarify more accurately the psychopathological features that distinguish it from postnatal depression to provide more targeted treatment that will also reduce the associated stigma of childbearing difficulties.

Sociodemographic analysis of the psychiatric domiciliary hospitalization (DH) program at Hospital General Universitario of Ciudad Real (HGUCR), Spain

M. E. Sánchez-Escalonilla[1], E. Segura[2], A. Muñoz[1]*, C. Herranz[1], M. Viaña[1], I. Diéguez[1] and Á. Esquembre[1]

[1]Hospital Universitario La Paz, Madrid and [2]Hospital Universitario de Ciudad Real, CR, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.812

Introduction: Domiciliary hospitalization emerged in the late 20th century as a new mental health intervention, designed to providing care of patients with mental disorders at home. This approach offers benefits to hospitals, patients and their surroinding support systems (Megías, F. et al. EVES 2004; 16: 11-107). Although numerous international studies have evaluated the quality and advantages of domiciliary hospitalization, there is a paucity of research in Spain.
Objectives: To describe and compare the sociodemographic characteristics of psychiatric patients admitted to the Short-term Hospitalization Unit (UHB) at HGUCR with those of patients admitted to DH Unit from January 1 to December 31, 2019; and to compare this results with the statistics found in other similar studies.
Methods: This study is a descriptive observational analysis of 281 patient admissions to psychiatric hospitalization units (UHB or DH) in 2019 at HGUCR. The variables analyzed include the type of hospitalization, age, sex, marital status, type of cohabitation and employment status. SPSS was used as a statistical analysis tool. A literature review was carried out, using PubMed to identify comparable national and international studies.
Results: The mean age of patients was 44±15 years, with no significant differences between patients admitted to UHB and those admitted to DH unit, consistent with findings from other studies. The percentage of men and women is similar, with a majority of singles (40%) or married/in partnership (38%) compared to those who were separated or widowed. Regarding types of cohabitation, 37% of patients lived with their own family, 35% with their family of origin and 18% lived alone, with no significant differences between the two types of hospitalization. As regards employment status, the largest group (27%) was inactive, followed by 18% who were incapacitated and 17% of active workers. Significant differences were found in employment status: there were more active people in DH and more incapacitated individuals in UHB. However, we found that in other studies from Germany, there were significantly more unemployed people in DH (Bechdolf et al. FDNP 2011; 79 (1): 26-31). This can be explained by the exlusion criteria for DH at HGUCR, which include patients with severe social problems and multiple or decompensated organic comorbidity. Therefore, it is consistent that most of DH patients were in relatively good health and capable of working actively before admission.
Conclusions: No significant differences between DH and UHB were observed in most variables. Where differences were observed, they could be explained by the differing exclusion criteria between the two types of hospitalization. Our results are similar to those reported in other studies.

Appetite-regulating hormones, executive functions, and eating attitudes in adults with ADHD: A case-control study

Ö. Bayirli[1]*, A. Kandeğer[1], S. Abuşoğlu[2], A. E. Yorulmaz[2], B. Sağliyan[1], S. Kaya[1] and Y. Selvİ[1]

[1]Psychiatry and [2]Biochemistry, Selçuk University, Konya, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.813

Introduction: Although the literature suggests a strong association between attention deficit hyperactivity disorder (ADHD) and obesity, the underlying mechanisms remain unclear. Eating attitudes and appetite-regulating hormones (ARH) are considered to play a role in this relationship. Recent studies have shown that ARH may be linked to executive functions, and dysregulation of these hormones may help explain the connection between ADHD and obesity.
Objectives: We aimed to investigate the levels of ARH, executive functions, eating attitudes, and ADHD symptoms in adults with ADHD compared to healthy controls.
Methods: The study included 44 drug-naive non-obese adults with ADHD who had no comorbid psychiatric diagnoses and 44 healthy controls matched for age, gender, education, and body mass index (BMI). All participants were diagnostically assessed using the Structured Clinical Interview for DSM-5 Disorders-Clinician Version. Also, participants completed the Adult ADHD Self-Report Scale, the Mind Excessively Wandering Scale, the Hospital Anxiety and Depression Scale, and the Eating Attitude Test (EAT). A battery of neuropsychological tests—Stroop Test (ST), Cancellation Test, Serial Digit Learning Test (SDLT), Wisconsin Card Sorting Test (WCST), and Judgment of Line Orientation Test (JLOT)—was administered. The serum samples obtained from fasting blood, after centrifugation were stored at -80°C until the time of analysis, at which point ARH levels (insulin, leptin, neuropeptide Y, orexine A, ghrelin, adiponectin) were measured using the ELISA method. The study was approved by Selçuk University Local Ethics Committee with the decision numbered 2023/328.
Results: Adults with ADHD exhibited worse ADHD symptoms, disordered eating attitudes, more severe anxiety and depression, and reduced executive functioning compared to healthy controls. Although ADHD groups showed more disordered eating attitudes compared to healthy controls, there was no significant difference in ARH levels between the two groups; however, these hormone levels were associated with specific parameters from ST, SDLT, WCST, and JLOT. Linear regression analyses to identify factors associated with each ARH separately revealed significant F values, except for ghrelin, which explained a unique variance ranging from 23.5% to 36%. These results indicated that visuospatial ability was associated with each ARH levels, even after controlling for age, gender, years of education, body mass index, severity of disordered eating attitudes, and the absence of an ADHD diagnosis.
Conclusions: Our findings suggest that dysregulation of ARH may associate cognitive processes related to executive functioning independent of disordered eating attitudes, BMI, and ADHD diagnosis. However, these hormones may be mediating factors in relation between ADHD and obesity, and to figure out this relation, longitudinal clinical studies with larger samples are needed.

Balancing Dopamine: Managing Parkinson's Disease and Psychiatric Symptoms through Agonist-Antagonist Pharmacotherapy

J. C. Hall[1]*, G. Legerme[2], D. Nolasco[2], A. Wu[2] and B. Carr[2]

[1]College of Medicine and [2]Department of Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.814

Introduction: Parkinson's disease (PD) is characterized by basal ganglia dopamine depletion, leading to motor symptoms. Psychiatric symptoms, like psychosis, are associated with dopamine overactivity in the mesolimbic and mesocortical system. PD patients sometimes require both motor and psychiatric treatment. However, the pharmacologic treatments for each have opposing dopaminergic effects. Understanding the balance between dopamine antagonists to treat psychosis while increasing dopamine agonists (DAs) to treat PD is a difficult clinical task.
Objectives: We aim to explore how dopamine agonists and antagonists affect the responsiveness of dopamine receptors in various brain regions.
Methods: We conducted a comprehensive literature review on pharmacological management of patients with PD and concurrent psychiatric symptoms. Special attention was given to balancing dopamine agonists (e.g., Carbidopa-Levodopa) for PD and dopamine antagonists (e.g., Quetiapine) for psychiatric symptoms.
Results: While dopamine agonists and antagonists appear counterintuitive when used concurrently, their efficacy is contingent on target brain regions. DAs (Carbidopa-Levodopa) are most beneficial for increasing dopamine deficits in the striatum and nigrostriatal pathway, where voluntary movement is controlled. In PD, this pathway is primarily affected, and DAs are used to target the striatum's high concentration of D1 and D2 sub-receptors. Gold-standard DAs mainly target D1 and D2 receptors.
Dopamine antagonists mitigate excess dopamine activity in the mesolimbic and mesocortical systems, which affect reward, memory, and executive functioning. These systems possess a high concentration of D3 and D4 sub-receptors. Typical antipsychotics have strong D2 receptor affinity, making them counterintuitive to DA motor treatment. Atypical antipsychotics have partial D2 affinity, but also readily bind D3 and D4. Some atypicals minimize D1/D2 affinity to allow DAs to be more effective. Quetiapine is currently used for psychosis in PD, but the drug's MOA is not fully understood. Cariprazine binds D3 well but does cause extrapyramidal effects with its D2 affinity. Clozapine strongly binds D4 but can have severe adverse effects. Additionally, pramipexole and ropinirole have strong D3 and D4 affinity. Ultimately, the key lies in symptom control: achieving optimal motor function while controlling psychiatric manifestations.
Conclusions: PD management with concurrent psychiatric disease requires diligent pharmacologic balance of countering dopamine treatments. Dopamine agonists and dopamine antagonists do have opposed pharmacodynamics, but clinicians must understand that certain pharmacologic agents do not all target the same brain area nor dopamine sub-receptor. Clinicians must use this pharmacologic knowledge to carefully balance these therapies by adapting to the individual patient's symptomatology and treatment response.

Detecting electrophysiological alterations in psychiatric disorders through event-related microstates: a systematic review

F. F. Marzocchi[1]*, A. Perrottelli[1], G. Di Lorenzo[2], C. D'Amelio[3], E. Caporusso[1], G. M. Giordano[1], L. Giuliani[1], A. Melillo[1], P. Pezzella[1], P. Bucci[1], A. Mucci[1] and S. Galderisi[1]

[1]University of Campania "Luigi Vanvitelli", Naples; [2]University of Rome "Tor Vergata", Rome and [3]University of L'Aquila, L'Aquila, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.815

Introduction: Measurements of event-related potentials (ERP), recorded through electrophysiology (EEG) during sensory and cognitive processing tasks, have been widely employed to investigate the pathophysiological basis of mental health disorders. In the last two decades, the analysis of EEG microstates (MS) has been increasingly applied to ERP data. This methodology allows the detection of spatio-temporal changes in neuronal activity potential at the scalp level, providing new insights into neurobiological alterations detectable in psychiatric disorders.
Objectives: The current systematic review aims at providing an extensive and detailed description of the studies that characterized alterations in ERP-microstates in psychiatric and neurodevelopmental disorders.
Methods: A systematic review of English articles using PubMed, Scopus and Web of Science databases was undertaken in April 2024. The review included case-control studies that employed ERP-microstates analysis to compare MS features between subjects (age > 10 years) diagnosed with a mental health disorder and healthy controls.
Results: Out of the 756 records screened, 15 studies were included in the final qualitative synthesis. The studies included patients with schizophrenia (n=7), alcohol use disorder (n=2), borderline personality disorder (n=1), panic disorder (n=1), autism (n=1), major depressive disorder (n=1), post-traumatic stress disorder (n=1) and attention-deficit/hyperactivity disorder (n=1).
The studies investigated alterations of MS characteristics through different types of tasks. Cartool and RAGU were the main software used for MS analysis. Only rarely studies used similar tasks, showing comparable microstate maps. Fourteen of 15 studies showed a significant difference ($p<0.05$) in MS characteristics between patients and healthy controls. Main differences regarded parameters such as duration, area under the curve and the order of occurrence of MS.
Conclusions: The present literature review aims to highlight the effectiveness in using microstate analysis to identify spatio-temporal alterations in brain electrical activity in subjects with psychiatric disorders, showing the possible implications of the use of this technique in clinical practice and its advantages, as compared to ERP peak analysis.

Procrastination as a transdiagnostic construct in psychiatric disorders: a conceptual scope review

M. S. M. Barbosa[1,2], E. L. Guidugli[2], G. S. M. Barbosa[2], M. E. G. Melati[3], N. B. Pagliari[3], P. B. E. da Silva[4], P. H. P. Dutra[4], V. R. Xavier[4], E. H. Grevet[5] and Y. A. Ferrão[2,6]*

[1]Psychiatry, USP-Riberirão Preto, Ribeirão Preto; [2]Psychiatry, UFCSPA, Porto Alegre; [3]Medicine, UNISINOS, São Leopoldo; [4]Medicine, UFCSPA; [5]Psychiatry, UFRGS and [6]Psychiatry, HMIPV, Porto Alegre, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.816

Introduction: Procrastionation is commonly conceptualized as an irrational, conscious, and sometimes intentional tendency to delay the start or to complete tasks or decisions, despite consequences. The behavior may be present in several psychiatric disorders, especially OCD, ADHD and anxiety disorders However, there is no consensus definition of procrastination, nor established pathophysiology or motivation.
Objectives: To analyze the descriptive psychopathology as well as the presence or absence of associated symptoms, motivations, and consequences of procrastination. In sequence, to conceptualize the construct of "procrastination" based on the literature published and define the motivations and consequences of the behavior for the individuals.
Methods: The scoping review complies with the recommendations of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) and included articles published English, Spanish and Portuguese, between 1973-2023 and indexed in PubMed/MEDLINE, LILACS, Scielo, EMBASE, Scopus, Web of Science, and PsycINFO database. Research conducted in animals, poster publications, conferences in scientific conclaves, and letters to the author were excluded.
Results: We found 387 studies with different designs (295 [76,2%] were cross-sectional, 12 [3,1%] systematic reviews and 5 [1,3%] were meta-analysis) and published in English (86,6%), Spanish (9,3%) and Portuguese (3,9%). Only 5 studies (1.3%) used populations with AHDH and 1 study (0.02%) used a population with OCD, 7 studies (1.8%) used populations with other disorders (Depression, Anxiety) and 374 studies (96.4%) involved students (mainly university students), workers, or the general population. Of the population the majority was female (63,98%), single, young and has some occupation. In 323 articles, at least one scale was used to assess procrastination, with a total of 40 different ones. Furthermore, 337 studies define procrastination and 305 use the definition of other authors.
Conclusions: Procrastination is a complex event, so far without a defined concept. More investigation is necessary for a more comprehensive understanding of this phenomenon.

Mental and functional disabilities in patients with chronic pain

O. O. Khaustova[1]* and A. E. Asanova[1]

[1]Medical Psychology-Psychosomatic Medicine and Psychotherapy, Bogomolets National Medical University, Kyiv, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.817

Introduction: Pain has a significant impact on a person's quality of life, limiting general activity (work, social interaction, problems with family relationships, hobbies/interests, self-care ability), contributing to the development of mental disorders such as depression and anxiety.
Objectives: Our study aimed to determine the level of anxiety, depression, and functional disabilities caused by chronic pain among outpatients in order to further dynamic research of the long-term consequences.
Methods: The study group included 85 outpatients with chronic pain. As a part of psychiatric screening, the HADS depression and anxiety scale was used to study psychopathological symptoms. The WHO self-questionnaire WHODAS 2.0 was used to study the dysfunction caused by chronic pain.
Results: The study found that a significant part of patients with chronic pain had symptoms of anxiety 38% and depression 46% of varying severity. The medial WHODAS 2.0 score among all patients with pain and patients with comorbid depression and anxiety was 23.62 (95% CI: 21.19-24.63), 32.80 (95% CI: 30.33-35.16), and 34.35 (95% CI: 32.11-37.60), respectively. Disability was significantly higher in patients with depression (1.72, $p < 0.01$) and anxiety symptoms (1.60, $p < 0.01$) than in patients with chronic pain without anxiety and depression.
Conclusions: Effective treatment of chronic pain requires a comprehensive approach using psychotherapeutic, psychopharmacological, and physical therapy.

The Role of Extraversion and Psychopathological Symptoms in Drug Resistance in Psychiatric Patients: A Preliminary Study

M. N. Modesti[1]*, J. F. Arena[2], A. Del Casale[2], S. Ferracuti[3], C. Guariglia[1,4] and S. De Persis[5]

[1]Department of Psychology; [2]Department of Dynamic and Clinical Psychology and Health Studies; [3]Department of Human Neuroscience, Sapienza University of Rome; [4]Cognitive and Motor Rehabilitation and Neuroimaging Unit, "Santa Lucia" Scientific Institute for Research, Rome and [5]Department for the Protection and Promotion of Mental Health, Local Health Unit, Rieti, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.819

Introduction: Drug resistance is a major clinical challenge in psychiatry, with limited understanding of influencing factors. Personality traits and psychopathological symptoms may contribute to drug resistance, affecting treatment response to standard interventions.
Objectives: This study aims to assess whether personality traits, mainly neuroticism and extraversion, and psychopathological symptoms correlate with drug resistance profiles in clinically stable patients with severe mental disorders.
Methods: The study included 36 outpatients (17 males, 19 females) consecutively treated at the Mental Health Centre of Rieti, Italy. Patients were diagnosed with Major Depressive Disorder (39%), Bipolar Disorder (25%), Schizophrenia (28%), and other diagnoses, including Obsessive-Compulsive Disorder (8%). Drug resistance was defined as a lack of response to previous antidepressant treatments, requiring either dual antidepressant therapy, add-on therapy with a tricyclic or lithium, or a lack of response to atypical antipsychotic treatments, necessitating either dual atypical antipsychotic therapy, the addition of a typical antipsychotic, or the prescription of clozapine. Mann-Whitney U tests were used to compare 11 patients with a drug resistance profile to the remaining 25, and stepwise logistic regression was conducted to assess the association between drug resistance (dependent variable) and study variables, including the Brief Psychiatric Rating Scale (BPRS), Eysenck Personality Questionnaire factors (e.g., extraversion, neuroticism), and Global Assessment of Functioning (GAF) scores. The local ethics committee approved this study (Protocol No. 0948/2023).
Results: Mann-Whitney U tests revealed significant differences between groups in total BPRS scores ($p = 0.032$) and the BPRS Negative Symptoms subscale ($p = 0.001$), with higher scores in the drug-resistant group. GAF scores also differed significantly ($p = 0.022$), with lower scores in resistant patients. Logistic regression showed that extraversion had a significant negative association with drug resistance ($\beta = -0.803$, $p = 0.033$), suggesting higher extraversion is linked to reduced resistance. The BPRS Negative Symptoms factor had a significant positive association ($\beta = 0.467$, $p = 0.026$), while Positive Symptoms showed a trend toward a positive relationship ($\beta = 0.508$, $p = 0.059$). The final model explained a substantial proportion of variance (McFadden's $R^2 = 0.543$) and improved over previous models (ΔX^2, $p = 0.042$).
Conclusions: Extraversion negatively correlates with drug resistance profiles in clinically stable patients with severe mental disorders. BPRS negative symptoms are positively correlated with resistance, and positive symptoms show a similar trend. This study highlights the importance of personality and psychopathological aspects in treatment response and the need for personalized interventions for patients with drug resistance.

Attention to effective treatment for Attention Deficit Hyperactivity Disorder (ADHD) - A data science project

Y. Bloch[1]* and L. Mosco[2]

[1]child &Adolescent outpatient clinics & Research authority, Shalvata mental health center, Hod Hasharon and [2]School of Medicine, Tel Aviv university, Tel Aviv, Israel
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.820

Introduction: ADHD (Attention-Deficit/Hyperactivity Disorder) is a common treatable disorder that impairs daily functioning along the life span. Pharmacotherapy plays a central role in managing ADHD, but adherence rates can be low, impacting treatment effectiveness.
Objectives: To compare the adherence to the specific medication used to treat ADHD on specific patient populations.
Methods: In this study, we used "Clalit Medical Services" anonymized data base and focused on the first year of treatment with the four available first-line pharmacotherapy products: Methylphenidate tablets, Methylphenidate Slow Release tablets, Methylphenidate Long Aacting capsules, and Oros Methylphenidate tablets. Analyzing data from 214,035 patients of all ages diagnosed with ADHD who initiated pharmacotherapy between 2000 and 2022, we used a Negative Binomial Regression to develop a model to predict the number of prescriptions purchased in the first year of treatment, serving as a proxy for adherence. Our main focus was on identifying medications that enable better adherence.
Results: Oros Methylphenidatehad the highest number of predicted purchases (RR CI 95%: 5.85-5.96). After adjusting for calendar year effects, our results identified gender, age group, and socioeconomic status (SES) as significant predictors of adherence. A significant interaction effect revealed that the predicted number of purchases for a specific medication is influenced by the patient's SES level, i.e., for the lower SES levels adherence with Methylphenidate was better than adherence with Oros Methylphenidate.
Conclusions: The choice of the specific medication available as first-line treatment for ADHD, has a significant effect on adherence. Oros Methylphenidatehas has better adherence than the other MPH formulas. This would guide physicians to prefer the use of Oros Methylphenidateas first line therapy. This is not true for the lower SES. Strengthening our assumptions that knowledge about medication adherence and patient characteristics are potential indicators for improving the treatment of ADHD.

Plasma microRNAs reveal a schizophrenia patient subgroup with high inflammation and severe symptoms

T. Miyano[1]*, T. Mikkaichi[1], K. Nakamura[1], Y. Yoshigae[2], K. Abernathy[3], Y. Ogura[2] and N. Kiyosawa[1]

[1]Translational Science Department II; [2]Translational Research Laboratories, Daiichi Sankyo Co., Ltd., Tokyo, Japan and [3]Clinical Research Department, Sirtsei Pharmaceuticals, Inc., North Carolina, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.821

Introduction: Schizophrenia is a complex and highly heterogeneous psychiatric disorder, and it is crucial to understand the different pathophysiology among patients to realize precision psychiatry.
Objectives: This study aims to evaluate the potential of plasma microRNAs (miRNAs) as clinical biomarkers to stratify schizophrenia patients based on molecular profiles and understand the heterogeneous pathophysiology.
Methods: We measured the Positive and Negative Syndrome Scale (PANSS) scores, which are severity scores of clinical symptoms of schizophrenia, along with levels of 179 plasma miRNAs in 26 schizophrenia patients experiencing acute psychosis. We applied hierarchical clustering analysis for the plasma samples on miRNA levels to explore patient subgroups. We then conducted miRNA set enrichment analysis, literature-based text mining and manual literature survey on characteristic miRNAs for each patient subgroup to interpret the heterogenous pathophysiology. This study has been approved by the Ethical Research Practice Committee of Daiichi Sankyo Co., Ltd.
Results: The schizophrenia patients were stratified into three subgroups based on the plasma miRNA profiles. One of these patient subgroups showed a tendency to have relatively high PANSS scores. This patient subgroup was characterized by distinctively low levels of four miRNAs. The enrichment analysis revealed an enrichment of 'Immune Response' pathways associated with these four miRNAs. Consistent with the enrichment results, literature-based text mining confirmed that these four miRNAs were frequently associated with 'inflammation' and IL-1β, IL-6, and TNFα in the literature. We also identified literature-based experimental evidence demonstrating that these four miRNAs reduce IL-1β, IL-6 and TNFα. These results suggest that the patient subgroup with high PANSS scores has relatively high inflammation.
Conclusions: miRNAs may potentially be clinical biomarkers that reflect both the symptoms and molecular pathology of schizophrenia, and they may be able to identify patient subgroups with relatively high inflammation. Such patient stratification based on molecular profiles is expected to be a key tool to realize precision psychiatry, e.g., prescribing right drugs for right patients.

Hashimoto's encephalopathy in a patient with hypothyroidism and bipolar disorder: a case report

C. Bey[1,2]*, T. Ach[3,4], A. Ben Abdelkarim[3,4] and J. Mannaï[2,3]

[1]Laboratory of Physiology and Pathophysiology of physical exercise; L.R.19ES09, University of Sousse, Faculty of Medicine of Sousse, 4000, Sousse; [2]Psychiatry department, Ibn El Jazzar University Hospital of Kairouan, Kairouan; [3]University of Sousse, Faculty of Medicine of Sousse, 4000 and [4]Endocrinology department, Farhat Hached University Hospital of Sousse, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.822

Introduction: Hashimoto's encephalopathy (HE) is a rare, steroid-responsive neuropsychiatric disorder associated with Hashimoto's thyroiditis. The pathophysiology of HE remains unclear, but it is hypothesized to involve an autoimmune mechanism, distinct from thyroid hormone levels. The condition often presents with a variety of neurological and psychiatric symptoms, including cognitive decline, seizures, mood disorders, and movement abnormalities. Timely diagnosis and treatment are crucial to prevent further neurological impairment.
Objectives: This report highlights a case of HE in a patient with bipolar disorder and hypothyroidism.
Methods: A 42-year-old male patient, followed in psychiatry for bipolar disorder type I and in endocrinology for hypothyroidism secondary to Hashimoto's thyroiditis, was admitted to the

endocrinology department of Farhat Hached hospital, Sousse, due to fatigue, psychomotor retardation, and an enlarged goiter, in the context of discontinuation of his replacement therapy. Laboratory tests revealed a significantly elevated TSH level of 17.5mUI/L, indicating profound hypothyroidism. Hospitalization was therefore prompted by this endocrine decompensation to reinitiate treatment and to monitor him to prevent complications.
During the hospital stay, thyroid hormone replacement therapy was resumed. However, despite adequate treatment, the patient quickly became unstable, exhibiting vague persecutory delusions, marked irritability, changes in behavior, distractibility, attention problems, insomnia and confusion. This clinical picture raised the possibility of either a manic relapse with psychotic features, potentially triggered by the resumption of thyroid treatment, or Hashimoto's encephalopathy.
Further investigations, including brain imaging and anti-thyroid peroxidase antibodies (ATPO) measurement, were performed. Brain imaging was normal, and ATPO were elevated. Given the clinical history and elevated thyroid antibodies, the diagnosis of Hashimoto's encephalopathy was considered. The patient was started on corticosteroid therapy (prednisone), leading to a significant improvement in both psychiatric and cognitive symptoms within weeks.
Results: This case illustrates the importance of considering HE in patients with neuropsychiatric symptoms and underlying thyroid disease. The combination of elevated ATPO levels and progressive psychiatric deterioration, with normal neuroimaging, and significant improvement with immunomodulatory treatment supports the diagnosis of HE. It is a rare condition with a reported prevalence of 2.1/100000. It presents with a wide range of neurological and psychiatric symptoms and the presentation varies among patients.
Conclusions: This case underscores the need for increased awareness of HE as a differential diagnosis in patients with thyroid disorders and neuropsychiatric manifestations.

The hidden wolf – Case report of valproic acid drug-induced cerebral lupus erythematosus

S. C. Steininger[1]*, R. Mansky[1], A. Reichert[1], K. Brändle[1], S. Bacanovic[2], W. Kawohl[3,4] and F. Xepapadakos[3,4]

[1]Old Age Psychiatry, Clienia Schloessli, Private Psychiatric Hospital and Academic Teaching Hospital of the University of Zurich and of the University of Nicosia Medical School, Oetwil am See/Zurich; [2]Radiology, Männedorf Hospital, Männedorf; [3]Clienia Schloessli, Private Psychiatric Hospital and Academic Teaching Hospital of the University of Zurich and of the University of Nicosia Medical School, Oetwil am See/Zurich, Switzerland and [4]Department of Basic and Clinical Sciences at the University of Nicosia Medical School, Nicosia, Cyprus
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.823

Introduction: Neuropsychiatric symptoms associated with valproic acid were already described in the 1980s. Valproic acid is known to cause valproate encephalopathy and hyperammonemia[(1,2)]. Rarely it can cause drug induced lupus erythematosus[(5)]. Previous studies and case reports have documented manifestations such as rash, pulmonary involvement, pleuritis and carditis due to valproate-induced lupus erythematosus. However, little is known about other manifestations[(3,4,6)]. To date, there are no descriptions of cerebral drug-induced lupus erythematosus due to valproic acid.
Objectives: We report the case of a female 63-year-old patient who was initially treated in our inpatient clinic for prolonged delirium and major neurocognitive disorder following severe traumatic brain injury with bilateral traumatic intracerebral temporal bleeding eight months prior. Symptoms from the severe traumatic brain injury included aphasia, impulse control disorder, reduced frustration tolerance and depression, which were treated with valproic acid and quetiapine. The patient experienced a strongly fluctuating, progressively deteriorating neuropsychiatric syndrome that began six months before hospitalization. Additionally, a fluctuating neurological syndrome including temporary complete hemiparesis, hyperreflexia and loss of consciousness, which lasted from 30min to hours, and halluzinations was observed. The patient also developed epileptic seizures, which could not be managed by a combined antiepileptic therapy with valproic acid, brivaracetam and clobazam. Previous examinations (brain-MRI and CT, CFS, extended lab testing) excluded acute cerebrovascular insult, encephalitis and hyperammonemia.
Methods: The diagnosis of cerebral vasculitis was considered after excluding infection or cerebrovascular insult. Anti-nuclear antibodies and anti-histone Antibodies were detected in the blood sample. Anti-NMDA receptor antibodies as well as antibodies for paraneoplastic syndromes and Bickerstaff encephalitis were not detected. MRI scans over eight months showed an increase of white matter lesions periventricular and in the brain stem.
Results: Based on these results and the medical history, we considered a drug-induced vascular lupus erythematosus due to valproic acid. We initiated immunosuppressive therapy with high-dose prednisone while tapering valproate acid. Within days, the neurological symptoms declined and epileptic seizures ceased.

Image 1:

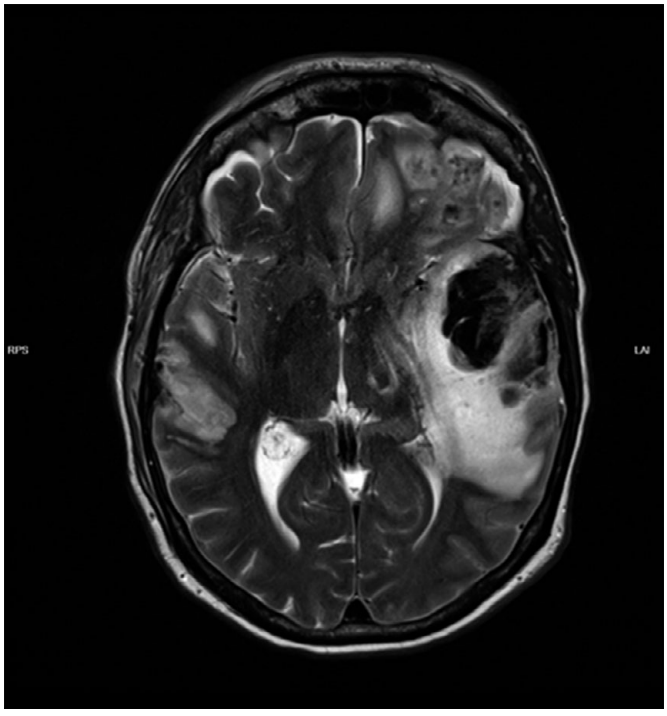

Image 2:

Imange 2: Six weeks after treatment with valporic acid, white matter lesions increase.

Image 3:

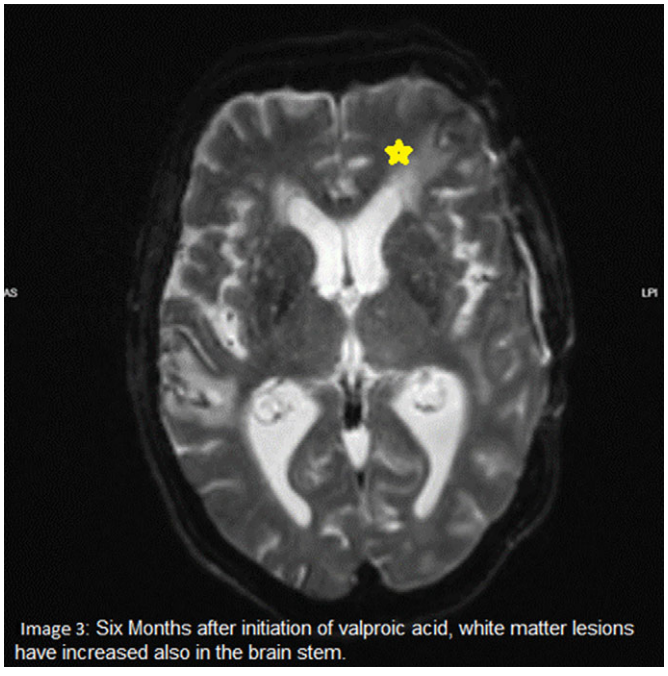

Image 3: Six Months after initiation of valproic acid, white matter lesions have increased also in the brain stem.

Conclusions: This is the first described case of valproic acid-induced cerebral lupus erythematosus. There are no established recommendations for therapy or knowledge about the course and outcome of this condition. This case highlights the importance of evaluating valproate-induced lupus erythematosus in patients with fluctuating neuropsychiatric symptoms under valproic acid medication, in addition to valproate-induced encephalopathy. Prednisone might be a viable treatment option.

"Step by Step" Toward Recovery for People with Severe Mental Illness – The Example of a Community Mental Health Structure on the Outskirts of Lisbon

M. Andrade[1]*, F. Ramalheira[1], A. Nunes[1] and L. Gil[1]

[1]Hospital Júlio de Matos - ULS São José, Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.824

Introduction: Addressing severe mental illness requires assertive community intervention. The "Assertive Program – Step by Step", implemented in 2016, involves a mental health team in the Sintra region (Lisbon). Through a case manager model and regular patient contact, an Individualized Care Plan is developed to ensure treatment continuity, coordinate psychosocial interventions, and reduce both the frequency and duration of hospital admissions. The goal is to contribute to clinical improvement, enhance social functioning, and improve the quality of life for individuals with severe mental illness through several measures: regular psychiatric consultations; promotion of adherence to psychopharmacological treatment; individual or group psychological support; participation in rehabilitation programs; psychoeducational programs for patients and families; and facilitation of general medical consultations and social support.
Objectives: This study aims to characterize the sociodemographic profile, occupational status, and number of hospital readmissions among patients followed by the Assertive Program, and to reflect on the relevance of these interventions in preventing relapses.
Methods: A retrospective analysis of data collected from the clinical records of patients enrolled in the Assertive Program in September 2024, with a minimum follow-up period of one year.
Results: In September 2024, a total of 29 patients were enrolled in the Assertive Program, with 19 receiving follow-up for more than one year. The average age was 36.4 years, and 68.4% were male. The majority of patients were either single (68.4%) or divorced (21.1%), and most were not working, with 52.6% being unemployed and 5.3% retired. The predominant diagnosis was schizophrenia (52.6%), followed by Bipolar Affective Disorder (31.6%) and Psychosis Not Otherwise Specified (10.5%). The average number of total hospital admissions was 2.9 (maximum 12, minimum 0). After joining the Assertive Program, 68.4% (n=13) of patients were not readmitted to the hospital. Of those readmitted (31.6%; n=6), most had a diagnosis of schizophrenia (n=4) and were unemployed (n=5).
Conclusions: This study highlights the specific sociodemographic profile of patients with severe mental illness, who appear to be predominantly single and unemployed. The proposed program may help reduce the number of relapses in the care of this patients. Hospital readmissions appear to occur primarily among unemployed patients, underscoring the need for close, personalized follow-up, with a focus on improving occupational functionality.

Cultivating new identities through horticulture, cooperation and mutual learning: the SOGNI project

A. Barbieri[1]

[1]PSYCHIATRY, ASL CN1, CUNEO, Italy
doi: 10.1192/j.eurpsy.2025.825

Introduction: Circular economy is a model of production and consumption entailing both environmental and social aspects. The collaborative dimension of this model is evident in the reuse of waste that can constitute a resource for other productive processes, encouraging cooperation and exchange. Also, the regeneration of disused spaces, in both urban and rural contexts, can stimulate social participation, cohesion and community development, thus becoming a resource for community-oriented interventions in the field of mental healthcare.
Objectives: In 2024 a horticultural activity has been developed on the fields surrounding the facility, to grow edible species (mainly herbs and small fruits). The activity involved people hosted in the TC, local farmers, students of one agricultural high school and one catering school, to develop processes of agricultural products' cultivation, exchange and transformation, as well as mutual learning. In particular, the project entails the reuse of TC's organic waste (to produce compost), the cultivation of culinary plants and fruits, the production of derivatives (e.g. juices and jams) in the cooperation with the abovementioned schools, local producers, and consumers. The exchange of both products and skills aims to constitute (also metaphorically) fertile ground for the germination of new opportunities, supporting care in a broad sense and cultivating new individual and group identities. The original meaning of the acronym – "dreams" – points to the dreamlike dimension of a project that – within the controlled, safe perimeter of a pilot intervention – introduces innovative (sometimes bizarre) practices and unprecedented relationships between heterogeneous social actors, inviting the latter to "suspend every judgment". Hopefully, configurations experienced during the pilot project and evidence supporting their therapeutic potential will be translated into the waking life, providing the basis for improved practice that intersects mental health, sustainability, and social cohesion.
Methods: observational work and data collection conducted by healthcare professionals and an ethnographer.
Results: The performance of practical tasks and the prolonged time of the activity throughout months provided each person with the time needed to gradually explore new relational spaces. The aim of growing food, a necessary step in this circular and collective enterprise, supported motivation as well as the development of a social identity of the group, who felt part of the wider community and actively involved in its development.
Conclusions: Preliminary findings suggest further investigation and encourage collaboration between different social actors to develop inclusive, effective, and community-based interventions in the field of mental health and recovery.

Inpatient Rehabilitation Psychiatry: A Literature Review and Illustrative Case Series

A. Keng[1,2*], G. D. Eom[2,3] and O. Ghaffar[2,3]

[1]Psychiatry, Baycrest Centre for Geriatric Care; [2]Psychiatry, University of Toronto and [3]Psychiatry, Sinai Health, Toronto, Canada
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.826

Introduction: Physical rehabilitation is usually required after serious illness or injury; there is a significant need for simultaneous psychiatric rehabilitation as well. Psychiatric consultation to inpatient rehabilitation units presents with unique clinical questions distinct from consultation to other units.
Objectives: To present a literature review and an illustrative case series of common psychiatric referrals from physical rehabilitation units.
Methods: First, the current literature was reviewed on PubMed looking at current models of psychiatric consultation to inpatient physical medicine and rehabilitation units. Second, cases were reviewed from tertiary post-acute care units including stroke, acquired brain injury, post-fracture fast and slow stream, and complex continuing care. Third, thematic analysis was performed to extract illustrative themes presented in a case series of four mock patients.
Results: There is a paucity of literature on psychiatric consultation to inpatient physical rehabilitation units. The current literature, however, supports high utilization of psychiatric consultation in comorbid physical illness (Daly et al 2023, PMR). Four major themes emerged on psychiatric consultation to inpatient physical rehabilitation: (1) Interdisciplinary management of basophobia [the fear of falling], (2) Managing severe persisting mental illness and addressing medications that increase the risk of falling, (3) Managing new onset trauma-related disorders and pain-related disorders, (4) Assessing partial cognitive improvement and impairment in the setting of brain injury.
Conclusions: Psychiatrists often deal with patients recovering from an episode of serious physical illness or injury. There is significant overlap between the work done in physical and psychiatric rehabilitation. Patient and staff education, judicious prescribing and de-prescribing, and interdisciplinary management are critical to successful outcomes.

Disclosure of Interest: None Declared

Analysis of adherence and dropout factors from psychosocial treatment among people with serious mental illness

M. O. Pires[1*], C. Osório[2], S. Ramos[3] and R. Quelhas[3]

[1]Unidade Local de Saúde da Guarda, Guarda; [2]Unidade Local de Saúde do Tâmega e Sousa, Penafiel and [3]Unidade Local de Saúde de Matosinhos, Matosinhos, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.827

Introduction: Psychosocial treatment is a crucial component of the rehabilitation process for individuals with serious mental illness

(SMI). However, adherence to these interventions is often low, with high dropout rates posing challenges to successful outcomes. Understanding the factors that influence patient adherence, and dropout is essential for improving program efficacy and patient well-being.
Objectives: This study aims to analyze the demographic, clinical, and motivational factors that contribute to adherence or dropout from the "*Programa Mais de Perto*" (PMDP), a psychosocial rehabilitation initiative for individuals with SMI, in order to enhance patient retention and optimize therapeutic outcomes.
Methods: The study included all patients with SMI enrolled in the PMDP activities until December 2023. Data were collected through clinical file reviews and telephone interviews using a structured questionnaire, including the World Health Organization Disability Assessment Schedule (WHODAS 2.0). Demographic and clinical variables, as well as patient-reported experiences, were analyzed to identify factors associated with continued participation or dropout.
Results: The study initially included 87 patients, of whom 41 adhered to the program and 46 dropped out. However, after further filtering and questionnaire analysis, a subset of 36 patients was evaluated in detail (22 in the adherence group and 14 in the dropout group). The adherence group had lower disability scores on WHODAS 2.0 and reported higher intrinsic motivation, such as improving physical and mental well-being. In contrast, the dropout group highlighted external pressures from mental health professionals as reasons for initial participation and cited fatigue, lack of integration, and distance from the program as reasons for discontinuation. *Tai Chi Chuan* was the most popular activity (39% participation), while the *Book Club* had the lowest engagement (3%).
Conclusions: Intrinsic motivation is a key predictor of adherence to psychosocial rehabilitation programs, while external pressures may increase dropout risk. Enhancing flexibility, offering a wider range of activities, and fostering peer support systems could improve retention rates. These findings reinforce the importance of adapting psychosocial interventions to the needs and motivations of individuals with SMI for better long-term outcomes.

EPP609

Assessing the Impact of a Men's Mental Health Peer Support Program Using Participatory Methods

R. Whitley[1]

[1]Psychiatry, McGill University, Montreal, Canada
doi: 10.1192/j.eurpsy.2025.828

Introduction: There is a growing interest in the field of men's mental health, given that men experience elevated rates of certain mental health outcomes including suicide, substance use disorder and overdoses. Evidence suggests that certain male sub-populations are at particular risk, including fathers who are divorced or separated. This increased risk has been attributed to several factors including painful separation from children, an intense decrease in social support, and a sense of failure and shame associated with marital breakdown. Despite these risks, there is a lack of official services targeted at divorced or separated fathers with mental health issues, with only a few grassroots programs available for this demographic. One such service is a peer support program known as Pères Séparés (seperated fathers). This program is officially accredited by the *ministère de la Santé et des Services sociaux du Québec* to provide psychosocial support including one-on-one peer coaching, weekly support groups and financial/legal advice to divorced or separated men in Montreal.
Objectives: We set out to conduct a project using a method known as participatory video. The aim was to elicit the lived experience of service users, including their experiences within the peer support program, and represent these experiences in a short video that can be used for the education of other peers, health care providers, family members and the general public.
Methods: The project involved creating a workgroup of program service users who were initially trained in basic video-techniques. Workgroup members then interviewed each other about their experiences on camera. All interviews were transcribed, with workgroup members reading the transcripts and distilling prominent themes from these interviews for inclusion in the final video.
Results: The resultant 20 minute video contained three themes (i) the unique struggles of separated fathers including intense loneliness, isolation, depression, and suicidality; (ii) the important of the program in reducing this isolation and providing invaluable social support; and (iii) the rehabilitative role of peer support in providing psychosocial education regarding self-care, social reintegration and pathways to recovery from mental health issues. The video was shown in a series of screenings at targeted settings including health-care, community and educational venues. It was also uploaded to social media where it has been viewed over 5,000 times.
Conclusions: The results imply that such grassroots peer-support programs are very well-situated to help vulnerable fathers in their recovery. Moreover, this program provides a model that can be used as a template elsewhere. Indeed, relevant organizations, funders and service providers could consider creating and implementing similar peer support programs oriented towards seperated fathers. These can benefit such men, their families and society as a whole.

Phase 3 program of evenamide, a glutamate release modulator, as add-on in patients with treatment-resistant schizophrenia: design of a potentially pivotal, international, randomized, double-blind, placebo-controlled trial

R. Anand[1]*, A. Turolla[2], G. Chinellato[2], R. Giuliani[2], F. Sansi[2] and R. Hartman[3]

[1]R&D, APC, St Moritz, Switzerland; [2]R&D, Newron Pharmaceuticals SpA, Milan, Italy and [3]R&D, NeurWrite LLC, Morristown, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.829

Introduction: Treatment-resistant schizophrenia (TRS) develops in ~30% of patients, resulting in higher hospitalization rates, morbidity, mortality, and suicidality, and increased costs (Pompili et al CNS NDDT 2017; 16 870-884). Despite inconsistent findings of its efficacy, antipsychotic polypharmacy (APP) is frequently prescribed in an attempt to treat refractory symptoms (Correll ClinNorthAm 2012; 35 661-681). While marketed APs all act through the modulation of 5HT/DA transmission, clozapine, the only drug approved for TRS,

seems to act on multiple receptor systems (Brunello et al NPP 1995; 13 177-213). The need to modulate non-monoaminergic targets is supported by findings of excessive glutamatergic activity, rather than increased dopamine synthesis, in patients with TRS (Demjaha et al BioPsy 2014; 75 11-3). Evenamide, devoid of biological activity at >150 CNS targets, is able to normalize excessive glutamate release without affecting basal levels. Evenamide has demonstrated benefits in several animal models of psychosis (monotherapy and add-on to AP). Benefit of evenamide as add-on was demonstrated in a phase 2, open-label trial (Anand et al IJNPP 2023; 174 216-229) and in a phase 2/3 randomized, double-blind study in patients not responding adequately to SGAs.
Objectives: Evaluate the efficacy, safety, and tolerability of evenamide 30 mg bid as add-on treatment in patients with documented TRS receiving AP treatment but not adequately benefitting from a stable therapeutic dose.
Methods: This is a prospective, potentially pivotal, phase 3, randomized, double-blind, placebo-controlled, 1-year international study, with a primary efficacy endpoint at 12 weeks and long-term efficacy endpoints at 26 and 52 weeks. Eligible patients must have a diagnosis of TRS according to the TRRIP consensus guidelines (Howes et al AmJPsy 2017; 174 216-229). During the 6-week screening period and throughout the study, adherence to background AP(s) and evenamide will be confirmed through measurements of plasma levels. Selection criteria include CGI-S of mildly to severely ill (3-6); BPRS total score ≥45, with a score ≥18 on core symptoms of psychosis, and PANSS total score ≥70. An Independent Eligibility Committee will determine patients' eligibility. Patients improving ≥20% on the BPRS or ≥1 category on the CGI-S during the screening period will be excluded. Efficacy (PANSS, CGI-S/C, Q-LES-Q-SF, PSP scales) and safety (vital signs, ECG, lab tests, physical/neurological/eye exams, ESRS-A, CDSS, C-SSRS) will be evaluated at regular intervals.
Results: Results from this study will determine whether addition of evenamide 30 mg bid to APs is associated with clinically important benefit in TRS patients.
Conclusions: Positive results would support the role of glutamate modulators for the optimal treatment of TRS.

Myocardial deformation and pro-arrhytmic indices in a group of first-episode patients with psychosis after one year of antipsychotic treatment

M. Plakoutsis[1], A. Bechlioulis[2], A. Rammos[2], S. Sioros[2], A. Karampas[1], G. Georgiou[1], D.-D. Koutsogianni[1], L. Mihalis[2], K. Naka[2] and P. Petrikis[1]*
[1]Department of Psychiatry and [2]2nd Department of Cardiology, University of Ioannina, Ioannina, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.830

Introduction: Heart Rate Variability assesses the autonomic system function. We have previously reported increased sympathetic activation (i.e. increased proarrhythmic risk) and asymptomatic left ventricular myocardial dysfunction in a group of drug-naïve, First Episode Patients with psychosis. We performed the same cardiological evaluation in a subgroup of these patients one year after the initiation of antipsychotic treatment.
Objectives: To find out the impact of antipsychotic medications in cardiac function.
Methods: Thirty three consecutive patients diagnosed with first psychotic episode were included in the current analysis. None of the patients had a previous history of cardiovascular diseases. All patients were assessed by 24-hour Holter ECG monitoring (including QT analysis and heart rate variability indices) and a thorough echocardiographic study (including myocardial strain analysis – global longitudinal strain GLS) at baseline (shortly after stabilization) and 1 year after treatment.
Results: The mean age of our population was 29±7 years, 75% were males and their body surface area was 1.87±0.21 m^2. At baseline 1) the mean value of QTc was normal in all subjects although the greatest QTc value measured was above 500msec in 35% of patients, 2) SDNNI<50 msec was observed in 50% of the patients, all patients had an abnormal HRV index, low RMSSD <20 msec was observed in 35% of patients, no patient had abnormally low PNN50 values. No patient had evidence of overt structural heart disease and the value of left ventricular ejection fraction was within normal range (57.5±5.1 %). GLS was decreased (i.e. < -16%) in 25% of patients. At follow-up maximum QTc value (517±52 vs 485±69, p=0.014) and PNN50 (14.1±12.1 vs 9.8±10.5, p=0.05) were increased while left atrial volume index (20.1±6.3 vs 23.3±6.4, p=0.031) and GLS (-18.6±2.5 vs -17.5±2.5, p=0.007) were decreased compared to baseline. No other significant changes were observed at follow-up. At follow-up, abnormal GLS, QTc max, SDNNI, HRV index, RMSSD and PNN50 values were observed in 16%, 60%, 38%, 96%, 15% and 0% respectively of included patients.

Normal values
SDNNI >100 (especially <50)
HRV INDEX >60
RMSSD 13-48 MS
Pnn50 -3 – 43%
Conclusions: In patients with a first psychotic episode without a previous history of cardiovascular disease or risk factors, a significant proportion showed abnormal autonomous system function and subclinical myocardial dysfunction of the left ventricle. After 1 year of treatment, improvement was observed in left ventricular function and parasympathetic system activity with a concomitant increase QTc interval. Optimal management of psychotic episodes may lead to an amelioration of the risk of future myocardial impairment without affecting the risk for arrhythmias and sudden death.

Examination of Hematological Parameters in Patients with First-Episode Psychosis within the Bipolar Disorder or Schizophrenia Spectrum

E. Uzun Uysal[1]*, Ö. A. Uysal[2] and B. İnce[2]
[1]Arnavutköy State Hospital and [2]Bakırköy Training and Research Hospital for Psychiatry, Neurology and Neurosurgery, İstanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.831

Introduction: First-episode psychosis (FEP) provides a crucial opportunity to investigate these biological markers before the influence of long-term treatment or disease progression. Both bipolar disorders with psychotic features and schizophrenia spectrum disorders are linked to systemic inflammation, and examining blood cell counts and inflammatory ratios may provide insights into the biological foundations of these conditions.
Objectives: This study aims to compare key hematological parameters and inflammation markers (neutrophil/lymphocyte ratio (NLR), platelet/lymphocyte ratio (PLR), monocyte/lymphocyte ratio (MLR)) between untreated first-episode psychosis patients diagnosed with psychotic mania, schizophrenia spectrum disorders, and healthy controls, examining potential differences between these groups.
Methods: 55 patients (F:28, M:27) diagnosed with schizophrenia spectrum disorder, 68 patients (F:38, M:30) diagnosed with bipolar disorder, all without a history of treatment, who were admitted to psychiatric clinics due to a first-episode psychosis, and 61 healthy volunteer individuals (F:24, M:37) matched for age and gender were included in the study. Hemogram data were obtained from medical records, and the hemograms taken within the first 48 hours of the patients' admissions were used in the study.
Results: The white blood cell, neutrophil, and monocyte counts were significantly higher in both patient groups than healthy individuals. The eosinophil count varied between the groups, with patients diagnosed with schizophrenia spectrum disorder having significantly lower counts compared to healthy individuals (p=0.003). When the analysis was conducted by gender, white blood cell, neutrophil, and monocyte counts were found to differ in women from both patient groups compared to healthy individuals, while in men, only the eosinophil count was lower in patients diagnosed with schizophrenia spectrum disorder (p=0.023). There were no significant differences in the NLR and PLR between the groups. The MLR value showed no difference between male patients and healthy individuals, but it varied between the groups in women, with patients diagnosed with psychotic mania having higher MLR compared to the other groups (p=0.01).
Conclusions: Changes observed in specific hematological parameters in both bipolar disorder and schizophrenia spectrum patients may contribute to understanding the pathophysiology of these disorders. However, given the heterogeneity in the presentation and etiology of these conditions, larger-scale and prospective studies are needed to determine the roles of these parameters in their pathophysiology. It may also be necessary to consider gender-based differences when assessing the potential roles of these hemogram parameters in the pathophysiology of the diseases.

The Laughing Gas Trap: Subacute Spinal Degeneration with Normal B12 levels and Co-Morbid Functional Gait Disorder

A. G. Buciuc[1]* and M. Hadjikyriakou[2]

[1]Psychiatry, University of Miami/Jackson Health System and [2]Psychiatry and Behavioral Sciences, Bruce W. Carter Department of Veterans Affairs Medical Center, Miami, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.832

Introduction: Subacute combined degeneration (SCD) of the spinal cord is a well-known neurological disorder commonly associated with vitamin B12 deficiency. However, the condition can also present in individuals with normal B12 levels, making diagnosis more difficult.
Objectives: This paper aims to examine the diagnostic challenges posed by subacute combined degeneration of the spinal cord in patients with normal B12 levels. Specifically, it aims to highlight the importance of early screening for nitrous oxide use and the complexities introduced by co-occurring functional gait disorders.
Methods: Literature research was conducted using PubMed databases. The following keywords were used "whippets" or "nitrous oxide" or "inhalant use disorder", and "subacute degeneration of spinal cord" and/ or "normal B12 levels". Furthermore, a comprehensive clinical evaluation was conducted, including a detailed inquiry into the patient's substance use history.
Results: The 56-year-old patient developed symptoms of subacute combined degeneration (SCD) despite normal B12 levels. He experienced worsening tingling sensations, starting in the extremities and moving upward, along with new gait instability requiring a cane. Initially denying substance use, he later admitted to daily nitrous oxide inhalation, which disrupts B12 metabolism and causes spinal demyelination, leading to neurological deficits even with normal B12 levels. The presence of a functional gait disorder complicated the diagnosis, but persistent questioning about substance use and recognizing the effects of nitrous oxide were key to accurate diagnosis.
Conclusions: This case highlights the importance of early and comprehensive substance use screening, particularly in patients presenting with unexplained neurological symptoms. The disruption of B12 metabolism by nitrous oxide can cause significant spinal cord degeneration, even when serum B12 levels are normal. This underscores the need for detailed, persistent questioning about substance use in clinical settings, particularly for patients with risk factors for inhalant abuse. Additionally, an awareness of the multifaceted nature of functional gait disorders is essential for accurate diagnosis and optimal patient outcomes. Routine screening for nitrous oxide use and a thorough examination of gait abnormalities can aid in the timely detection and treatment of subacute spinal degeneration, preventing further neurological damage. By incorporating recommended screening questions and being vigilant about the neurological effects of nitrous oxide, clinicians can better address the diagnostic challenges of SCD and functional gait disorders.

Nomophobia and other psychological symptoms among nursing students community

M. Efstathiou[1]*, A. Grammeniati[1], K. M. Panoutsopoulou[1], V. Kakaidi[2], S. Mantzoukas[2], M. Gouva[1] and E. Dragioti[1]

[1]Department of Nursing, Research Laboratory Psychology of Patients, Families & Health Professionals, School of Health Sciences, University of Ioannina and [2]Department of Nursing, Research Laboratory Integrated Care, Health & Well-being, School of Health Sciences, University of Ioannina, Ioannina, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.833
Introduction: Nomophobia among university students is recognized as an addictive issue, as their attention is often difficult to divert from smartphones, especially during class. This issue is increasingly evident among nursing students, who frequently check

their smartphones during class ($p < 0.001$), making nomophobia an important concern.
Objectives: We conducted an umbrella review aimed at assessing the prevalence of different psychological and behavioral symptoms among nursing students, including nomophobia, anxiety, sleep disturbances, fear, and stress.
Methods: This meta-synthesis combined evidence from 20 systematic reviews and meta-analyses, incorporating 354 primary studies. Publication records were retrieved from PubMed, CINAHL, PsycINFO, and Scopus. The methodological quality of each meta-analysis was assessed using the AMSTAR-2 tool. Reporting followed the PRISMA guideline checklist.
Results: Our synthesis revealed that 28% (95% CI: 24%–33%) of nursing students experience psychological and behavioral symptoms. Nomophobia/smartphone addiction was observed at 30% (95% CI: 12%–49%). Other prevalent symptoms included anxiety at 29% (95% CI: 17%–40%), sleep disturbances at 48% (95% CI: 5%–91%), stress at 27% (95% CI: 17%–37%), and fear at 41% (95% CI: 7%–75%).
Conclusions: Our findings suggest that nursing students are increasingly involved in nomophobia. As smartphones play a central role in daily life, digital detoxification is not easy. Although our research did not explore the relationship between nomophobia and other symptoms, the presence of issues such as anxiety, sleep disturbances, fear, and stress in nursing students warrants further investigation.

Tunisian Parental Perspectives on Smartphone Use: Assessing Its Impact on Children

S. Hamzaoui[1]*, K. Mahfoudh[1], D. Mezri[1], U. Ouali[1], A. Aissa[1] and R. Jomli[1]

[1]Razi Hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.834

Introduction: The rapid increase in smartphone usage among minors raises significant concerns about problematic smartphone use in children and adolescents. As the first generations immersed in high-tech media, today's youth may be more vulnerable to its negative effects compared to older age groups. Understanding these impacts is essential as smartphones become integral to daily life.
Objectives: This study seeks to assess the prevalence of problematic smartphone usage among a group of children, explore its impact on social, emotional, and academic outcomes, identify associated risk factors, and above all evaluate parental awareness and intervention strategies.
Methods: An online questionnaire was administered to parents of children aged from 1 to 18 years. It included sociodemographic information, the Smartphone Addiction Proneness Scale (SAPS) and additional questions designed to explore various aspects of smartphone use.
Results: In total, 100 parents participated in the study. The preliminary results revealed that 60% of children started using smartphones before the age of 6 years and displayed signs of problematic smartphone use, with a notable negative correlation between high usage and academic performance. Additionally, half of parents expressed concerns about their children's social skills, reporting that excessive smartphone use often diminished social interactions, communication and attention. Withdrawal symptoms were common, with 30% of parents indicating that their children experienced anxiety or restlessness when separated from their devices. Finally, 86% of parents expressed interest in receiving expert advice on healthy and balanced smartphone use for their children.
Conclusions: The results indicate a troubling trend of smartphone addiction among children.This highlights the urgent need for greater parental awareness and active strategies to manage smartphone use. Future research should focus on developing and evaluating intervention programs aimed at fostering healthier technology habits in children.

Motivation to treatment-seeking among individuals with addiction to benzodiazepines: a qualitative study

C. Krüger[1]*, S. Burmester[1,2], J. Franck[2,3], M. Hedlund Lindberg[1,4] and J. Westman[1,5,6]

[1]Department of Neurobiology, Care Sciences and Society, Karolinska Institutet, Huddinge; [2]The Stockholm Centre for Dependency Disorders, Stockholm Health Care Services, Region Stockholm; [3]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm; [4]Department of Medical Sciences, Psychiatry, Uppsala University, Uppsala; [5]Academic Primary Care Centre, Region Stockholm and [6]Department of Health Care Sciences, Marie Cederschiöld University, Stockholm, Sweden
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.835

Introduction: Many individuals with long-term use benzodiazepines and benzodiazepine-like hypnotics, commonly prescribed for the short-term management of anxiety or sleeping problems, develop addiction. It is therefore important to better understand what motivates individuals with addiction to quit. Few prior qualitative studies have explored patients' perceptions and experiences of addiction to benzodiazepines in the context of motivation to seek treatment.
Objectives: This study explored how individuals perceive addiction to benzodiazepines and aimed to describe the experiences that motivated them to seek treatment.
Methods: This exploratory qualitative study was conducted among nineteen adults (≥18 years) diagnosed with sedative, hypnotic, or anxiolytic use disorder. Participants were purposively recruited from a publicly funded outpatient addiction clinic in Sweden and were undergoing tapering treatment at the time of their in-depth interviews. The interviews, which followed a semi-structured guide, were completed between April 2021 and February 2023. Transcripts were analyzed using reflexive thematic analysis by a multidisciplinary team. All participants provided written informed consent and the study was approved by the Swedish Ethical Review Authority (Dnr. 2019-05302).
Results: Participants described perceptions of addiction and motivation to quit in terms of the growing harms they experienced from continued use of benzodiazepines. We identified three themes that reflect the nonlinear process and multifaceted consequences which to a "tipping point" where individuals made the decision to seek treatment. Theme one described how benzodiazepine use required

increasing mental energy and time, and how participants felt their freedom was restricted by the need to "hunt" for medication. In theme two, participants described facing a crossroads regarding their benzodiazepine use as the effectiveness decreased. Some participants defined addiction in relation to the negative cycle of dose escalation and withdrawal symptoms they experienced, which also motivated them to seek treatment. Theme three discusses the ways that benzodiazepines negatively impacted different psychosocial and practical aspects of daily life, including conflicts related to changes in personality and negative impacts on relationships, which resulted in further areas of motivation.
Conclusions: The results suggest that individuals with addiction to benzodiazepines reach the decision to seek treatment both through processes of change over time and through individual factors that act as a tipping point. These motivational factors are of clinical importance in the decision to seek treatment and should be identified by healthcare providers and cultivated in individuals with addiction to benzodiazepines.

From prevention to treatment of addiction: Porto's comprehensive approach through the Municipal Health Plan

J. V. Santos[1]*, P. Pinto Oliveira[2], D. Lopes[2], A. Machado[2], S. Almeida[2], M. A. Moreira[2], E. Ramos[3], J. Coutinho[4] and M. Pinto[5]

[1]ULS Santo António / University of Porto; [2]ULS Santo António; [3]University of Porto / ISPUP; [4]CRI Porto Central and [5]University of Porto / CINTESIS, Porto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.836

Introduction: The Porto Municipal Health Plan for 2022-2024 prioritized initiatives targeting addictions within the community. Built in the collaboration between the Public Health Unit, the Faculty of Psychology (FPCEUP), and the Drug Addiction Intervention and Reduction Division (DICAD), Porto aimed to comprehensively address addiction-related challenges. This includes developing monitoring tools, identifying areas lacking intervention, and promoting innovative social programs.
Objectives: To define and implement a plan from prevention to treatment of addictive behaviors and addiction within the Porto Municipal Health Plan.
Methods: After defining priorities within this scope, tasks were defined together with the different institutions of the Municipality, including disseminating information on tobacco and alcohol legislation and improving community literacy on health-conscious environments. Additionally, integrated projects focus on evaluating existing interventions, identifying best practices, and fostering collaboration among entities to address addiction effectively were listed as main steps.
Results: By aligning with strategic objectives outlined in the Porto Municipal Health Plan, such as building citizen and professionals' capacity, improving prevention strategies, and facilitating access to resources, Porto is addressing addictive behaviors comprehensively. Initiatives include capacity building, implementing intervention strategies, and promoting harm reduction approaches in recreational settings.
Conclusions: Porto's efforts to combat addiction highlight its commitment to public health. Through targeted communication, integrated projects, and resource optimization, Porto aims to mitigate the impact of addictive behaviors and promote a healthier community, aligning with the Municipal Health Plan.

Sociodemographic characteristics and quality of life between persons with addiction disorders and their caregivers

O. B. Sbutega Filipovic[1], D. Raketic[2] and R. Peric[2]*

[1]Day hospital for chemical and non-chemical addictions and [2]Special Hospital on Addictions, Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.837

Introduction: Disorders caused by alcohol and opiate addiction lead to physical, mental and socioeconomic deterioration not only of the patient, but also of their families. Family caregivers are persons who provide unpaid care to other family members who need supervision or help in case of illness or disability, as well as to persons with special needs (1). Studies have shown that the illness of one family member affects the quality of life of other family members, especially the caregiver of the patient (2). Previous studies indicate that the support of family members is of great importance and influence on the initiation of addiction treatment, compliance and participation in it, but also on the outcome itself, i.e. the success of the treatment (3).
Objectives: Primary aims of this study included sociodemographic characteristics and analysis of the quality of life between persons with addiction disorders and their caregivers.
Methods: The study included 136 patients who were being treated at the Special Hospital for Addiction Diseases in Belgrade, for the treatment of addiction to psychoactive substances (opiates and opioids or alcohol), and 136 of their caregivers. Data on respondents were collected in the period from April to October 2014. During this research, a cross-sectional study was conducted. As measuring instruments in this research, in addition to the general questionnaire, specific questionnaire was used for assessment of quality of life (*36 item Short-Form Health Survey – SF-36* (4,5).
Results: Sociodemographic characteristics indicate that there are more male addicts, as well as female caregivers ($p< 0.001$). Psychoactive substance addicts belong to the age group ≤39 years, compared to caregivers who belong to the group older than 50 years ($p<0.001$). The marital status of the respondents showed that the largest percentage of patients were without a partner, while the same number of guardians were married ($p<0.001$). The socioeconomic status of the respondents showed a statistically significant difference in relation to the socioeconomic conditions of the patients and their caregivers. SF-36 domain scores in caregivers were similar to those in with addictive disorder, with the exception that 2 domains were significantly lower, related to physical functioning ($p < 0.001$) and bodily pain ($p = 0.003$). A greater number of patients report a better state of health compared to last year compared to caregivers who consider their health to be the same or worse in the mentioned period ($p<0.001$).
Conclusions: Assessment of the quality of life of persons addicted to psychoactive substances, as well as their caregivers, is an important

aspect of the therapeutic protocol in order to provide the necessary help and more successful treatment.

EPP623

The Association Between Internet Game Addiction and Social Anxiety Symptoms Among Adolescents in The Kingdom of Saudi Arabia

B. A. Alsubaie[1]*, N. Alhujaili[2], S. Alzahrani[3], F. Aljahdali[2], W. Alghamdi[1], M. Almatrafi[2] and A. Alghamdi[2]

[1]Psychiatry; [2]Medicine, King Abdulaziz University, Jeddah and [3]Psychiatry, King Salman Specialist Hospital, Hail, Saudi Arabia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.838

Introduction: Internet gaming addiction (IGA) can have a significant impact on the characteristics of individual gamers, and may even be a contributing factor to the development of social anxiety symptoms. This study of adolescent Saudi Arabian Internet gamers examined the influences of Internet gaming time and probable Internet Gaming Disorders (IGDs). It investigated the association between Internet game addiction and social anxiety symptoms among them.
Objectives: The aim of this study was to investigate the association between internet game addiction and social anxiety symptoms among Saudi adolescents. Since very few researches examined the association between internet game addiction and psychiatric illnesses among Saudi youth, Our study focused on social anxiety symptoms which has not been done so far.
Methods: A cross-sectional, survey was conducted from March to June of 2023 among adolescents in the Saudi population. Probable Internet Game Addiction was measured by using the DSM-5 checklist and the Arabic version of the Social Phobia Inventory (SPIN) was used to evaluate social phobia or anxiety.
Results: A total of 764 participants were enrolled in the current study, majority of gaming addiction participants were 15-16 years old. There was a significant association between gender and gaming addiction (p-value ≤ 0.05). 86.6% of Saudis have been significantly associated with gaming addiction. The majority of the participants have moderate social phobia compared to severe social phobia. There was a significant association between social phobia and age (p-value ≤ 0.05). 34.9% of male participants have moderate social phobia and 24.6% of females have moderate social phobia. There was an insignificant association between social phobia and nationality. The participants with gaming addiction showed 37.2% had mild, 60.5% had moderate, 68.1% had severe and 79.5% had very severe social phobia. There was a significant association between Social Phobia and gaming Addiction (p-value≤0.05).
Conclusions: This study examines the association between video game addiction and social anxiety amongadolescents in Saudi Arabia. Despite its limitations of less sample size and small setting, the findings imply a significant correlation between IGA and these psychological concerns, particularly among male adolescents. Excessive video gaming use leads to higher levels of social anxiety. Future research should adopt experimental or longitudinal designs to establish causal relationships and consider the potential reciprocal nature of the association. Mental health educators and practitioners should be mindful of the adverse impacts of excessive video gaming, with a specific focus on male adolescents who might be more susceptible to heightened social anxiety.

Circle of Security (COSP) Implementation in a Public Clinical Setting in Spain

L. Garcia Murillo[1]*, A. Cañuelo Marquez[1], L. Mallol[1], M. Diaz de Neira[1], M. Morales[1] and I. Palanca[1]

[1]Psiquiatría, Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.839

Introduction: Evidence shows that attachment insecurity and disorganization increase the risk of developing psychopathology. The Circle of Security-Parenting Intervention (COSP; Cooper, Hoffman & Powell 2009) is designed to enhance secure attachment between caregivers and children under six years old, based on decades of attachment research. This evidence-based program has been translated into 14 languages and is present in almost 30 countries. However, in Spain, it is not currently offered in the public system, despite having a public health, education, and social services system intended to provide universal coverage.
Our team works in a Child Psychiatry Consultation, where we evaluate toddlers when Autism Spectrum Disorder (ASD) is suspected by general pediatricians or schools. Over the years, we've found that many children do not have ASD but instead present attachment difficulties that the system does not currently support.
Objectives:
- To provide parents whose children present difficulties that don't meet the criteria for disorders receiving resources from the educational or social system with tools to help their children.
- To implement an intervention in a public clinical setting in Spain, specifically in a Child Psychiatry Consultation, that could help caregivers with attachment difficulties.

Methods: From the patients referred to our hospital for ASD evaluations, we identified seven parents whose children didn't meet the criteria for a neurodevelopmental disorder but presented attachment difficulties and could benefit from COSP.
We conducted a group with these parents, consisting of 90-minute sessions over eight weeks. The program provides caregivers with relationship tools, with each chapter building on the previous one. COSP uses visual support and offers participants opportunities to reflect and learn how to better understand and respond to both children's and caregivers' needs.
Results: Six of the seven caregivers who began the group completed it. The caregiver who didn't finish had to leave due to medical issues but requested to rejoin future sessions to complete all eight chapters.

In the satisfaction survey, participants gave the highest possible ratings. Some statements from participants included: "The group has been essential to understanding how I relate to my daughter," "I can now see relationships from a new perspective," and "COSP offers very useful tools."
All participants said they would recommend the program to other parents, stating COSP is something every caregiver should become familiar with.
Conclusions: This pilot group established an initial framework for providing parents who attend our medical consultation and present attachment problems with an intervention that meets their needs. Given the evidence that secure attachment is key to preventing psychopathology, interventions such as COSP should be more frequently offered.

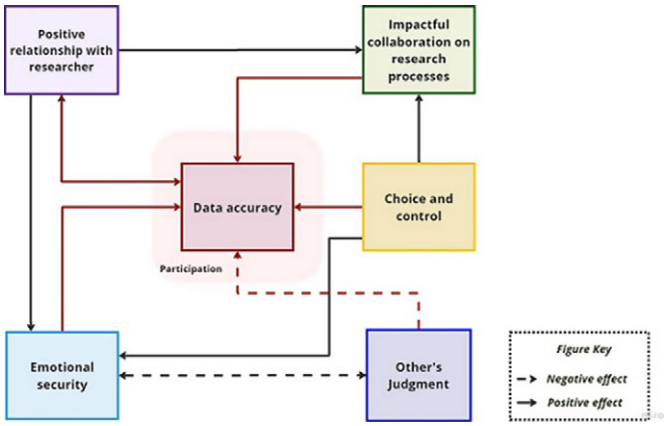
EPP626

Beyond Participation: Adolescents' Perspectives on Meaningful Engagement and Data Quality in Health Research

M. Karimipour[1]*, E. Soneson[1] and M. Fazel[1]

[1]Psychiatry, University of Oxford, Oxford, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.840

Introduction: A lack of participation from representative populations, limited long-term engagement, and potentially inaccurate self-reported responses have compromised the validity of health research findings in adolescents. Despite positive trends in some areas of adolescent health, others—such as mental health—have alarmingly deteriorated, highlighting the continuous need for adolescent health research. Therefore, it is vital to explore barriers to meaningful participation of adolescents and the factors that contribute to decreased data quality.
Objectives: This study aimed to examine adolescents' preferences and concerns about participating in health research to inform strategies for improving their likelihood of participation, meaningful engagement, and the provision of accurate responses.
Methods: Nine focus groups were conducted at three secondary schools and two sixth form colleges in England to explore the perspectives of 46 adolescents aged 16 to 18 years. The constructivist grounded theory methodology was employed to develop a framework that offers insights into the mechanisms influencing young people's participation, engagement, and provision of accurate responses in health research.
Results: "Five categories emerged as underlying factors that contribute to adolescents' participation, meaningful engagement, and provision of accurate responses. Participants suggested that a (1) *Positive Relationship with Researchers* cultivates an atmosphere of (2) *Emotional Security*, which in turn minimises the potential influence of (3) *Others' Judgments*. If adolescents are given some (4) *Choice and Control* over research processes and the data they provide, they are more likely to feel secure, which encourages continued engagement and accurate responses. The combination of a *Positive Relationship with Researchers* and young people's *Choice and Control* over research processes allows them to perceive their participation as an (5) *Impactful Collaboration in Research Processes*, empowering them to participate and provide accurate answers, especially to questions about their personal life experiences."
Image 1:



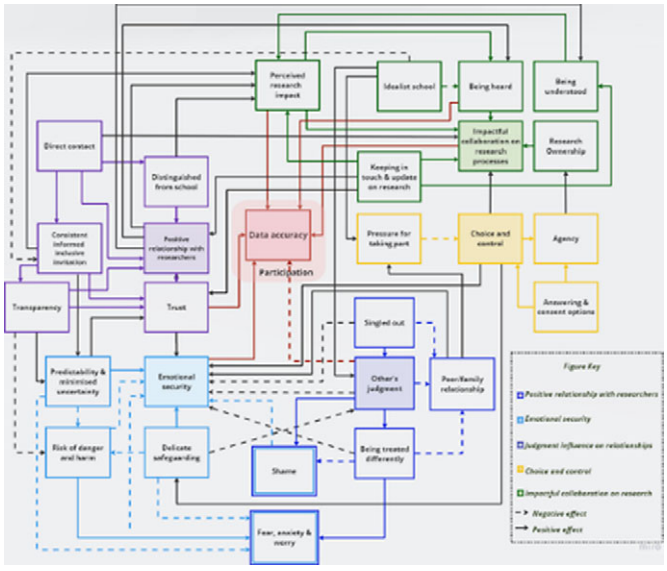


Image 2:

Conclusions: This study suggests that adolescent health research would improve by investing more in building positive relationships with young people. This can be achieved by offering them choice and control over study processes as much as feasible, as well as by highlighting the expected impacts of their participation. Given the concerns surrounding judgment and potential legal or safeguarding issues related to research participation, open and reassuring discussions about these aspects would support adolescents' emotional security throughout the research process. The current study recommends balancing attention between research processes and the emotional and relational aspects of adolescents' experiences of health research.

doi: 10.1192/j.eurpsy.2025.841

Introduction: Developmental language delay in children is characterized by the qualitative and quantitative underdevelopment of vocabulary and insufficient expressive language skills. These delays frequently co-occur with mental health issues including the emotional and behavioral sphere difficulties and it may result in adaptation difficulties in school. A multifactorial etiology has been identified for developmental language delay, highlighting the necessity for early prediction and intervention tools. The early prediction of speech and language delays in children under one year of age can help to prevent complications of the existing impairments in future.
Objectives: To develop an algorithm of developmental language delay prediction in toddlers, based on anamnesis data.
Methods: The training dataset had been collected from anamnesis of 232 children aged 18 till 36 months. Signs of developmental language delay had been presented in 50% children; typical language development had been presented in the other half of the sample. The neural network architecture had been developed using the Python 3.0 programming language and the Keras library. The compiled neural network had been trained on data which represented anamnesis of children under 1 year old. 70% of the collected data array were used for neural network training, 30% were used for validation.
Results: The algorithm architecture consisted of direct propagation neural network of 5 Dense layers. A one-dimensional tensor of 58 values had been fed to the input of the network. At the output, the value of the probability of developmental language delay had been obtained. During 1000 of training iterations the accuracy of 95% had been achieved. Sensitivity and specificity of the model reached 95% and 100%, respectively.
Conclusions: For the first time in the world, a neural network model of predicting the developmental language delay in early age children had been developed. This model considers data of intrauterine period of development, as well as the life of a child up to 1 year. It may help to prevent severe mental disorders which are comorbid to speech disorders.

Gender-Specific Manifestations and Diagnostic Challenges of Autism Spectrum Disorder in Women: A Focused Study

B. Mihaela[1]*, N. Anatol[1], J. Dorin[1] and V. Oprea[2]

[1]Department of Mental Health, Medical Psychology, and Psychotherapy, Nicolae Testemițanu State University of Medicine and Pharmacy of the Republic of Moldova, Chișinău and [2]Department of Mental Health, Medical Psychology, and Psychotherapy, Nicolae Testemițanu State University of Medicine and Pharmacy of the Republic of Moldova, Chișinau, Moldova, Republic of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.842

Introduction: Autism Spectrum Disorder (ASD) is often underdiagnosed in women due to gender-specific manifestations and the use of diagnostic criteria primarily based on male presentations. This underdiagnosis can lead to delayed or inadequate support and interventions for women with ASD. There is a growing recognition of the need for gender-sensitive diagnostic approaches to better identify and support women on the spectrum.
Objectives: This study aims to explore the unique manifestations of ASD in women, identify key diagnostic challenges, and propose recommendations for refining diagnostic criteria to improve accuracy and timeliness of diagnosis in female populations.
Methods: A mixed-methods approach was employed, combining quantitative data from standardized ASD diagnostic tools (e.g., ADOS-2, ADI-R) and qualitative data from in-depth interviews with 50 women diagnosed with ASD. Participants were recruited from clinical settings and ASD support groups. Data were analyzed using thematic analysis to identify gender-specific behavioral patterns and diagnostic challenges, while statistical analysis compared symptom presentation between male and female groups.
Results: Women with ASD exhibited distinct behavioral patterns, such as enhanced social masking abilities, higher levels of camouflaging, and differences in special interests compared to men. Table 1 highlights the frequency of common ASD symptoms in women vs. men, demonstrating significant differences in social communication ($p < 0.05$) and repetitive behaviors ($p < 0.01$). Table 2 illustrates the discrepancy in diagnostic ages between genders, with women receiving a diagnosis on average 5 years later than men. Table 3 outlines the diagnostic tools used and their respective sensitivity rates for female ASD presentation. Figure 1 visually represents the comparative analysis of symptom profiles by gender, showing a higher prevalence of internalizing symptoms in women.
Conclusions: The study confirms that ASD in women often presents differently, leading to significant diagnostic delays and underdiagnosis. Gender-specific manifestations, such as social masking and camouflaging, challenge the current diagnostic criteria, which are largely based on male-centric data. To improve the diagnosis and care of women with ASD, it is crucial to adapt existing diagnostic tools to account for these gender differences and develop new guidelines that reflect a broader spectrum of presentations.

Use of attention deficit hyperactivity disorder medication among Danish children and adolescents from 2010-2020

M. H. Stoltz-Andersen[1,2]*, M. Ernst[2], S. Dalsgaard[3,4,5], R. T. Wesselhøft[1,2] and L. Rasmussen[2]

[1]Research Unit of Child and Adolescent Mental Health, Mental Health Services in the Region of Southern Denmark; [2]Clinical Pharmacology, Pharmacy and Environmental Medicine, Department of Public Health, University of Southern Denmark, Odense; [3]Center for Child and Adolescent Psychiatry, the Mental Health Services of Capital Region,

Glostrup Hospital, Glostrup; [4]Department of Clinical Medicine, Faculty of Health and Medical Science, University of Copenhagen, Copenhagen and [5]National Center for Register-based Research, Business and Social Sciences, Aarhus University, Aarhus, Denmark
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.843

Introduction: To ensure rational drug use, there is a need to continously monitor the use of medication for attention deficit hyperactivity disorder (ADHD) among children and adolescents.
Objectives: The aim was to describe the use of ADHD medication among Danish children and adolescents.
Methods: We used data on filled prescriptions of ADHD medication to Danes aged 5-17 years between 2010 and 2020. We calculated the incidence rate, and prevalence proportion, and described treatment duration, age at initiation, prescriber type, and concurrent use of psychotropic medication. Analyses were stratified by age and sex.
Results: The incidence rate of ADHD medication use followed a u-shaped pattern among boys from 2010-2020. This was most pronounced for boys 10-13-years old, with an incidence rate of 0.62 per 100 person-years in 2010, decreasing to 0.35 in 2013, and rising to 0.59 in 2020. The incidence rate among girls increased continuously from 2010 to 2020. The prevalence proportion increased in girls from 0.65% in 2010 to 1.04% in 2020 and in boys from 2.22% in 2013 to 2.65% in 2020. Girls started ADHD medication later than boys (median age 13 vs 11). Child- and adolescent psychiatrists issued 90% of initial prescriptions in 2010 with an increasing proportion over time. Sixty-four percent of 5-9-year-olds and 43% of 10-13-year-olds were covered by an ADHD prescription after five years compared to 27% of 14-17-year-olds. Approximately 20% users in 2020 had concurrent use of other psychotropic medication.
Conclusions: Use of ADHD medication increased in Denmark from 2010-2020. The steady increase in use among girls likely reflect an increased awareness of ADHD in girls. However, the delayed treatment onset in girls should be a focus of attention.

Victimization in Youth with Autism Spectrum Disorder in Tunisia: Prevalence and Associated Factors

R. Ayoub[1]*, A. Beji[1], H. Ben Abid[1], K. Younes[2] and A. Guedria[1]
[1]Child and Adolescent Psychiatry Department, Fattouma Bourguiba university Hospital-University of Monastir and [2]Regional Rehabilitation Unit, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.844

Introduction: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder that attracts interest, fascination, and controversy. Due to their developmental characteristics that hinder autonomy and socialization, children with ASD appear to be vulnerable and prone to victimization. Indeed, victimization has severe consequences for these children, who face risks of rejection and stigmatization. However, research on this phenomenon in Tunisia is still limited, highlighting a significant gap in the current knowledge base.
Objectives: Our study aimed to determine the prevalence of victimization among children and adolescents with ASD consulting at the Regional Rehabilitation Unit of Monastir- Tunisia and identify the associated factors.
Methods: This is a cross-sectional analytical study. It included children and adolescents with ASD aged between 5 and 18 years consulting at the Regional Rehabilitation Unit in Monastir during the year 2023. Sociodemographic and clinical data of the children were collected using a pre-established form created by the working group. We used the Juvenile Victimization Questionnaire ScreenerSumVersion (JVQ-SSV) to assesse childhood victimization and major forms of aggression against youth.
Results: Our study included 74 participants, demonstrating a male predominance with a sex ratio of 6.4. The average age of the patients was 9 years, ranging from 6 to 14 years.The main results of our study showed that participants with ASD are particularly vulnerable to victimization, with 77% having experienced at least one victimizing event in their lifetime and nearly 69% in the past year. The most commonly reported victimization events included bullying (56.7%), peer or sibling aggression (50%)… Our results revealed that 56.2% of these incidents occurred at school. Additionally, nearly 46% of children with ASD were reported by their parents to be perpetrators of victimization towards other. Univariate analysis identified significant factors associated with victimization, including the parent's age, attendance at specialized education centers, and being a perpetrator of victimization.
Conclusions: The social inclusion of children with ASD, though crucial, remains fragile amid widespread victimization in both school and family environments. The concerning repercussions of these experiences necessitate focused efforts to develop and implement strategies that safeguard and support these children. Addressing the multifaceted nature of victimization and promoting protective measures are essential for improving their well-being and fostering a more inclusive environment.

Can Executive Functions and Severity of Attention Deficit Hyperactivity Disorder Predict Symptom Levels of Developmental Coordination Disorder in Children with Attention Deficit Hyperactivity Disorder? a Preliminary Study

F. U. Dundar[1]* and H. A. Guler[1]
[1]Child and Adolescent Psychiatry, Selcuk University, Konya, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.845

Introduction: Attention Deficit Hyperactivity Disorder (ADHD) is a childhood-onset disorder characterized by symptoms of attention deficit, hyperactivity and impulsivity, and executive functioning difficulties. Developmental Coordination Disorder (DCD) is a neurodevelopmental disorder that involves motor coordination problems with frequent difficulties in movements that most typically developing children can easily accomplish. The most common comorbidity accompanying DCD is ADHD. It has been reported that DCD frequently accompanies ADHD even if it is not at the diagnostic level and may cause loss of functionality in daily life. In this study, we aimed to investigate the relationship between DCD

symptoms and ADHD severity and executive functions in children and adolescents with ADHD without a diagnosis of DCD.
Objectives: The study sample consisted of children aged 7-15 years with ADHD who were evaluated in the outpatient clinic of the Department of Child and Adolescent Psychiatry at Selçuk University. Children with medical conditions requiring physical therapy, neurological disorders, DCD, tic disorders, movement disorders, autism spectrum disorder, and intellectual disability were excluded from the study.
Methods: The Turgay Disruptive Behavior Disorders Screening and Evaluation Scale based on DSM-IV was used to determine the severity of ADHD and the Stroop Test was used to evaluate executive functions. Revised Developmental Coordination Disorder Battery was applied for the symptoms of DCD. Ethics committee approval for the study was obtained from Selçuk University Faculty of Medicine Local Ethics Committee. (2024/411)
Results: 15 girls and 19 boys between the ages of 7-15 participated in the study. The mean age was 10.71±2.83 years. A significant correlation was found between patients' Turgay attention subscale (p:0.010), oppositional defiant subscale (p:0.027) and conduct disorders subscale (p:0.028) scores and DCD symptom levels. No correlation was found between Stroop test results and DCD symptom levels.
Conclusions: In this study, the relationship between ADHD severity, executive functions and symptoms of DCD in children and adolescents diagnosed with ADHD was examined. The findings indicate that ADHD severity and DCD symptoms may be related in individuals with ADHD without a diagnosis of DCD. This may indicate that in individuals diagnosed with ADHD, DCD symptoms may be related to ADHD severity rather than executive functions. The fact that the study was single centered and the sample size was small limits the generalizability of the findings. Studies with larger samples are needed.

Family dynamics and adolescent behavioral disorders: Insights from the NKI Rockland Sample

M. Grigoriou[1]*, J. von Trott[2,3] and P. Lalousis[2,3]

[1]Psychology, University of Limassol, Limassol, Cyprus; [2]Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, United Kingdom and [3]Department of Psychiatry and Psychotherapy, Ludwig-Maximilian-University Munich, Munich, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.846

Introduction: Familial dynamics profoundly impact the behavioural development of adolescents. This study investigates the impact of family-related behaviours, such as hyperactivity, aggression, and callous-unemotional features, on social responsiveness and the propensity for behavioural disorders, offering essential insights for targeted interventions.
Objectives: The study aimed to: (1) examine the influence of hyperactivity, aggression, callous-unemotional traits(CU), and thrill-seeking behaviour on social responsiveness and behavioural disorders; (2) assess the predictive efficacy of various behavioural traits through structural equation modelling (SEM) and logistic regression; and (3) recommend practical interventions derived from these findings.
Methods: Data were obtained from adolescents 12 to 17 years participating in the enhanced Nathan Kline Institute Rockland Sample (NKI-RS), a continuous, institutionally focused initiative designed to establish a large-scale lifespan sample. Behavioural evaluations comprised the Behaviour Assessment System for Children (BASC), Social Responsiveness Scale (SRS), and Inventory of Callous-Unemotional Traits (ICU-P). Structural Equation Modelling (SEM) was utilised to investigate the intricate associations between behavioural characteristics and social responsiveness (Figure 1), whereas logistic regression was applied to forecast the probability of behavioural disorders (Figure 2).
Results: Structural Equation Modelling analysis indicated that CU traits were the most significant predictor of diminished social responsiveness ($\beta = 0.738$, $p < 0.001$), succeeded by hyperactivity ($\beta = 0.384$, $p = 0.069$) and agression ($\beta = 0.183$, $p = 0.038$). Engagement in fun-seeking behaviour demonstrated a protective effect ($\beta = -0.638$, $p = 0.001$). Logistic analysis indicated that elevated ICU-P scores heightened the probability of behavioural problems (OR = 2.09, $p < 0.001$), whereas fun-seeking behaviour diminished this probability (OR = 0.52, $p < 0.001$), yielding an AUC of 0.83 (Figure 3).

Image 1:

Conclusions: CU qualities represent the most significant risk factor for behavioural disorders, whereas a propensity for fun-seeking behaviour offers a protective effect. Practical implementation should focus on two main areas: (1) early screening for CU traits

and hyperactivity in family settings to identify at-risk adolescents, and (2) promoting adaptive fun-seeking activities that enhance social responsiveness and reduce behavioral risks. Family-oriented therapies that include good social activities and behavioural management can markedly diminish the risks associated with behavioural disorders.

Psychiatric Care for Children and Adolescents After the Onset of Type 1 Diabetes: Implementation of a Multidisciplinary Programme

J. Sánchez-Cerezo[1]*, A. Guzmán De Lazaro[1], L. García Murillo[1], R. Paricio Del Castillo[1], A. Cañuelo Márquez[1], A. Pascual Aranda[1] and I. Palanca Maresca[1]

[1]Department of Psychiatry, Division of Child and Adolescent Psychiatry, Puerta de Hierro University Hospital, Majadahonda, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.847

Introduction: Type 1 Diabetes Mellitus (T1DM) is a chronic autoimmune disease characterized by the destruction of insulin-producing beta cells in the pancreas. It commonly presents in childhood or adolescence. As one of the most prevalent chronic conditions in children, T1DM significantly affects the lives of patients and their families. In Western Europe, the incidence rate is 10-20 new cases per 100,000 individuals per year. T1DM requires structured insulin self-management, blood glucose monitoring, physical activity, and a healthy diet what can be challenging for children and adolescents. T1DM in children and adolescents is associated with various psychosocial problems, including a heightened risk of psychiatric disorders such as depression or anxiety, and problems with eating, alcohol use, or sleep. Effective management requires a multidisciplinary approach, involving psychiatric care to address mental health concerns and improve disease management.
Objectives: Here we present a novel programme that aims to address the integration of psychiatric care for children and adolescents with T1DM by facilitating early detection of mental health issues, enhancing education for patients, families, and healthcare providers, promoting multidisciplinary collaboration, and offering tailored treatment. We present preliminary outcomes of our programme.
Methods: Our programme at the Puerta de Hierro University Hospital involves comprehensive mental health assessments for paediatric T1DM patients. Paediatricians refer patients to Child Psychiatry after T1DM onset. The initial evaluation includes a clinical history, mental health background, risk factor assessment, and the completion of routine measures. Follow-up is scheduled based on the clinical presentation with a maximum treatment time of 12 months. Image 1 shows the flowchart with the referral and treatment process in our programme. Our multidisciplinary team consists of one child and adolescent psychiatrist, one clinical psychologist and one mental health nurse and we work collaboratively with paediatricians.
Results: From October 2023 to September 2024, we received 13 referrals (61.5% females) with a mean age of 10.4 years. Of those, 38.5% had a diagnosis of emotional disorder, 30.8% attention-deficit hyperactivity disorder, 7.7% conduct disorder, 15.4% required parenting support, and 15.4% required psychological support. Patients and families show high rates of improvement regarding their mental health problems and psychological adjustment and are satisfied with the care provided.

Image 1:

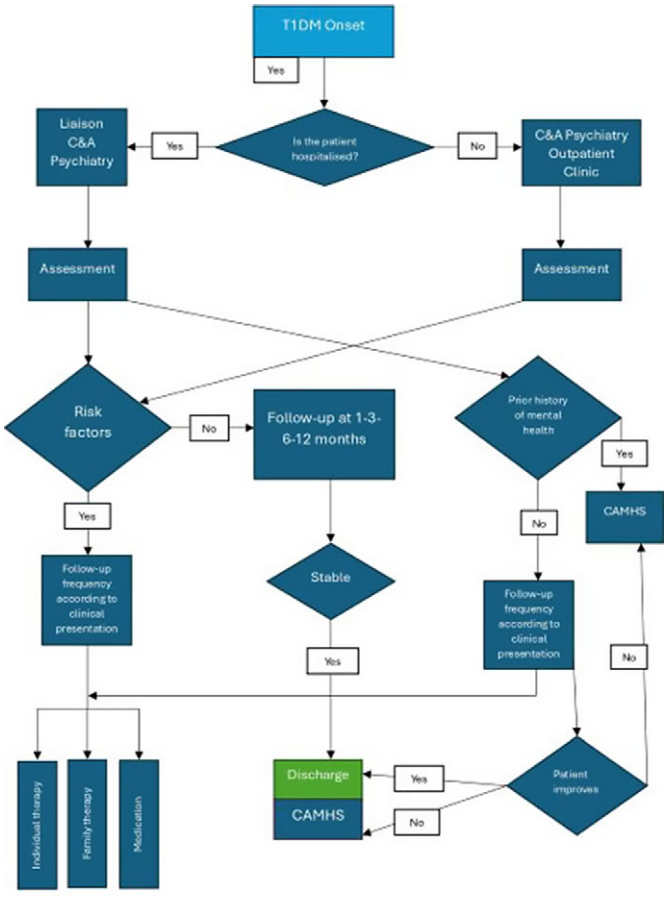

Figure 1. Flowchart of referral and treatment process.
CAMHS = Child and Adolescent Mental Health Service; C&A = Child and adolescent; T1DM = Type-1 Diabetes Mellitus

Conclusions: Early and effective psychiatric intervention is crucial in managing the complex needs of children and adolescents with T1DM. The implementation of this multidisciplinary programme is feasible, and it has shown promising results. In the future, a randomised controlled trial should be conducted to assess the effectiveness of this intervention.

Early-onset psychosis as a manifestation of Fahr's syndrome: a case report

M. Uzar[1]*, W. Zwolińska[1] and A. Słopień[1]

[1]Department of Child and Adolescent Psychiatry, Poznan University of Medical Sciences, Poznan, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.848

Introduction: Fahr's syndrome/disease is a rare neurological disorder characterized by calcification in brain areas such as the basal

ganglia, cerebellum, and subcortical white matter. The disorder may manifest with both neurological and psychiatric symptoms. Fahr's syndrome has a genetic basis and is inherited in an autosomal dominant manner. It may also develop as a result of injuries, carbon monoxide poisoning, or hormonal disturbances. If the calcification is idiopathic, the term Fahr's disease is used.
The neurological symptoms of the condition include motor disorders, delirium, and dementia. However, it may also manifest in psychiatric symptoms such as anxiety, obsessive-compulsive symptoms, cognitive decline, psychotic symptoms, and mood disorders. Available data indicate that the early onset of Fahr's syndrome symptoms is associated with a worse prognosis compared to the later onset.
Objectives: Our work aims to emphasize the necessity to look for/exclude the neurological basis of early forms of psychosis.
Methods: Herein, we present a case report of a thirteen-year-old patient hospitalized in the Department of Child and Adolescent Psychiatry in Poznań because of persistent psychotic symptoms. Due to severe headaches, episodes of vomiting, balance disorders, and hallucinations experienced before psychiatric hospitalization, the patient was referred to a neurological ward where imaging tests were performed revealing calcifications in both globi pallidi. Consequently, Fahr's syndrome was diagnosed.
During the patient's hospitalization in the Department of Child and Adolescent Psychiatry, her mother reported that the patient had exhibited aggressive and self-aggressive behavior. Moreover, the patient's school performance had been deteriorating for approximately two years before being admitted to the hospital. The girl described visual hallucinations (seeing figures) and auditory hallucinations (thought echo and hearing voices telling her to harm herself) that had been occurring for over a year. She expressed delusions of reference and delusions of thought insertion.
Interestingly, during the further diagnostic process, similar neurological changes as in the patient were found in her mother's brain. This was unexpected because it was the patient's father who was treated for schizophrenia (for formal reasons, it was not possible to check whether he also had neurological changes).
Results: The patient was diagnosed with both schizophrenia and Fahr's syndrome. Pharmacotherapy was implemented (olanzapine and then additional aripiprazole), and she was also provided with psychotherapeutic care. The implemented treatment has led to only partial improvement.
Conclusions: Further studies on Fahr's syndrome are needed to better understand the disease course across the lifespan. Neuroimaging seems essential in early-life psychosis to exclude possible neurological basis of the condition.

Association between personality traits and medication adherence in people who live with type 2 diabetes and hypertension: A systematic review

K. Dimou[1]*, T. Stamoulis[1], M. Kourakos[1], E. Dragioti[1], S. Mantzoukas[2] and M. Gouva[1]

[1]Research Laboratory Psychology of Patients, Families and Health Professionals, Department of Nursing, School of Health Sciences, University of Ioannina and [2]Research Laboratory of Integrated Health, Care and Well-being, Department of Nursing. School of Health Sciences, University of Ioannina, Ioannina, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.849

Introduction: Chronic diseases, such as type 2 diabetes and hypertension, are rapidly increasing worldwide. These conditions can have significant negative impacts on patients' daily lives.
Objectives: Our aim was to investigate the correlation between personality traits and medication adherence as part of self-care among individuals living with type 2 diabetes and hypertension.
Methods: We conducted a thorough and comprehensive literature search for published articles in PsycINFO, CINAHL, and PubMed from inception to September 2024, following PRISMA guidelines. The included studies were primary quantitative research conducted in English and focused on adults aged 18 and above, diagnosed with hypertension or type 2 diabetes mellitus.
Results: We identified a total of 41 studies that met our inclusion criteria, analyzing the relationship between personality traits and medication adherence. Specifically, 23 studies indicated that traits such as agreeableness were associated with improved medication adherence in individuals with type 2 diabetes, while traits such as extraversion and neuroticism were linked to reduced adherence. With regard to hypertension, 18 studies showed neuroticism was associated with decreased medication adherence, while extraversion was associated with increased medication adherence.
Conclusions: Personality traits play a crucial role in self-care, with one of its key aspects being adherence to medication in chronic conditions such as type 2 diabetes and hypertension.

Affective temperaments, anxiety, and depression as predictors of perioperative pain and analgesic requirements

N. Mate-Horvath[1], N. Acs[2] and X. Gonda[3,4]*

[1]Department of Anesthesia and Perioperative Care; [2]Department of Obstetrics and Gynaecology; [3]Department of Psychiatry and Psychotherapy and [4]NAP3.0 Neuropsychopharmacology Research Group, Semmelweis University, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.850

Introduction: Psychological factors, including personality and temperament show an association with various somatic conditions and may also influence perioperative analgesic requirements. Understanding the role of psychological factors could help personalise pain management, improving well-being of patients and reducing postoperative complications. Affective temperaments (AT) have previously been associated with course and characteristics of several somatic conditions, but have not been studied in this context.
Objectives: We aim to investigate the association between ATs and postoperative analgesic needs in a prospective study.
Methods: In our ongoing study we plan to enroll 350 women awaiting non-obsetrical, non-oncological gynecological surgery. Type of surgery and anesthesia are standardized. Psychological evaluation is carried out at three timepoints: 5 days preoperatively (ATs, anxiety, depression, pain catastrophizing)? 24 hours postop

(amount and quality of pain experienced, anxiety, depression, current pain catastrophizing); 7 days postop (same as before, plus length of stay and quality of life). Tools include TEMPS-A (ATs), STAI-S and T (anxiety), PHQ9 (depression), PCS (pain catastrophizing) and BPI (pain experience and QoL). Intraoperative vital parameters and opioid use are also observed, as well as the use of postoperative analgesic medications. Statistical associations between pain and psychological factors are analysed using MANOVA, regression, correlation and path analysis.
Results: Currently we are at 50% of our data collection (N=175). At this stage of our research we already have significant preliminary results. Apart from psychological factors, age has a negative predictive effect on pain experienced on day 1 ($p<0.001$, $st\beta=-0.327$, $R2=0.14$) and also predicts the effectiveness of painkillers on day 1 ($p=0.006$, $st\beta=0.036$). When controlled for age ATs also predict pain experienced on day 1: anxious scores predict amount of pain experienced ($p=0.049$, $st\beta=0.283$), whereas higher dysthymic scores predict smaller amount of pain experienced ($p=0.006$, $st\beta=-0.382$). Preoperative anxiety and pain expectations do not seem to predict pain, but pain expectations predict how pain effects overall mood (postop day 1 $p=0.002$, $st\beta=0.227$ and day 7 $p=0.035$, $st\beta=0.226$). Postop day 7 pain is less influenced by the investigated factors, but state anxiety on postop day 1 predicts postop pain on day 7 ($p=0.028$, $st\beta=0.251$).
Conclusions: Our study may help in clinical practice to identify patients who are likely to experience more postoperative pain. While age is a significant negative predictor of early and late postoperative pain, when controlling for age, ATs seem to be sensitive predictors of early postoperative pain experience, whereas other investigated factors have a less direct effect on pain experience. Further data analysis with more complex models is needed after data collection is finished.

Risk of Developing Major Mental Disorders in Hypertensive Patients: A Retrospective Observational Study Using the Common Data Model

H.-C. Kim[1]

[1]Psychiatry and Brain Research Institute, Keimyung University School of Medicine, Daegu, Korea, Republic Of
doi: 10.1192/j.eurpsy.2025.851

Introduction: Chronic medical conditions like hypertension may increase the risk of mental disorders such as anxiety and depression.
Objectives: This study aimed to investigate if hypertension is associated with a higher incidence of major mental disorders, including anxiety disorders, depressive disorders, bipolar disorders, psychotic disorders, sleep disorders, vascular dementia, and Alzheimer's dementia, compared to controls.
Methods: I analyzed standardized data from patients with hypertension (n = 48,466) and those without hypertension (n = 442,660) at a university hospital. Clinical data was standardized into a common data model. Using propensity score matching (PSM) at a 1:5 ratio, I compared the incidence of mental disorders between the hypertension and control groups over a 5-year period. A multivariate Cox proportional hazards model was used to estimate the risk of mental disorders, with hazard ratios (HR) and 95% confidence intervals (CI).
Results: After PSM, the hypertension group had a higher prevalence of being elderly (over 60 years old) and having conditions like diabetes, hyperlipidemia, atrial fibrillation, cerebrovascular disease, and heart disease compared to controls. The hypertension group also had significantly increased use of antithrombotic agents, beta-blockers, calcium channel blockers, diuretics, acid-related disorder drugs, diabetes medications, lipid-modifying agents, and opioids. The incidence rates per 1,000 patient-years for mental disorders were as follows: anxiety disorders (7.22 vs. 4.49), depressive disorders (8.51 vs. 5.47), bipolar disorders (1.13 vs. 0.91), psychotic disorders (0.18 vs. 0.22), sleep disorders (16.32 vs. 8.60), vascular dementia (0.77 vs. 0.14), and Alzheimer's dementia (9.29 vs. 2.53). Compared to controls, the hypertension group had a higher risk of developing vascular dementia (HR, 6.03; 95% CI, 4.34–8.44; $p<0.01$), Alzheimer's dementia (HR, 3.89; 95% CI, 3.56–4.24; $p<0.01$), sleep disorders (HR, 1.96; 95% CI, 1.85–2.07; $p<0.01$), anxiety disorders (HR, 1.69; 95% CI, 1.56–1.83; $p<0.01$), and depressive disorders (HR, 1.64; 95% CI, 1.52–1.76; $p<0.01$). There were no significant differences for bipolar disorders (HR, 1.17; 95% CI, 0.95–1.43; $p=0.12$) or psychotic disorders (HR, 0.85; 95% CI, 0.51–1.34; $p=0.50$).
Conclusions: Hypertensive patients have an increased risk of major mental disorders, particularly vascular dementia, Alzheimer's dementia, sleep disorders, anxiety disorders, and depressive disorders. Older age, age-related diseases, and various medication uses contribute to this increased risk.

Innovative Approaches to Addressing Addiction in Real-World Clinical Settings

A. K. Sikora[1,2*], S. T. Kayahan[3], M. Dzis[4] and J. Dąbrowska[5]

[1]Psychiatry, Addictions and Medical Psychology Department, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine; [2]HOSPITAL OF THE MAZOWIECKIE VOIVODESHIP DREWNICA, Warsaw, Poland; [3]Turkish Republic Ministry of Health Yalvaç State Hospital, Isparta, Türkiye; [4]Psychiatry, Psychology and Sexology, Danylo Halytsky Lviv National Medical University, Lviv, Ukraine and [5]Szpital Bielański im. Ks. Jerzego Popiełuszki, Warsaw, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.852

Introduction: Addiction is a complex condition affecting millions globally, involving behaviors from substance use to behavioral addictions like gambling disorder (GD). It frequently co-occurs with psychiatric disorders, such as bipolar disorder (BD) and bulimia, complicating treatment. Individuals with BD are six times more likely to develop GD, especially men. This presentation explores managing various forms of addiction across different populations.
Objectives:
1. Provide updated knowledge on addiction and its comorbidities.
2. Explore integrated treatment for co-occurring psychiatric disorders.
3. Highlight the role of cultural contexts in addiction treatment.
4. Equip clinicians with practical tools for comprehensive addiction care.

Methods: Four key areas of addiction management are discussed using case studies and comparative analysis:

1. Compulsive Sexual Behavior in Veterans: Examining compulsive sexual behavior as a PTSD symptom, diagnosis, and treatment approaches.

2. Polish Addiction Treatment Standards: A comparative analysis of Polish standards and recent reforms, and their impact on practice.
3. Dual Diagnosis: Alcohol Addiction and Bulimia: Case-based discussions on integrating treatment for co-occurring alcohol addiction and bulimia.
4. BD and GD Comorbidity: Reviewing pharmacological (e.g., lithium) and psychosocial interventions for BD-GD comorbidity.

Results:
1. Compulsive Sexual Behavior in Veterans: Tailored interventions improve outcomes for veterans.
2. Polish Addiction Standards: Reforms improve accessibility, but aligning with European standards for dual diagnosis remains challenging.
3. Dual Diagnosis: Integrated treatment for alcohol addiction and bulimia improves outcomes and reduces relapse rates.
4. BD and GD Comorbidity: Lithium and psychosocial interventions stabilize mood and reduce gambling, but more research is needed.

Conclusions: Innovative approaches to addiction management, particularly for co-occurring psychiatric disorders, improve clinical outcomes. Tailored interventions for veterans, analysis of treatment standards, and integrated strategies for dual diagnoses provide practical solutions for clinicians. Further research is needed to optimize treatments for BD-GD comorbidity.

Impact of Vortioxetine on Inflammatory Biomarkers and Quality of Life in Patients with Chronic Heart Failure and Comorbid Depression: A Comparative Analysis of CRP, TNF-α Levels, and Functional Outcomes

A. K. Sikora[1,2*], O. Pityk[1] and S. Fedorov[3]

[1]Psychiatry, Addictions and Medical Psychology Department, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine; [2]HOSPITAL OF THE MAZOWIECKIE VOIVODESHIP DREWNICA, Warsaw, Poland and [3]Therapy and Family Medicine Chair of Postgraduate Faculty, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.853

Introduction: Chronic heart failure (CHF) is a progressive condition often accompanied by comorbid depression, which exacerbates the overall disease burden and worsens clinical outcomes. Inflammatory processes play a crucial role in the pathophysiology of both CHF and depression. Biomarkers such as C-reactive protein (CRP) and tumor necrosis factor-alpha (TNF-α) are known to be elevated in these conditions. Vortioxetine, a multimodal antidepressant, is recognized for its efficacy in treating depression, but its impact on inflammatory markers and heart failure outcomes remains underexplored.

Objectives:
1. To assess the impact of Vortioxetine on CRP levels in patients with CHF and comorbid depression.
2. To evaluate the effect of Vortioxetine on TNF-α levels in the same patient population.
3. To measure the improvements in quality of life and functional outcomes using the MLHFQ and KCCQ scales.
4. To determine the significance of the observed changes in both biomarker levels and functional outcomes.

Methods:
- Patients: A cohort of 30 patients with chronic heart failure and comorbid depression was selected. Baseline inflammatory biomarker levels and functional outcomes were recorded.
- Intervention: All patients were treated with Vortioxetine at a dose of 10 mg/day for six months.
- Biomarkers: CRP and TNF-α levels were measured before and after six months of treatment.
- Functional Outcomes: MLHFQ, and functional status was evaluated using the KCCQ. Both assessments were conducted before and after the treatment period.

Results: Biomarkers:
- CRP: Baseline CRP levels ranged from 2 mg/L to 256 mg/L, with a mean of [89mg/L]. After six months of treatment, CRP levels significantly decreased, ranging from [2mg/L], with a mean post-treatment CRP level of [10,2mg/L].
- TNF-α: Baseline TNF-α levels ranged from 0 pg/mL to 523 pg/mL, with a mean of [118pg/mL]. After treatment, TNF-α levels showed a significant reduction, with a range of [0pg/mL] and a mean post-treatment level of [18,9pg/mL].

Functional Outcomes:

- MLHFQ Scores: The mean MLHFQ score before treatment was [67], which improved by 54% after six months of Vortioxetine treatment.
- KCCQ Scores: The mean KCCQ score before treatment was [12], which improved by 46% after treatment.

Conclusions: Vortioxetine has demonstrated significant potential in treating both the mental and physical aspects of chronic heart failure and comorbid depression. The observed reductions in CRP and TNF-α levels, along with the notable improvements in MLHFQ and KCCQ. scores, highlight its ability to address both inflammatory processes and patient-reported outcomes. Further research is needed to explore the long-term effects of Vortioxetine in larger patient populations and to better understand the mechanisms underlying its anti-inflammatory properties.

The Impact of Childhood Trauma on Fatigue: Preliminary Results Highlighting Emotion Dysregulation as a Mediator in Multiple Sclerosis

A. Süleyman[1*], E. Akça[1], K. Ağan Yıldırım[2], G. Sünter[2] and Ö. Yanartaş[1]

[1]Psychiatry and [2]Neurology, Marmara University School of Medicine, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.854

Introduction: Fatigue is one of the most significant factors impairing functionality in patients with multiple sclerosis (MS). Research has demonstrated that psychological factors, in addition to neurobiological ones, play a crucial role in fatigue among MS patients.

Previous research has demonstrated that emotional neglect and emotional abuse are associated with fatigue in patients with MS (Pust et al. Front Psychiatry 2020; 11:811). While the role of emotion dysregulation as a mediator between adverse childhood experiences and long-term effects of childhood trauma has been studied, this relationship has not been previously examined in patients with MS.
Objectives: This study aims to investigate the association between adverse childhood experiences and fatigue and to examine the mediating effect of emotion dysregulation in patients with MS.
Methods: Patients with MS followed in the Neurology Outpatient Clinic at Marmara University, who were evaluated during their clinical examination to be cognitively competent and without any physical disabilities that would prevent them from completing the forms, were included in the study. Adverse childhood experiences were assessed using the expanded version of the Childhood Trauma Questionnaire (CTQ-33), emotion dysregulation was measured by the 16-item Difficulties in Emotion Regulation Scale (DERS-16) and fatigue was evaluated using the Fatigue Severity Scale. The impact of CTQ subscale scores on fatigue and the mediating role of emotion dysregulation were analyzed using SPSS with Process Macro v4.2.
Results: A total of 119 patients completed the survey, with a mean age of 37.45 years, and 71.4% of the participants were women. Emotional abuse and emotional neglect were associated with fatigue in patients with MS. The effect of emotional abuse on fatigue was mediated by emotion dysregulation, with the total effect being 0.81 (95% CI [0.04, 1.58]), the direct effect -0.12 (95% CI [-0.86, 0.63]), and the indirect effect 0.93 (95% CI [0.50, 1.55]). Similarly, the relationship between emotional neglect and fatigue was also mediated by emotion dysregulation, with the total effect being 0.66 (95% CI [0.10, 1.22]), the direct effect -0.05 (95% CI [-0.60, 0.49]), and the indirect effect 0.71 (95% CI [0.39, 1.10]). These results indicate that emotion dysregulation fully mediates the effects of both emotional abuse and emotional neglect on fatigue in patients with MS.
Conclusions: Our findings indicate that the link between fatigue severity and emotional neglect or abuse in MS patients is fully mediated by difficulties in emotion regulation. Consequently, it is suggested that interventions aimed at enhancing emotion regulation strategies may potentially mitigate the effects of adverse childhood experiences on MS-related fatigue. Further research, especially focused on intervention strategies, is needed in this area.

Unlocking Potential: The Re-emerging Role of Thyroid Hormone Therapy in Treatment-Resistant Depression

M. Cameira[1]*, P. Abreu[1], M. Pereira[1], M. Soares[1], I. Vidó[1] and I. Lopes[2]
[1]Hospital Júlio de Matos - ULS São José, Lisboa and [2]Hospital do Barreiro - ULS Arco Ribeirinho, Barreiro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.855

Introduction: Treatment-resistant depression (TRD) poses a significant challenge in clinical psychiatry, affecting a substantial proportion of patients who do not respond adequately to standard antidepressant therapies. Recent studies have rekindled interest in thyroid hormone therapy as a potential augmentation strategy for enhancing treatment outcomes in both unipolar and bipolar depression. Thyroid hormones, particularly levothyroxine (LT4) and triiodothyronine (LT3), have been shown to influence mood regulation through their interactions with neurotransmitter systems, thereby offering a promising avenue for improving depressive symptoms in TRD patients.
Objectives: This study explores the potential of thyroid hormones, specifically levothyroxine (LT4) and triiodothyronine (LT3), to enhance treatment outcomes for patients who have not adequately responded to standard antidepressant therapies. It also synthesizes recent findings on the safety profile of thyroid hormone therapy and examines potential gender differences in treatment response.
Methods: A comprehensive review of the literature was conducted, focusing on studies published in the ten years that examined the role of thyroid hormones in TRD. Databases such as PubMed were searched for randomized controlled trials, meta-analyses, and observational studies that assessed the effects of LT3 and LT4 on depressive symptoms and treatment outcomes.
Results: The literature review shows that adjunctive triiodothyronine (T3) significantly enhances treatment response in treatment-resistant depression. A randomized trial found that 53% of patients on T3 had a ≥50% improvement in depression scores after three weeks, compared to 19% for those on levothyroxine (LT4). While LT4 may benefit chronic cases, T3 is generally preferred for its superior efficacy. Thyroid hormone therapy also benefits bipolar depression, especially in rapid cycling patients. Functional imaging studies indicate that supraphysiologic LT4 can improve symptoms by modulating anterior limbic network activity. Some evidence suggests women may respond better than men. Overall, thyroid hormone therapy is well tolerated, with low incidences of adverse effects like tremor, anxiety, and palpitations. However, long-term efficacy remains mixed, with some studies showing no significant differences compared to placebo, and the safety of high-dose therapy is uncertain, highlighting the need for further research.
Conclusions: Thyroid hormone therapy, particularly LT3 and LT4, is a promising augmentation strategy for treatment-resistant unipolar and bipolar depression. While LT3 is noted for its rapid response, further research is needed to clarify its long-term safety and optimal dosing. These findings highlight the importance of considering thyroid therapy for patients who do not achieve satisfactory outcomes with conventional antidepressants.

Silexan reduces functional impairment in patients with a major depressive episode

H.-P. Volz[1], S. Klement[2], E. Seifritz[3] and S. Kasper[4]*
[1]Medical Advisor, Würzburg; [2]Dr. Willmar Schwabe GmbH & Co. KG, Karlsruhe, Germany; [3]Psychiatric Hospital, Zürich, Switzerland and [4]Medical University of Vienna, Vienna, Austria
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.856

Introduction: In a multi-centre, double-blind, randomised, placebo- and reference-controlled clinical Phase III trial in patients with a mild to moderate major depressive episode, Silexan, a special essential oil from *Lavandula angustifolia,* demonstrated a clinically meaningful and statistically significant antidepressant effect (Kasper *et al.* Eur Arch Psychiatry Clin Neurosci 2024; Apr 1, Epub ahead of print). Patients with depression often experience functional impairment, i.e. in their ability to perform activities of daily

living, in their capacity to form and maintain interpersonal relationships, and in their work productivity.
Objectives: We present data from the trial to assess the impact of the symptoms of the depressive episode on the patient`s functional abilities in daily living.
Methods: Adult patients (≥18 years) suffering from a major depressive episode of mild to moderate severity according to ICD-10 were included. Further inclusion criterion was a total score of 19 – 34 points in the Montgomery-Åsberg-Depression Rating Scale (MADRS). Randomised patients took 80 mg Silexan, 50 mg Sertraline, or placebo once daily over 8 weeks. Functional impairment was assessed using the change of the Sheehan Disability Scale (SDS total score) between baseline and week 8, changes of each SDS single item "work" (item 1), "social life/leisure activities" (item 2), and "family life/home responsibilities" (item 3), as well as the number of lost (DL) and underproductive days (DU). The scientific questions if the active treatment groups are superior to placebo in improving functional impairment was investigated as secondary objectives, which were analysed descriptively using an analysis of covariance model with factors for treatment and centre and the baseline value as covariate.
Results: The full analysis set consisted of 498 patients. The changes of the SDS total score differed by 2.40 ($p<0.001$) points (adjusted mean difference) in favour of Silexan compared to placebo and by 0.82 ($p=0.267$) points in favour of Sertraline compared to placebo. The mean differences between Silexan and placebo were 0.98 points for item 1, 0.65 for item 2, and 0.78 for item 3 ($p<0.05$, each). Compared to placebo, both DL ($p=0.055$) and DU ($p=0.011$) occurred less frequently with Silexan. In the primary efficacy endpoint of the trial, the change of the MADRS total score, Silexan was significantly superior to placebo ($p<0.01$).
Conclusions: With Silexan treatment, patients with a major depressive episode coped better with work, social life, or family responsibilities and had fewer lost or underproductive days.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.857

Introduction: ESCAPE-LTE was a phase 4, long-term, open-label extension (OLE) study for patients (pts) with treatment resistant depression (TRD) who were continuing esketamine nasal spray (ESK-NS) treatment following ESCAPE-TRD. ESCAPE-TRD was a randomised, phase IIIb trial comparing the efficacy and safety of ESK-NS versus quetiapine extended release (Q-XR), when both were flexibly dosed alongside an ongoing selective serotonin/serotonin-norepinephrine reuptake inhibitor (SSRI/SNRI), in pts with TRD. The study demonstrated that ESK-NS significantly increased the probability of achieving remission at Week 8, and of being relapse-free through Week 32 after remission at Week 8, versus Q-XR (Reif *et al.* NEJM 2023; 389 1298–309).
Objectives: To assess the long-term safety, tolerability and efficacy of ESK-NS alongside an SSRI/SNRI in pts with TRD. Here, the study design of ESCAPE-LTE is described; top-line results will be reported in the poster.
Methods: ESCAPE-LTE was a single-arm, 2-year OLE to ESCAPE-TRD in 14 countries. Pts eligible for ESCAPE-LTE were those who completed ESK-NS treatment in combination with an SSRI/SNRI in ESCAPE-TRD through to the end of the study (Week 32), continued to benefit from the ESK-NS treatment regimen and for whom commercial ESK-NS was not accessible in their country. The starting dose of ESK-NS was based on the pts' dose (28 mg [≥65 years and adults of Japanese ancestry], 56 mg or 84 mg) and frequency (weekly or biweekly) at completion of the maintenance phase (Week 32) of ESCAPE-TRD. Investigators were able to change the dose and frequency within label recommendations during the OLE based on clinical judgment.
The primary objective was to assess the long-term safety and tolerability of ESK-NS. The secondary objective was to assess the long-term efficacy of ESK-NS based on the proportion of pts being relapse-free at Week 104 (or end-of-study).
The primary endpoints were the number of pts who developed treatment-emergent adverse events, and suicidal ideation and behaviour, assessed by the Columbia-Suicide Severity Rating Scale (C-SSRS). Safety assessments also included body weight and vital sign measurements and clinical laboratory tests. The secondary endpoint was no relapse until the end of the prospective observation at Week 104 (or end-of-study); relapse was defined as a worsening of depressive symptoms as indicated by a total Montgomery-Åsberg Depression Rating Scale (MADRS) score of ≥22 at two consecutive assessments; hospitalisation for worsening depression, suicide prevention or attempt; or any other event assessed by the investigator to be indicative of relapse.
Results: 183 pts were enrolled in the ESCAPE-LTE. Top-line study results will be reported in the poster.

Conclusions: Results from the ESCAPE-LTE will provide evidence for the long-term safety, tolerability and efficacy of ESK-NS as a treatment for pts with TRD.

Male Depression – Are gender-related personality traits associated with the severity of depressive symptoms?

V. Rößner-Ruff[1]*, J. Krieger[1], K. Friedrich[1], C. A. Penkov[1], M. Ziegenbein[1], F. Führmann[2] and I. T. Graef-Calliess[3]

[1]Research and Development, Wahrendorff Clinic, Sehnde; [2]Research and Development, KRH Psychiatry Wunstorf, Wunstorf and [3]Clinic for Psychiatry and Psychotherapy, ZfP Südwürttemberg, Ravensburg, Germany

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.858

Introduction: Higher prevalence & incidence rates of depressive disorder in women compared with men are among the recurring findings from epidemiologic & clinical studies. The literature suggests that this is not due to a lower need for treatment of depression in men. In the context of the concept 'male depression' (MD), it is often argued that men tend to have so called 'non-typical' depressive symptoms. These symptoms (such as aggressiveness, irritability, alcohol use, risk-taking & antisocial behavior) are rarely considered in the diagnosis of depressive disorders, which may lead to underdiagnosis. With regard to the occurrence of 'non-typical' depressive symptoms and the concept MD, the importance of masculine personality traits is often discussed. The topic of the session is the extent to which gender-related personality traits such as masculine, feminine, androgynous & undifferentiated are associated with the occurrence and severity of 'non-typical' and 'typical' depressive symptoms in women and men with a depressive disorder.
Objectives: The results of a study in a clinical setting will be presented. The aim of the study was to investigate whether above mentioned gender-related personality traits are associated with increased severity of depressive symptoms and whether there are differences between women & men.
Methods: Depressive symptoms (GMDS & BDI II) and gender-related personality traits (GEPAQ) were assessed in female & male patients (≥ 18 years) with an unipolar depressive disorder (ICD-10). Participants were recruited from inpatient settings & day clinics of specialized psychiatric-psychotherapeutic hospitals in Germany. The multicenter study with a cross-sectional design has been completed. Data from the clinical sample were analyzed using multiple linear regression analysis.
Results: Multiple linear regression analysis: criteria variable **GMDS** & predicting variable **GEPAQ** (**masculine** pt) b-coefficient women = -1.36 (n.s.) & b-coefficient **men** = **-1.48** ($p \leq .01$); criteria variable GMDS & predicting variable GEPAQ (feminin pt) b-coefficient women = .12 (n.s.) & b-coefficient men = .79 (n.s.); criteria variable **BDI II** & predicting variable **GEPAQ** (**masculine** pt) b-coefficient women = -1.72 (n.s.) & b-coefficient **men** = **-4.23** ($p \leq .01$); criteria variable BDI II & predicting variable GEPAQ (feminin pt) b-coefficient women = .95 (n.s.) & b-coefficient men = .-24 (n.s.)
Conclusions: Gender-related personality traits are associated with the occurrence and severity of 'non-typical' & 'typical' depressive symptoms. They should be considered in the diagnosis & treatment of depression. Gender differences have also been identified. In men, the expression of masculine personality traits does not lead to an increase in depressive symptoms, especially not in 'non-typical' depressive symptoms, as was originally thought. Based on these and other recent findings, the concept of MD can be critically discussed.

Retrograde autobiographical amnesia following electroconvulsive therapy in patients treated for depression - a mixed-methods systematic review with meta-analysis and thematic meta-synthesis

A. Stachura[1,2]*, A. Butler[2,3], A. Borek[2,3], M. Chrétien[2], T. Sheth[2], H. Mithoowani[2], A. Kuc[1], H. Pham[1], A. Ćwiek[1], P. Jażdżyk[1] and M. Wójcik[1]

[1]2nd Department of Psychiatry, Institute of Psychiatry and Neurology, Warsaw, Poland; [2]Department for Continuing Education and [3]Nuffield Department of Primary Care Health Sciences, University of Oxford, Oxford, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.859

Introduction: Electroconvulsive therapy (ECT) is a treatment received by approximately 1.4 million people worldwide annually, depressive disorder being the most prevalent indication. Retrograde autobiographical amnesia (RAA) refers to difficulties in retrieving memories of past events. Despite being the most commonly reported side effect of ECT, its nature, duration and impact on patients' lives remains uncertain.
Objectives: (1) Assessing RAA severity in patients treated with ECT for depression compared with other treatment methods. (2) Assessing RAA severity in patients treated with right unilateral (RUL) vs bilateral (BL) ECT for depression. (3) Assessing overall RAA severity (pre-post effect) following an acute course of ECT. (4) Summarising patients' lived experiences of RAA following ECT for depression.
Methods: This systematic review was registered prospectively with PROSPERO (CRD42024445105). Seven databases were searched for eligible articles. Quantitative and qualitative studies assessing RAA in patients treated with ECT for depression published since 1985 were included. Abstract, full-text screening and data extraction were done in duplicates and independently. Quantitative data were meta-analysed using random effects model and qualitative data were analysed using thematic meta-synthesis.
Results: Of initial 6126 records, 22 quantitaive and 20 qualitative studies were included. ECT caused significantly greater RAA compared with other treatments (SMD -0.73, 95% CI -1.31; -0.15, I2=54%, Figure 1). BL treatment caused significantly greater RAA than RUL (SMD -0.29, 95% CI -0.57; -0.01, I2=32%, Figure 2). The pre-post effects were big for RUL (SMD -0.77, 95% CI -1.15; -0.38, I2=93%, Figure 3) and BL ECT (SMD -1.16, 95% CI -1.79; -0.52, I2=93%). The main effect moderator was RAA assessment tool. Few studies reported delayed effects of ECT on RAA. Four analytical themes were identified from qualitative data: (1) Uncertainty regarding the cause, nature and severity of memory loss may cause distress for patients, undermine the quality of information provision and post-ECT care. (2) Ambiguous testimonies – perception of

memory loss often shaped by ECT effectiveness. (3) Returning to 'normal' daily life may be a challenging, frustrating and lonely process, which requires developing adaptive coping strategies. (4) Some memories may not come back for years; re-leaning facts about oneself and reshaping own identity may be important steps on the journey to recovery.

Image 1:

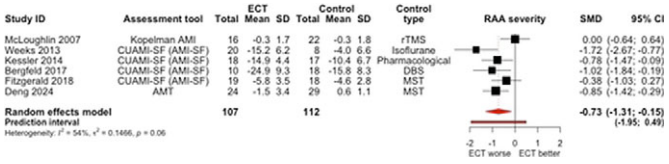

Image 2:

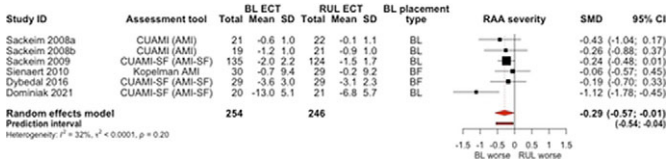

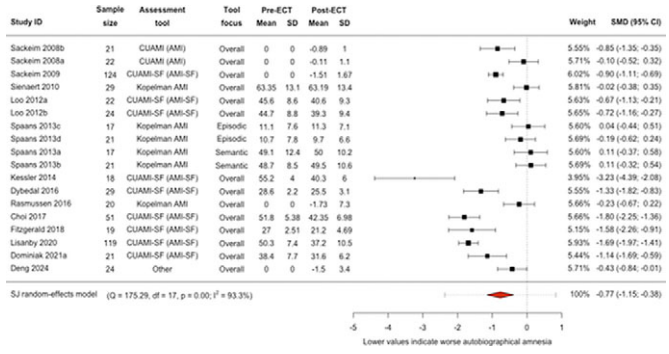

Image 3:

Conclusions: ECT causes more severe (sometimes long-lasting) RAA than other forms of treatment with BL being more harmful than RUL. RAA measurement is not unified hindering identifying technical aspects of ECT, which may impact memory loss. Information provision and post-ECT care could be improved by reducing uncertainty around the nature and severity of RAA.

Rebalancing Life: A "MOBILE" Model for Addressing Mood Instability and Occupational Challenges in MDD

S. Volovic Shushan[1,2]*, A. Stern[3] and N. Josman[1]

[1]The Faculty of Social Welfare and Health Sciences, Department of Occupational Therapy, University of Haifa, Haifa; [2]"Clalit" health services, "Shalvata" Mental Health Hospital, Hod-Ha'Sharon and [3]Faculty of Health Sciences, Occupational Therapy Department, Ben-Gurion University of the Negev, Beer Sheva, Israel

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.860

Introduction: Major Depressive Disorder (MDD) is one of the most well-known causes of disability worldwide. It is characterized by a persistent pattern of low mood, low self-esteem, and loss of interest and pleasure, leading to extensive functional impairment. Another characteristic is emotional dysregulation, leading to mood instability (MI), a frequent and intense fluctuations in emotions over time. MI affects the daily function of people with MDD. MI and daily function difficulties disrupt the ability to manage daily routine, causing impairment in occupational balance (OB) and affecting the resilience and quality of life (QoL) of people with MDD.

Objectives: A preliminary cross-sectional study was conducted to advance the understanding of MI and its relationships to daily function, OB, and QoL in people with MDD.

Methods: "MOBILE" Model Development: Data was collected using various assessments, utilized by Ecological Momentary Assessment (EMA), zooming in on real-life patterns of daily lives of people with MDD. Based on the research findings, a theoretical model, the **Mood-Occupation Balance Reciprocal Model (MOBILE),** was constructed, presenting the relationships between the variables.

Results: This presentation will showcase the research findings and the reciprocal relationships between study variables, which form the foundation for this model development.

Conclusions: The "Mobile" model addresses the two core components of depression - MI and functional impairment, and explores their relationships to QoL, OB, participation, and personal resilience in people with MDD. The model serves as a platform for building a personalized clinical intervention, which will be tested in further research.

Implications for Future Practice: Currently, most treatments offered for MDD combine pharmacological and psychosocial treatments. Yet, their efficacy in improving functional abilities is limited. The development of the current model, and subsequently the development of a clinical intervention, allows for the expansion of treatment options for people with MDD. In this way, it may assist in reducing the heavy burden of the disease, improve functioning, and prevent recurrence. Additionally, the use of EMA allows for the efficient and accurate collection of data, thereby extending the diagnostic and treatment processes from the clinic to everyday environments.

doi: 10.1192/j.eurpsy.2025.861

Introduction: There are limited data to guide treatment continuation decisions for clinicians caring for patients with treatment resistant depression (TRD). Identifying the magnitude of early improvement (at Weeks 4 and 8) as a predictor of long-term outcomes for TRD can guide treatment continuation decisions.
Objectives: To evaluate the probability of achieving response or remission by Week 32 in patients with TRD after 4 or 8 weeks of esketamine nasal spray (ESK-NS) treatment, flexibly dosed in combination with an ongoing selective serotonin/serotonin-norepinephrine reuptake inhibitor (SSRI/SNRI).
Methods: ESCAPE-TRD was a randomised phase IIIb trial comparing the efficacy of ESK-NS versus quetiapine extended release, both in combination with an ongoing SSRI/SNRI, in patients with TRD (Reif *et al.* NEJM 2023; 389 1298–309). Remission was defined as a Montgomery-Åsberg Depression Rating Scale (MADRS) total score ≤10, and partial response and response as ≥25% and ≥50% improvements, respectively, in total MADRS score (or remission). Long-term outcomes were based on the best outcome on-treatment across 32 weeks (≥1 instance of response or remission) from earliest outcome endpoint onwards. Non-responder imputation (NRI) was applied after treatment discontinuations.
Results: 336 patients were randomised to ESK-NS; 334 received ≥1 dose. **Table 1** shows long-term outcomes following at least partial response, response or no partial response at Weeks 4 and 8. For example, among those who had at least a partial response at Week 4, 94.1% and 79.8% had response and remission by Week 32, respectively.

Image 1:

Table 1. Long-term outcomes following outcomes at Week 4 and 8

	Week 4			Week 8		
	No partial response N=98	At least partial response[a] N=238	Response N=120	No partial response N=78	At least partial response[a] N=258	Response N=174
% patients (N=336)	29.2	70.8	35.7	23.2	76.8	51.8
% response at any point by Week 32[b]	56.1	94.1	100.0[c]	29.5	95.7	100.0[c]
% remission at any point by Week 32[b]	39.8	79.8	93.3	19.2	81.0	89.7

[a]Week 4 and 8 at least partial response includes partial response, response and remission; [b]Percentages of patients achieving response or remission are relative to the percentage of patients achieving each outcome (no partial response, at least partial response or response); [c]By definition of "response/remission at any point by Week 32" these values are 100%.

Conclusions: This analysis demonstrated a relationship between short- and long-term outcomes. Presence of at least partial response at Week 4 led to more favourable outcomes by Week 32. Moreover, most patients with response by Week 4 achieved remission by Week 32. Continued symptom improvements were observed beyond the induction phase even in some patients with no partial response at Week 4.

Efficacy and safety of vortioxetine in cardiological patients

A. Schelchkova[1], J. Barylnik[1*] and D. Samoylova[1]

[1]Saratov State Medical University, Saratov, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.862

Introduction: The most important conditions for the using of antidepressants in cardiological practice are good tolerability, minimal interaction with other drugs, and the absence of a toxic effect. All of the above qualities among antidepressants have a multimodal antidepressant – vortioxetine.
Objectives: Evaluation of the efficacy and safety of vortioxetine in the treatment of concomitant depressive disorders in cardiological patients.
Methods: 37 patients aged 45-66 years who were admitted for inpatient treatment at the Regional Clinical Cardiology Dispensary with a diagnosis of "coronary heart disease, Angina pectoris II-III FC" were examined. Upon the hospitalization, they were consulted by a psychiatrist. During the consultation, the patients were diagnosed with a Major depressive disorder, single episode, moderate (F 32.1 according to ICD – 10). Therapy of depressive disorder was carried out in average therapeutic doses with vortioxetine for 8 weeks. To evaluate the efficacy, scales and questionnaires were used: HADS, PDQ–20, CGI–C, SF–36. Statistical processing of the

material was carried out using a package of applied statistical programs: Excel, Word (version 2108).
Results: Analysis of the results of assessing the severity of depressive and anxiety manifestations on the HADS scale and the level of cognitive functioning using the PDQ questionnaire allowed us to state that at the end of 8 weeks of therapy with vortioxetine, 89% of patients showed significant clinical improvement. The positive dynamics of patients is confirmed by data on the CGI–C scale. The answers to the SF–36 questionnaire indicate an improvement in the life quality indicators. Statistically significant changes were observed in the parameters "Physical condition", "Mental health" and "Vital activity".
The tolerability of vortioxetine in all patients was good, side effects in 13.5% of the subjects in the form of dizziness, nausea and daytime drowsiness were reduced within 1 week.
There were no significant changes in the biochemical parameters of blood, coagulogram, electrolyte composition. When assessing the indicators of blood pressure, heart rate, there was a significant improvement in indicators by the end of the research. In 8 weeks, the frequency of angina attacks and arrhythmias significantly was decreased.
Conclusions: When prescribing vortioxetine to patients with cardiological pathology for 8 weeks, there was distinct positive dynamics both in terms of indicators of the cardiovascular system, and in the emotional sphere, cognitive and social functioning.

Depression in multiple sclerosis and associated factors

N. Ben Hamed[1]*, A. Aissa[1], A. Souissi[2], A. Labyedh[1] and R. Jomli[1]
[1]psychiatry A, razi hospital and [2]neurology department, LR18SP03 and Clinical Investigation Center Neurosciences and Mental Health - university hospital center Razi, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.863

Introduction: Multiple sclerosis (MS) is a chronic, immune-mediated disorder that affects the central nervous system, leading to a range of neurological impairments. Depression is a common comorbidity in MS, affecting up to 50% of patients over the course of the disease. This association not only worsens functional outcomes but also increases disability, reduces treatment adherence, and negatively impacts overall quality of life.
Objectives: The aim of this study is to assess the prevalence of depression in patients with MS and identify its associated factors.
Methods: A cross-sectional study was conducted in the neurology department of Razi University Hospital (Tunisia) between October 2023 and June 2024. Patients with a diagnosis of MS based on the 2017 McDonald criteria were recruited, excluding those with active disease relapses. Participants completed questionnaires covering sociodemographic data, medical history, clinical and radiological characteristicsand psychological symptoms. Disability was evaluated via the Expanded Disability Status Scale (EDSS). Depression, anxiety and stress were assessed using the DASS-21 scale. Insomnia was evaluated using the Pittsburgh Sleep Quality Index (PSQI). Data analysis was performed using SPSS version 26.
Results: A total of 83 patients with MS were recruited, with ages ranging from 19 to 66 years. The study population had a predominantly female sex ratio of 3.4. The majority of participants (75.9%) were from urban areas, and 74.7% had a university-level education. Moreover, 49.1% were married, and 60.2% were employed. Regarding medical history, 40.3% had a comorbid condition, and 30.1% had a psychiatric history. The mean age at disease onset was 26 ± 10 years. First-line treatments (interferon, glatiramer acetate, teriflunomide, dimethyl fumarate) were prescribed to 27.7% of patients. Second-line treatments (natalizumab, ocrelizumab, fingolimod) were prescribed to 69.9% of patients.
In our study, the prevalence of depression was 52.6% according to the DASS-21 scale. In our population, 24.1% had severe depression, 18.1% had moderate depression, and 10.4%. Depression was significantly associated with employment status (p=0.05), socioeconomic status (p=0.02), personal organic history (p=0.01), personal psychiatric history (p=0.02), the presence of more than 10 lesions on MRI (p=0.01), disability status measured by the EDSS score (p=0.03), as well as anxiety, insomnia, and stress (p<0.001).
Conclusions: The relationship between MS and depression is complex. Routine screening for depression during MS follow-ups is crucial. Effective management of mood disorders in MS patients can significantly improve their quality of life.

Outpatient Intravenous Ketamine Protocol for Psychiatric Care at the General Hospital of Corfu

M. Demetriou[1]*, P. Argitis[1], M. Peyioti[2], V. Anagnostopoulou[1] and Z. Chaviaras[1]
[1]Psychiatry Department, General Hospital of Corfu, Corfu and [2]University General Hospital of Alexandroupolis, Alexandroupolis, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.864

Introduction: Intravenous (IV) ketamine has garnered increasing attention as a rapid-acting treatment for severe psychiatric conditions such as major depressive disorder (MDD) and suicidal ideation, particularly in treatment-resistant cases. Unlike traditional antidepressants, which often take weeks to exhibit therapeutic effects, IV ketamine can provide relief within hours. While the nasal spray form of ketamine has been approved for clinical use, it remains costly and may not be accessible to all patients. Developing a standardized, cost-effective protocol for the outpatient administration of IV ketamine could enhance treatment accessibility while maintaining safety and efficacy.
Objectives: To develop and evaluate a protocol for the outpatient administration of IV ketamine that ensures patient safety, maximizes clinical effectiveness, and reduces costs compared to alternative ketamine formulations, while maintaining practical outpatient management without requiring inpatient monitoring.
Methods: This study enrolled 46 patients diagnosed with treatment-resistant MDD. Each patient received an initial IV ketamine infusion at a dose of 0.2 mg/kg, followed by 0.5 mg/kg in subsequent sessions, administered over 45 minutes in a 100 mL saline solution. Treatments were performed in an outpatient setting with close monitoring during the infusion and for one hour post-infusion. Symptom improvement was evaluated using standardized psychiatric assessment tools, such as the Montgomery-Åsberg Depression Rating Scale (MADRS) and the Hamilton Depression Rating Scale (HAM-D).

The protocol also outlined strategies for managing side effects, including transient dissociation, nausea, and hypertension.
Results: The outpatient ketamine protocol demonstrated rapid and significant symptom relief in the majority of patients, with most reporting improvement after the first or second session. Adverse effects were generally mild, with the most common being transient dissociation and elevated blood pressure, both of which resolved without requiring additional intervention. Importantly, the need for expensive inpatient care or nasal spray formulations was minimized, making the treatment more accessible. The cost savings compared to other ketamine delivery methods were notable, making this protocol a viable option for outpatient psychiatric care.
Conclusions: This study establishes that IV ketamine can be safely and effectively administered in an outpatient setting, offering rapid symptom relief for treatment-resistant MDD while minimizing side effects and reducing overall treatment costs. The protocol presents a practical, cost-effective alternative to more expensive ketamine formulations, providing a feasible solution for broader clinical use in psychiatric outpatient settings. Further research is recommended to validate these findings across larger patient populations and explore long-term outcomes.

Prevalence and Associated Risk Factors of Toxoplasma gondii IgG Antibodies in Patients Diagnosed with Depression from Western Romania: A Case–Control Study

A. G. Mihu[1,2], S. Grada[1]*, L. E. Piros[1], S. A. Sprintar[2], A. M. Lupu[3] and T. R. Olariu[3,4]

[1]Department of Biology and Life Sciences; [2]"Aurel Ardelean" Institute of Life Sciences, "Vasile Goldis" Western University, Arad; [3]Discipline of Parasitology, "Victor Babes" University of Medicine and Pharmacy and [4]Clinical Laboratory, Municipal Clinical Emergency Teaching Hospital, Timisoara, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.865

Introduction: Chronic toxoplasmosis has been reported to cause neuroinflammation in humans, linking it to neuropsychiatric disorders, including depression.
Objectives: To assess the prevalence of *Toxoplasma gondii* IgG antibodies in patients diagnosed with depression from Western Romania and compare the findings with a control group of healthy volunteers from the general population without any psychiatric disorders.
Methods: We included 230 participants, consisting of 115 psychiatric patients diagnosed with depression at the Psychiatric Clinic, County Emergency Hospital of Arad, Western Romania. These patients were matched by age and gender with a healthy control group of 115 volunteers. Clinical evaluations, a brief questionnaire to assess the risk factors, and laboratory tests were conducted, including serological testing for the presence of *Toxoplasma gondii* IgG antibodies.
Results: In both the study group and the control group the mean age was 52.96 ± 10.29 years and 72/115 (62.61 %) were female. A significantly higher seroprevalence of *Toxoplasma gondii* IgG antibodies was demonstrated in patients with depression when compared to healthy volunteers (p value <0.001). We noted a higher prevalence of *Toxoplasma gondii* IgG antibodies in depressive patients aged between 50-59 years (p value = 0.008) and 60-69 years (p value = 0.03) when compared to their counterparts from the control group. Females diagnosed with depression presented a significantly higher seroprevalence of *Toxoplasma gondii* IgG antibodies (p value <0.001) when compared to healthy female volunteers. No difference between the two groups was noted when we assessed the participants educational level, contact with the soil, consumption of undercooked meat and contact with cat feces.
Conclusions: The presence of *Toxoplasma gondii* IgG antibodies was significantly higher in depressive patients attending the Psychiatric Clinic in Arad County, Western Romania, when compared to healthy controls. Our findings suggest a potential link between chronic *Toxoplasma gondii* infection and depression.

State and Trait Characteristics Based on Affective Temperament in Patients with Major Depressive Disorder

K. A. Kang[1]

[1]Psychiatry, Asan Medical Center, Seoul, Korea, Republic Of
doi: 10.1192/j.eurpsy.2025.866

Introduction: Affective temperament is associated with various clinical characteristics in patients with mood disorders. However, little is known about clinical characteristics based on affective temperament specifically in patients diagnosed with major depressive disorder (MDD).
Objectives: This study aims to explore the impact of affective temperament on both the traits and states of individuals diagnosed with MDD.
Methods: This study consecutively recruited 247 outpatients, aged 18 to 49, presenting for their initial visit to a mood disorder clinic. Affective temperament was assessed using the Temperament Evaluation of the Memphis, Pisa, Paris and San Diego-Autoquestionnaire. A Z-score of 1 or higher on each affective temperament was defined as a dominant affective temperament. The patients completed various assessments, including the Patient Health Questionnaire-9, Generalized Anxiety Disorder-7, Seasonal Pattern Assessment Questionnaire, Alcohol Use Disorders Identification Test, Hypomania Checklist-32, Interpersonal Sensitivity Measure, and Depressive Symptom Index - Suicidality Subscale. Multiple linear regression analysis was conducted to identify the impact of affective temperament on both psychiatric states and trait characteristics.
Results: This study comprised 247 patients with a mean age of 29.34 ± 9.16, of whom 152 (61.5%) were female. Depressive (β = 0.247, p < 0.001) and irritable temperament (β = 0.138, p = 0.032) were positively associated with the severity of depressive symptoms, while hyperthymic temperament (β = -0.123, p = 0.041) showed a negative association. Furthermore, depressive (β = 0.246, p < 0.001), irritable (β = 0.195, p = 0.002) and cyclothymic temperament (β = 0.148, p = 0.018) were positively associated with the severity of anxiety symptoms. Cyclothymic (β = 0.211, p = 0.001) and anxious temperament (β = 0.136, p = 0.027) were positively correlated with seasonality. Hyperthymic temperament showed a positive correlation with harmful drinking patterns (β = 0.179, p = 0.006). Also, hyperthymic (β = 0.200, p = 0.002) and cyclothymic temperament (β = 0.140, p = 0.036)

were positively correlated with hypomanic features. Cyclothymic (β = 0.255, $p < 0.001$) and anxious temperament ($\beta = 0.173$, $p = 0.004$) were positively correlated with hypersensitivity to interpersonal rejection. Depressive temperament (β = 0.184, p = 0.004) was positively associated with the severity of suicidality.

Conclusions: Among patients with MDD, variations in psychiatric states and traits were observed based on the dominant affective temperaments. This suggests a correlation between affective temperaments and diverse psychopathological manifestations. Consequently, there appears to be a need for further research to elucidate the therapeutic implications associated with affective temperaments.

Esketamine in Treatment Resistant Depression: Acute Effects on Dissociation and Therapeutic Effects at the End of the Induction Period

G. Lombardozzi[1]*, G. D. Kotzalidis[1], G. Trovini[1], G. Albanesi[1], G. Civita[1], D. Donato[1], V. Giovanetti[1] and S. De Filippis[1]

[1]Psychiatry, Villa von Siebenthal Neuropsychiatric Clinic, Genzano di Roma, Roma, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.867

Introduction: Esketamine has been linked to dissociation, which was claimed to predict or not to predict antidepressant response. Speculations regarding predictivity were based on results obtained with the CADSS, a scale investigating dissociative symptoms, with higher scores indicating more symptoms.

Objectives: To investigate the effect of intranasal esketamine on dissociation and its subsequent influence on clinical response, we administered the CADSS 40 minutes after inhalation at the first esketamine administration and 40 minutes after the ninth inhalation and measured clinical response through the Clinical Global Impressions-Severity (CGI-S), the Young Mania Rating Scale (YMRS), the Montgomery-Åsberg Depression Rating Scale (MADRS), and the 24-item Brief Psychiatric Rating Scale (BPRS).

Methods: We included 61 adults (33 women and 28 men; age, mean, 52.69±11.80, range 20-73 years) with Thase & Rush (J Clin Psychiatry 1997;58 [Suppl 13]:23-29) treatment-resistant depression. All patients received intranasal esketamine spray and were assessed at the first and ninth administrations (one month after the first administration, i.e., the end of the induction period and the beginning of maintenance), at the day of the spray after 40 min with the CADSS and 1 month later with the CGI-S, the BPRS, the MADRS, and the YMRS.

Results: CADSS scores dropped from 6.59±7.42 40 min after the first administration to 3.12±4.41 40 minutes 1 month later (dropped by 3.48 points, 47.27% of baseline); t=3.15; p=0.0021. CGI-S scores dropped from 5.12±0.61 at baseline to 3.95±0.76 1 month later (t=9.32; p<0.00001). BPRS scores dropped from 51.85±11.55 at baseline to 41.21±10.64 after 1 month (t=5.29; p<0.00001). MADRS scores dropped from 34.29±7.89 at baseline to 22.61±9.07 after 1 month (t=7.59; p<0.00001). Responders (≥50% drop of MADRS from baseline) were 12 patients (19.67%), while remitters (MADRS score≤10) were 2 (3.28%). YMRS scores moved from 2.18±2.59 at baseline to 1.72±2.37 1 month later (t=1.02; p=0.309, n.s.), always in the normal range. Blood pressure 40 minutes after spray at the first administration was unchanged in 35 patients, increased in 16 (maximum by 20 mmHg), and decreased in 10 (maximum drop 20 mmHg). Contrary to previous claims, CADSS scores did not correlate at any time with scores on clinical scales or therapeutic response (Pearson's r from 0.232 with p=0.072 to 0.013 with p=0.918). As for side effects, 15 patients reported dissociation, 15 sedation, 8 vertigo, 8 dizziness, 6 confusion, 5 headache, 4 nausea/vomiting, and 0 hypertension.

Conclusions: Patients in our sample scored very low on the CADSS. At the end of the induction period, esketamine was associated with significant decreases in the severity of psychopathology.

Disclosure of Interest: None Declared

Descriptive study on esketamine and ketamine treatment in real-world patients with a diagnosis of resistant depression

E. A. Ródenas Vera[1]*, S. Sabater[2], P. Alvarez[3], S. Oller[3] and I. Riedel[3]

[1]psychiatry department; [2]Hospital del Mar, Barcelona, Spain and [3]Psychatry, Hospital del Mar, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.868

Introduction: Depressive disorder is one of the health problems that carries the greatest burden of morbidity, with high prevalence and impact on people's quality of life. It also affects the family environment and contributes to the social and economic burden on health systems (World Health Organization, depression, 2023). Currently, the treatment of depression has limitations and there is a high frequency of patients who do not respond despite multiple trials of antidepressants. Up to two-thirds of patients diagnosed with depression do not achieve remission despite treatment, and 30% of patients are considered treatment-resistant, defined as a minimum of two failures to previous treatments, in adequate doses and duration (Gaynes et al., 2019). Recent innovations in the management provide promising opportunities to improve the symptomatology of these patients. New drugs such as ketamine and esketamine, which have glutamatergic neuromodulatory properties, are used under supervision for the treatment of patients with treatment-resistant depression (Vasiliu, 2023).

Objectives: The aim is to describe a sample of real-world patients with a diagnosis of resistant depression referred to esketamine/ketamine treatment. The individuals were being followed by psychiatrists of a public hospital in the city of Barcelona and were selected to start treatment indicated by the refractoriness and severity of the episode.

Methods: We used a database that collected multiple sociodemographic, clinical and treatment variables of 32 patients with refractory depression who were referred to treatment with esketamine/ketamine. SPSS software was used for data processing. All the patients in the group were followed up by psychiatry in a public hospital in the city of Barcelona during the period from July 2015 to September 2024.

Results: Of the 32 patients evaluated, 11 were male (34.4%) and 21 were female (65.6%). The mean age at the time of receiving ketamine/ketamine treatment was 53 years with a standard deviation of 10.7. Nearly 60% had a comorbid psychiatric diagnosis. Twenty-eight percent had undergone electroconvulsive therapy. The mean

number of previous episodes was 3.72 with a median of 2.5. Regarding the response to treatment we found that it was partial in 15 patients (46.9%) and complete remission could be obtained in 7 patients (21.9%), with no response to treatment in 10 of them (31.2%). In 5 patients the response was considered a late response.
Conclusions: In most of the patients a partial improvement was assessed as evidenced by a reduction in the Montgomery-Asberg Depression Rating Scale (MADRS). Few cases obtained a complete remission with treatment.
As limitations to the results, we can refer to the small sample size. However, we consider that the severity and chronicity of the episodes make the description of the response in a real world group seem of interest for future studies.

Accident-Related Stress in the Elderly: A Review of Current Trends and Implications for Mental Health

A. Argyriadis[1]*, E. Kotrotsiou[1], S. Kotrotsiou[2], D. Katsarou[3], A. Patelarou[4], E. Patelarou[4] and A. Argyriadi[5]

[1]Nursing, Frederick University, Nicosia, Cyprus; [2]Nursing, University of Patras, Patra; [3]Department of Preschool Education Sciences and Educational Design, University of the Aegean, Rhodes; [4]Nursing, Hellenic Mediterranean University, Heraklion, Greece and [5]United Arab Emirates University, Al Ain, United Arab Emirates
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.869

Introduction: Accidents, whether minor or severe, can have significant psychological impacts, especially in elderly populations. Stress related to accidents often exacerbates pre-existing conditions or leads to new mental health challenges such as anxiety, depression, or post-traumatic stress disorder (PTSD). The psychological impact of accidents on elderly individuals is often compounded by physical frailty, social isolation, and diminished coping mechanisms. Following an accident, elderly individuals may face prolonged recovery periods, limited mobility, and a reduced sense of independence, all of which can heighten stress levels. Additionally, the fear of future accidents may lead to avoidance behaviors, further isolating them from social interactions and routine activities, thus exacerbating anxiety and depression. Pre-existing mental health conditions, such as mild cognitive impairment or chronic illness, can worsen under accident-related stress.
Objectives: This study aims to explore recent trends in understanding and addressing accident-related stress in elderly individuals, focusing on the psychological, social, and physiological factors contributing to their vulnerability. The primary objective of this study is to examine the psychological, social, and physiological factors that increase the vulnerability of elderly individuals to accident-related stress.
Methods: A mixed-methods approach was used, combining a systematic review of literature from 2015 to 2024 and interviews with mental health professionals. The sample consisted of 30 peer-reviewed studies and 25 elderly individuals aged 65 and above who had experienced accidents within the last year. Studies were selected based on relevance to accident-related stress in the elderly, with an emphasis on post-accident psychological outcomes and interventions.
Results: Results indicated that the elderly are more susceptible to prolonged stress responses following accidents due to physical fragility, social isolation, and reduced coping mechanisms. The review also highlighted an underutilization of mental health services in this demographic, despite the availability of stress-reduction programs. Furthermore, findings showed that older adults who participated in targeted mental health interventions, such as cognitive-behavioral therapy and peer support groups, experienced better outcomes in managing stress compared to those who did not.
Conclusions: In conclusion, accident-related stress in the elderly presents unique challenges that require specialized attention. Healthcare providers should prioritize early identification and tailored interventions to mitigate the long-term psychological effects of accidents in this vulnerable population.

Mental Health Protection Programme BOJE (Colours) for LGBTQIA+ people in Croatia – Empowering Resilience

J. Hubler[1]*, A. Vuk[2], I. Barun[3], L. Mijalkovic[3], M. Supe[1], J. Pravdic[1] and V. Grosic[2]

[1]Substance use and Addiction Treatment Day care unit; [2]Department of integrative psychiatry and [3]Department of psychiatry, University Psychiatric Hospital Sveti Ivan, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.870

Introduction: The phenomenon of minority stress frequently emerges as a contributing factor to mental health discrepancies among sexual and gender minority people, manifesting in elevated rates of mental distress, anxiety, depression, suicidality and substance misuse (Plöderl et al. Int. Rev. Psychiatry 2015; 27 367-385, Russell et al. Annu Rev Clin Psychol. 2016; 12 465–487). Building on insights from previous research, the Mental Health Protection Programme BOJE (Colours) was launched to offer comprehensive support tailored to the needs of LGBTQIA + individuals within the Croatian public mental healthcare system.
Objectives: The presentation of the BOJE - Mental Health Protection Programme that aims to address minority stress to offer specialized support tailored to the unique needs of LGBTIQ+ individuals, fostering resilience and well-being.
Methods: In October 2023, a multidisciplinary team at the University Psychiatric Hospital Sveti Ivan in Zagreb, Croatia, formed a Mental Health Protection Programme BOJE which consists of a counseling center, an outpatient clinic and a three-month therapeutic and educational cycle for LGBTQIA+ users. Additionally, a platform was provided for training healthcare professionals in LGBTQIA+ affirmative practice. The goal is to offer support, create an inclusive, safe environment and raise awareness of LGBTQIA+ mental health needs.
Results: To date, 50 participants have been supported, with 50% identifying as TGD. We had approximately 574 procedures (counsellings, psychiatrist consultations and reviews and psychotherapies) and two cycles of closed-group workshops have been completed with a low dropout rate, and most participants rated the program as useful or very useful for their mental well-being.
Conclusions: Despite the recognition of the mental health disparities between sexual and gender minority people and the general population there is still limited availability of gender-affirming

mental and physical health services. The investigation of how affirming healthcare access influences resilience building among transgender and gender non-binary individuals highlighted the urgent need for additional interventions in public healthcare systems. Following this, a mental health program for LGBTQIA+ individuals was launched within the Croatian healthcare system to buffer the negative health effects of minority stress and improve mental health among sexual minorities and gender-diverse populations.

Unveiling Loneliness in Multiple Sclerosis: Insights from a Nationwide Cross-Sectional Study in Greece

M. Bakola[1], A. K. Sakaretsanou[1], K. S. Kitsou[1]*, N. Vaitsis[1], S. Aggelakou-Vaitsi[1], M. E. G. Elsayed[2], K. Argyropoulos[1], P. Gourzis[3] and E. Jelastopulu[1]

[1]Department of Public Health, University of Patras, Medical School, Patras, Greece; [2]Department of Psychiatry, Carl von Ossietzky University Oldenburg, School of Medicine and Health Sciences, Oldenburg, Germany and [3]Department of Psychiatry, University of Patras, Medical School, Patras, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.871

Introduction: Multiple sclerosis (MS) is a chronic and progressive inflammatory autoimmune disease of the central nervous system. Beyond physical symptoms, it can cause various socio-affective symptoms such as depression, anxiety, sleep disorders and loneliness, leading to a significant psychosocial burden.
Objectives: This study aimed to identify factors contributing to loneliness in MS patients and to examine its associations with psychological distress, stigma, and resilience.
Methods: We conducted a nationwide cross-sectional study of patients with MS from October 2022 to January 2023. Data were collected using an online questionnaire, which included sociodemographic information, disease characteristics, experiences of social stigma, psychological distress, coping strategies, and perceived social support. Validated tools used were the Stigma Scale of Chronic Illness (SSCI-8), Kessler Psychological Distress Scale (K10), Brief Resilient Coping Scale (BRCS), and UCLA Loneliness Scale.
Results: A total of 108 patients, 69.4% women, mean age 44.8 years, participated in the study. Higher loneliness scores were associated with greater psychological distress ($p<0.001$) and higher perceived stigma ($p<0.001$). Inversely, higher loneliness levels correlated with lower resilience ($p<0.001$). Patients living in small urban or rural areas reported higher levels of loneliness compared to those in large urban centers ($p=0.002$). Additionally, full-time employment ($p=0.032$) and better financial status ($p = 0.025$) were associated with reduced loneliness, while a family history of psychiatric illness was linked to higher loneliness ($p=0.043$).
Conclusions: This study reveals that loneliness is an important issue in MS patients and is associated with mental health problems, stigma and reduced coping resilience. Patients living in smaller urban areas, with poorer financial status, or a family history of psychiatric illness are particularly vulnerable. Addressing loneliness should be a priority in psychosocial interventions to improve quality of life. Future research with larger samples is recommended to confirm and extend these findings.

Recognition of Mental Illness among Primary Care Providers in Hungary: Strengths and Limitations

V. Swisher[1]*, D. Ori[2,3] and R. Wernigg[4]

[1]Psychology, The Pennsylvania State University, State College, United States; [2]Psychology, Semmelweis University; [3]Psychology, Heim Pal National Pediatric Institute and [4]National Directorate-General for Hospitals, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.872

Introduction: With 1 in every 8 people living with a mental disorder according to the World Health Organization, the need for appropriate identification and treatment of mental health conditions is paramount. As the majority of people with mental health problems seek help and receive their mental health care from primary care providers (PCPs), PCPs assume an important role in the identification of mental illness.
Objectives: This study examined mental health literacy and predictors of disorder recognition among primary care providers (PCPs) in Hungary.
Methods: Hungarian PCPs (n = 208) completed a survey assessing demographics, mental health stigma, and exposure to mental health. Participants read six vignettes describing obsessive-compulsive disorder (OCD) harm/aggression subtype (OCD-Aggression), OCD order/symmetry subtype (OCD-Order), generalized anxiety disorder (GAD), social anxiety disorder (SAD), panic disorder (PD), and major depressive disorder (MDD) and were asked to identify each condition and provide treatment referrals. Descriptive analyses were used to characterize disorder recognition rates, perceived disorder causes, and treatment referrals. Binary logistic regression analyses were conducted to examine the degree to which demographic characteristics, mental health stigma, and exposure to mental health predict accurate disorder recognition.
Results: Identification rates for each vignette were: OCD-Aggression (27.9%), OCD-Order (75.5%), SAD (34.1%), GAD (76.0%), PD (78.8%), and MDD (91.3%). First-choice treatment referrals were a psychiatrist for OCD-Aggression (63%), OCD-Order (53.8%), and MDD (46.6%), a psychologist/therapist for SAD (58.7%) and GAD (48.6%), and a PCP for PD (39.9%). Anxiolytics (e.g., benzodiazepines) were the most commonly recommended medication for the anxiety disorders. Mislabeling conditions was significantly associated with older age (for GAD, OCD-Aggression, PD and MDD), male gender (for GAD), greater mental health stigma (for OCD-Order), and not having a family member/friend with a mental health condition (for SAD).
Conclusions: Findings highlight strengths (e.g., depression recognition) and limitations (e.g., OCD-Aggression) in knowledge of mental health conditions among PCPs in Hungary. Our findings add to the literature by outlying potential intervention targets (e.g., increasing education on appropriate anxiolytic use) to improve mental health literacy in primary care. Future research should investigate the efficacy of psychoeducation interventions, particularly for

OCD and anxiety disorders, in improving the mental health literacy of PCPs in Hungary.

Associated factors of the quality of therapeutic alliance in people with severe mental illness: A systematic review

M. Tetzlaff[1,2*], J. Bruins[1,3] and S. Castelein[1,2,3]

[1]Research, Lenits Psychiatric Institute; [2]Faculty of Behavioral and Social Science, University of Groningen and [3]Rob Giel Research center, University Medical Center Groningen, University Center for Psychiatry, Groningen, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.873

Introduction: Given the high rates of disengagement of psychological and/or psychopharmacological treatment in individuals with severe mental illness (SMI), building a strong therapeutic alliance (TA) in treatment is crucial. Despite the awareness of a favorable role of the TA in mental health care for people with SMI, there is a paucity of research that contributes to the formulation of concrete guidelines for establishing a strong TA.
Objectives: This review aims to systematically synthesize existing literature of associated factors of the TA across six domains: client, mental health professionals (MHPs), clinical, social, care, and other. These include the views of clients with SMI, MHP, and independent raters of the TA.
Methods: Parallel literature searches in PsycInfo, Medline, and PubMed between 2000-2022 identified 2699 possible articles, of which n=53 met inclusion criteria.
Results: Associated factors of better client-rated TA were: high insight, secure attachment, higher outcome expectancy at baseline, specific personality traits, less internalized stigma, more therapists' empathy and frequent use of supportive techniques by MHP. MHP-rated and/or independent observer-rated TA was significantly related to: more insight, sex of client (female), MHP without anxious attachment, and less severe symptomatology of client.
Conclusions: Clinical symptom severity only affected TA when rated by MHP, but not when rated by clients. Attachment style affects the TA bidirectionally: clients' secure attachment to the MHPs may help modify maladaptive attachment patterns, and anxious/insecure attachment style from either client or MHP affects the TA negatively. Furthermore, having an early positive click with the client builds the foundation for a later stable and supportive relationship, making the client more likely to continue perceiving the alliance as positively as treatment progresses. It is therefore crucial to provide a warm and supporting environment from the start of treatment, where clients have the opportunity to overcome perceived (self-)stigma and develop a positive mindset towards outcome expectations. Focusing on supportive techniques like providing feedback or shared agenda setting instead on the clients clinical symptomatology solely might result in a more favorable perception of the TA. Notably, current TA measurements assume a one-on-one relationship between clients and MHP, while nowadays multiple MHPs are involved. We recommend re-evaluating the assessment of TA within SMI care.

People with unbearable psychiatric suffering and a chronic death wish: Who are they and what changes do they experience in the care and expertise centre Reakiro? A Belgian cross-sectional study

T. Vanhie[1*], S. Verdegem[1], L. Bemelmans[1], P. Onghena[2] and J. Vandenberghe[2]

[1]Reakiro, University Psychiatric Centre, KU Leuven and [2]KU Leuven, Leuven, Belgium
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.874

Introduction: People with unbearable psychiatric suffering and a chronic death wish are a subgroup of patients with Severe and Persistent Mental Illness (SPMI; Moureau *et al.*, FiP 2023; 14:1094038). They suffer from at least one, but usually multiple psychiatric disorders, in a chronic course, resulting in severe limitations in psychosocial functioning (Woods *et al.*, CJP 2008; 53 725-736.). Their chronic death wish is rooted in their struggle with life and death and diminished perspective on the alleviation of their suffering. They are at risk for suicide and/or are eligible to request euthanasia as legislated in Belgium. Reakiro is a Belgian pilot project and a drop-in, care and expertise centre developing tailored mental healthcare for this target population in addition to continued care as usual.
Objectives: To describe psychological and existential characteristics, care needs, experienced changes and the correlations between these variables in 107 consecutive Reakiro patients who agreed to participate in this study.
Methods: The Beck Scale for Suicide Ideation (BSSI), Dutch Empowerment Scale (DES), Herth Hope Index (HHI), Meaning In Life Measure (MILM), Existential Concerns Questionnaire (ECQ), Outcome Questionnaire-45 (OQ-45) and the Change Questionnaire (CQ) were administered combined with an assessment of their life and death wish and of how they experience the care in Reakiro.
Results: The BSSI (M = 21.78, SD = 8.48), DES (M = 113.39, SD = 20.42), HHI (M = 24.15, SD = 5.40), MILM (M = 5.39, SD = 1.50), ECQ (M = 62.13, SD = 12.10) and OQ-45 (M = 98.93, SD = 20.50) show heightened levels of suicidality, existential anxiety and symptomatology and lowered levels of hope, meaning in life and empowerment, compared to other psychiatric and non-clinical samples. Longer trajectories in Reakiro were correlated with heightened hope and lowered symptomatology, but not with suicidality. The preliminary CQ-analysis revealed 31 participants reporting positive changes in their relation to life and death, to self and others and to hope and future; 8 participants reported negative changes in their relation to life and death.
Conclusions: The results depict a concrete profile of the severity of the suffering and suicidality in these patients. The mixed-methods design reveals a major group that does not report any change and

suffers greatly, but also a minor group that reports positive changes and even lowered suicidality. Clinical implications for psychiatric healthcare professionals will be discussed.

Differences in stigmatizing attitudes towards people with mental illness between psychiatry trainees and Family Medicine trainees: A comparative study

M. K. Khamassi[1,2]*, B. N. Saguem[1,2], A. Rhouma[1,2] and J. Nakhli[1,2]

[1]Department of psychiatry, Farhat hached hospital and [2]Research Laboratory LR12ES04, University Of Sousse, Faculty Of Medecine Of Sousse, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.875

Introduction: Mental illness stigma continues to be a significant challenge in healthcare. Trainees in different medical fields may have varying levels of exposure and understanding, which can shape their attitudes towards patients with mental health conditions.
Objectives: To examine differences in stigmatizing attitudes towards people with mental illness between Family Medicine trainees and psychiatry trainees.
Methods: A comparative study was conducted. Psychiatry trainees affiliated with the faculties of medicine in Tunisia (n=120) and Family Medicine trainees affiliated with the faculty of medicine of Sousse (n=206) were invited to respond to a survey comprising the Attribution Questionnaire (AQ-27), a measure that evaluates nine stigma factors, blame, pity, anger, help, dangerousness, fear, segregation, avoidance, and coercion. Higher scores indicated more endorsed stigma. Self-report measures of affirming attitudes were also used, including the Self-Determination Scale (SDS), the Empowerment Scale (ES), and the Recovery Scale (RS). Higher scores represent enhanced views of these concepts.
Results: In total, 94 psychiatry trainees and 66 Family Medicine trainees responded to the survey, with respective response rates of 78% and 32%. The two groups were comparable in terms of age, gender, family and personal psychiatric histories.
Family Medicine trainees reported significantly higher AQ-27 total scores (p=.042). Additionally, they reported significantly higher scores for blame (p=.025), dangerousness (p=.006), fear (p=.048), and segregation (p=.005) stigma factors.
No significant differences between the two samples were found in avoidance (p=.525), coercion (p=.379), pity (p=.741) and help (p=.092).
Concerning affirming attitudes, there were no significant differences between the two groups in SDS (p=.148), RS (p=.552), and ES (p=.727) scores.
Conclusions: Results revealed that psychiatry trainees endorse less stigmatizing attitudes towards patients with mental illness, particularly regarding the dangerousness of these patients. Nevertheless, they still endorse negative attitudes regarding the concept of recovery and affirming attitudes towards patients with mental illness. Anti-stigma interventions should promote not only increased contact but also other strategies that will promote believing in recovery and social inclusion.

Promotion of emotional competence in nurses who cares people in end of life: a continuous improvement project for mental health nursing care

C. Laranjeira[1,2]* and A. Argüelles[3]

[1]School of Health Sciences; [2]ciTechCare, Polytechnic Institute of Leiria, Leiria and [3]Medical-surgical specialty ward, Hospital Distrital de Santarém, Santarém, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.876

Introduction: The constant contact with death and dying processes increases the risk of mental suffering in nurses. The evidence suggests the need for training programs in the area of promoting emotional competence that allow the management of emotions and consequently the improvement of care for people at the end of life.
Objectives: Capacitate a group of nurses to promote emotional competence towards end-of-life patients, through a specialized intervention in Mental Health and Psychiatric Nursing; and evaluate attitudes and coping with death and levels of emotional competence [and respective capabilities], pre and post-intervention.
Methods: A continuous quality of care improvement project was carried out based on the Deming cycle, with pre and post intervention evaluation. The following instruments were applied: Veiga-Branco Emotional Competence Scale - Reduced (EVCE-reduced); Scale for Assessment of the Profile of Attitudes about Death; and, Coping with Death Scale. The training program consisted of seven in-person sessions, in groups, with approximation to the principles of psychoeducational intervention and based on the cognitive-behavioural sequence.
Results: Eleven nurses participate in program. Most of respondents were female (90%) aged between 26 and 50 years (M=36±7.98). Regarding the coping with death scale, it was possible to observe in the factor "coping with one's own death", after application of the program, an overall average of 73.38 (SD=4.21), verifying statistically significant differences between the pre- and post-intervention ($Z=1.963$, $p< 0.05$). It was also possible to observe an increase in the global score of EVCE-reduced (M=170.01; SD=20.88), accompanied by a slight increase in capabilities: self-awareness (M=45.88; SD=4.64) and empathy (M=28.13; SD=3.44). Regarding the scale referring to the profile of attitudes towards death, there was an increase in the attitude of acceptance by approach (M=44.00; SD=12.22). On the contrary, there was a decrease in the fear attitude (M=24.63; SD=9.61), in the avoidance attitude (M=11.25; SD=4.49) and the attitude of acceptance as an escape (M=14.25; SD=4.50), compared to pre-intervention values.
Conclusions: Our findings indicate that there is an integration of death as a natural event and an integral part of life. On the other hand, adequate management of fear of death and a non-avoidance attitude contribute to more compassionate care, and therefore more centered on the person at the end of life. Besides, this study allow us to confirm the importance of training programs in socio-emotional regulation, as they focus on the mobilization of intra and

interpersonal resources, as well as the expressiveness of emotions in the face of one's own death and the death of others, enabling the development of deeper levels of introspection.

"Postnatal" Outpatient Program for Postpartum Women at the University Psychiatric Hospital Vrapce, Zagreb

S. Martic-Biocina[1]

[1]Department of Social Psychiatry, Psychiatric Clinic Vrapce, Zagreb, Croatia
doi: 10.1192/j.eurpsy.2025.877

Introduction: Postpartum mental health challenges are common, with some women experiencing anxiety, depressive symptoms, or difficulties related to childcare and familial support. To address these issues, the University Psychiatric Hospital Vrapče in Zagreb, Croatia, launched the "Postnatal" outpatient program in 2023, offering structured support for women in the postpartum period.
Objectives: The objective of the program is to provide psychological support for women with children aged 0–2 years through a combination of online and in-person group therapy, to address postpartum mental health issues and provide a supportive environment.
Methods: The program is promoted through the clinic's website, social media, maternity hospitals, pediatric centers, and visiting nurse services. Women join the program through self-referral or on the recommendation of healthcare professionals. A team of three psychiatrists conduct an initial assessment, and approximately 80% of those evaluated are admitted into the program. The program comprises two 90-minute weekly sessions: an online educational workshop and an in-person group therapy session. Each cycle lasts for 8 weeks, followed by monthly 90-minute in-person group meetings.
Results: A total of 45 participants have completed the program so far. About 30% of participants met the clinical criteria for anxiety or depressive disorders, while there were two cases of postpartum psychosis. The majority reported non-specific concerns, such as tension, insomnia, fatigue, and emotional instability. Around 30% indicated a lack of support from their partners, and 10% had pre-existing psychological diagnoses (including OCD, borderline personality disorder, and anxiety-depressive disorder). Most participants were first-time mothers, with around 10% being second or third-time mothers. In the program, participants share experiences related to conception, pregnancy, maternity hospital stays, postpartum mental health changes, and the challenges of maternal care. Participation rates have been consistently high, with only one dropout. Post-program evaluations show a high level of satisfaction, with participants highlighting the group meetings and peer support as the most valuable aspects.
Conclusions: The "Postnatal" program has demonstrated positive outcomes in providing support to postpartum women. The combination of educational workshops and group therapy has been effective in addressing both clinical and non-specific postpartum challenges. Further cycles and long-term follow-ups are recommended to evaluate the program's sustained impact.

Examining the impact of loneliness and resilience on mental health: Empirical evidence from a nationally representative sample of American college students

P. J. Sullivan[1], J. Ruiz-Menjivar[1], X. Zhang[1], B. R. Carr[2]* and M. Abraczinskas[1]

[1]Department of Family, Youth and Community Sciences and [2]Department of Psychiatry / Anesthesiology, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.878

Introduction: Mental health disorders, including anxiety and major depressive disorder, are highly prevalent among college students, often leading to significant impairments in academic functioning and psychosocial well-being. Loneliness, characterized as subjective distress arising from a perceived deficit in social connectivity, is frequently associated with the exacerbation of psychiatric symptoms. In contrast, psychological resilience, defined as the capacity to adaptively manage stress and adversity, is increasingly recognized as a key protective factor against the development of psychopathology.
Objectives: Despite understanding the roles of loneliness and resilience, their combined effects on mental health, specifically anxiety and depression, have not been fully explored in a large-scale, diverse population of college students in the United States. This study seeks to address this gap.
Methods: Using data from the 2023-2024 Healthy Mind Study (N=104,729), we employed logistic regression to assess the predictors of anxiety and depression, focusing on two key predictors: loneliness and resilience. Our models also controlled for other relevant factors, such as campus climate, financial stress, and sociodemographic control variables, including sex, race/ethnicity, and traditional student status. Analysis was conducted with a sample delimited to undergraduate students (n=22,927).
Results: Feeling lonely was positively related to moderate-to-severe depression ($\beta = 2$, $p < 0.001$) and moderate-to-severe anxiety ($\beta = 1.45$, $p < 0.001$). Resilience was a protective factor and was negatively associated with self-reported moderate-to-severe depression ($\beta = -1.54$, $p < 0.001$) and moderate-to-severe anxiety ($\beta = -1.54$, $p < 0.001$). The effect of loneliness and resilience on depression and anxiety remains consistent with the baseline models after controlling for campus climate, financial stress, and sociodemographic variables. High levels of financial stress and perceived poor campus climate were positively related to moderate-to-severe depression and anxiety. Finally, female, non-White, and non-traditional-aged students were less likely to exhibit moderate-to-severe depression and anxiety.
Conclusions: The findings highlight the importance of loneliness and resilience in shaping mental health outcomes among undergraduate college students. Loneliness was negatively associated with

the evaluated mental health burdens, while resilience emerged as a protective factor against these outcomes. Our findings underscore the importance of considering loneliness, resilience, financial stress, and campus climate as variables of interest when designing mental health interventions to improve academic performance and overall well-being among undergraduate college students.

Faster rhythmic auditory stimulation induced less severe movement abnormalities in people with psychotic-like experiences

S.-M. Wang[1]*, L.-C. Kuo[2,3,4] and H.-M. Hsu[5]

[1]Department of Long-Term Care, National Taipei University of Nursing and Health Sciences, Taipei; [2]Department of Occupational Therapy; [3]Medical Device Innovation Center; [4]Institute of Allied Health Sciences, National Cheng Kung University, Tainan and [5]Point Robotics Medtech Incorporation, Taipei, Taiwan, Province of China

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.879

Introduction: People with psychotic-like experiences (PLE) have slow movements and uncontrolled movements, which are indicative of transition to psychotic disorders afterwards. Earlier research has reported that rhythmic auditory stimulation (RAS) is a promising therapeutic technique for movement abnormalities in people in the psychosis continuum. However, the small sample size was a major limitation in earlier research and restricted result generalizability.
Objectives: This study was to increase the sample size and examine if faster RAS induced faster movements and less uncontrolled movements at both hands in people with PLE.
Methods: A total of 55 right-handed people with PLE (age: 20.51 ±2.50 years; 28 females) and 55 age- and gender-matched right-handed healthy controls (age: 20.53±3.10 years; 24 females) were recruited. Participants used the index finger to perform the alternate touching task for each hand when the motion capture system recorded the movement procedure. They were required to follow each beat of RAS with the normal tempo (100% of the fastest movement tempo without RAS) and the fast tempo (110% of the fastest movement tempo), the order of which was counterbalanced, when performing the alternate touching task. Kinematic variables were calculated to reflect severity of slow movements and uncontrolled movements in participants.
Results: Two-way analysis of variance showed no interaction between groups and RAS in right-hand and left-hand kinematic values. People with PLE had slow movements at both hands and uncontrolled movements at the right hand. Faster RAS induced faster movements and less uncontrolled movements at both hands in people with PLE.
Conclusions: The major contribution of this study was to use a relatively large sample size to demonstrate effectiveness of faster RAS on inducing faster movements and less uncontrolled movements at both hands in people with PLE and thus increase result generalizability. Given that movement abnormalities are initial signs in the psychosis continuum and risk factors of transition to psychotic disorders, when healthcare practitioners design early intervention for movement problems in people with PLE, incorporating RAS in therapy is suggested.

Associations of working experience as public health physicians allocated in the rural area and mental health in young general practitioners

J.-Y. Yun[1,2]

[1]Department of Psychiatry, Seoul National University Hospital and [2]Yeongeon Student Support Center, Seoul National University College of Medicine, Seoul, Korea, Republic Of

doi: 10.1192/j.eurpsy.2025.880

Introduction: Young general practitioners allocated in the rural area sustain the community healthcare frontline and endure the limited medical resources and social supports. Physician mental health could affect the quality of healthcare.
Objectives: We examined the association of work-related experience with mental health in young public health physicians in the rural area.
Methods: Study promotional document was posted on the Korean Association of Public Health Doctors (PHD) website (http://kaphd.org) on July 2023. Three-hundred PHD (among the total 1,256 PHD) completed a web-based self-reported questionnaire on demographics, working experiences, and mental health on a first-come, first-served basis. Adjusted odds ratios(aOR) of depression, anxiety, lower self-esteem, and distress for working experiences in PHD were calculated in the multivariable logistic regression model with the best fit combinations of significant explanatory variables ($P<0.05$) in univariate logistic regression.
Results: Distress, depression, anxiety, and lower self-esteem were reported by 39.7%, 25.3%, 11.3%, and 8.7% of the PHDs, respectively. Higher odds of worse mental health in PHD were associated with patient-physician conflicts at workplace, isolated residence from local facilities, and higher workload. Conversely, perceived expertise utilization and social connections with peers were related to the lower odds of worse mental health in PHD.
Conclusions: This study highlights the needs of governmental policy targeting the young general practitioners in rural area to enhance the expertise utilization and social connectedness, and to reduce the patient-physician conflict.

Dementia with Lewy bodies: a review of disease-modifying therapies for α-synucleinopathies

A. Dar[1]* and S. Bhattacharyya[2]

[1]Hull York Medical School, York and [2]Faculty of Old Age Psychiatry, Wales, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.881

Introduction: Neurodegenerative disease prevalence is high in the elderly, as aged brains accumulate molecular and cellular damage.

Protein misfolding and aggregation are pathological processes underlying neurodegeneration, as seen in dementia. This coupled with oxidative stress, disrupted ubiquitin-proteosome system and neuroinflammation may contribute to neuronal damage. Lewy body dementia (LBD) collectively refers to Parkinson's disease (PD), Parkinson-disease dementia and dementia with Lewy bodies (DLB) (Delenclos, Moussaud, & McLean, 2017). It is characterised by Lewy body (LB) deposits in the CNS, predominantly compromised of misfolded α-synuclein protein. Disease-modifying therapy (DMT) targets underlying protein misfolding and promotes LB clearance.

Objectives:

- To review international trial data on DMT safety, tolerability and efficacy in DLB.
- To consider molecular basis for protein misfolding and DMT in DLB.

Methods: Two international registries (ClinicalTrials.gov; EU clinical trials register) were consulted to identify agents being tested in completed, ongoing and recruiting trials. Both databases were searched by disease "Lewy body dementia" or "LBD" or "alpha-synuclein pathology" and study type "interventional" for phase I-III trials. Trials solely investigating diagnostic biomarkers, approved symptomatic DLB treatment or PD without dementia symptoms were excluded from final analysis.

Results: 11 trials were found studying DMTs for DLB. 10 out of the 11 trials were in phase II and one in phase I. The main agents investigated were tyrosine-kinase inhibitors (TKIs), phosphodiesterase-9 inhibitors, β-adrenergic agonists, and β-GCase chaperones. Primary and secondary outcome measures were "safety/tolerability of agent", "changes in cognitive function" or "changes in serum/CSF α-synuclein". Results from a phase I trial demonstrated a 3.85 and 3.5-point increase in mini-mental state examination scores at 6 months with nilotinib doses 300mg and 150mg, respectively (Pagan *et al.,* 2016). Slight reduction was observed in CSF/plasma α-synuclein levels. Phase II trials for bosutinib versus placebo showed no significant difference in cognitive function (Pagan *et al.,* 2022). Ambroxol trials, a β-GCase enzyme enhancing inhibitory chaperone, remain in recruiting stages but have proven drug tolerability. Data on CSF biomarker changes in DLB was unavailable.

Conclusions: Current understanding of protein misfolding in α-synucleinopathies suggests that a single DMT may be insufficient in mixed pathology. Cocktail therapy targeting various misfolded proteins may be necessary for a cure. DMTs have limited use as most patients are diagnosed with advanced DLB. Sensitive diagnostic biomarkers with high specificity are required for accurate DLB diagnosis in the prodromal phase, a critical window for protein misfolding reversal with DMT. TKI cardiotoxicity may also limit clinical use of this DMT, especially in the elderly.

Elderly patients in psychiatry: Evolution and social challenges after a first hospitalization at an advanced age

D. Mezri[1]*, A. Gharbia[1], S. Hamzaoui[1], R. Hosni[1], U. Ouali[1], A. Aissa[1] and R. Jomli[1]

[1]Avicenne, Razi, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.882

Introduction: Due to longer life expectancies, improvements in psychiatry, and reduced stigma about mental health in Tunisia, we are seeing more elderly people hospitalized for the first time in our department. Caring for this group presents both social and clinical challenges. While we are getting better at handling the clinical aspects, we often forget the social factors, which are crucial for the progress, follow-up, and mental well-being of older patients. These social issues can also lead to relapses or new mental health problems in this population.

Objectives: Determine the evolution of elderly patients hospitalized for the first time in the psychiatric department.

Methods: This is a retrospective study. We examined the records of all patients aged over 65 who were admitted to the Avicenne Psychiatric Department at Razi Hospital from September 2022 to September 2024.

Results: A total of 22 patients were identified, including 16 men and 6 women. The average age of these patients was 68 years, with ages ranging from 64 to 80 years. The majority came from an urban background (81%). The educational level of our patients was primary at 19%, an university level at 34% and a secondary school education at 47%. Among our patients, 13% are still professionally active and 57% retired. The socioeconomic level of our patients was affluent in 42%, average in 34%, and low in 24%. Within our patient population, 61% were married, 24% divorced, 10% were single and 4% widow or widower. 23% of our patients were living alone and 77% were living with one or more family members. Concerning the diagnosis, we observed mental confusion caused by an organic pathology in 9%, a purely neurological cause of the disorder in 14% (dementia in 10% and Parkinson's disease in 4%), a depressive episode in 31%, a manic episode within the context of bipolar disorder in 37%, and schizophrenia in 9%. During hospitalization, 27% of the patients experienced family rejection from their relatives. After leaving the hospital, a significant number of patients were lost to follow-up (63%), 22% had regular follow-up and 13% attended appointments irregularly.

Conclusions: This study shows that more elderly patients are being hospitalized for the first time in psychiatry. Many face social challenges, such as family rejection and losing contact after leaving the hospital.The creation of retirement homes and social support systems may be a solution to provide safe living and support for these patients, helping them stay healthy and connected after hospitalization.

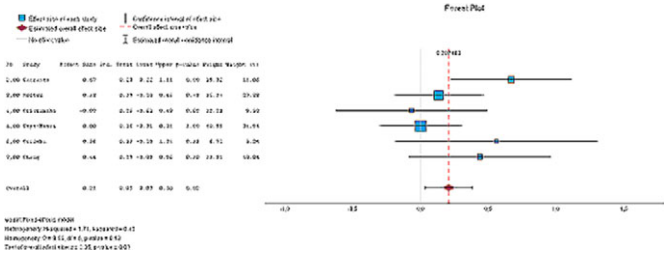
The Effectiveness of Multi-Component Support Programs for Alzheimer's Caregivers on Burden: A Systematic Review and Meta-Analysis



B. Şentürk Kiliç[1]*, D. Hiçdurmaz[1] and S. Karahan[2]

[1]Faculty of Nursing and [2]Faculty of Medicine/Biostatistics, Hacettepe University, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.883

Introduction: Alzheimer's disease, necessitates continuous, long-term care primarily provided by family members. As the disease progresses, caregivers experience increasing stress and burden. Research indicates that caregivers of Alzheimer's patients are at higher risk for depression, social isolation, and health problems. In order to help the caregivers, multi-component support programs, which integrate approaches such as education, psychoeducation, and social support, have shown more positive outcomes. However, systematic reviews and meta-analyses examining the impact of these programs remain limited.

Objectives: This systematic review and meta-analysis aimed to evaluate the effectiveness of multi-component support programs on the caregiver burden of individuals caring for Alzheimer's patients.
Methods: The research was conducted through searches in five databases (CENTRAL, CINAHL, PsycINFO, PubMed, WOS), focusing on randomized controlled trials that met the inclusion criteria. Two researchers independently evaluated the full texts, assessing risk of bias with the Cochrane 'Risk of Bias-2' tool and evidence quality using the GRADE tool. Participants included individuals aged 18 and older who were the primary caregivers for those diagnosed with Alzheimer's disease and had provided care for at least three months. The intervention included at least two types of support, such as skill training, education, counseling, or therapy. The primary outcome was caregiver burden.
Results: The review included 8 studies overall. Among the 1147 participants, only one study was web-based, while the other seven interventions were conducted face-to-face. The components of the interventions were mainly educational, supportive, and skill-building, with only one intervention including respite care. Overall risk of bias assessment recorded one study with high risk, four with unclear risk, and one with low risk. The effect sizes of the interventions were calculated based on the means and standard deviations of caregiver burden scores before and after the intervention, as well as follow-up measurements. The multi-component intervention programs were found to have an uncertain short-term effect (Cohen's d = 0.12; 95% CI: -0.06 - 0.29; p = 0.39) but were effective in the long term (Cohen's d = 0.21; 95% CI: 0.03 - 0.38; p = 0.02). The certainty of evidence for caregiver burden outcomes was determined to be low before the intervention and follow-up, and very low from pre-intervention to post-intervention measurements. The data is current as of 12/12/2023.

Sexuality in the Elderly: Challenges and Opportunities

F. G. Tavares[1]*, B. C. Araújo[1], B. T. Wildenberg[2], P. M. Esteves[2], L. Carrasqueira[3], J. A. Brás[2] and M. Coroa[2]

[1]Psychiatry, ULS Algarve, Faro; [2]Psychiatry, ULS Coimbra, Coimbra and [3]Psychiatry, ULS Região Leiria, Leiria, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.884

Introduction: Sexuality in the elderly has become an increasingly important topic in healthcare as the global population continues to age, raising new challenges and considerations related to the quality of life and well-being of older adults.
Objectives: This work aims to explore the barriers faced by the elderly regarding sexuality and propose strategies for promoting healthy and fulfilling sexuality at this stage of life.
Methods: A narrative review was employed on the topic, aiming to broadly and exploratorily understand the main aspects related to sexuality in the elderly population.
Results: Recent studies suggest that sexual activity can remain an important part of life for older individuals, positively influencing both mental and physical health. The main obstacles to healthy sexuality in old age can be broadly categorized into physiological, psychological, and sociocultural factors. **Physiological changes** include a natural decline in hormone levels, such as estrogen in women and testosterone in men, leading to reduced libido, vaginal dryness, and erectile dysfunction. Chronic illnesses like cardiovascular disease, diabetes, and arthritis, along with medications for these conditions, can further impact sexual function. **Psychological factors**, such as anxiety, depression, and reduced self-esteem due to aging-related body changes, also play a significant role in diminishing sexual desire and activity. **Sociocultural factors** include long-standing societal taboos around older adults and sexuality, which can lead to embarrassment, reluctance to discuss sexual health issues, and feelings of shame. Healthcare professionals can adopt several strategies to improve sexuality in aging such as o**pen communication.** Regular sexual health assessments should be integrated into routine care, including questions about sexual function, relationship satisfaction, and any challenges faced. **Medical interventions**, such as hormone replacement therapy or treatments for erectile dysfunction can address physiological barriers. **Psychosocial support** can improve communication, body image issues, and mental health factors like anxiety or depression that often accompany aging.
Conclusions: The approach to sexuality in the elderly should be multifaceted, integrating biopsychosocial perspectives, with an emphasis on promoting sexual education and providing appropriate treatments that address individual challenges. Healthcare professionals shouldadopt a welcoming and open attitude, encouraging dialogue on this topic to improve the quality of life of older adults.

Cluster analysis of aging and sexual well-being: Insights from Portuguese and Spanish older adults

S. von Humboldt[1]*, E. Cabras[2], G. Low[3] and I. Leal[1]

[1]William James Center for Research, ISPA – Instituto Universitário, Lisbon, Portugal; [2]Department of Education, Universidad Alfonso X el Sabio, Madrid, Spain and [3]Faculty of Nursing, University of Alberta, Edmonton, AB, Canada
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.885

Introduction: Aging well in a cross-cultural perspective may encompass pertinent challenges in terms of adjustment, sexual well-being and satisfaction with life in the late years.
Objectives: Considering the paucity of empirical data concerning cultural diversity of experiencing aging, this study aims to help fill this gap by assessing the specific patterns of sexual satisfaction,

adjustment to aging (AtA), and life satisfaction with life (SwL) of older adults in Portugal and Spain.
Methods: This cross-national study included 443 older adults, aged 65 and older, from Portugal and Spain. Five instruments were applied: (a) Adjustment to Aging Scale (ATAS); (b) Satisfaction with Life Scale (SwLS); (c) New Sexual Satisfaction Scale - Short (NSSS-S); (d) Mini-Mental State Exam; and (e) Sociodemographic, health and lifestyle questionnaire. K-means cluster analysis was employed to identify and characterize the clusters considering adjustment to aging, sexual satisfaction and life satisfaction. One-way ANOVAs were conducted to analyze differences for sexual-well-being among clusters.
Results: Findings indicated three clusters, which explained 79.3% (*R-sq* = 0.793) of the total variance: Cluster #1: "Well Adapted" (*n* = 37, 8.8%), Cluster #2: "Struggling to Adapt" (*n* = 141, 31.8%), and Cluster #3: "Active Agers" (*n* = 265, 59.8%). Participants in Cluster #1 were mostly Portuguese, with high levels of AtA, sexual satisfaction, and SWL. Conversely, Cluster #2 integrated mostly Portuguese participants with moderate sexual satisfaction, and lower levels of AtA and SwL. Participants from Cluster #3 were mostly Spanish with moderate levels of AtA and reduced sexual satisfaction and SwL.
Conclusions: This study innovates by exploring the elaborate interplay among sexual satisfaction, AtA, and SwL in a cross-cultural perspective, with implications for tailoring interventions, service planning, development and evaluation of culturally-diverse older populations.
Keywords: Adjustment to aging; cluster analysis; older adults; satisfaction with life; sexual satisfaction.

Noninvasive Neuromodulation Therapies: The Cure For Depression?

R. P. L. Andrade[1]*, V. H. Santos[2], N. Castro[1], I. Santos[1], F. Cunha[1], E. Almeida[1], J. Abreu[1] and H. Afonso[1]

[1]ULS Viseu Dão-Lafões, Viseu and [2]ULS Cova da Beira, Covilhã, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.886

Introduction: Depressive disorder is a common mental disorder, with an estimated 3.8% of the population experiencing it. Despite the advent of new antidepressant medication, many patients presenting with Major Depressive Disorder (MDD) do not recover after multiple trials. Although the prevalence of treatment-resistant depression (TRD) is not clear due to the lack of a standard definition, its prevalence ranges from approximately 30 to 70 percent.
Objectives: Considering the high prevalence of treatment-resistant depression, this work aims to evaluate the effectiveness of alternative treatments, namely Noninvasive Neuromodulation Therapies in the treatment of MDD.
Methods: Non-systematic literature review, using Pubmed as database, with the keywords "depression treatment", "neuromodulation" and "noninvasive neuromodulation".
Results: We can divide non-invasive neuromodulation into convulsive therapies (CV) and therapies that do not involve inducing a seizure. Additionally, we can also divide them into clinically available therapies and others only available in investigational settings. Regarding clinically available CV, we have Electroconvulsive Therapy (ECT), the oldest neurostimulation procedure. Being heavily studied, ECT is superior to pharmacotherapy for MDD based upon meta-analyses of randomized trials and is generally considered the most efficacious treatment for depression, albeit recurrence following remission is common.
Other CV, but still in investigational stages, are Magnetic seizure therapy (MST) and Focal electrically administered seizure therapy (FEAST) both showing positive results in prospective studies and MST in a small head-to-head randomized trials with ECT, that showed a similar efficacy between these two therapies.
Other clinically available, but not convulsive therapies, are Repetitive Transcranial Magnetic Stimulation (rTMS) and Cranial Electrical Stimulation (CES). Meta-analyses of randomized trials indicate that rTMS is beneficial for treating TRD, being also approved by the FDA. In its turn, multiple reviews indicate that no high-quality studies have demonstrated that CES is efficacious for MDD or TRD.
Additional non-convulsive therapies, available in investigational settings, include Transcranial Direct Current Stimulation, Transcranial Low Voltage Pulsed Electromagnetic Fields, Trigeminal Nerve Stimulation, Low Field Magnetic Stimulation and Transcutaneous Vagus Nerve Stimulation, with all of them showing positive effects in the treatment of MDD or TRD, except for Low field magnetic stimulation.
Conclusions: With this review, we were able to verify that clinically available non-invasive neurodomulation therapies, such as ECT and rTMS, present robust results in the treatment of MDD and TRD, however, resistance to these therapies also exists.
Considering the positive results of multiple novelty therapies, these could be the solution to this scourge.

Comparative Analysis of Postictal Delirium Following ECT and Post-Anesthesia Delirium

B. Cipion[1]*, P. A. White[2] and B. R. Carr[3]

[1]College of Medicine; [2]Anesthesiology and [3]Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.887

Introduction: Postictal delirium (PD) following Electroconvulsive Therapy (ECT) and Post-Anesthesia Delirium (PAD) are significant postoperative cognitive disturbances often encountered in the post-anesthesia care unit (PACU). While both manifest with cognitive impairments, their etiologies, clinical features, and management strategies differ. Recognizing these distinctions is essential to enhance patient care and outcomes, particularly in critical recovery settings where prompt recognition and intervention are paramount.
Objectives: This study compares delirium's onset, duration, and course following ECT-induced seizures and general anesthesia. It aims to elucidate the clinical features of PD and PAD and offer evidence-based recommendations for distinguishing and managing these conditions in the perioperative setting.

Methods: A comprehensive literature review was conducted, focusing on studies from 2000 to 2023 sourced from PubMed, MEDLINE, and Cochrane Library. Search terms included "postictal delirium," "Electroconvulsive Therapy," "post-anesthesia delirium," and "perioperative cognitive disorders." Key variables analyzed included onset, duration, cognitive and behavioral symptoms, associated risk factors, and treatment protocols for both conditions.
Results: The analysis revealed key differences between PD and PAD. PD generally presents immediately after ECT and resolves within minutes to hours, whereas PAD has variable onset, occurring immediately after surgery or several days later, with symptoms lasting hours to days. Cognitive symptoms also differ. PD is characterized by brief confusion and both anterograde and retrograde amnesia, while PAD presents with prolonged confusion, disorientation, and short-term memory impairment. Behaviorally, PD often involves repetitive, patterned, involuntary movements (stereotypies), such as hand flapping and rocking, whereas PAD is characterized by non-patterned agitation, including both voluntary and involuntary movements. PD typically includes fatigue and altered consciousness, while PAD may present with hallucinations, delusions, and significant sleep disturbances. Risk factors for these syndromes also vary. PD is linked to the intensity of the ECT stimulus and pre-existing neurological conditions, while PAD is influenced by factors such as patient age, type of surgery, anesthesia duration, and baseline cognitive status.
Conclusions: PD and PAD share clinical overlap, particularly in cognitive symptoms, but they differ in onset, duration, behavioral patterns, and associated risk factors. PD following ECT is typically brief and marked by stereotyped movements, while PAD presents with prolonged confusion and non-patterned agitation. Accurate differentiation between these conditions is crucial for appropriate diagnosis and management in the PACU setting. Further research is needed to uncover the underlying mechanisms and enhance therapeutic strategies for these syndromes.

Effect of intermittent theta-burst stimulation on chronobiological hypothalamic-pituitary-thyroid axis activity in resistant depressed patients

F. Duval[1]*, M.-C. Mokrani[1], V. Danila[1], T. Weiss[1], F. Gonzalez Lopera[1] and M. I. Tomsa[1]

[1]Psychiatry, Centre Hospitalier, Rouffach, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.888

Introduction: So far, the effects of intermittent theta-burst stimulation (iTBS) treatment—a form of repetitive transcranial magnetic stimulation (rTMS) technique—on the hypothalamic-pituitary-thyroid (HPT) axis activity are poorly understood. In depression, and especially in treatment resistant depressed patients (TRDs), this axis is often dysregulated. We have previously demonstrated that the difference between the 23:00 h and 08:00 h thyrotropin (TSH) response to protirelin (TRH) tests on the same day (ΔΔTSH test) is a very sensitive chronobiological index since it is reduced in about three quarters of major depressed inpatients.
Objectives: The present study aimed at assessing the effects of iTBS treatment applied to the left dorsolateral prefrontal cortex (LDPFC) in hospitalized TRDs (defined as having at least 2 treatment failures) with abnormal chronobiological HPT functioning at baseline (BL).
Methods: The ΔΔTSH test was performed in 18 TRDs and 18 matched healthy hospitalized control subjects (HCs). To be enrolled in this study, patients had to show at BL reduced ΔΔTSH values (i.e., < 2.5 mU/L) and a score of 18 or greater on the 17-item Hamilton Rating Scale for Depression (HAMD-17). All included TRDs were treated with antidepressants at the time of hospital admission. Drug dosages remained unchanged over the past month and kept stable throughout the course of iTBS. The ΔΔTSH test was repeated in all inpatients after 20 iTBS sessions (single daily session for 5 days of the week). Clinical response was defined as a reduction in HAMD-17 total score > 50% from BL and a final HAMD-17 score ≤ 8.
Results: Compared to HCs, ΔΔTSH values were lower in TRDs at BL ($p < 0.00001$ by U test). After 20 iTBS sessions, HAM-D scores decreased ($p = 0.001$ by T-test) and ΔΔ TSH values increased ($p = 0.01$ by T-test) compared to BL, although endpoint ΔΔTSH values remained lower than those of HCs ($p = 0.02$ by T-test). However, there was a relationship between the reduction in HAM-D scores from BL to endpoint and the increase in ΔΔTSH values (rho = - 0.54; $n = 18$; $p = 0.02$). At endpoint, 10 patients (55%) showed ΔΔTSH normalization (among them 8 [80%] were responders), while 8 patients (45%) did not normalize their ΔΔTSH (all were non-remitters) ($p = 0.001$ by Fisher Exact test).
Conclusions: Although the underlying mechanisms remain to be elucidated, the results of our present pilot study in TRDs suggest that successful iTBS treatment can restore a normal chronobiological activity of the HPT axis and vice versa.

ECT in Huntington's Psychosis - an unexplored therapeutic option

N. Ramalho[1]*, T. Rocha[1], J. F. Cunha[1], J. C. Moura[1], J. Leal[1], D. Seabra[1], I. Lopes[1], G. Santos[1], M. Rosa[1] and A. Garcia[1]

[1]Psychiatric and Mental Health Department, ULSAR, Barreiro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.889

Introduction: Huntington's disease (HD) is a progressive neurodegenerative disorder characterized by motor dysfunction, cognitive decline, and psychiatric symptoms. Among these psychiatric manifestations, psychosis occurs in a subset of patients, presenting significant challenges for both diagnosis and treatment. While pharmacological interventions, such as antipsychotics, are commonly used to manage psychosis in HD, they often come with limited efficacy and a high risk of adverse effects. Electroconvulsive therapy (ECT), traditionally employed in the treatment of severe mood disorders and treatment-resistant psychosis, has garnered minimal attention as a therapeutic option for psychosis associated with HD. This is proven by the absence of literature focusing specifically on the use of ECT for treatment of Huntington's Psychosis. This underexplored avenue holds potential, given ECT's neuroplastic and neurochemical effects, which may counteract the neurodegenerative processes seen in HD. Exploring the efficacy of ECT in HD-associated psychosis could not only provide symptom relief but also offer insights into the broader neuropsychiatric management of the disease.
Objectives: This review aims to highlight the therapeutic potential of ECT as a novel intervention in Huntington's psychosis, addressing the current gap in clinical research and therapeutic strategies.

Methods: A non-systematic review of the published literature using the PubMed/MEDLINE database with the MESH terms "huntington," "psychosis" and "ECT" was made. The articles were selected according to relevance.
Results: There were found 14 relevant publications that adress the use of ECT in HD. 11 of them were case reports and 3 were case series. Most of the studies show good results from the use of ECT in HD. There was improvement in several areas of the patient's mental state, namely depressive symptoms, irritability, psychotic symptoms and psychomotor agitation.
Few case studies reported worsening of the clinical picture, namely aggravation of the catatonic symptoms or cognitive impairment.
Conclusions: The limited but promising evidence from case reports and case series suggests that ECT may be an effective therapeutic intervention for addressing psychiatric symptoms, including psychosis, in patients with Huntington's disease. The majority of studies demonstrate positive outcomes. However, the findings are not universally positive, with a few reports noting potential worsening some symptoms. Given the complexity of managing psychiatric symptoms in HD, ECT presents itself as a valuable treatment option, particularly when pharmacological approaches prove ineffective or poorly tolerated. Nonetheless, the absence of larger, controlled studies on ECT for HD psychosis underscores the need for further research to validate its safety and efficacy.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.890

Introduction: The present study aimed to investigate the causal relationships among cognitive impairment, psychopathology, and real-life functioning in a large sample of people with schizophrenia, using a data-driven causal discovery procedure based on partial ancestral graphs (PAGs).
Objectives: This method may provide additional insights for identifying potential targets of therapeutic interventions to promote recovery in people with chronic schizophrenia.
Methods: State-of-the-art instruments were used to assess the study variables. Two PAGs were generated at baseline and after 4 years of follow-up to explain the nature of the causal relationships linking psychopathology, cognition, and functioning.
Results: The study sample was composed of 612 clinically stable patients with schizophrenia at baseline and 602 at follow-up. The PAGs suggested that working memory deficit is the first ancestor of the causal links, influencing all the other neurocognitive domains, social cognition, and functional capacity, which in turn affects everyday life functioning. From this domain of functioning a causal link is directed to disorganization and positive symptoms, and another to work skills and interpersonal relationships domains; the latter had a direct link to asociality and the other domains of negative symptoms. The structure of the PAGs did not differ significantly between baseline and follow-up, indicating the stability of the causal relationships.
Conclusions: The role of working memory deficits in the pathways to functional outcomes in schizophrenia highlights the importance of implementing integrated pharmacological and cognitive remediation interventions targeting neurocognition. The impact of everyday life and interpersonal functioning on the clinical presentation of schizophrenia suggests that integrated and personalized treatments, promoting relevant skills to improve these functional outcomes, may have a beneficial impact on clinical outcomes.

The association of antipsychotic treatment and side effects with societal recovery and happiness: A naturalistic cohort study of people in long term care for a psychotic disorder

S. Crutzen[1]*, S. Gangadin[2], K. H. Hua[3], W. Veling[4] and S. Castelein[1,5]

[1]Lentis Research, Lentis; [2]Rob Giel Research Center, University Medical Center Groningen, Groningen; [3]Apotheek Spaarne Gasthuis, Spaarne Gasthuis, Haarlem; [4]Psychosis Department, University Medical Center Groningen and [5]Faculty of Behavioural and Social Sciences, University of Groningen, Groningen, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.891

Introduction: Antipsychotics are used to manage psychotic symptoms and reduce the risk of relapse. However, the side effects associated with antipsychotic treatment are seen to hinder societal recovery and happiness by antipsychotic users.
Objectives: In this study, we investigate the association of side effects, antipsychotic dose and antipsychotic polypharmacy with societal recovery and happiness.
Methods: Data from a naturalistic longitudinal cohort was used (PHAMOUS, 2013-2021; n> 3000). Mixed effect linear regression models were used to investigate the association between subjective side effect burden, antipsychotic dose and antipsychotic polypharmacy with societal functioning and happiness. Moreover, the association of single antipsychotic side effects with societal recovery and happiness were investigated with mixed effect linear regression models.
Results: The subjective antipsychotic side effect burden and total antipsychotic dose were both negatively associated with societal recovery and happiness. Polypharmacy was additionally negatively related to societal recovery. Cognition, mood and anticholinergic side effects were most strongly associated with societal functioning.

Mood, sedation, cognitive, and sexual related side effect were most strongly associated with happiness.
Conclusions: The association between side effects and the antipsychotic dose and societal functioning and happiness in this population in long term care shows the importance of addressing overtreatment at an early stage. Future research should focus on whether addressing side effects, especially mood and cognition related side effects, is beneficial for societal recovery and happiness in the long-term.

Improvements in brain mechanisms associated with the aberrant salience hypothesis of psychosis following Avatar therapy for refractory auditory verbal hallucinations

A. Fortier[1,2]*, A. Dumais[1,2,3] and S. Potvin[1,2]

[1]Département de psychiatrie et d'addictologie, Université de Montréal; [2]Centre de Recherche de l'Institut Universitaire en Santé Mentale de Montréal and [3]Institut National de Psychiatrie Légale Philippe-Pinel, Montréal, Canada
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.892

Introduction: Nearly 40% of individuals with schizophrenia are resistant to medication. Treatment-resistant schizophrenia leads to increased health-risk behaviors and reduced quality of life. Avatar therapy *via* virtual reality seems to be a very promising solution for individuals with treatment-resistant schizophrenia. This therapy targets refractory auditory verbal hallucinations, one of the core positive symptoms of schizophrenia. This symptom is thought to reflect a direct experience of the aberrant salience of internal representations according to the aberrant salience hypothesis of psychosis. Strong evidence suggests that the striatum plays an important role in the development of positive symptoms, as individuals with schizophrenia show an increased activation of this brain region at rest. One of the mechanisms underlying Avatar therapy may involve a reduction in aberrant salience. However, the neural processes involved in this therapeutic approach remain largely unexplored.
Objectives: This study aims to investigate the brain mechanisms underlying Avatar therapy in treatment-resistant schizophrenia by examining spontaneous brain activity at rest using functional magnetic resonance imaging (fMRI).
Methods: Fourteen participants with treatment-resistant schizophrenia participated in nine sessions of Avatar therapy. They underwent resting-state fMRI scans before and after the therapy. Voxel-wise analyses of fractional amplitude of low-frequency fluctuations (fALFF) were performed to examine differences between post- and pre-therapy in regional patterns of spontaneous brain activity.
Results: Importantly, after the therapy compared to before the therapy, we found that participants with treatment-resistant schizophrenia had reduced fALFF in the right putamen. We also observed increased fALFF in the bilateral occipital, right inferior temporal, right angular gyrus, left medial temporal and left supramarginal gyri after the therapy.
Conclusions: The putamen is a part of the striatum which is known to play a significant role in the emergence of psychosis. Mainly, our results suggest that Avatar therapy regulates putamen activity at rest, suggesting that the neural mechanisms underlying the therapy involve the alleviation of aberrant salience.

The use of depot antipsychotics in patients with dual diagnosis of psychosis and substance use disorder is associated with improved quality of life, better general clinical outcome and fewer hospitalizations

E. I. Koiliari[1,2,3]*, I. Mouzas[1,2], G. I. Detorakis[1] and E. L. Pasparakis[1,2]

[1]Department of Psychiatry, General Hospital of Agios Nikolaos of Lasithi, Agios Nikolaos of Lasithi; [2]Department of Pathology, Laboratory of Alcohology of the Medical School of the University of Crete and [3]Department of Pathology, University General Hospital of Irakleion (PAGNI), Herakleion, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.893

Introduction: Co-occurring substance use disorders (SUDs) among individuals with schizophrenia are a prevalent and complex psychiatric comorbidity, which is associated with increased symptom severity, worsened illness trajectory and high rates of treatment non-adherence. Recent evidence suggests that the use of depot antipsychotics may provide an effective treatment option for individuals with this dual-diagnosis.
Objectives: Hypothesis testing: "Depot antipsychotics are associated with i) reduced hospitalizations, ii) improved quality of life and iii) improved patient functionality in dual diagnosis of psychosis and SUD".
Methods: 68 patients in community of Eastern Crete (Greece) participated (Male to Female ratio corresponds to 2.4:1). All of them manifested psychosis (24 with F.20 ICD-10 and 44 with F29.0 ICD-10). The median age was 41 years. 29.41% had dual diagnosis of psychosis and alcohol use disorders, 7.35% had dual diagnosis of psychosis and cocaine use disorders, while 26.47% had dual diagnosis of psychosis and cannabis Use disorder. 80.88% were on aripiprazole LAI, 8.82% on paliperidone LAI, 2.94 % on risperidone LAI and 7.35% on haloperidol LAI. For the evaluation of our hypotheses the instruments WHOQOL-BREF questionnaire and the CGI-S scale were used. The quality of life and the functionality of the patients and also the number of their hospitalizations were compared in each patient, before the initiation of the LAI medication and during the active treatment period. The minimum of follow-up period was 6 months.
Results: In our sample of 68 patients with depot antipsychotics therapy administrated at least for 6 months: a) Hospitalizations decreased statistically significantly from 1.01 ±1.54 to 0.01±0.12 (Paired Samples Wilcoxon Signed Rank Test p-value<<0.001), b) The CGI-S score decreased statistically significantly from 5.72 ±0.88 to 2.94±1.33 (Paired Samples Wilcoxon Signed Rank Test p-value<0.001), c) The score of the WHOQOL-BREF scale increased statistically significantly from 0.57 ±0.53, to 3.35±0.84 (Paired Samples Wilcoxon Signed Rank Test p-value<0.001). The same sample with depot antipsychotic treatment administrated at least for 3 months: a) The CGI-S score decreased statistically significantly from 5.72 ±0.88 to 2.34±0.89 (Paired Samples Wilcoxon Signed Rank Test p-value<0.001), b) The score of the WHOQOL-BREF scale increased statistically significantly from

0.57 ±0.53, to 2.3±0.89 (Paired Samples Wilcoxon Signed Rank Test p-value<0.001).
Conclusions: Depot antipsychotics medication significantly reduces the number of hospitalizations, when patients with psychosis and substance use disorders remain in therapy at least for 6 months. In addition, the administration of depot therapy, at least for 6 months, improves the quality of life and the functionality of these patients.

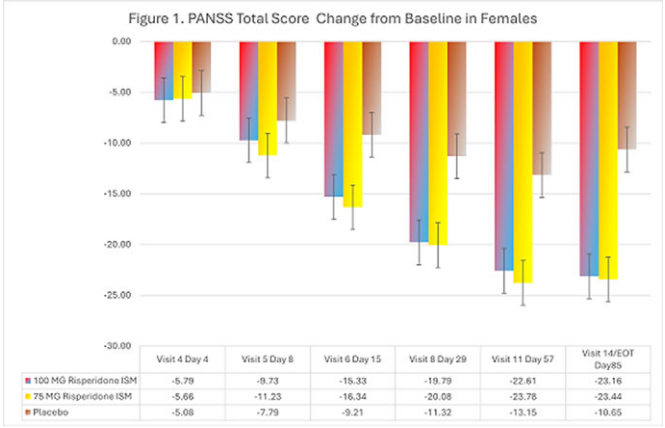
No sex-related differences in PANSS score reductions in adult patients with acutely exacerbated schizophrenia treated with Risperidone ISM

C. Sherifi[1]*, J. Martínez González[2], L. Anta Carabias[2], M. Almendros Gimenez[2], C. Salazar García[2] and C. U. Correll[3,4,5,6,7]

[1]Medical Affairs, ROVI Biotech Ltd., Croydon, United Kingdom; [2]Medical Department, Laboratorios Farmaceuticos ROVI S.A., Madrid, Spain; [3]Department of Psychiatry and Molecular Medicine, Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [4]Department of Psychiatry Research, The Zucker Hillside Hospital, Glen Oaks, NY, United States; [5]Department of Child and Adolescent Psychiatry, Charité Universitätsmedizin Berlin, Berlin, Germany; [6]Center for Psychiatric Neuroscience, The Feinstein Institute for Medical Research, New Hyde Park, NY, United States and [7]German Center for Mental Health, Partner Site Berlin, DZPG, Berlin, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.894

Introduction: There is a call to consider sex differences in mental health research [Galbally *et al.* CNS Drugs 2024; 38(7):559-570; Ercis *et al.* J Affect Disord. 2024; 352:171-192]. Sex-related differences in risperidone efficacy have been reported to be limited [Galbally *et al.* CNS Drugs 2024; 38(7):559-570]. Risperidone ISM (Risp-ISM) is a monthly long-acting injectable (LAI) formulation of risperidone, recently authorised in Europe, USA and some other countries.
Objectives: To investigate potential sex-related differences in the short-term efficacy of Risp-ISM LAI in adults with schizophrenia [Correll *et al.* NPJ Schizophr. 2020; 6(1):37].
Methods: Post-hoc analysis of a double-blind (DB), randomised, placebo-controlled, 12-week study conducted in participants with acutely exacerbated schizophrenia (NCT03160521). Data from the Positive and Negative Syndrome Scale (PANSS) were analysed by sex to reveal potential differences in efficacy versus placebo. The data were analysed within three separate study groups: 75 mg Risp-ISM, 100 mg Risp-ISM and placebo using a mixed effect with repeated measures model (MMRM). Herein, PANSS total scores changes from baseline (the primary efficacy endpoint) are shown.
Results: In the double-blind phase, 437 eligible participants were randomly assigned 1:1:1 to receive Risp-ISM 75 mg, 100 mg or placebo every 28 days. 144 (33%) were female and 293 (67%) male. Analysis showed no sex-related differences on PANSS total scores. After 12 weeks of treatment, the scores in PANSS Total as well in the Positive, Negative and General Psychopathology subscales were statistically significant lower for Risp-ISM 100 mg and 75 mg versus Placebo in both male and female subgroups. Specifically, decreases from baseline were significantly greater versus placebo at Day 8 (after first injection) and beyond in both sex subgroups at the 100 mg Risp-ISM dose versus Placebo; likewise, at Day 15 and beyond for the 75 mg Risp-ISM dose (Figures 1 and 2).

Image 1:



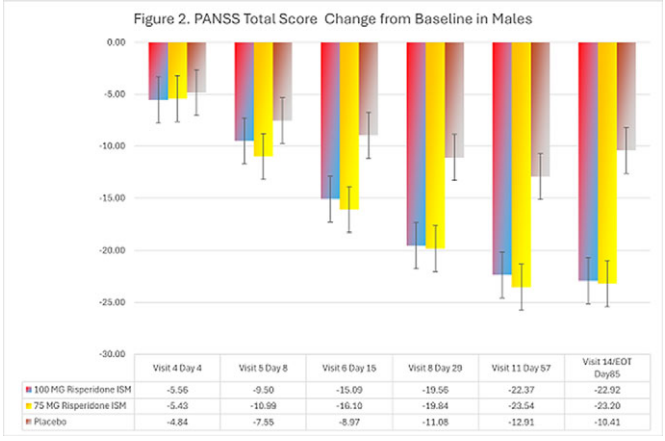


Image 2:

Conclusions: There were no statistically significant differences in efficacy, measured as PANSS score change from baseline, for male or female participants versus placebo regardless of Risp-ISM dose. Risp-ISM LAI provided significant improvement of the symptomatology as early as 8 days after first injection in acutely exacerbated patients with schizophrenia regardless of their sex.

When epilepsy triggers psychosis : understanding the mystery of postictal psychosis

A. Tarrada[1,2]

[1]Neuropsychiatry Unit, UMC Central, Nancy and [2]Neuropsychiatry Unit, Centre Psychothérapique de Nancy, Laxou, France
doi: 10.1192/j.eurpsy.2025.895

Introduction: Postictal Psychosis (PIP) is a severe psychiatric complication of epilepsy, defined by a brief psychotic episode, with a mean duration about 10 days, occurring after a cluster of seizures, or a focal seizure evolving to bilateral tonic-clonic seizure, and sometimes after a single seizure. Around 2 % of patients are affected by this disorder, mostly in long-lasting, drug-resistant temporal lobe epilepsy, but its prevalence is probably underestimated. (Kanemoto et al. Cambridge, 2011; p.67-79). PIP can lead to severe behavioral disturbances, such as agitation, violence and suicide (Tarrada et al. Epilepsy Behav, 2022). Multiple hypotheses exist about the pathophysiology of Postictal Psychosis (de Toffol et al. Encephale, 2016; p443-447). As the clinical manifestations of PIP are roughly stereotyped regardless of the epileptogenic zone, we assumed the existence of a common neurological pathway.
Objectives: We aimed to determine if a specific brain network sustained the psychotic episode, regardless of the localization of the epileptogenic zone.
Methods: We conducted a systematic review following the PRISMA guidelines (Cheval et al. Seizures, 2024; p 44-55). We included studies that provided EEG, and metabolic imaging performed during the presence of psychotic symptoms. Studies were not included, when the diagnosis of PIP was doubtful, or when the results EEG and/or imaging were not detailed enough.
Results: We included a total of 24 studies providing electrophysiological results(n=22) and metabolic imaging performed during the PIP(n=5). Temporal and frontal lobes seemed frequently involved, without clear evidence for lateralization. The EEG patterns were heterogenous, varying from unchanged to diffuse slowing. Metabolic pattern showed an increased perfusion within temporal and frontal lobes during PIP. These results correspond to the patterns described during postictal state, but they persisted throughout PIP, within regions larger than the epileptogenic zone and resolved with the recovery (Cheval et al. Seizures, 2024; p 44-55).
Conclusions: PIP symptoms are associated with an excessive persistence of postictal changes within extended frontotemporal networks. A hypothesis could be that PIP results from an abnormally prolonged and diffuse post-ictal dysregulation. Nonetheless this results is relatively imprecise and further studies should elucidate the subjective experience of the epileptic seizure, and the neuropsychological profile of patients with PIP episodes. Finally, these results could be also compared to the results of invasive EEG in patients with schizophrenia obtained in a previous controversial study, that showed the presence of epileptic activities in depth regions of the brain (Heath et al. Epilepsy Behav, 2005; p633-645), a pattern distinct from PIP, that would suggest epileptic psychoses have a pathophysiology different from primary psychoses.

Late Onset Schizophrenia: What Can We Learn? A Qualitative Study of Psychopathology and Social Factors Throughout Life

A. Urfer Parnas[1]*, C. Krogh[1], J. Nordgaard[2], M. Gram Henriksen[2] and J. E. Yttri[3]

[1]Psychiatry, Mental Health Hospital of Amager, Copenhagen; [2]Psychiatry, mental Health Center of Roskilde, Roskilde and [3]Psychiatry, mental Health of Slagelse, Slagelse, Denmark
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.896

Introduction: In 1943, Manfred Bleuler noted that late-onset schizophrenia (LOS) is an overlooked patient group, but accounts for 20% of all patients diagnosed with schizophrenia. There is a limited interest in this subgroup perhaps because of the focus on patients with early onset of schizophrenia currently. Patients with LOS differ from those with earlier onset by showing better premorbid functioning, cognitive and social skills and a less disorganized. There is limited information about the presence of premorbid near-psychotic or psychotic experiences in these patients.
Objectives: The main aims of this qualitative study were to investigate 1) the extent to which patients with LOS experience near-psychotic or psychotic episodes during their lives prior to their first contact with psychiatry, 2) whether their premorbid social life and level of functioning were affected, and 3) potential triggers before their initial interaction with the mental health care system.
Methods: Inclusion criteria comprised patients with a diagnosis of ICD-10 schizophrenia given at ages 36-59 years. They should not have had any prior contact with the psychiatric healthcare system before their first interaction with psychiatry. A semi-structured interview guide was developed for the study. All interviews were audio recorded and subsequently transcribed. The qualitative analysis consisted of an interaction between theoretical knowledge and empirical results aiming to identify interaction between psychopathology and social factors prior to the first contact with psychiatry.
Results: Most patients with LOS had experienced psychotic symptoms ranging from weeks to years before their first contact with psychiatry. Many had experienced nonspecific symptoms such as depression, fatigue, anxiety or sleeping disturbances for several years before their first psychiatric consultation. The majority reported feeling different throughout their life.
Eleven patients had been married for over three years, six divorced in the months preceding the outbreak. Nine participants had been out of the labor market for several years, the other had been dismissed or went on sick leave shortly just before their contact with psychiatry.
Many stressful life events occurred before their initial psychiatric consultation.

Conclusions: The diagnosis of LOS can easily be overlooked as these patients do not present the typical profile of persons with schizophrenia. However, they experience non specific and psychotic symptoms over years. A closer examination of these patients' coping strategies during the premorbid phase could provide new psychoeducational insights that may support the recovery of other patients with schizophrenia. The presence of psychotic symptoms several years before the first contact with psychiatry highlights that the onset of the illness is not merely a technical issue, but also a conceptual one.

Early mother-child relationships in schizophrenic patients hospitalised at the Arrazi psychiatric hospital in Salé

N. Ait Bensaid[1]*, M. Sabir[1,2] and F. El Omari[2]

[1]arrazi psychiatric hospital, Sale, Morocco and [2]HAS, arrazi psychiatric hospital, Sale, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.897

Introduction: Schizophrenia is a highly complex mental disorder. It is associated with hallucinations and delusions. Caring for a patient with schizophrenia presents major challenges, especially for mothers. The mother-child relationship is one of the first relationships to be formed, serving as the basis for other human relationships [1,2]. The mother is the most important person shaping the child's behaviour.
Although schizophrenia has biological and genetic causes, the environment in which the person grew up is very important.
Translated with DeepL.com (free version)
Objectives: To explore the childhood experiences of patients with schizophrenia with their mothers in order to identify the early mother-child relationship in these patients.
Methods: This was a descriptive cross-sectional study using a questionnaire including sociodemographic and clinical criteria as well as questions to assess patients' childhood experiences with their mothers and patients' feelings towards their mothers.
Inclusion criteria were patients' willingness to participate in the study. Participants were male schizophrenic patients over 18 years of age hospitalised at the Arrazi Psychiatric Hospital in Salé.
Exclusion criteria: intellectual disability.
Key words: Schizophrenia, mother-child relationship, emotions, patients.
Results: In this study, a total of 88 male patients with schizophrenia were collected. The majority had an average socio-economic status. Almost 77% were single and 89% lived with their families. All participants were unemployed. 91% had a substance use disorder, including tobacco and cannabis. 77% had reported psychological abuse by their mother and 55% had reported physical abuse. All the participants had received comparisons with other children and the majority reported having already felt that they were going to be abandoned by their mother. 75% reported having played the role of parent for their parents in childhood. 88% of the participants had feelings of anger and blame for their mother, 20% had feelings of security, 51% had ambivalent feelings of love and hate at the same time.
Conclusions: The present study showed that the early relationship between mother and child in patients with schizophrenia was associated with complex and ambivalent emotions and was also characterised by alternating feelings of hatred and love. Feelings of abandonment of the child and lack of attention to the child's basic needs caused patients many emotional problems towards their mothers.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.898

Introduction: The ecological hypothesis for schizophrenia supports the relationship between the urban environment and the clinical expression of severe psychosis. Housing conditions have been poorly studied.
Objectives: Our aim was to investigate the impact of housing conditions on schizophrenia, particularly in women.
Methods: A systematic literature search was conducted in PubMed, Scopus and ClinicalTrials.gov from inception to July 2024 according to the PRISMA guidelines. Search terms: (housing conditions) OR (poor housing) AND health AND schizophrenia.
Results: The search yielded 301 articles, from which 16 were included. Only three studies reported results specifically to women.
1) Building (n=4). Poor housing conditions associated with better self-esteem (n=1), but increased incidence of schizophrenia in African-Caribbeans (n=1). Despite difficulties in accessing adequate housing (n=1), schizophrenia patients showed high resilience (n=1).
2) Housing environment (n=4). Living in deprived neighbourhoods associated with higher negative symptoms (n=1) and poor community adjustment (n=2). Importance of the house's proximity to places for recreation (n=1).
3) Living in group/independent housing (n=3). Women living in institutions need more physical care than men (n=2). Living in shared accommodation reduces social loneliness and quality of life (QoL) (n=1).
4) Private homes/ boarding houses (n=3). Boarding houses are the least preferred type of community accommodation compared to private homes (n=3).
5) Social support/QoL (n=2). Lower QoL is associated with non-institutional housing (n=1). Housing type may influence cognitive function (n=1).

Conclusions: Inadequate housing is negatively associated with mental health outcomes in schizophrenia. Few studies have investigated light, ventilation and internet access with health and QoL. Future studies should investigate housing conditions, especially in women.

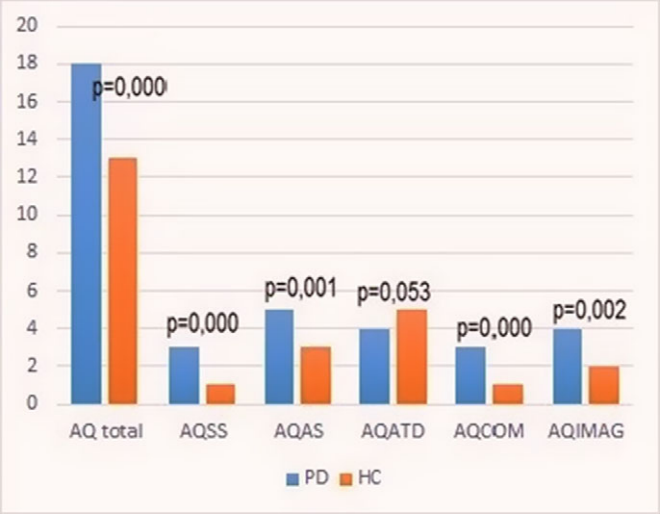
The profile of autistic traits in patients with psychotic disorders

M. Milovanovic[1], M. Vlaisavljevic[1], R. Grujicic[1,2], S. Perovic[1] and V. Mandic Maravic[1,2]*

[1]Institute of Mental Health and [2]Psychiatry, School of Medicine, University of Belgrade, Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.899



Introduction: Autistic traits are typical, but not pathognomonic for autism spectrum disorders (ASD) and they can also be observed in individuals with psychotic disorders (PD). The Adult Autism Spectrum Quotient (AQ) serves as a screening test for autism, assessing five categories of autistic traits (AT). Previous research has shown that both ASD and PD have significantly higher AQ scores compared to healthy population (1).
Objectives: To evaluate the profile of AT in patients with PD compared to healthy controls (HC), as well as to compare the profiles of AT between individuals with schizophrenia and those with unspecified psychotic disorder.
Methods: This cross-sectional study included 38 individuals with PD and 80 HC. The instruments used in the research included: AQ50, Social Adaptation Self-Evaluation Scale – SASS, and Sheehan Disability Scale.
Results: Sociodemopraphics are shown in table 1. The PD group had significantly higher scores than the HC for the overall AQ score and its sub-scores, except for attention to detail (ATD) (Graph 1). In the whole sample, there was a significant negative correlation between AQ scores and social functioning (Pearson Correlation .331, p=0,000). There were no differences between patients with schizophrenia and unspecified psychotic disorder regarding AQ score (p=0,466), while patients with schizophrenia showed significantly lower social and overall functioning (SASS total p=019; Sheehan total p=0,001).

Table 1

	PD (n=38)	HC (n=80)	Test	P
Sex (male)	22 (58,9%)	34 (41,4%)	X^2=3.25	0,086
Age (years)	41,8 ± 12,8	34,3 ± 11,7	t=-3,22	0,06
Treatment duration	16,7 ± 9,9			
ICD-10 diagnosis				
F20	22 (56,4%)	-		
F29	17 (43,6%)	-		
SASS total	40,5 ± 7,4	44,7 ± 5,9	t=3,4	0,02
Sheehan total	13,3 ± 8,5			

Graph 1 legend
AQSS – AQ social skills; AQAS – AQ attention switching; AQATD – AQ attention to detail; AQCOM – AQ communication; AQIMAG – AQ imagination

Image 1:

Conclusions: Recognizing autistic symptoms in individuals with PD can be important for their social functioning, as well as for establishing an individualized approach to treatment, both pharmacological and non-pharmacological. It appears that AT impact social functionning differently in HC vs PD group. Further studies on correlation of AT with clinical outcomes in PD are warranted.

Mental Labyrinth: A Case of Treatment-Resistant Schizophrenia and Solutions

F. N. Meral[1]* and F. Ekici[1]

[1]Psychiatry, Selcuk University, Konya, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.900

Introduction: Despite advancements in the pharmacological treatment of schizophrenia, one-third of patients do not respond favorably. In many treatment algorithms, the lack of response after using two antipsychotic treatments at doses equivalent to 400–600 mg/day of chlorpromazine for four to six weeks is considered treatment-resistant schizophrenia.

Objectives: This case report aims to examine the unresponsive symptoms in a case of treatment-resistant schizophrenia, the patient's clinical course, and the approach to the treatment process.
Methods: The hospitalized patient's socio-demographic characteristics, medical and psychiatric history, and current complaints were examined in detail. Medications used, previous hospital visits, and admissions were evaluated.
Results: A 34-year-old male was first hospitalized in 2016 during military service due to disorganized behaviors, preventing completion of service. A year later, noncompliance led to repeated hospitalizations for grandiose delusions and disorganized behaviors. Despite effective doses and durations of aripiprazole, risperidone, olanzapine, and paliperidone injection, his symptoms persisted. Upon presenting to us, his treatment was paliperidone 150 mg/month and risperidone 4 mg/day. Due to auditory hallucinations and persecutory and referential delusions, he was admitted for schizophrenia management. Clozapine was added per protocol, increased to 700 mg/day, then reduced to 500 mg/day due to anticholinergic side effects; weekly hemogram monitoring showed no agranulocytosis. Fluvoxamine was added for control and religious obsessions, increased to 300 mg/day. With partial symptom regression and ongoing resistance, eight sessions of electroconvulsive therapy were administered without reduction in psychotic symptoms. Observing benefits from typical antipsychotics, haloperidol loading doses of 50 mg, 150 mg, and 200 mg were given. After an 85-day hospitalization, significant improvement allowed discharge planning. He was discharged on clozapine 500 mg/day, fluvoxamine 300 mg/day, and haloperidol decanoate injection. Outpatient follow-ups showed remission and complete regression of psychotic symptoms.
Conclusions: This case underscores the importance of treatment approaches in managing treatment-resistant schizophrenia. Formulating an effective treatment plan in such cases is often challenging and prolonged. As demonstrated, when initial treatments are inadequate, various steps are implemented per treatment protocols. In treatment-resistant patients, combining clozapine, ECT, and long-acting typical antipsychotics can effectively achieve long-term stabilization. The significance of regular follow-up, side effect management, and individualized treatment plans is evident in this case.

Very Early Onset Psychosis and the Autism Spectrum – Challenges of Differential Diagnosis

A. F. Silva[1]*, A. C. Rodrigues[1], A. C. Matias-Martins[1], F. Santos[1], P. Coelho[1], R. M. Lopes[1], T. Vieira[1] and V. Melo[1]

[1]Psiquiatria, Unidade Local de Saúde do Médio Tejo, Tomar, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.901

Introduction: Schizophrenia (SCZ) and Autism Spectrum Disorder (ASD) are complex neurodevelopmental disorders with overlapping cognitive, social, and behavioral symptoms. Although each has distinct diagnostic criteria, shared traits such as impaired social cognition, communication difficulties, and atypical behaviors, often blur the distinction between them. This overlap is particularly challenging in cases of very early onset psychosis (before age 13), where symptoms like social withdrawal, unusual behaviors, and communication difficulties closely mirror those of ASD, complicating accurate diagnosis.
Objectives: This study aims to explore the diagnostic challenges of distinguishing between ASD and early psychosis through a comprehensive review of published literature and a case report.
Methods: A bibliographic review was conducted using articles from PubMed, focusing on the terms "Autism Spectrum Disorder", "Early Psychosis", and "Early Onset Schizophrenia". Additionally, a case report was presented to illustrate the complexities in differentiating these overlapping conditions.
Results: This study highlights the difficulty of distinguishing ASD from early psychosis due to overlapping symptoms, particularly in young patients. ASD is typically characterized by persistent social communication difficulties and repetitive behaviors, while early psychosis involves hallucinations, delusions, and disorganized thinking. However, some children with ASD may also exhibit psychotic-like symptoms, such as paranoia or unusual perceptual experiences, mimicking early-onset schizophrenia. These findings underscore the importance of comprehensive diagnostic assessments that include developmental history, symptom trajectory, and family background. Increasing evidence shows that ASD and early psychosis share genetic, neurobiological, and environmental risk factors, supporting the idea of a neurodevelopmental continuum where both conditions may be viewed as different points along a shared spectrum of neurodevelopmental disruption.
Conclusions: This work calls for a more integrated approach to diagnosing ASD and early psychosis, especially in cases of very early onset. A continuum model suggests these disorders may represent points along a spectrum of neurodevelopmental disorders rather than entirely separate entities. Future research should prioritize long-term studies to identify specific markers, such as genetic, brain imaging, and cognitive profiles, that can better differentiate between ASD and early psychosis and guide more targeted, personalized interventions.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.902

Introduction: Flight crew members are subjected to various stressors that can disrupt their sleep-wake cycle, leading to a higher prevalence of sleep disorders.
Objectives: to assess the prevalence of sleep disturbances among flight crew members of a private airline company in Tunisia.
Methods: A cross-sectional study was conducted involving flight crew members employed by a private airline in Tunisia who

underwent periodic medical examinations at the Occupational Medicine and Pathology Department in a University Hospital in Sousse. Data collection included socio-demographic information, lifestyle habits, and professional details, gathered through a structured questionnaire. The Sleep Condition Indicator (SCI) was used to screen for insomnia disorder.

Results: The study included 160 participants, predominantly female (60%). Sixty-five percent of the population was over 40 years old. A significant majority (58.8%) were smokers, while 41.3% consumed alcohol. Coffee consumption was high, with 84.4% of participants reporting regular consumption. Regarding professional data, 71.3% of participants were flight attendants, with a median length of service of 15 years. The majority of participants (65%) had flown medium-haul flights (less than 5 hours) in the preceding month. Insomnia was reported in 23.1% of participants.

Conclusions: Our findings highlight the importance of screening for sleep disorders through periodic medical examinations which can significantly contribute to improving sleep quality, enhancing alertness, and ultimately enhancing aviation safety.

Trazodone augmentation could be a beneficial treatment for persistent insomnia in patients with comorbid PTSD and MDD that are good responders to escitalopram or sertraline: A one-group pretest-posttest study

V. Huljev[1]*, S. Nadalin[2,3], V. Kugelman[4], B. Aukst Margetić[5,6], Ž. Šurina Osmak[7] and M. Vilibić[3,8]

[1]Department of Psychiatry, Neuropsychiatric Hospital Dr Ivan Barbot, Popovača; [2]Department of Psychiatry, General Hospital "Dr. Josip Benčević", Slavonski Brod; [3]School of Medicine, Catholic University of Croatia, Zagreb; [4]Department of Psychiatry, General Hospital Varaždin, Varaždin; [5]Department of Psychiatry, Dubrava University Hospital; [6]School of Medicine, University of Zagreb; [7]Ministry of Defence of the Republic of Croatia and [8]Department of Psychiatry, Sestre Milosrdnice University Hospital Centre, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.903

Introduction: Antidepressants are a valuable treatment option for patients with PTSD and MDD. Sleep is an important dimension of both: PTSD and MDD. Insomnia is a common residual symptom in patients with PTSD and MDD comorbidity who are generally good responders to SSRI monotherapy.

Objectives: To explore wheather trazodone evening augmentation could be beneficial for persistent insomnia in patients with comorbid PTSD and MDD that are generally good responders to one of followed SSRIs: escitalopram or sertraline.

Methods: Thirty outpatients (N=30) with comorbid war-related PTSD and MDD who are generally good responders to escitalopram (20 mg daily, N=15) or sertraline (100 mg daily, N=15) except persistent insomnia, were augmented with 100 mg trazodone. Trazodone was prescribed one-two hours before the sleep. Each patient met ICD-11 as well as DSM-V criteria for both: PTSD and MDD. No patient had psychiatric premorbidity, excluded by MINI. There was no significant somatic comorbidity that could influence the persistance of insomnia. Four sleep-related parameters were evaluated at two time points: at zero-point and 12-weeks after trazodone augmentation. This parameters/efficacy measures included: the improvement on the recurrent distressing dream item of the Clinician Administered PTSD Scale (CAPS-RDDI), reduction of the amount of time needed to fall asleep, prolongation of sleep duration, and reduction in the average number of arousals per night during the last seven days before assessment.

Results: All sleep-related parameters improved significantly at the end of a 12-weeks follow-up: sleep duration prolongation ($p<0.001$), sleep latency decrease ($p<0.001$), median number of arousals per night decrease ($p<0.001$), and CAPS-RDDI median decrease ($p<0.001$).

Conclusions: Trazodone augmentation could be a beneficial treatment strategy for persistent sleep problems in patients with comorbid PTSD and MDD who are generally good responders to escitalopram or sertraline monotherapy.

Trauma-involved care: knowledge, attitudes, and practices of mental health professionals

F. İnci[1], F. Oflaz[2]*, A. Büyükbayram Arslan[3], B. Şimşek Arslan[4] and N. Kılıç[5]

[1]Health Science Faculty, Niğde Ömer Halis Demir University, Nevşehir; [2]School of Nursing, Koç University, İstanbul; [3]Health Science Faculty, İzmir Katip Çelebi University, İzmir; [4]Health Science Faculty, Burdur Mehmet Akif ErsoyUniversity, Burdur and [5]Health Science Faculty, Artvin Çoruh University, Artvin, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.904

Introduction: The number of people exposed to trauma has increased due to disasters, epidemics, wars, and various man-made causes occurring worldwide- including Turkey. Therefore, the principles of trauma-informed care should be applied in all healthcare settings and incorporated into policies and institutional frameworks (Saunders et al., 2023; Greer, 2023; Huo et al., 2023). Although mental health professionals are experienced in the effects of trauma, a more systematic approach is required to enhance awareness of and achieve widespread trauma-informed care. In Turkey, there is no standardized guide or algorithm for providing care and treatment to trauma victims, and no guide has been developed to ensure a common understanding of care in approaching trauma among mental health professionals.

Objectives: This study examined the knowledge, skills, and stance of professionals providing mental health services in Turkey regarding trauma-informed care, as well as their intervention skills related to trauma. This constitutes the first phase of the studies to establish a fundamentally trauma-informed care model in existing mental health settings.

Methods: The study was conducted with a cross-sectional design, and the convenience sampling method was used. The study population was mental health services professionals in Turkey. The participants were recruited by researchers through social media platforms, and only those accepting participation were included in the study. The study was completed with 197 participants who filled out the survey forms.The data were collected using the Trauma-

Informed Care Scale and the Trauma Intervention Skills Scale through an online survey. The data were analyzed using Spearman correlation analysis, Mann Whitney U, and Kruskal Wallis tests.
Results: More than half of the participants were unaware of the concept of trauma-informed care (55.3%), and only 14.2% felt competent in presenting this care model. In trauma-informed care scores, gender, age, and education level did not create a significant difference ($p>0.05$), while those who have received information about trauma-informed care during their years of education scored higher ($p<0.05$). Compared to other professionals, nurses had higher trauma-informed care scores, and psychologists had an augmented ability to intervene in trauma patients.
Conclusions: The results of the research indicated that while mental health professionals possess knowledge about trauma, they did not reach the desired level in developing attitudes towards trauma-informed care and feeling competent in this area. Trauma-informed care seemed more about providing information related to procedures performed in the clinic or ensuring that the patient was not traumatized during the procedure. Therefore, more studies are needed to evaluate TIC practices in the much-needed mental health field.

Psychological assistance to adolescents after spinal cord injury

Y. Sidneva[1,2]*, E. Lvova[1] and S. Valiullina[1]

[1]rehabilitation, Clinical and Research Institute of Emergency Pediatric Surgery and Trauma and [2]neuropsychiatric, N.N. Burdenko Neurosurgery Institute, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.905

Introduction: Spinal cord injury (SCI) is a severe trauma that leads to disability and decreased social activity. Recently, the number of patients among children has been growing. In Russia, the share of spinal cord injury in the structure of all injuries is 18.3%.
Post-traumatic consequences include neurological, motor and somatic disorders, as well as psychological ones. Psychological support for children with severe SCI is an important link in comprehensive rehabilitation at all its stages. There are data in the literature on the psychological state after spinal cord injuries, but this is in adults.
Objectives: to study psychological problems in adolescents after severe spinal cord injury in the early stages of rehabilitation.
Methods: 50 patients (12-18 years old) admitted for treatment and rehabilitation on the 1st-3rd day after spinal cord injury. Psychological diagnostics included: clinical interview; Anxiety and Personality Disorders Inventory (Spielberger 1983, adapted by Khanin); Beck Depression Inventory (Beck 1961, version for adolescents); Recovery Locus of Control (Partridge, Johnston 1989).
Results: All patients (100%) had psychological problems of varying severity: 80% of adolescents - high level of reactive anxiety; 28.3% - low motivation for rehabilitation; 33.3% - depression (of which 30% - reactive depression; 3.3% - masked depression). Symptoms could be combined and observed in the same patient.
Children with high levels of personal anxiety in combination with reduced levels of motivation had difficulties in adaptation to rehabilitation.
Conclusions: All patients (100%) require psychological support in order to correct emotional background and motivation. Differentiated specialized assistance, including psychological, will increase the effectiveness of rehabilitation. This will help to adapt adolescents with post-traumatic deficiency to the changed conditions of life, improve its quality and return them to their previous social environment.

The prevalence of insomnia symptoms in adults with depression: a systematic review

M. Toynbee[1,2], D. Zygmunt[1], R. Levett[1], S. Moghaddacy[1] and S. Pappa[1,2]*

[1]West London NHS Trust and [2]Imperial College London, London, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.906

Introduction: Insomnia symptoms are commonly reported by people with depression, and their effective treatment is associated with reduced affective symptoms and improved patient outcomes. However, to date, estimates of the rates of co-morbid insomnia in individuals with depression are mainly based on sub-analyses of epidemiological studies of general populations, often relying on self-reported or historical depression diagnoses. To our knowledge there has been no systematic review of studies evaluating the prevalence of insomnia symptoms in people with an established diagnosis of depression.
Objectives: To summarise and synthesize the available evidence of studies reporting on the prevalence of insomnia symptoms in adults with depression using a systematic review.
Methods: Comprehensive searches of MEDLINE, EMBASE, Pubmed, PsycINFO, and TRIP using search terms related to depression and insomnia with no language restrictions, were performed. The titles and abstracts were screened independently by two reviewers and the full texts of studies identified were assessed against predefined criteria, namely: 1) primary studies of 2) adults (18 years and over) with depression, 3) reporting prevalence of insomnia symptoms. The review protocol was registered with Prospero.
Results: 4,477 unique references were identified, of which 80 full texts were reviewed after title and abstract screening. Thirteen studies, with a combined total of 10,394 participants and published between 2001 and 2023, met the inclusion criteria and were included in the analysis. Seven studies were from the US, and one each from China, Turkey, S. Korea, Belgium, and the Netherlands, while one included participants from both Malaysia and Australia. The mean prevalence rate of clinically significant insomnia symptoms in adults with a diagnosis of depression was 79%. The systematic review has a number of limitations including a small number of eligible studies covering a wide range of geographic populations with varying thresholds for reporting insomnia, and that establishing the prevalence of insomnia symptoms was not the primary aim of most of the studies. Further meta-analysis in this research was not carried out due to high heterogeneity between studies.

Conclusions: To our knowledge, this is the first systematic review of studies reporting on the prevalence of insomnia symptoms in adults with depression. The main finding is that at least three in four adults with depression have clinically meaningful insomnia symptoms; such high prevalence rates are consistent with previously reported figures. Therefore, given the positive clinical outcomes from treatment, services for adults with depression should routinely offer targeted interventions in identifying and managing co-incident insomnia symptoms. Future research should aim to refine the estimates of co-occurrence of insomnia and depression in different clinical populations.

Evaluation of Hospital Applications of Former Earthquake Victims Due to Re-Traumatization Through Media

H. O. Torun[1]*, B. Akdöner[2] and T. Sarıkavak[3]

[1]Psychiatry, İzmir City Hospital, İzmir; [2]Psychiatry, Near East University, Girne and [3]Psychiatry, Atlas University, İstanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.907

Introduction: The 2020 Aegean Sea earthquake occurred on October 30, 2020, 23 km from the Seferihisar district of Izmir, with a magnitude of 6.9. It caused the death of a total of 119 people and the injury of 1053 people in Turkey and Greece. After this earthquake, many people were observed to have symptoms of post-traumatic stress disorder and received treatment. The two major earthquakes centered in Kahramanmaraş on February 6, 2023 also caused great destruction in Turkey. After this earthquake, an increase in the mental complaints of people who had previously experienced the earthquake in Izmir Seferihisar was observed and these people applied to the psychiatry outpatient clinic.
Objectives: Revealing how much former earthquake victims are affected by similar events through the media.
Determining the situations that cause people to be re-traumatized.
Observing the effects of the media on mental health.
Methods: This study investigated the effects of former earthquake victims who applied to Izmir Seferihisar State Hospital after these new earthquakes, and who were not in the earthquake region at the time of the earthquake and who did not have any losses or injuries to relatives or acquaintances, through the media. For this purpose, after the earthquake centered in Kahramanmaraş, the Adult Resilience Scale and the Post-Traumatic Stress Disorder Checklist for DSM-5 were applied to these individuals at their first application, and it was questioned whether the individuals had received pharmacotherapy and psychotherapy after the previous Aegean Sea earthquake. It was also investigated how the individuals followed the news about the new earthquake. Afterwards, whether the individuals received treatment and the duration of this treatment were recorded, and the Post-Traumatic Stress Disorder Checklist for DSM-5 was applied to the individuals at the 1st, 3rd, 6th, 9th and 12th months.
Results: People who have received psychotherapy are 1.9 times less likely to need treatment afterwards.
Women are 4.1 times more likely to be affected by the media and use SSRIs.
People who have lost their homes need treatment as often as those whose close relatives have died.
The risk of people who do not receive treatment after a disaster being affected by the media and receiving treatment is 3.4 times higher than those who received treatment during the first disaster.
Conclusions: After disasters, when another disaster occurs, PTSD symptoms can be observed again in former disaster victims. Post-traumatic psychotherapy can also be protective in terms of future situations. Watching traumatic events in the media can cause PTSD symptoms to be seen even if no relatives have been harmed.

An audit on sensitive documentation of suicide attempts and behaviour in Mount Carmel Hospital discharge summaries

N. Borg[1], R. Gambin[1]*, G. Gatt[2] and F. Cassar[1]

[1]Mental Health Services, Attard and [2]Mater Dei Hospital, Msida, Malta
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.908

Introduction: Suicide attempts should always be recorded in a patient's discharge summary as this aids risk assessment and management. Discharge letters provide valuable information to outpatient and emergency services and guide risk assessment. However, they are available to be read by patients and their loved ones. Insensitive wording or graphic detail can contribute to feelings of shame and guilt and perpetuate stigma towards our patients.
Objectives: This audit aimed to assess quality of documentation of suicide attempts and behaviour on Mount Carmel Hospital (MCH) discharge summaries with respect to the International Association of Suicide Prevention (IASP)'s Language guidelines. It also aimed to assess the effectiveness of a short presentation intervention on suicide given to foundation (FY) doctors.
Methods: For the first cycle, discharge letters of patients admitted to MCH between January and July 2023 were screened according to inclusion criteria. Included discharges were assessed for adherence to IASP's language guidelines. The authors then gave a short presentation to FY doctors during their rotation, highlighting the importance of using sensitive language on suicide in discharge summaries. The second cycle was carried out between January and July 2024 and results were compared to the first cycle.
Results: In the first cycle, a total of 1393 patients were admitted between January and July 2023. 26% of discharge letters did not use appropriate suicide-related terminology. Of these, the most common issues were with excessive description of the attempt (53%) and use of the phrase 'commit suicide' (28%). In the second cycle, a total of 1335 patients were admitted between January and July 2024. 20% of discharges did not use appropriate suicide-related terminology (n = 34). The intervention significantly reduced the use of the phrase 'commit suicide' (OR 0.279; CI 0.0921 to 0.8452, p = 0.0240).
Conclusions: In the first cycle, one out of every four patients admitted on a background of suicidal behaviour received a discharge summary that it potentially insensitive or stigmatising in nature. This decreased to one in five after the short intervention. These results are promising especially given that the intervention is neither time consuming nor costly. Simply making foundation year doctors aware and guiding them on how to write about suicide can not only

improve the quality of patient care but also reduce iatrogenic harm. Additionally, foundation doctors should be supported and supervised by more senior firm members to ensure that discharge letters are not only of good quality but also written sensitively and sensibly.

Intensive Care and Emergency Nurses' Attitudes and Stigma Towards Suicidal Behavior and Related Factors

N. Karabulut[1]* and Ç. Yüksel[2]

[1]Department of Psychiatric Nursing, Ankara University and [2]Department of Psychiatric Nursing, Health Sciences University, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.909

Introduction: The first place to intervene in individuals who have attempted suicide is often the emergency department. These individuals may then be referred to intensive care units for close monitoring of physical findings and treatment, depending on the results of the suicide attempt. The attitudes and stigmatisation of nurses in the emergency department and intensive care unit toward suicide affect the quality of care provided. It is important to determine the attitudes and stigmatisation of nurses.
Objectives: This study aims to determine the attitudes and stigma levels of nurses working in intensive care and emergency services towards suicidal behaviour and to examine the related factors.
Methods: The research is descriptive, cross-sectional and correlational. The research was conducted with 82 volunteer nurses working in the emergency room and intensive care unit of a hospital in Turkey between January and March 2023, with approval from the ethics committee and the institution. Nurses filled out the Personal Information Form, Attitude Towards Suicide Attempt Scale and Stigma of Suicide Scale. In data analysis; Independent samples t-test, One-way ANOVA, and Welch test were used in cases where variances were not homogeneously distributed. Bonferroni and Games-Howell methods were preferred among post hoc multiple comparison tests. Pearson correlation was used for the relationship between continuous variables, and Spearman correlation analysis was used for categorical variables.
Results: The mean score of the nurses' Attitudes Towards Suicide Attempt Scale was 98.78±9.16. The mean scores of the Stigma of Suicide Scale; Stigma, Isolation\Depression, Sublimation\Normalization sub-dimensions were 71.95±18.09, 57.68±10.94, 27.11±6.86, respectively. The mean score of the Sublimation\Normalization sub-dimension of the Stigma of Suicide Scale of those who had attempted suicide in their close circle was higher than those who had not, and the results were significant ($p<0.05$). In the same sub-dimension, the mean scores of those who gave care to patients who attempted suicide were lower than those who did not, and the results were significant ($p<0.05$). The total score of the Attitude Towards Suicide Attempt Scale had a positive and statistically significant effect on the Stigma of Suicide Scale ($\beta=0.562$, $t=6.071$, $p<0.001$).
Conclusions: These results indicate that nurses have high levels of negative attitudes towards suicidal behaviour, stigmatize it, associate suicide with depression and isolation, consider suicide normal, or glorify people who commit suicide. The presence of those who have attempted suicide in the immediate environment and providing care to individuals who have attempted suicide was associated with nurses' attitudes and stigmatisation towards suicidal behaviour. It was found that nurses' negative attitudes towards suicide had an increasing effect on their stigmatisation.

Prevalence and risk factors of passive suicidal ideation among healthcare professional during residency

A. F. Rodríguez Barrera[1], M. Cabello Salmerón[1], A. Cano Arenas[1], M. F. Bravo Ortiz[2], D. Carracedo Sanchidrián[2], D. Hernández-Calle[3] and E. Lara Pérez[4]*

[1]Universidad Autónoma de Madrid; [2]Hospital Universitario La Paz; [3]Hospital Ramón y Cajal and [4]Universidad Complutense de Madrid, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.910

Introduction: Health professionals are a vulnerable population, prone to mental health problems such as suicidal behaviors. Suicidal ideation (passive and active) is a potential indicator of committing suicide. Passive suicide ideation has been undervalued as an indicator of suicide risk for not having a plan to commit suicide. Despite the high risk, few studies have examined the prevalence and factors related to the presence of passive suicidal ideation in healthcare residents.
Objectives: Determine the prevalence and associated factors of passive suicidal ideation among resident healthcare professionals, including physicians, nurses, and psychologists.
Methods: This cross-sectional study involved a non-probabilistic sample of 775 healthcare professionals. Data were collected via a self-administered survey distributed to teaching units in hospitals across Spain. Key variables included passive suicidal ideation (yes/no), year of residency, and personality traits (neuroticism, extraversion, openness, agreeableness, conscientiousness), assessed with the Spanish adaptation of the NEO-PI-R Personality Inventory. Descriptive analyses summarized categorical and continuous variables. Associations between passive suicidal ideation and independent variables (age, gender, personality traits, drug consumption, mental health specialization, residency program) were analyzed using logistic regression models.
Results: Among the total sample, 13.42% exhibited passive suicidal ideation. In terms of personality traits, individuals with higher levels of neuroticism and openness demonstrated an increased likelihood of experiencing passive suicidal ideation, whereas higher scores in extraversion were associated with a decreased probability of such ideation. Additionally, the use of prescribed medication and instances of self-medication were found to be related to passive suicidal ideation.
Conclusions: A notable proportion of healthcare professionals experience suicidal ideation during their residency. The findings of this study indicate that preventive measures for suicidal ideation should be implemented during the residency period for healthcare professionals.

Mechanisms of suicidal behavior development in military personnel

S. Moroz[1]*, V. Semenikhina[1] and M. Sheludenko[1]
[1]MUNICIPAL ENTERPRISE DNIPROPETROVSK MULTIPROFILE CLINICAL HOSPITAL FOR PROVISION OF PSYCHIATRIC CARE » DNIPROPETROVSK REGIONAL COUNCIL, Dnipro, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.911

Introduction: Suicide risk correlates with the nature of psychotraumatic factors that act directly during military service, their severity, duration of exposure, and individual adaptive capacities of military personnel. The development of suicidal behavior occurs against the background of anxiety and depressive syndromes in military patients and is aggravated by concomitant addictive behavior.
Objectives: To investigate the relationship between the mechanisms of development of suicidal behavior in the military and psychopathological status that potentiate suicidal activity.
Methods: The following diagnostic scales were used: Suicide Risk Scale of the Los Angeles Suicide Center, Sad People Scale (W.M. Patterson, H.H. Dohn, J. Bird), Spielberger-Hanin Scale of Reactive (Situational) and Personal Anxiety (STAI), Hospital Anxiety and Depression Scale (HADS), Hamilton Rating Scale for Depression, Impact of Event Scale (IES-R). Review of existing literature on suicidal behavior among military personnel.
Results: 38 patients with a suicide attempt (within the diagnostic criteria F 43, F 32, F 31, F07 according to ICD-10) were examined during 6 weeks of inpatient care. It was established that the psychopathological presuicidal period in the examined patients was formed against the background of high levels of anxiety (38% of patients), anhedonia (26% of patients), feelings of sadness and hopelessness (19% of patients), addictive behavior (13% of patients), feelings of anger and irritability (4% of patients). In 43% of cases, the formation of suicidal behavior in military personnel was observed against the background of violations of interpersonal relationships: self-isolation behavior (22%), conflict (13%), and antisocial actions (8%). The duration of the pre-suicidal period are several minutes (23% of patients), several days (44% of patients), a month or more (33% of patients). The dominant methods of suicide attempts among the observed military personnel are self-inflicted wounds (61%), poisoning (18%), gunshot wounds (11%), hanging attempts (8%) and self-arson (2%). The reaction of suicidal people to an unsuccessful suicide attempt depends on the current mental state of the military personnel, often with a critical assessment, less often - suicidal-fixed.
Conclusions: In most cases, the development of suicidal behavior in military personnel occurs against the background of anxiety, depressive symptoms, post-concussion disorders, anhedonia, and concomitant addictions. Prevention of suicide among military personnel should include early detection of the main psychopathological symptoms and timely crisis therapy.

Development of artificial intelligence algorithms trained with real-world data for suicide risk prevention in pediatric and adult patients: The IDICIUS Project

C. Peña Gómez[1,2], M. Fradera[1,2,3]*, M. Caravaca[1,2], J.-F. Martínez[4], D. Roche[5], J. Giraldo[1,2,3], J. A. Escofet[4], E. Barberia[6] and D. Palao[1,2,3]
[1]Unitat de Neurociència Traslacional, Institut d'Investigació i Innovació Parc Taulí (I3PT-CERCA), Sabadell; [2]Institut de Neurociències (INc), Universitat Autònoma de Barcelona, Bellaterra; [3]Centro de Investigación Biomédica en Red de Salud Mental, Instituto de Salud Carlos III, Madrid; [4]Health Quality and Assessment Agency of Catalonia; [5]Research Institute for Evaluation and Public Policies (IRAPP), Universitat Internacional de Catalunya (UIC) and [6]Institute of Legal Medicine and Forensic Sciences (IMLCFC), Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.912

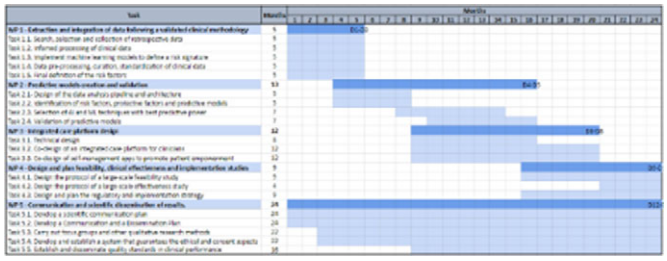
Introduction: Suicide is currently the leading external cause of mortality in Europe and one of the main causes of premature death. Suicidal behavior is highly heterogeneous, making it difficult to predict in clinical practice. However, among people who die by suicide, 83% had attended primary care in the previous year, and 50% had done so within 30 days of their death. Moreover, well-known suicide risk factors are already recorded in routine electronic health records (EHRs). Therefore, the development and implementation of artificial intelligence tools can help improve the prevention of suicidal behavior.
Objectives: The aim is to design a platform based on predictive artificial intelligence (AI) predictive models that allows preventing suicide risk, addressing both suicidal attempts and/or ideation, as well as deaths by suicide, using clinical, biological, and sociodemographic factors through real-world data (RWD) from EHRs in a large sample of pediatric and adult patients undergoing psychiatric treatment.
Methods: This is a retrospective population-based study that uses structured and anonymized EHRs of a large sample of pediatric and adult patients who received mental health care between 2018 to 2024. The IDICIUS project consists of five work packages (Figure 1):

- Extraction and integration of data from different sources: EHRs from Mental Health and Primary Care services; database of outpatient medicines invoiced by pharmacies from the Catalan Health Service; and all suicidal behaviors from the Suicide Risk Code register and also suicide deaths.
- Predictive models creation and validation
- Integrated care platform design
- Design and plan feasibility
- Scientific dissemination of results

Results: We have identified approximately 40,000 patients who visited the Mental Health service at Parc Taulí Hospital between 2018 and 2024, of whom 162 died by suicide. The integration of these databases (Figure 2) has been achieved through the collaboration and coordination of three different public entities over the course of more than a year, ensuring compliance with legal and ethical standards at each step, given the sensitive nature of the

data and its intended use in the development of an AI predictive algorithm.

Image 1:



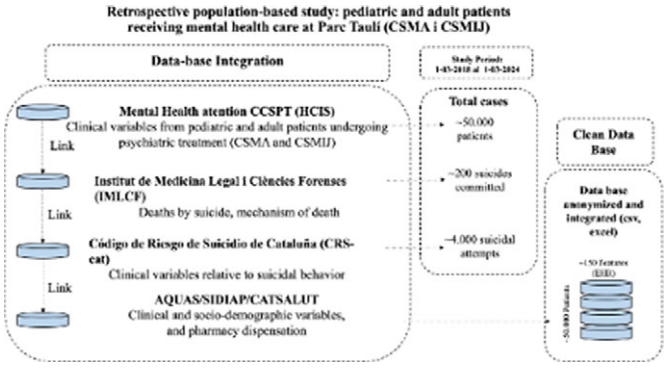


Image 2:

Conclusions: We are now moving forward with the subsequent phases, aiming to make a decisive contribution to the more effective and efficient management of suicidal behavior in clinical populations. The potential clinical utility of the results obtained in the prediction of suicide is analyzed, applying the AI algorithm in real clinical practice conditions. The aim is to improve the information available, through the use of alarms that help clinicians in decision-making to improve suicide prevention in primary care (risk detection) and in specialized mental health care (detection of significant variations in baseline risk).

Violence and Suicide Risk in Sub-Saharan Africa: The Case of Senegal

J. A. D. Tine[1]*, V. Petit[2] and H. M. Langet[3]

[1]Medecine, University Cheikh Anta Diop of Dakar, Dakar, Senegal; [2]CEPED, Université Paris Cité, Paris, France and [3]Swiss Centre for International Health (Digital Health Unit) / Research-IT, Swiss Tropical and Public Health Institute, Bale, Switzerland

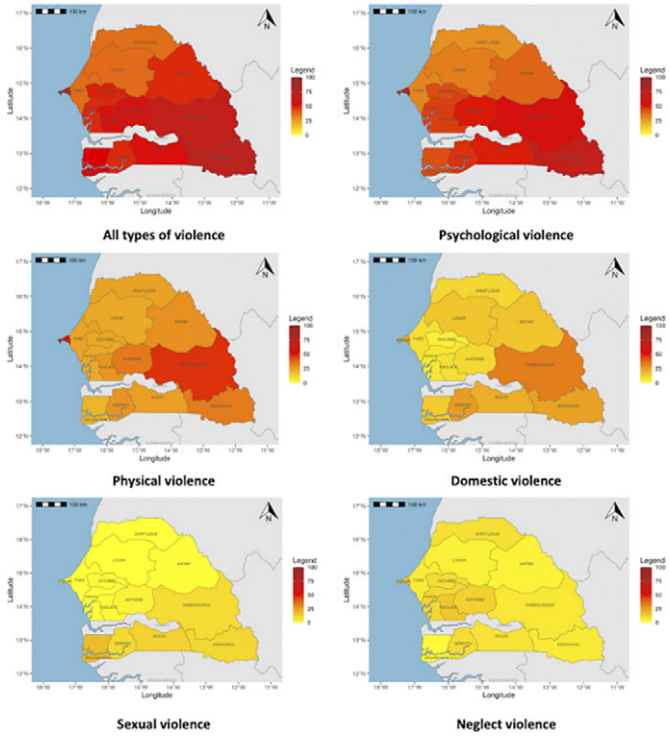
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.913

Introduction: Assessing violence and suicide risk is a critical preventive action in the fight against suicide.
Objectives: This study aimed to analyze the vulnerability factors associated with violence and suicide risk in the general Senegalese population.
Methods: This was an observational, population-based, national, cross-sectional, descriptive, and analytical survey. Data collection was conducted from July to August 2023 on 496 randomly selected households proportionally distributed according to the demographic weight of different areas. The assessment of suicide risk was derived from the Mini International Neuropsychiatric Interview (MINI) V5. Data were directly entered into ODK, and analysis was performed using R software. Ethical approval was granted by the National Health Research Ethics Committee of Senegal.
Results: A total of 2,174 individuals were surveyed, with a mean age of 41.4±12.2 years. The prevalence of violence in Senegal was 52.76%. The most common forms were psychological violence (47.38%), verbal violence (43.47%), and physical violence (32.84%) (Refer to table I: Distribution by type of violence). Associations of violence were observed, with physical violence associated with psychological violence accounting for 19.59%. Women were more exposed to the different type of violence. Geographic disparities were identified, with the Dakar region emerging as the main hotspot for these forms of violence (refer to image 1: mapping of violence by region of Senegal). The suicide risk was found to be 8.4%, with a high level at 1.66%. Regardless of the type of violence, the suicide risk was elevated; it was 47.6% for sexual violence (refer to image 2: Distribution of Suicide Risk According to the Type of Violence). Unfortunately, recourse to victim assistance was low, with 6.2% of victims receiving psychological support and 10.4% receiving police assistance.

Table I: Distribution by type of violence

Nature of violence (N=2174)	Numbers	Percentages (%)	IC 95%
Physical violence	714	32.84	[31 - 35]
Sexual violence	83	3.82	[3.1- 4.7]
Psychological violence	1030	47.38	[45 - 50]
Neglect violence	204	9.38	[8.2 - 11]
Domestic violences	332	15.27	[14 -17]
Verbal violence	945	43.47	[41 - 46]
Domestic harassment	273	12.56	[11 -14]
Domestic assault	184	8.46	[7.3 - 9.7]
All violences	1147	52.76	[51 - 55]

Image 1:



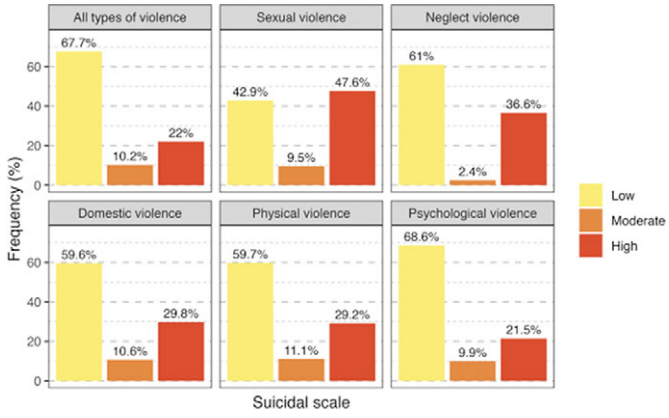


Image 2:

Conclusions: Violence was significant in Senegal, with gaps in administrative and medicopsychological assistance. The suicide risk is high, but suicide remains underreported. It is crucial for Senegal to have a political and health framework with a public health approach centered on vulnerable groups for managing violence and suicide risks.

Keywords: Violence, Suicide risk, Senegal, Africa

EPP727

Readiness of Pediatric General Emergency Department Personnel to Provide Initial Intervention for Suicidal Patient

S. Blum[1], G. Zalsman[1] and S. Yihya[1]*

[1]Geha Mental Health Center, Petah Tikva, Israel
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.914

Introduction: Youth suicide is a significant public health issue, ranking as the third leading cause of death among youth worldwide. Pediatric emergency departments (PEDs) play a critical role as the first line of care for suicidal patients. However, PED personnel, who often lack psychiatric training, need to be equipped with the skills necessary to assess suicidality and provide immediate intervention. This study explores the readiness of non-psychiatric medical personnel in Israeli PEDs to identify and care for suicidal children and adolescents.

Objectives: The primary objective is to evaluate the readiness of non-psychiatric PED personnel to detect and intervene with suicidal youth. Specific objectives include assessing:

1. Frequency of suicidal patient encounters in PEDs.
2. Training and confidence in managing suicidal cases.
3. Experience and self-assessed ability to provide immediate care to suicidal patients.

Methods: This cross-sectional study surveyed 87 non-psychiatric PED medical staff across Israel using a questionnaire distributed through REDCap. The survey included both quantitative questions on a 5-point Likert scale and open-ended qualitative questions. Data were analyzed using descriptive statistics for quantitative responses and thematic analysis for qualitative data.

Results: A majority (76%) reported treating suicidal patients within the past year, though only 35% felt confident in providing care. Training levels were insufficient, with participants scoring an average of 2.25/5 on whether they had received adequate training. Most respondents (45%) expressed a need for further education in pediatric psychiatry, and 60% disagreed with the adequacy of current tools for identifying and managing suicidality. The qualitative analysis revealed a perceived gap in training and preparedness, emphasizing the importance of specialized education.

Conclusions: Israeli PED personnel frequently encounter suicidal youth but often feel underprepared to provide appropriate care. There is a clear need for enhanced training programs, particularly in suicide prevention, to equip medical staff with the tools necessary to effectively identify and treat at-risk patients. Recommendations include curricular updates and specialized workshops for PED personnel to improve suicide intervention outcomes.

EPP728

Evaluation of the Adequacy of Eating Disorder Training in Psychiatric Residency Programs in Turkey: A Cross-Sectional Study

B. Akan[1], S. Kukurt[2], B. Ozel[3]* and G. Aşut[3]

[1]Psychiatry, Pamukkale University, Denizli; [2]Psychiatry, Bezmialem Vakif University, Istanbul and [3]Psychiatry, Baskent University, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.915

Introduction: Eating disorders (ED) are serious mental illnesses affecting both physical and psychological health. In Turkey, no systematic research has been conducted on the adequacy of ED education in psychiatric residency programs. This study aims to evaluate the perceptions of psychiatric residents regarding the adequacy of their ED training and to offer suggestions for curriculum development.
Objectives: The primary objective is to assess psychiatric residents' perceptions of the adequacy of their training in EDs and compare this with their training in other psychiatric disorders. Additionally, the study aims to propose improvements to the training curriculum.
Methods: A cross-sectional online survey was conducted among 133 psychiatric residents across Turkey. Participants were recruited through social media groups for psychiatric residents, and data were collected in August 2024. The minimum sample size was determined to be 111, based on power analysis. The survey included sociodemographic questions (age, gender, institution type, years of residency) and questions regarding ED training, supervision experience, and other psychiatric disorders. Categorical variables were summarized using percentages and frequencies, while continuous variables were presented as means and medians. McNemar's test was used to assess differences in training and self-efficacy between two diagnostic groups. Ethical approval was obtained from Başkent University (KA24/297).
Results: The mean age of the participants was 28.3 years (SD: 2.1), and the average duration of their residency was 2.6 years (SD: 1.1). Regarding ED training, 46.2% (n=62) reported receiving theoretical lessons, while 84.2% (n=112) reported no supervision. Additionally, 56.4% (n=75) considered their ED training insufficient, and 55.2% (n=73) felt inadequately prepared to manage EDs, which was significantly different from other disorders (for psychotic disorders: $\chi^2 = 34.225$, p <.001; $\chi^2 = 29.167$, p <.001, anxiety disorders: $\chi^2 = 9.031$, p =.003; $\chi^2 = 35.027$, p <.001, sleep disorders: $\chi^2 = 18.581$, p <.001; $\chi^2 = 34.028$, p <.001, neurocognitive disorders: $\chi^2 = 34.028$, p <.001; $\chi^2 = 30.031$, p <.001).
Conclusions: This study demonstrates that psychiatric residents in Turkey, perceive their training in EDs as inadequate. This may stem from the limited time allocated to ED education, lack of supervision, and insufficient clinical experience. The perception that EDs are less common and complex could contribute to limited resources being allocated to their education. These inadequacies may affect residents' ability to manage ED patients effectively. A comprehensive review of training programs, including more practical experience and supervision, could address these deficiencies.

Balint group putting on medical trainees in psychiatric internship: first findings and pilot project at Fribourg University, Switzerland

I. Gothuey[1,2]* and C. C. Devaud[3]

[1]Adult Service, Fribourg Mental Health Network, Marsens; [2]Fribourg University and [3]Forensic Service, Fribourg Mental Health Network, Fribourg, Switzerland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.916

Introduction: Balint groups are recognized for preventing burnout and ehanced empathy by general practionners. Since few years, they are also identified for enhancing empathy by medical students for difficult patients. With the introduction of a six weeks psychiatric internship during the master medical studies at Fribourg University, a compulsory participation in four Balint Group sessions was implemented for medical trainees during there clinical psychiatric rotation.
Objectives: Hilighting main psychiatric topics concerns by medical trainees during the first and the second years of implementation Hypothesing about imposition participation for medical trainees versus a freely participation.
Methods: An intervision space between group leaders take place to supervising this new design..Each group leader made a presentation about the groupal dynamic and the broached subjets during their session with medical trainees.
These finding were wrintig, discussed beteween and compiled, in order to target a future enquiry's questions.
Results: The fisrt year, main topics concern psychiatry's foundations: what to do when a relative or friend is hospitalized? How to manage relational distance? How far should one be empathetic towards suicidal patients or directive with the setting of care? It was noticed an emotionally context where the tendency of students to identify with the patient was prevalent.
In consequence's, the groupal dynamic required a great attention on the part of the moderators, to enhancing and building the medical identity of the trainees.
During the second year, in contrast, the emotional climate was quieter, the cases presented in a more balanced way.Trainees were distanced from the patient's position as victim and accept better identify to the therapists.

Image 1:

Table 1: Content of sessions presented during the first year

Number	Clinical vignette	Peer review	Thematics
1.1	Hospitalization in PAFA[1] mode of a patient who was a friend	Peers find him too smiley: defensive mechanism?	Mental illness affects all of us
1.2	Family interview where the trainee feels that the clinic manager has been "too distant".	Peers find it difficult to manage the loyalty conflict	The asymmetry of the relationship is more extensive in psychiatry
1.3	The child psychiatry trainee is on the same bus as the teenager who has just run away...	Peers support him	The trainee's vulnerability is greater
1.4	The trainee attends the announcement of a restraint measure[2] to a demented patient in psycho-geriatrics	Peers re-identify with the 'victim' patient	Dismay and incomprehension about MLLs[3]
1.5	Trainee attends a warrant for a "suicidal" patient and feels the need to comfort him with a gesture	Awareness of their tendency to identify with the "victim" patient	Difficulty in assuming the protection of a patient against their will and the need to comfort them with a gesture

Image 2:

Table 2: Content of sessions presented during the second year

Number	Clinical vignette	Peer review	Thematics
2.1	Patient coming to Switzerland for EXIT[4]	Need for 'tools' to assess capacity for discernment	Medical ethics for the purpose of end of life[5]
2.2	Patient transferred in restraint to another ward	Need for better supervision of physician assistants	Need for debriefing after restraint
2.3	85-year-old female patient who has been seeing ghosts for years	When does a "locally accepted belief" become a psychiatric symptom?	Inscribing the psychiatric symptom in the socio-cultural context
2.4	Young Iranian patient who attempted suicide to oppose his dismissal	How can you help if you can't act against the decision?	Medicine is not above the law
2.5	Female patient who ordered oxycodone[6] via Internet	Should this opioid be weaned on demand of the OCN? ?	Medicine must assert its field of expertise

Conclusions: Balint group for medical student during their immersion in the psychiatry field are useful to help students to improve empathy in the patient relationship and to better understanding the specificity of the doctor relationship in psychiatry. But the confrontation with the mental illness and their treatment, especially seclusion treatment, asked a lot of questions from the trainees. The students during the first year of Balint introduction showed a great identification with the patient, essentially catched by the manifest speech and complaints. We observed some changes between the both year, with some hypothesis: better prepared students with previous teaching but also the better frame for their attend by the medical staff in hospital or in ambulatory services.
Further studies must be conducted with qualitative items (satisfaction enquiry by the students, and quantitative findings.

INTERRUPTED TALK: Exploring the barriers encountered by psychiatry trainees with utilising a CBT-based framework in patient clinical encounters in an NHS Trust – A qualitative study

A. Obiekezie[1]*, F. Dewsnap[1] and J. Anderson[2]
[1]SABP, Surrey and [2]Brighton and Sussex Medical School, Brighton, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.918

Introduction: The UK Royal College of Psychiatrists and the General Medical Council both recognise the value of and commend the use of Cognitive Behavioural Therapy (CBT) in understanding and treating Psychiatric disorders. It is now mandatory to incorporate in CBT in psychiatry training. Previous research and the authors' own experiences as a trainee have shown that despite being trained in CBT, there continues to be limited use of CBT in routine clinical practice by psychiatry trainees. This study was conducted at a UK NHS Trust as an educational service evaluation.
Objectives: Despite trainees receiving extensive CBT training and completing a 12-session CBT case early in their training, many do not use this skill. The objective of the study was to explore any barriers psychiatry trainees encountered in utilising CBT in routine clinical practise.
Methods: A qualitative, ethnographic approach using focus group discussions was used. Three Focus groups were conducted. These were audio-recorded and transcribed verbatim, then analysed using a General Thematic Analysis. A coding framework was used to organise emergent themes into five broad categories and are shown in the results section.
Results:

Table 1: Barriers to CBT use

Training Factors	Patient Factors	Psychiatrist/ Clinician Factors	Systemic Factors	Other Factors
Not taught in medical schools Insufficient training Training too abstract Time-lag between training and practice Lack of access to information on further training Trainers' emphasis No familiarity with integrating into assessments	Patient Willingness Suitability Patient preference for medication Patient mindset about psychiatrist's role Not considered tangible by patients Poor rapport with medics in in-patient settings Severity of illness	Few advocates Subspecialisation Lack of confidence Unavailability of senior clinicians Culture of clinicians Lack of autonomy Lack of practise Not part of Doctor's role	Time Type of care setting (Community vs Inpatient) Pressure on services. No senior modelling Lack of clarity of concept Focus on other areas at assessment. Lack of supervision No therapist continuity or formalised follow-up	CBT is too structured

Conclusions: Psychiatry trainees were eager to use their CBT skills more often yet find barriers hindering their aspirations. In a specialty where talking with patients can sometimes be as effective as offering them medications, having a deeper understanding of the hindrances trainees encounter with regularly deploying this skill is crucial.

Navigating the Challenges of Conducting Training Programs for Serious Mental Disorders for different stakeholder in Slum in Bangladesh

D. T. Rashid Soron[1]*, K. S. Azmery[1], F. Ahmed[1], M. Rahman[1], M. Belaluzzaman[1], A. A. Mamun[1] and T. Consortium[2]
[1]Telepsychiatry Research and Innovation Network, Dhaka, Bangladesh and [2]University of Warwick, Coventry, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.919

Introduction: Mental health treatment gap is over 92% in Bangladesh. The situation is more disappointing for those living in the slums in this country where basic health care and other facilities are limited. Due to the lack of easy and affordable access to biomedical care, the slum populations predominantly seek mental health care from traditional and faith-based healers, community health workers (CHWs), and local medicine sellers for serious mental disorders. In the TRANSFORM research, we are working with these 4 important stakeholders and codeveloped two different training programs clustering them in two different groups. In one group, we provided training for traditional and faith based healers and in another group community health workers and medicine sellers and a total 153 people received our 3 days long codeveloped training in 4 batches.
Objectives: We aimed to document the different types of challenges; we encounter to conduct 3 days long training program on serious mental disorders in two groups in the 4 batches.

Methods: A mixed-methods approach was employed to document challenges faced in three stages: pre-training assessment, during-training documentation, and post-training evaluation. During the pre and post feedback assessment we asked participants to provide feedback on specific challenges they faced. The process documentation and event notes throughout the program were collected. After training of each batch, we organized FGDs to gather qualitative insights about the challenges and separate FGD was organized with the facilitators, organizing team members and researchers to get their views also. Thematic analysis was performed on qualitative data, and descriptive statistics were used to assess quantitative findings.
Results: The challenges were clustered in 5 key thematic areas 1) challenge related to manage the diversity of the training participants within the group in terms of age, educational level, religions, 2) challenge related to time and schedule management – due to the rain, traffic jam, ramadan and eid holidays, 3) sociocultural and stigma related challenges: such as old women were unwilling to take part in role 4) Challenge emerged due to disaster **:** A devastating fire ravaged the slum leaving thousands homeless during the training, in addition the heavy rain and storm, 5) political and policy related challenges - During the fourth training batch, political unrest led to roadblocks and safety concerns, making it difficult for participants and facilitators to attend the training.
Conclusions: The understanding and early identification of challenges might be helpful in successful implementation of psychiatry training in different settings.

The Role of Emotional Competencies and Mentalization in Burnout Development Among Psychiatry Residents: Longitudinal Findings from the QASP Project

L. Tarchi[1]*, G. Castellini[1], V. Ricca[1] and A. Fiorillo[2]

[1]Health Sciences, University of Florence, Florence and [2]Mental Health, University of Naples, Luigi Vanvitelli, Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.920

Introduction: Burnout is a pervasive issue among psychiatry residents, with long-term consequences for both individual well-being and the quality of care provided to patients. The role of emotional competencies, including emotional regulation, self-awareness, and mentalization, is increasingly recognized as critical in mediating burnout outcomes, according to the job demands-resources model of burnout.
Objectives: The study objective was to investigate predictors of burnout and burnout correlates in a sample of psychiatry trainees.
Methods: This study examines longitudinal data from the QASP project (*Questionnaire and Assessment of Stress and Performance in psychiatry residents*), which also aims to assess the relationship between emotional exhaustion, depersonalization, and personal accomplishment in medical residents across multiple centers in Italy. Using a mixed longitudinal model, we explored predictors of burnout and its correlates, in particular mentalization deficits, emotional dysregulation, and attachment insecurity.
Results: The study involved 827 psychiatry residents enrolled across different psychiatry training programs in Italy, enrolled in two waves: 2022 and 2023. To date, 351 follow-up assessments were retrieved. Emotional exhaustion showed a rapid increase during the early years of residency, then stabilizing in later years (Figure 1).
The results also indicated a strong relationship between increased exposure to violence and elevated burnout dimensions. However, coping strategies were observed to evolve and refine during residency training, with psychiatry trainees displaying a shift from avoidance to problem-focused approaches over time. Residents were also more likely to report less attachment insecurity after one year of training (Longitudinal Mixed Models - Figure 2).
Interpersonal competencies, sustained by mentalization skills, were observed as following a coupled longitudinal trajectory with burnout, so that an increase in interpersonal competencies was associated with a lower elevation in burnout dimensions (Figure 3).

Image 1:

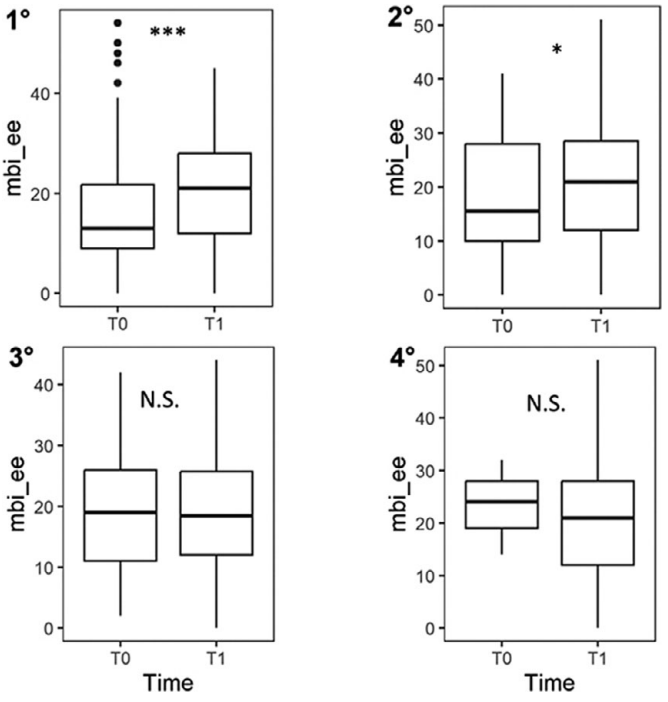

Image 2:

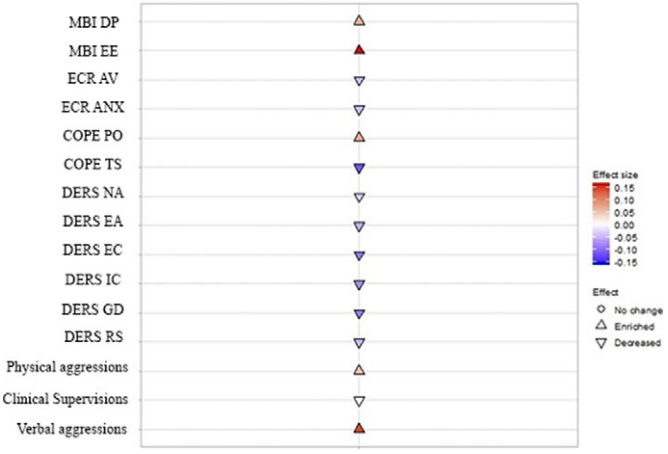

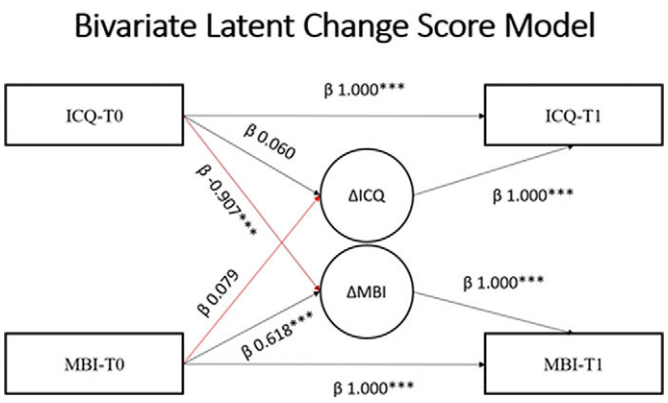

Image 3:

Conclusions: Our findings suggest that enhancing emotional personal and interpersonal competencies could mitigate burnout, improve training outcomes, and potentially increase later workforce retention among psychiatry trainees. These results underscore the need for interventions targeting emotional competencies and mentalization during psychiatric training, such as focused clinical supervisions by senior staff members. Such interventions could enhance residents' resilience, promote effective coping mechanisms, and ultimately improve the quality of psychiatric care.

PsychED – A National Teaching Programme to Boost Medical Student Engagement in Psychiatry

R. Hafes[1], D. Varma[2]*, N. Stanton[3] and S. Thakaria[4]
[1]Psychotherapy; [2]Liaison Psychiatry; [3]Forensic Psychiatry and [4]Children and Adolescent, CNWL, London, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.921

Introduction: In the 2019 *Choose Psychiatry* guidance for medical schools in the UK, medical students voiced a need for more extracurricular activities focused on mental health. They specifically requested the inclusion of psychiatric clinicians in their education to deepen their understanding of psychiatry and its different roles. Applications for core psychiatry training have risen dramatically, leading to oversubscription in recent years. In response to this demand, *PsychED UK*, a national teaching programme was created to further foster students' knowledge and interest in psychiatry.

Objectives:

- Increase medical students' engagement in psychiatry as a career.
- Enhance students' knowledge and confidence in psychiatric practice.
- Boost interest in psychiatry through practical insights and exposure.

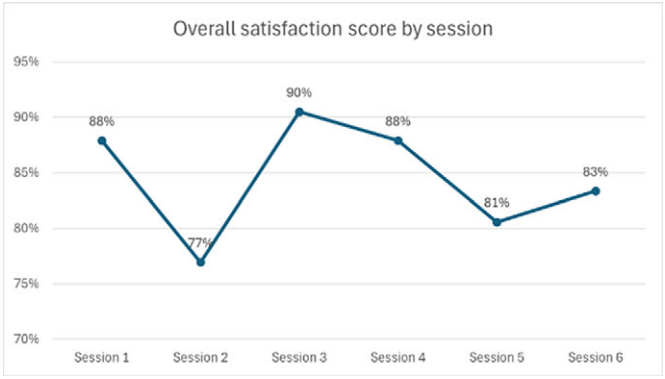
Methods: Between December 2023 and February 2024, six one-hour teaching sessions were offered to medical students and Foundation Programme trainees through Medall, a virtual healthcare platform, delivered by consultants, registrars, and core trainees, ensuring a broad range of experiences.

In order to increase engagement we selected different types of presentation content: session 1 and session 4 focused on practical and personal tips on life as a psychiatry trainee, session 2 and session 3 delivered high-yield content tailored to support exam revision and lastly session 5 and session 6 gave an insight into subspecialties, providing a glimpse into exciting career pathways beyond the general practice.

Pre- and post-session questionnaires were used to measure the satisfaction scores, including likert scale ratings focusing on the student's knowledge, confidence, and interest in a career in psychiatry and free text box for qualatative data.

Results: We had a strong turnout, with 126 attendees participating across six sessions. The audience included a diverse range of individuals, from first-year medical students to Foundation Year 2 trainees, with participants joining from across the UK and even internationally. The results showed strong overall satisfaction, with all sessions scoring 77% or higher. Sessions 1, 3, and 4 received the highest satisfaction ratings, and Sessions 1 and 4 had the highest percentage of attendees providing feedback, indicating strong engagement with the content. Free-text feedback analysis highlighted that attendees were seeking more personal experiences and insights from current core trainees.

Image 1:



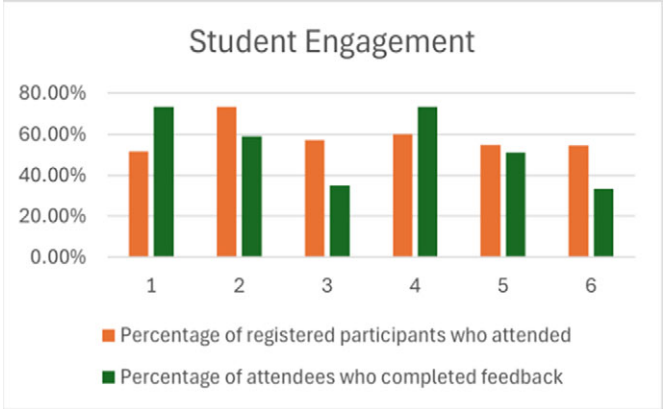


Image 2:

Conclusions: The *PsychED UK* programme effectively enhanced medical students' knowledge and confidence in psychiatry, addressing key areas identified in previous student feedback. Based on these positive results, a second series of teaching sessions is planned, with further refinements to the programme. Due to the high level of engagement and satisfaction with sessions 1 and 4, the second cycle will be presented by two speakers in a conversational format, focusing on the experiences of psychiatry trainees.

Perceived Stigmatization in Patients with Opioid Use Disorder followed up at Arrazi Psychiatric Hospital in Salé

N. Ait Bensaid[1,2]*, M. Sabir[1,3] and F. El Omari[3]

[1]arrazi psychiatric hospital, Sale; [2]hopital psychiatrique arrazi salé, Salé and [3]HAS, arrazi psychiatric hospital, Sale, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.922

Introduction: Stigmatization has been associated with unfavorable outcomes for individuals with mental illnesses, as it acts as a barrier to seeking help and achieving age-appropriate functional goals. Among mental disorders, people with schizophrenia are most frequently stigmatized, followed by those with alcohol-related disorders, substance use disorders, and depressive disorders.
Substance use disorders have often been viewed as stigmatizing conditions
Objectives: To assess perceived stigmatization and its consequences among patients followed and hospitalized for the management of opioid use disorder in the addiction service at Arrazi Psychiatric Hospital in Salé.
Methods: This is a descriptive cross-sectional study using a questionnaire that includes socio-demographic and clinical criteria, as well as an assessment of perceived stigmatization among patients followed and hospitalized for the management of opioid use disorders in the addiction service at Arrazi Psychiatric Hospital in Salé.
Perceived stigmatization was measured using the Perceived Stigma of Addiction Scale (PSAS). This scale consists of 8 items measuring perceived stigma among substance users.
Inclusion criteria: patients of both sexes, aged 18 to 65, diagnosed with opioid use disorder.
Results: A total of 72 responses were retained. Approximately 60% were male, the majority lived with their families, and about 85% were unemployed. Codeine and tramadol were the most commonly used substances, while heroin was less prevalent. Psychiatric comorbidity was present in about the majority of participants (anxiety disorder, depressive disorder, personality disorder, and 2% with psychosis).
The mean (standard deviation) score of the perceived stigma scale for the study population was 21.23. The mean perceived stigma score was significantly associated with the place of residence, with significantly higher perceived stigma found in participants living alone. Stigmatization was also higher depending on the route of opioid administration and was correlated with the participants‘ socio-economic status.
Conclusions: The study suggests that stigma is a major concern among patients with opioid use disorders. Further research is needed to assess the relationship between stigma and the extent of substance use, personality factors, treatment-seeking behaviors, and its impact on quality of life. Studies could evaluate the evolution and trajectory of stigma throughout treatment in order to develop interventions that could help address the issue of stigma in mental health.

The association between Major Depressive Disorder and Cannabis Use Disorder: a meta-analysis and meta-regression analysis

J. Alemar[1]*, J. M. Castaldelli-Maia[2,3] and M. O. Pozzolo Pedro[3]

[1]Faculdade de Medicina do ABC, Santo André, Brazil; [2]Neuroscience, Faculdade de Medicina do ABC, Santo André and [3]Psychiatry, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.923

Introduction: Major Depressive Disorder (MDD) is one of the most common psychiatric conditions, while cannabis is the most widely used illicit drug globally. Both MDD and Cannabis

Use Disorder (CUD) hold significant epidemiological and health implications. Emerging evidence suggests a co-occurrence between cannabis abuse, dependence and depression, though studies remain limited.
Objectives: To estimate the percentage of individuals with CUD who have comorbid MDD and those with MDD who have comorbid CUD.
Methods: PubMed, SciELO, and Google Scholar were searched using keywords: ((abuse, cannabis[MeSH Terms]) OR (cannabis dependence[MeSH Terms])) AND ((depressive disorder, major [MeSH Terms]) OR (depressive disorder[MeSH Terms])). Original articles in English or Portuguese were included. Data collection followed PRISMA, MOOSE guidelines, and JBI critical appraisal. The final sample included 53 articles: 36 for the first meta-analysis and 17 for the second. A heterogeneity test (Q test) and "leave-one-out meta-analysis" were used. Prevalence rates were aggregated using random-effects models. Meta-regression and sensitivity analyses were conducted.
Results: MDD showed a high prevalence among individuals with CUD, at 31.12% (95% CI: 25.71% to 36.80%). Prevalence was not significantly influenced by year, age, gender, population type, assessment period, region, or diagnostic criteria. CUD prevalence among those with MDD was 10.95% (95% CI: 7.08% to 15.53%), with higher rates in men and younger individuals. CUD prevalence appears to be increasing over time, though population type and assessment period did not significantly affect overall prevalence.
Conclusions: This meta-analysis reveals a high prevalence of MDD among individuals with CUD and a significant prevalence of CUD among those with MDD, confirming a strong comorbidity. Cannabis use may exacerbate depressive symptoms, while those with MDD are at higher risk of developing CUD. Age, gender, and geographical factors influence this relationship. With increasing cannabis use, particularly among younger populations, the CUD-MDD comorbidity presents a growing public health issue. Further research is needed to explore the longitudinal link between these disorders.

Prevalence of depression and anxiety symptoms among first-generation medical students

S. Aljhani[1]*, A. Alhasan[2], W. Almohaimeed[2], R. Almeshal[2], E. almeshal[2] and I. AlWahhabi[2]

[1]Psychiatry and [2]Qassim University, Buraydah, Saudi Arabia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.924

Introduction: Medical students face high demands in college, which may cause significant psychological stress and mental health problems, such as depression and anxiety. Several studies worldwide have shown that such individuals are more likely to experience anxiety. However, few studies have examined how generational status and being a first-generation medical student lead to mental health issues.
Objectives: In this study, we aimed to estimate the prevalence of depression and anxiety in first-generation medical students (FGMS) compared with non-FGMS and to determine the correlation between socioeconomic factors and other variables with depression and anxiety in FGMS.
Methods: This cross-sectional study was conducted among medical students at the College of Medicine. A self-administered questionnaire was distributed to the students using convenience sampling. The questionnaire comprised socio-demographic information (e.g. age, gender, marital status), a General Anxiety Disorder (GAD-7) scale to assess anxiety, and a Patient Health Questionnaire (PHQ-9) to assess depression among medical students.
Results: Among the 309 medical students who completed the questionnaire, 65.4% were female and 75.7% were FGMS. The prevalence of anxiety and depression among medical students was 36.2% and 39.5%, respectively, and was higher among FGMS, but not significantly different ($p<0.05$). Independent risk factors for anxiety and depression among FGMS included a previous history of mental disorders and lack of social and emotional support, while fair sleep quality was identified as a significant independent preventive factor for anxiety and depression. The prevalence rates of anxiety and depression among patients with FGMS were 39.3% and 41.9%, respectively. A previous diagnosis of mental disorder was a significant risk factor for anxiety and depression, whereas fair sleep quality was a significant protective factor. Further research is needed to identify the factors that influence anxiety and depression among FGMS in our region.
Conclusions: Anxiety and depression are common among first-generation medical students. FGMS with a history of mental disorders tended to exhibit symptoms of both anxiety and depression compared to the rest of the FGMS. However, satisfactory sleep quality could result in better mental condition in FGMS. Institutional measures should be adopted to help students improve their living conditions. Furthermore, institutional leaders should spearhead the destigmatisation of psychological disorders and advocate help-seeking behaviours when students need mental help, particularly when they are anxious or depressed.

Is there a place for Psychosocial Rehabilitation in Alcohol Use Disorders? – A Retrospective Analysis of the profile of frequent Users of an Inpatient Alcohol Unit in Lisbon

M. Andrade[1]*, M. Cameira[1], I. Pereira[1], A. Ferreira[2], S. Morais[3] and J. Teixeira[1]

[1]Hospital Júlio de Matos - Unidade Local de Saúde São José, Lisbon; [2]Hospital de Setúbal, Setúbal and [3]Hospital Garcia de Orta, Almada, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.925

Introduction: Alcohol dependence is a chronic condition associated with multiple relapses, leading to recurrent admissions to inpatient units. The success of treatment is closely tied to the psychosocial rehabilitation of these patients, as a means to ensure long-term abstinence.
Objectives: We aim to characterize the psychosocial profile of frequent users of an Inpatient Alcohol Detoxification Unit in Lisbon and to reflect on the need for psychosocial interventions to prevent relapse risk.
Methods: A retrospective analysis of data collected from the clinical records of patients admitted two or more times within one year to

an Alcohol Detoxification Unit in Lisbon, during the period between January 2022 and December 2023.
Results: During the study period, 37 patients with two or more admissions in a year were identified. The average age was 51.9 years, and 67.6% were male. It was found that 48.6% of the patients were divorced or separated; more than half of the patients were unemployed at the time of admission (62.2%), and nearly half were experiencing financial hardship (48.6%). In terms of integration into rehabilitative and abstinence maintenance structures, 40.5% had attended the Day Care Center of the Hospital Center, and only 5.4% had been part of a Therapeutic Community (TC). Before their last admission, 8.1% of the patients had been referred to a TC, 10.8% to the Day Care Center, and 51.4% to outpatient care, while 24.3% left against medical advice. In contrast, during the last admission in the study period, 13.5% were referred to the Day Care Center, and 35.1% to a TC.
Conclusions: The results highlight the need for psychosocial intervention and rehabilitation in patients with alcohol use disorder. Treatment should include a multidisciplinary approach that takes into account socioeconomic support and integration into rehabilitative structures, as these promote long-term abstinence and therapeutic success.

Psilocybin: Systematic review of its use in the treatment of depression

P. Andres-Olivera[1,2]*, J. de la Iglesia[1,2], E. Dominguez-Alvarez[1], P. Soto'Gonzalez[3], C. P. Rodriguez[4], C. Munaiz-Cossio[4], R. K. Gonzalez-Bolaños[4], R. Brito-Rey[4], C. Marín-Lorenzo[4] and B. Arribas-Simon[5]

[1]Psichiatry, CAUSA; [2]Medicine; [3]USAL; [4]CAUSA, Salamanca and [5]Psichiatry, HCUV, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.926

Introduction: Psilocybin, a psychedelic compound, has shown potential in treating depression, especially in cases resistant to conventional treatments. This study systematically reviews the scientific literature to assess its efficacy and safety.
Objectives: The main objective of this study is to evaluate the therapeutic effects of psilocybin for the treatment of depressive disorder through a systematic review of the current scientific literature
Methods: An exhaustive search was conducted in databases such as PubMed and Web of Science, using specific MeSH term and selecting studies published between 2019-2024 that investigated the effects of psilocybin in treating depression.
Results: The included studies demonstrated significant improvements in depressive symptoms with psylocibin compared to standard treatments. Studies reports a rapid and sustained symptom reduction, with few adverse effects.
Conclusions: Psilocybin could be an effective and safe alternative for treating depression, providing symptomatic relief with fewer treatment sessions and a favorable safety profile. However, further research is needed to overcome current limitations and fully understand its therapeutic potential and underlying mechanisms.

Wernicke's encephalopathy in patient with alcohol dependence

M. P. Pando Fernández[1], P. Martínez Gimeno[1], M. Calvo Valcárcel[1], M. A. Andreo Vidal[1], M. D. L. Á. Guillén Soto[1], M. B. Arribas-Simón[1]*, C. Alario Ruiz[1], O. M. Segurado Martín[1], G. Guerra Valera[1], M. Fernández Lozano[1], M. J. Mateos Sexmero[1], N. Navarro Barriga[1], B. Rodríguez Rodríguez[1], A. Aparicio Parra[2], G. Lorenzo Chapatte[1], M. Rios Vaquero[1], L. Rojas Vázquez[1], A. Monllor Lazarraga[1], L. Sobrino Conde[1], F. J. González Zapatero[1], L. del Canto Martínez[1] and M. E. Espinosa Muth[1]

[1]Psiquiatría and [2]HCUV, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.927

Introduction: The worldwide prevalence of Wernicke-Korsakoff syndrome is thought to range from 0-2%. Those at greatest risk include the homeless, the elderly, and psychiatric patients (1). In treatment, typical regimens include high doses of intravenous thiamine, three times daily for at least three days. Electrolyte abnormalities should be corrected and fluids replaced.
Objectives: We are interested in studying the evolution of a patient with alcohol withdrawal syndrome progressing to wernicke's encephalopathy.
Methods: We conducted a literature review by searching for articles in Pubmed.
Results: A 40-year-old male, with no medical or surgical history of interest, alcohol consumer, was admitted to the hospital ICU for an episode of ataxia and agitation in the context of four days of alcohol abstinence. He was sedated and orotracheal intubation was performed and treatment was started with thiamine, tiapride and diazepam. After hemodynamic and respiratory stability, the patient was transferred to the Internal Medicine ward where he presented clinical symptoms compatible with Wernicke's Encephalopathy (cerebellar ataxia and nystagmus). Psychiatry was consulted to adjust treatment and to carry out a psychosocial approach for discharge (alcohol withdrawal center).
The patient's evolution has been favorable with the adjustment of psychopharmacological treatment. In the neurological examination we observed nystagmus and cerebellar ataxia. In the psychopathological examination the suspicious contact, psychomotor restlessness, mild generalized tremor in both MMSS are remarkable. Speech difficult to understand due to language barrier. Traits of impulsivity in the foreground. Unstructured biological rhythms. Partial insight. Intellectual functions and volitional abilities preserved.
In the complementary tests without significant remarkable alterations. In the treatment adjustment, a de-escalation of diazepam has been carried out for discharge. Treatment with pregabalin, tiaprizal, thiamine and vitamins B1-B6-B9 was also prescribed. Recommendation of absolute cessation of alcohol consumption and follow-up by internal medicine, psychiatry and social work.
Conclusions: Wernicke-Korsakoff syndrome is a clinical diagnosis and Wernicke's encephalopathy should be suspected in any person at risk of thiamine deficiency presenting oculomotor findings, ataxia or confusion (1). Thus, in our patient presenting ataxia and nystagmus in the context of alcohol abstinence and some malnutrition, an early approach with thiamine can be performed to prevent progression to Korsakoff's syndrome.

Once amnesia and executive deficit are present, Korsakoff's syndrome should be suspected. The key to good outcomes is therefore to detect Wernicke's encephalopathy early and treat it with thiamine (1). Severe concomitant infections, including sepsis of unknown origin, are frequent during Wernicke's phase (2). In our patient there were no complications.

Problematic internet use among adolescents in Sousse, Tunisia: Prevalence and correlates

R. Ayoub[1,2]*, M. Fakhfekh[1], M. Ajmi[1,2], A. Lajnef[1], M. Oueslati[1] and A. Guedria[1,2]

[1]Child and Adolescent Psychiatry Department, Fattouma Bourguiba university Hospital and [2]University of Monastir, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.928

Introduction: Cyberaddiction, characterized by excessive and uncontrollable internet use, has been linked to various psychological and behavioral issues. Adolescents are particularly vulnerable to these risks, as they are heavy users of digital platforms, often spending long hours online for social interaction, entertainment, and gaming. While research on this issue is expanding, our study seeks to contribute further insights into the factors associated with problematic internet use and its implications for adolescent well-being.
Objectives: The objective of our study was to determine the prevalence of cyberaddiction among adolescents in Sousse, Tunisia and to investigate its relationship to self-esteem.
Methods: We conducted a descriptive cross-sectional study with analytical objectives among adolescents aged 12 to 18 from schools in Sousse Medina, Tunisia during February, March, and April 2024. We used a demographic information form, the Young Internet Addiction Test and the Rosenberg Self-Esteem Scale for data collection.
Results: Our population consisted of 416 adolescents. The most represented age group was 14 years old (22.1%), with a mean age of 15.05 ± 1.7 years. The sample comprised 236 females (56.7%) and 180 males (43.3%). Our findings indicate that 83.2% of participants exhibited problematic internet use with potential life consequences, 11.3% showed occasional excessive use but maintained control, and 5.5% experienced severe repercussions from their internet use. Additionally, 43% of participants spent more than 2 hours per day online. A statistically significant relationship was observed between the amount of time spent online and cyberaddiction ($p = 0.009$, with higher levels of cyberaddiction associated with increased internet usage. According to the Rosenberg Scale, 51.9% of adolescents had low self-esteem, however, no statistically significant relationship was observed between self-esteem and cyberaddiction.
Conclusions: Our findings highlight a concerning prevalence of problematic internet use among adolescents, with no significant correlation identified between self-esteem and cyberaddiction. This suggests that other underlying factors may contribute to the challenges faced by this population. It is crucial for healthcare professionals and policymakers to prioritize preventive measures and awareness campaigns, promoting healthier online habits and ultimately fostering the well-being of young people in an increasingly digital world.

Cyberaddiction and anxiety-depressive disorders among adolescents in Sousse, Tunisia: Prevalence, Patterns, and Implications

R. Ayoub[1,2]*, Y. Akkari[1], M. Ajmi[1,2], A. Lajnef[1], M. Oueslati[1] and A. Guedria[1,2]

[1]Child and Adolescent Psychiatry Department, Fattouma Bourguiba university Hospital and [2]University of Monastir, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.929

Introduction: As global internet usage continues to expand, concerns regarding its effects on adolescent mental health have gained prominence. Cyberaddiction and anxiety-depressive disorders are increasingly recognized as interconnected among adolescents. Excessive use of digital platforms, social media, and online gaming can contribute to heightened stress, social isolation, and emotional instability. Understanding these dynamics is essential for developing effective mental health strategies and encouraging healthier online behaviors among adolescents.
Objectives: This study aimed to investigate the relationship between cyberaddiction and anxiety-depressive disorders among adolescents in Tunisia.
Methods: This is a cross-sectional, descriptive, and analytical study, that was conducted on adolescents aged 12 to 18, enrolled in three educational institutions in Sousse, Tunisia. Data were collected using the Young Internet Addiction Scale and the Hospital Anxiety and Depression Scale (HADS). A pre-established data collection form was used to gather additional demographic and behavioral information.
Results: Our study included a population of 416 adolescents, with a mean age of 15.05 ± 1.724 years. The majority of the participants were female (56.7%). Among the participants, 41.6% were high school students, and 58.4% were middle school students. Our results showed that 83.2% of participants exhibited problematic internet use, with potentially adverse effects on their daily lives. Additionally, 11.3% managed to maintain control over their internet usage despite occasionally exceeding planned time, while 5.5% experienced severe internet addiction, significantly impacting their personal and social lives Regarding internet usage patterns, the majority (64.9%) reported that social media was their primary online activity, while 35.1% preferred online gaming. The HADS revealed that 43% of the participants experienced varying degrees of anxiety disorders, and more than half (50.7%) showed symptoms of depressive disorders. Notably, 88.5% of the participants displayed symptoms of both anxiety and depression. A statistically significant correlation was observed between anxiety-depressive disorders and cyberaddiction ($p = 0.008$).
Conclusions: Our study highlights a concerning prevalence of both cyberaddiction and anxiety-depressive disorders among adolescents. These findings emphasize the urgent need for preventive measures and targeted interventions. Addressing these issues through education, mental health support, and regulated internet use could mitigate the negative impacts on adolescents' well-being.

A validation study of the Hungarian version of the Prediction of Alcohol Withdrawal Severity Scale: the role of kindling mechanism

O. Bagi[1]*, B. K. Kádár[1], F. F. Farkas[1], J. Gajdics[1], I. K. Pribék[1] and B. A. Lázár[1]

[1]Addiction Research Group, Department of Psychiatry, University of Szeged, Szeged, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.930

Introduction: The critical importance of preventing, recognizing early, and effective treatment of complicated form of alcohol withdrawal syndrome (cAWS) lies in its high mortality rate. cAWS include alcohol-related seizures (ARS), and delirium tremens (DT). The Prediction of Alcohol Withdrawal Severity Scale (PAWSS) was developed to identify patients at risk of developing cAWS. Recently, history of ARS and/or DT ("kindling mechanism"-related predictors) have been suggested as the strongest risk factor for developing cAWS.
Objectives: The present study aimed to validate the Hungarian version of the PAWSS as suitable for evaluating the risk of developing cAWS and determining the significance of past ARS and/or DT occurrences.
Methods: A total of 70 inpatients were enrolled from at the Department of Psychiatry, University of Szeged, Hungary in 2023 with a principal diagnosis of AWS. PAWSS, Severity of Alcohol Dependence Questionnaire (SADQ) and Alcohol Use Disorders Identification Test (AUDIT) were used. Demographic variables (age, sex) and clinical outcomes (development of cAWS) were collected. Statistical analyses were performed using Receiver Operating Characteristic (ROC) analysis, binary logistic regression analyses and chi-square test.
Results: The ROC analysis showed that ≥ 6 is the optimal cutoff point in our sample. The sensitivity (73.91%), specificity (82.98) and positive- (68.00%) and negative- (86.67%) predictive values were highest for the threshold value of 6. In the first binary logistic regression model our results indicate that the PAWSS score of 6 or more was identified as a significant predictive factor for the current cAWS (OR = 12.332; 95% CI = 3.468–43.85; p < 0.001). The results of the second binary logistic regression showed that the history of the cAWS (OR = 6.811; 95% CI = 2.084–22.25; p = 0.001) and the SADQ total score (OR = 1.048; 95% CI = 1.001–1.10; p = 0.043) were significant predictive factors for the current cAWS. The chi-square test results showed significant difference between the rate of the history of cAWS and the current cAWS ($\chi 2$ (1) = 13.0; $p < 0.001$) and 21.4% (n = 15) of the patients had both current and previous cAWS. The Phi-coefficient was 0.431, which indicates that the history of complicated AWS has a relatively strong effect on the current cAWS.
Conclusions: Our results revealed that the Hungarian version of PAWSS is a valid tool for predicting cAWS with a different cutoff score compared to the original version. Furthermore, our findings suggest that the risk of developing cAWS is independent of the severity of alcohol use disorder. Our results also demonstrated that a history of cAWS is a significant predictor in the development of future episodes of cAWS.

EPV0017

Exploring the Nexus of Nicotine Dependence and Schizophrenia in a Clinical Case Study

S. Ben Aissa[1]*, N. Chaima[1], R. Khouloud[1], L. Amine[1] and M. Wahid[1]

[1]Psychiatry D, Razi Hospital, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.931

Introduction: Studies in the general population and those based on clinical assessments of individuals with schizophrenia have shown a high degree of overlap between schizophrenia and substance-related disorders.
The prevalence of substance abuse throughout life is so common that the likelihood of a specific link inevitably arises. Various hypotheses have been proposed to explain the high comorbidity between schizophrenia and substance abuse, making these patients challenging to manage due to potential pharmacological interactions between the substances they consume and neuroleptic medications.
Objectives: To explore the nexus between nicotine dependence and schizophrenia through a case report and a review of the literature.
Methods: We discuss a 40-year-old divorced man, father of one daughter, unemployed, with a history of psychiatric follow-up in private care for seven months before admission for untreated schizophrenia, and polyaddiction to substances including tobacco, cannabis, and cocaine.
He was transferred to our facility for management of behavioral disorders and aggression with a refusal of oral treatment. The patient had been incarcerated in France for four years for assault with a bladed weapon. He was admitted to our emergency psychiatric service with his brother due to arson within his residence where he lives alone. Upon admission, the patient was well-oriented in time and space, with neglected hygiene, easy contact, neutral facial expressions, sad mood, blunted affect, motor instability, and a dissociative syndrome: irrelevant responses, tangential speech, and persecution delusions without a specific persecutor, confirming his behavioral disorder and trivializing it with impaired judgment and no suicidal ideations.
Results: The patient was hospitalized and underwent a complete blood test and ECG, both of which returned normal results, and was treated with olanzapine 10 mg/day and chlorpromazine 200 mg/day. During his hospitalization, he made several attempts to start fires within the ward, explaining his actions as a constant desire to inhale smoke to relieve discomfort, and he experienced a craving for smoke. After a month in our facility, and following the resolution of the dissociative and delusional syndromes, we scheduled a leave for the patient to assess clinical improvement. Upon returning from leave, the patient expressed multiple persecutory delusions towards family members who prevented him from starting a fire in his garden, which he considered necessary for his well-being.
Conclusions: Comorbidity between addiction and schizophrenia is very common in our social context, and management should be simultaneous, without neglecting the importance of family support.

Vulnerability factors of problematic cannabis use

A. Mhalla[1,2], A. Ben Haouala[2]*, M. Ben Mbarek[2], N. Faouel[2], B. Amamou[2] and F. Zaafrane[2]

[1]Laboratory Research LR05E10 and [2]Laboratory research LR05ES10, University of Monastir, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.932

Introduction: The cannabis use has increased widely in Tunisia during the ten past years, especially in adolescents and young adults. Cannabis use can lead to mental and physical health problems.
Objectives: The aim of the study was to determine the factors associated to problematic cannabis use.
Methods: This was a cross-sectional descriptive and analytical study including 115 subjects arrested for suspected drug use, carried out using a pre-established questionnaire, the CAST (Cannabis Abuse Screening Test) for the assessment of cannabis use, the Hamilton Anxiety and Depression scale, the 5-word Test of Dubois for memory evaluation, and the Rosenberg scale for the assessment of self-esteem.
A urine dosage of cannabis was also performed.
Results: The mean age of the study population was 25.19 ± 6.7 years. The sex ratio was 8.16. the problematic users represented 73.9% of the study population. The cannabis was used in the form of joints. Memory decline was noted in 73% of the cases, and 52% of users had anxiety and depression symptoms.
Problematic use was associated to male gender ($p<0.001$), to an age older than 21.5 years ($p= 0.01$), to early initiation ($p= 0.005$), to memory decline ($p= 0.003$) and the higher scores of anxiety ($p< 0.001$)
Conclusions: The frequency of cannabis consumption and the vulnerability factors of problematic use must be taken into account in prevention campaigns.

Substance use and mental health in pediatric type 1 diabetes: key predictors of academic failure

C. Bey[1]*, T. Ach[1,2] and A. Ben Abdelkarim[1,2]

[1]University of Sousse, Faculty of Medicine of Sousse, 4000 and [2]Endocrinology department, Farhat Hached University Hospital of Sousse, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.933

Introduction: Type 1 Diabetes (T1D) is an invisible condition, yet it can be difficult for young people to accept. Many attempt to hide or downplay their illness, potentially leading to significant psychological distress.
Objectives: The objective of this study is to determine the prevalence and characteristics of academic failure among children with T1D, as well as the associated risk factors, including the impact of substance use such as tobacco, alcohol, and cannabis.
Methods: This is a retrospective, descriptive, and analytical study conducted at the Endocrinology Department of Farhat Hached Hospital in Sousse, covering the period from January 2015 to January 2020. The study analyzed the school and professional trajectories of T1D patients, considering their clinical, biological, and social data. Academic failure, the dependent variable, was defined as either the interruption of studies or the repetition of at least one academic year. Additionally, the prevalence of smoking, alcohol, and cannabis use in this population was recorded.
Results: The study included 70 patients (31 males and 39 females), with a mean age of diagnosis of T1D at 7.36±4.41 years. Academic repetition was observed in 71.4% of cases, and school dropout in 47.1%. The reasons for academic delays were attributed to recurrent hospitalizations (31.4%) and glycemic instability, including hyper/hypoglycemic episodes (17.1%). Multivariate analysis adjusted for diabetes type revealed that significant risk factors for academic failure included: ≥5 hospitalizations for ketosis ($p=0.037$) and higher mean HbA1c levels at recent consultations ($p=0.001$). Protective factors were functional insulin therapy ($p=0.031$) and the use of insulin analogs ($p=0.004$). Concerning substance use, tobacco addiction was present in 22.9% of patients, alcohol consumption in 14.3%, and cannabis use in 8.6%. Patients using tobacco and alcohol exhibited a higher risk of school dropout and lower academic performance, with a significant correlation between cannabis use and glycemic instability.
Conclusions: The risk of academic failure among T1D patients is substantial and should not be underestimated. Frequent hospitalizations, poor glycemic control, and substance use (especially tobacco and cannabis) further exacerbate this risk. The physical and psychological complications of T1D, combined with the socioeconomic challenges and limited access to medical care in rural or isolated areas, contribute to school dropout. This study highlights the importance of comprehensive medical and psychosocial support to improve both health and academic outcomes in this vulnerable population.

Trauma-Addiction Link Among Women in Harm Reduction

S. Matmati[1], E. khelifa[1], A. mtiraoui[2] and C. bey[1]*

[1]razi hospital, tunis and [2]psychiatry, hopital farhat hached, sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.934

Introduction: The life journeys of women who have experienced childhood violence are often marked by great complexity. This study aimed to better understand the links between childhood trauma and the development of substance use disorders, in order to propose therapeutic interventions tailored to the specific needs of these women
Objectives: identify the most frequent types of trauma and their frequency in the studied sample. To describe the most commonly used substances, patterns of use, and the severity of substance use disorders.
Methods: sample of 53 women who frequented harm reduction centers participated in this study. The Childhood Trauma Questionnaire (CTQ) was employed to evaluate experiences of childhood trauma, while the Drug Use Disorder Identification Test (DUDIT) was utilized to assess the severity of substance use disorders. Data collection was conducted anonymously, and subsequent analysis was performed using statistical software spss.

Results: In our study, 53 women consulting risk reduction centers met the inclusion criteria.

- A history of childhood trauma (CTQ ≥ 35) was observed in 92.5% of cases (n=49). Severe trauma scores were found in:
- 45% for emotional neglect
- 23% for physical neglect
- 51% for emotional abuse
- 59% for physical abuse
- 21% for sexual abuse
- A drug dependence (DUDIT ≥ 2) was observed in 72% of cases (n=38), i.e., all women in the study who used psychoactive substances. The most frequent dependencies were related to cannabis (53%), followed by benzodiazepines (41%) and pregabalin (36%).
- Injectable drug use was observed in 23% of cases, with Subutex being the most common (n=10; 5%). Two women used heroin (1%).

Conclusions: These results highlight the importance of integrating a trauma-informed approach into the care of women with substance use disorders. Specific therapies, such as trauma-focused cognitive-behavioral therapy (TF-CBT), can be particularly beneficial in helping these women manage their post-traumatic symptoms and reduce their substance use.

Between Violence and Addiction: The Complex Journeys of Resilient Women

S. Matmati[1], E. Khelifa[1], C. Bey[1]* and A. Mtiraoui[2]

[1]razi hospital, manouba and [2]farhat hached hospital, sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.935

Introduction: Violence against women is a significant public health issue with devastating consequences for victims. It's a complex and often hidden phenomenon rooted in deep-seated gender inequalities. Faced with distress and trauma, some victims may develop self-medication behaviors, such as substance use.
Objectives: This descriptive study aims to characterize the experiences of violence among 53 women who sought help from the ATL, MST SIDA, and ATIOST associations.
Methods: Data was collected through individual interviews with each of the 53 participants. An interview guide was developed to cover different types of violence (physical, psychological, sexual, economic), their frequency, intensity, and their consequences on substance use, using the DUDIT questionnaire.
Results: The sample consisted of women with an average age of 36.04 ± 10.31 years, ranging from 18 to 58. The results show that all participants experienced multiple and recurrent forms of violence, primarily psychological (insults, denigration, control, isolation) and physical (hits, slaps, threats). Sexual violence, although less frequently reported, was also identified in 32%. The most common type of violence was physical (77%), mainly occurring within the couple (49%). 72% of women presented a substance use disorder. The most commonly used substances were cannabis (53%), followed by benzodiazepines (41%), and pregabalin in third position (36%).
Conclusions: This descriptive study highlights the complexity of the experiences of violence faced by women seeking help from harm reduction associations. The results underscore the urgent need to address this issue and develop tailored responses to the specific needs of these women. Future research could explore in greater detail the risk and protective factors associated with violence against women, as well as the long-term effects of this violence on mental and physical health.

Investigating the Intentional Google Effect: A Pilot Study Using Antisaccade Eye-Tracking Paradigm

A. M. Bukinich[1]*, D. A. Bazhenova[1], G. D. Vzorin[1] and A. M. Konovalova[1,2]

[1]Faculty of Psychology, Lomonosov Moscow State University and [2]Department of Pedagogy and Medical Psychology, Sechenov University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.936

Introduction: There is growing concern that the internet may have a detrimental effect on users, leading to addiction and cognitive decline. One well-known empirical study, conducted by Sparrow, Liu, and Wegner (2011), presented two types of the so-called Google effect (intentional and mnemonic) as evidence. In this study, participants answered either difficult or easy yes/no trivia questions, followed by a Stroop task involving internet-related and neutral words displayed in different colors. The reaction times were slower for internet-related words, but only after the difficult trivia questions, which was interpreted as evidence of automatic internet priming in challenging situations. However, subsequent replication attempts were unsuccessful. We hypothesized that the Stroop paradigm may not be valid due to the lack of semantic interference and that the antisaccade task would be more sensitive.
Objectives: To investigate the intentional Google effect using the antisaccade eye-tracking paradigm.
Methods: A pilot study was conducted (N=37). Participants answered a series of difficult or easy yes/no trivia questions, followed by the appearance of either an internet-related or neutral image on the left or right side of the screen. The task required participants to look in the opposite direction of the stimulus, with oculomotor activity recorded by the SMI Hi-Speed system (1250 Hz). Reaction time and the number of errors were measured.
Results: Logistic regression and ANOVA results did not show a significant influence of question difficulty, stimulus type, or their interaction on error probability ($B = -0.22$, $SE = 0.22$, $z = -0.94$, $p = 0.35$) or reaction time ($F = 0.31$, $p = 0.58$).
Conclusions: These preliminary results do not support the hypothesis for the intentional Google effect, further research and discussion in the context of internet-addiction are needed.

Disclosure of Interest: None Declared

Breaking the Cycle: Understanding Frequent Relapses in Alcohol Treatment – The Impact of Patient Engagement and Prevention Strategies through Retrospective Analysis

M. Cameira[1]*, Â. Ferreira[2], I. Pereira[1], M. Andrade[1], S. Morais[3] and J. Teixeira[1]

[1]ULS São José - Hospital Júlio de Matos, Lisboa; [2]ULS Arrábida - Hospital de São Bernardo, Setúbal and [3]ULS Almada-Seixal- Hospital Garcia de Orta, Almada, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.937

Introduction: Alcohol use disorder is a significant Public Health issue with substantial socioeconomic impact, morbidity, and mortality. Achieving therapeutic success remains challenging due to frequent treatment dropouts, relapses, and readmissions. It is estimated that 20-40% of patients discontinue detoxification treatment prematurely, with some studies highlighting the influence of psychiatric comorbidities, polysubstance use, unemployment, and impulsivity. Premature discontinuation increases the risk of medical complications and worsens prognosis. Although anti-craving medications have demonstrated efficacy in preventing relapse, they remain underprescribed.
Objectives: This study aims to identify and analyze determinants of readmissions, particularly in patients with a history of treatment dropout, and propose strategies to enhance therapeutic success.
Methods: A two-year retrospective analysis was conducted on readmitted patients, with a focus on previous dropouts, within the 12 months prior to their last hospitalization for alcohol detoxification at ULS São José - Hospital Júlio de Matos. The analysis included sociodemographic data, comorbidities, anti-craving therapy, integration into therapeutic communities (TC), and post-discharge outcomes.
Results: A total of 37 patients were identified with readmissions in the past 12 months. Of these, 9 (24.3%) had left their previous admission against medical advice, most of whom had experienced 4 or more admissions. There was a similar gender distribution, with all patients being single or divorced, 66.7% unemployed, and the same percentage experiencing economic hardship. Two-thirds had psychiatric comorbidities. None had recently received anti-craving medication, and only 2 (22.2%) had prior involvement with a TC. During their readmission, 44% were discharged to a TC or Day Center, and 2 left again against medical advice.
Conclusions: It was found that many frequent users discharged themselves against medical advice from previous hospitalizations. These patients showed a high prevalence of socioeconomic problems and psychiatric comorbidities, with none receiving anti-craving therapy. In the future, it will be essential to analyze the reasons for these dropouts to improve the effectiveness of treatment during hospitalization. It is concluded that therapeutic plans must be personalized and tailored to the patients' multiple needs to ensure better adherence.

Addictive Behaviors among University Students in Kenitra, of Internet and Social Media: An Exploratory Study

A. CHAKER LAMRANI[1]*, S. BOULBAROUD[2], M. RMILI[1], M. ALAYACHI[1] and F.-Z. AZZAOUI[1]

[1]Ibn Tofail University, Laboratory of Biology and Health, KENITRA and [2]Sultan My. Slimane University, Polydisciplinary Faculty, BeniMellal, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.938

Introduction: As the accessibility of new technology becomes easier and its usage longer, especially among university students, the repercussions on content consumption and behaviors must be examined and addressed, both for prevention and remediation.
Objectives: The aim of this study is to assess the degree of addictive behaviors associated with the use of the internet and social media. Through a questionnaire, data was collected from a random sample of university students in Kenitra.
Methods: 58 students participated in the study (21.29 ± 1.69) (38 women and 20 men), distributed as follows: 31% in the first year, 32% in the second year, and 36% in the third year. Of these, 94% reported owning a smartphone for at least one year.
Results: 17% reported using internet for more than 12 hours per day. 37% recharge their balance immediately after it is depleted, and 41% become frustrated when they receive no response to a message, 38% are constantly awaiting new notifications. Nearly 30% reported that internet use affects their studies, health, and causes conflicts with their parents.
Girls are more connected than boys and cannot tolerate being without internet access ($p < 0.05$, respectively). The number of repeated semesters is highly correlated with the duration of smartphone ownership and significantly correlated with age ($p < 0.05$). Furthermore, a strong correlation is observed between the duration of internet use and the allocated budget ($p < 0.05$), as well as the ability to tolerate the absence of internet access ($p < 0.05$).
The regression test shows that an increase in the allocated budget for internet connection leads to an increase in the time spent using smartphone applications ($\beta = 0.42$), and the model explains 47% of this relationship. Additionally, the nature of the application used can explain 30% of the increase in the number of repeated semesters among university students ($\beta = 0.30$), this parameter is also explained by the duration of smartphone ownership by 10% ($\beta = 0.33$).
Conclusions: Internet access is facilitated by smartphones, which fosters attachment behaviors among university students that can lead to addiction and certainly have an influence on academic progress, health, and family relationships.

Disclosure of Interest: None Declared

The relationship between immuno-biochemical indicators and clinical manifestations of alcoholic and/or mixed forms of addiction in adolescents

T. V. Chernobrovkina[1], S. A. Zozulya[2]*, Z. V. Sarmanova[2], I. N. Otman[2], A. V. Masyakin[1], E. V. Bryun[1] and I. Y. Kotova[1]

[1]FGBUZ "Moscow Scientific and Practical Center of Narcology", DZM and [2]FSBSI "Mental Health Research Centre", Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.939

Introduction: Identification of the effects of experimentation with psychoactive substances and the formation of addictive behavior in adolescents in risk groups requires the development of new approaches to the clinical and laboratory examination for the prevent severe complications of intoxication and treatment of addiction. One of the biological indicators of complications from the use of psychoactive substances during the period of brain development may be neuroinflammation, in addition to metabolic disorders and disorders of other internal organs.

Objectives: To study the relationship between the levels of inflammatory markers and biochemical blood indicators with the clinical symptoms in adolescents with alcohol and substance intoxication.

Methods: Clinical and laboratory examinations included 40 patients aged 14 to 17 years diagnosed with behavioral and mental disorders due to alcohol use and/or combined alcohol and substance abuse. In blood plasma, the activity of leukocyte elastase (LE) and α1-proteinase inhibitor (α1-PI), as well as the level of autoantibodies (AB) to S100B and basic myelin protein (MBP) were measured. The results were compared with the corresponding normative indicators.

Results: The relationship between the level of immune system activation and the activity of the pathological process in the brain served as the division of patients into groups. The 1st group (58.3%) was characterized by high activity of LE and α1-PI and an increased level of aAT to MBP ($p<0.05$). The 2nd group (42.7%) was distinguished by low LE activity and a high level of other markers ($p<0.01$). In the 1st group, a higher monocyte content, an increase in creatine phosphokinase activity, uric acid level, aspartate aminotransferase and alanine aminotransferase ratio, a decrease in gamma-glutamyltransferase activity and serum iron and ferritin level were found compared to the 2nd group. In the 2nd group, the increase in the number of neutrophils was associated with a relatively increased platelet content, as well as higher levels of alkaline phosphatase activity, creatinine content, total and direct bilirubin. In the 1st group, signs of attention deficit, autoaggression, and increased tolerance to the dose of the substance used were detected more often. In the 2nd group, pronounced tension and irritability, a longer duration of drug use, and more severe clinical manifestations of withdrawal syndrome were observed.

Conclusions: The introduction of indicators of neuroinflammation, associated with ferroptosis mechanisms, initially clinically asymptomatic, into the cluster of clinical and laboratory studies will specify the diagnostics of individual changes in reactivity and health disorders in adolescents at the stage of drug addiction. This will substantiate and increase the effectiveness of the prevention of addictions and early disability among adolescents at risk.

EPV0029

Examining the associations between mental well-being, emotional regulation, social anxiety, and excessive smartphone use

S. Csibi[1]*, N. Pirwani[2], M. Csibi[3] and A. Szabo[2]

[1]Faculty of Psychology, Department of Sciences and Letters, George Emil Palade University of Medicine, Pharmacy, Science, and Technology, Targu Mures, Romania; [2]Institute of Health Promotion and Sport Sciences, Faculty of Education and Psychology, ELTE Eötvös Loránd University, Budapest and [3]Institute of Special Education, Faculty of Pedagogy, Eszterházy Károly Catholic University, Eger, Hungary

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.940

Introduction: Interpreting and perceiving adequately others' emotions and the regulative processes within one's mental health are barriers or predisposing factors in the development of smartphone addiction.

Objectives: The research explores the role of mental health, fear of negative perception, and assessment of other people's emotions, which influence excessive smartphone use.

Methods: The survey included 400 respondents, of whom 104 were men (26%), 293 women (73.2%), and three persons (0.8%) who indicated a different gender. The mean age of the participants was 25.9 years (SD 10.9). Registered answers refer to demographic data (gender, age, smartphone usage habits) as well as psychological measures: a Smartphone Application-Based Addiction Scale (SABAS), a Mental Health Continuum Scale (MHC), an Assessing Emotions Scale (AES), and Fear of Negative Perception Questionnaire (FNPQ).

Results: Results show a significant negative correlation between the SABAS score and global mental well-being ($r(398) = -.15$, $p = .005$) and a significant positive correlation between the SABAS score and fear of negative perception ($r(398) = .27$, $p = .001$). Using SABAS's cutoff point (23 points), non-problem ($M = 59.6$, $SD = 11.4$) and problem users ($M = 55.8$, $SD = 11.3$) differ significantly in global mental well-being ($t(398) = -2.9$, $p = .004$) and each of its sub-factors, emotional, social, and psychological well-being; as well as non-problem ($M = 20$, $SD = 8.2$) and problem users ($M = 24.1$, $SD = 8.4$) in fear of negative perception ($t(398) = 4.3$, $p = .001$). Relevant associations between emotional regulation and problematic smartphone use we did not find.

Conclusions: The resulting data will support to investigation of the role of mental health well-being factors in the development of problematic smartphone usage, besides prevention and psychotherapeutic intervention.

Disclosure of Interest: None Declared

Impact of problematic mobile phone use among Nursing Students

A. M. Cybulska[1]*, K. Rachubińska[1], D. Schneider-Matyka[1], S. Mazurkiewicz[2] and E. Grochans[1]

[1]Department of Nursing, Pomeranian Medical University in Szczecin and [2]Independent Public Provincial Hospital in Szczecin, Szczecin, Poland

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.941

Introduction: Technological development and the ever-expanding range of functions that a mobile phone offers to its users cause that more and more people overuse this device. The problem of smartphone addiction and nomophobia has become a significant social problem, especially among young mobile phone users. It has been observed that excessive use of smartphones can cause psychological problems, such as increased levels of stress, anxiety, depression, decreased cognitive function, and can also negatively affect students' academic activities.
Objectives: The primary aim of the study was to assess the extent of phone addiction among nursing students. Additionally, the researchers aimed to investigate the impact of various variables, including socio-demographic and psychological factors, on the severity of pathological phone use among nursing students.
Methods: This survey based study was performed using the author questionnaire and standardized research tools: the Nomophobia Questionnaire (NMP-Q), the Mobile Phone Problem Use Scale for Adolescents (MPPUSA), the Athens Insomnia Scale (AIS), and the Depression, Anxiety, and Stress Scale version 21 (DASS-21).
Results: The study involved 303 nursing students of the Pomeranian Medical University in Szczecin. A subjective feeling of addiction to a mobile phone was noted in 51.16% of respondents, and to the internet in 22.44%. In addition, 66.34% of the respondents had sleep problems. Some 38.28% of the nursing students did not show symptoms of depression, 38.61% had normal levels of anxiety, and 37.62% had normal levels of stress. Phone use was significantly more problematic among single people and those in an informal relationship, as well as among younger respondents. Analysis of the data revealed statistically significant positive correlations between problematic phone use according to the MPPUSA and the severity of depression, anxiety, stress, and insomnia according to the AIS.

Variable		MPPUSA [score]	
		r	p
NMP-Q	No possibility of communication	0.531	**< 0.001**
	Loss of connectivity	0.6	**< 0.001**
	Being unable to get the news	0.682	**< 0.001**
	Inconvenience	0.64	**< 0.001**
DASS-21	Level of depression	0.324	**< 0.001**
	Level of anxiety	0.333	**< 0.001**
	Level of stress	0.404	**< 0.001**
AIS		0.317	**< 0.001**

Conclusions: The vast majority of nursing students use a mobile phone correctly and do not exhibit symptoms of nomophobia. Age and marital status are the sociodemographic variables that have a statistically significant effect on the pathological pattern of smartphone use. There is no statistically significant relationship between mobile phone addiction and gender or place of residence. Phonoholism statistically significantly positively correlates with nomophobia, as well as the severity of depressive symptoms and insomnia. Moreover, the more pathological the smartphone use, the higher the levels of anxiety and stress experienced by nursing students.

Disclosure of Interest: None Declared

doi: 10.1192/j.eurpsy.2025.942

Introduction: Workaholism is an addiction, however the obsessive-compulsive components alone may prove insufficient in determining its nature.
Objectives: The aim of the following study was to determine the mediating role of depressiveness in the relationships between workaholism and personality traits according to the five-factor model among Polish women.
Methods: The research study was carried out among 556 women residing in the West Pomeranian Voivodeship in Poland. The research was based on a survey performed using a questionnaire technique. The following research instruments adapted to Polish conditions were employed to assess the incidence of work addiction among female adults: The NEO Five-Factor Inventory (NEO-FFI), The Work Addiction Risk Test (WART) Questionnaire, and The Beck Depression Inventory–BDI I-II.
Results: A positive correlation between the intensity of neuroticism and the work addiction risk was revealed ($\beta = 0.204$, $p < 0.001$). A partial mediation (35%) with the severity of depression symptoms as a mediating factor was observed ($\beta = 0.110$, $p < 0.001$). Respondents characterized by high neuroticism showed a greater severity of the symptoms of depression ($\beta = 0.482$, $p < 0.001$), which is a factor increasing the work addiction risk ($\beta = 0.228$, $p < 0.001$). Respondents characterized by a high level of extraversion displayed lower severity of the symptoms of depression ($\beta = –0.274$, $p < 0.001$). A negative correlation between the intensity of agreeableness and the work addiction risk was revealed ($\beta = –0.147$, $p < 0.001$). A partial mediation (27.8%) was observed. A positive correlation between the intensity of conscientiousness and the work addiction risk was revealed ($\beta = 0.082$, $p = 0.047$). Respondents characterised by a high level of conscientiousness showed a lower severity of depression symptoms ($\beta = –0.211$, $p < 0.001$).

Table 1. Indirect and total effects: Mediation model 1 - Neuroticism

			95% CI*				
Type	Effect	b	Lower	Upper	β**	z	*p*-value
Indirect	N ⇒ BDI ⇒ WART	0.149	0.092	0.213	0.110	4.800	<0.001
Component	N ⇒ BDI	0.241	0.205	0.275	0.482	13.270	<0.001
	BDI ⇒ WART	0.618	0.398	0.851	0.228	5.230	<0.001
Direct	N ⇒ WART	0.277	0.157	0.403	0.204	4.540	<0.001
Total	N ⇒ WART	0.426	0.319	0.534	0.314	7.790	<0.001

NEU—neuroticims, WART—Work Addiction Risk Test, N – Neuroticism, BDI—Beck Depression Inventory–BDI I-II, b—unstandardized regression coefficient, β—standardized regression

coefficient, *p*—significance level; * Confidence interval (CI) computed with method: bootstrap percentiles; ** Beta (β) is completely standardized effect size.
Conclusions: Depressiveness plays the role of a mediator between neuroticism, extraversion, agreeableness as well as conscientiousness, and work addiction. Depressiveness is a factor which increases the risk of work addiction.

Behavioral addictions an updated look in the child and adolescent population

Y. D'Hiver Cantalejo[1]*, A. Helo Basha[1], V. Ros Fons[1] and C. Delgado Gandia[1]

[1]Psiquiatria, Hospital Nuestra Señora Del Prado, Talavera de la Reina, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.943

Introduction: BEHAVIORAL ADDICTIONS AS A REPETITIVE PATTERN OF BEHAVIOR WITH DECREASE IN SELF-CONTROL AND A POWERFUL DESIRE TO CARRY OUT IT, DESPITE THE NEGATIVE CONSEQUENCES; WITH ACCOMPANYING SYMPTOMATOLOGY OF IRRITABILITY, CONCERN AND ANXIETY.
Objectives: ANALYZE THE RESULTS ON REPORTS OF BEHAVIORAL ADICTIONS
Methods: IN THE REPORTS ON BEHAVIORAL ADDICTIONS, ESTUDES (SURVEY ON THE DRUG USE IN SECONDARY EDUCATION IN SPAIN, 14-18 YEARS OLD) AND EDADES (SURVEY ON ALCOHOL AND DRUGS IN SPAIN) WE FOUND THE FOLLOWING:

- MANY MINORS PARTICIPATE IN GAMBLING GAMES.
- THE USE OF THE INTERNET, GAMBLING WITH MONEY AND VIDEO GAMES ARE VERY COMMON PRACTICES.
- ONLINE BETTING GAMES ARE MORE PREVALENT IN YOUNG PEOPLE.
- WITHIN THE PATHOLOGICAL GAME, A GREATER PREVALENCE OF BEHAVIOR IS OBSERVED RISK.
- WITHIN THE ABUSIVE USE OF THE INTERNET, GREATER CONSUMPTION OF CANNABIS AND ALCOHOL.

Results: REGARDING THE TREATMENT, THE USEFULNESS OF COGNITIVE PSYCHOTHERAPY IS RECOGNIZED. BEHAVIORAL AND THE USE OF PSYCHODRUGS SUCH AS NALMEFENE AND NALTREXONE.
Conclusions: ADDICTION TO THE INTERNET AND VIDEO GAMES COULD BE RECOGNIZED AS PSYCHIATRIC DIAGNOSES WHEN THEY LEAD MORE COMPLEX CHARACTERISTICS. SOME STUDIES PROPOSED TO TAKE INTO ACCOUNT THE EMOTIONAL NEEDS AND THE IMPULSIVITY, WHILE OTHERS, TALK ABOUT THE NEURO-BIOLOGICAL-GENETIC COMPONENT OF ADDICTIONS.

Benefits and Challenges of Transition from High-Dose Methadone to Buprenorphine Depot: A Case Report

M. Delic[1]

[1]Center for Treatment of Drug Addiction, University Psychiatric Clinic Ljubljana, Ljubljana, Slovenia
doi: 10.1192/j.eurpsy.2025.944

Introduction: Opioid dependence is a complex condition that often requires long-term treatment and care. Methadone, a synthetic full opioid agonist, and buprenorphine, a partial agonist at the opioid receptor, are commonly used in substitution therapy for opioid dependence, typically administered as an oral liquid or sublingual tablet. Transitioning from high-dose methadone to buprenorphine for the treatment of opioid use disorder (OUD) poses a risk of precipitated withdrawal. This risk arises from introducing a high-affinity partial agonist (buprenorphine) at the mu-opioid receptor after it has been occupied by a lower-affinity full agonist (methadone). As a result, this transition is usually only performed for patients on low doses of methadone (<30-40 mg). Microdose induction has been proposed as a potential solution to facilitate a smoother transition to buprenorphine.
Objectives: To present a case report of a rapid transition from high-dose methadone to buprenorphine depot, highlighting both the benefits and challenges of this process.
Methods: This case report describes a patient who was switched from 150 mg of methadone to 32 mg of sublingual buprenorphine using microdosing, and subsequently transitioned to a weekly 160 mg buprenorphine depot injection.
Results: The patient was successfully transitioned to sublingual buprenorphine and later to buprenorphine depot without experiencing withdrawal symptoms. Even later, the patient reported no signs of withdrawal and was satisfied with the buprenorphine dosage. The patient attended monthly check-ups with the doctor; however, 15 days after the transition, he began consuming alcohol and soon after, started using cocaine.
Conclusions: This report supports the use of microdose induction for initiating buprenorphine, particularly for patients stabilized on high doses of methadone who may struggle with traditional buprenorphine induction methods. Although the patient remained abstinent from opioids, he quickly relapsed with alcohol and cocaine, issues that had not been present during his methadone treatment. Regular and more frequent therapeutic assessments are very important for many patients to prevent relapse.

The Relationship Internalized Stigmatization and Depression among Adolescents with Substance Use: A Cross-Sectional Study

M. Demir[1]*, F. C. Gümüş[2] and G. Dikeç[3]

[1]Nursing; [2]Psychiatric Nursing, Dicle University, Diyarbakır and [3]Psychiatric Nursing, Fenerbahçe University, İstanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.945

Introduction: Although stigmatization is a barrier to treatment for many individuals and groups, individuals with mental disorders are the most affected by stigmatization. Among mental disorders, substance use disorders are the group with high levels of social stigma and internalized stigma. Internalized stigma may lead to a decrease in self-esteem and withdrawal from society and may increase depressive symptoms. Among individuals who use substances, depressive symptoms are high due to both the effects of the substances used and the psychosocial and legal problems experienced. In the literature review, no study examining the relationship between internalized stigma and depression in adolescents was found.
Objectives: This study aimed to examine the relationship between internalized stigma and depression in a group of adolescents diagnosed with substance use disorder.
Methods: The study was conducted between December 2023-March 2024 with 71 adolescents between the ages of 12-18 who were diagnosed with substance use disorder and admitted to the outpatient clinic of university hospital in a city located in the southeastern part of Turkey. Information Form, Internalized Stigma of Mental Disorders Scale-Adolescent Form (ISMI-AF), and Beck Depression Inventory (BDI) were used for data collection.
Results: The mean age of the adolescents was 15.97 years (1.51); 85.9% were male, 59.2% were high school students, and 90.1% had severe depressive symptoms. According to the Pearson correlation analysis, no significant relationship was found between the total scores of the ISMI-AF and BDI; however, BDI, educational status of the adolescent, and academic achievement was found to be statistically significant as determinants of the ISMI-AF (R2=0.29). It was determined that the variables specified in the model explained 24% of the ISMI-AF (Adjusted R Square = 0.24)
Conclusions: Almost all of the adolescents who participated in this study were found to have severe depressive symptoms. In addition to depression, adolescents' school life and academic achievement were important variables explaining internalized stigma. Since adolescents' school attendance may be a situation that will prevent substance use, interventions to be carried out in cooperation with mental health professionals and school nurses are very important.

Westernisation of Alcohol Consumption in Women: A Rapid Pathway to Dependence and Increased Detoxification Service Use

Â. Ferreira[1]*, I. Pereira[2], M. Cameira[2], M. Andrade[2], S. Morais[3] and J. Teixeira[2]
[1]São Bernardo Hospital, Setúbal; [2]Júlio de Matos Hospital, Lisbon and [3]Garcia de Orta Hospital, Almada, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.946

Introduction: The Westernisation of alcohol consumption habits among women has led to increased alcohol intake and a rise in Alcohol Use Disorder (AUD) cases in females. Although AUD prevalence remains higher in men (7.7% compared to 1.5% in women), women display distinct features in the disorder's progression, such as the telescoping effect, where the transition from initial consumption to dependence occurs more rapidly. This trend underscores the importance of studying frequent female users of alcohol detoxification services to identify contributing factors to this accelerated progression.
Objectives: This study seeks to characterise frequent female users of alcohol detoxification services, focusing on gender differences, particularly the faster progression of alcohol dependence in women and the influence of Westernisation on their drinking habits.
Methods: A retrospective analysis was performed on clinical records from 2022 to 2023 for patients hospitalised at the Alcohol Treatment and Rehabilitation Unit. The analysis included patients who were hospitalised two or more times within a 12-month period. Demographic, psychosocial, and clinical variables were compared, with a particular focus on female patients.
Results: Of the 360 patients admitted between 2022 and 2023, 37 were readmitted within 12 months. Women constituted 29.7% of these cases, with an average age of 52 years (compared to 51 in men), and were more often divorced or separated (81.8% vs 76.9%) and unemployed (72.7% vs 69.2%). Psychiatric family history (72.3% vs 65.4%) and psychiatric comorbidities (90.9% vs 61.5%) were more prevalent in women. Women also had a higher total number of hospitalisations (4.09 vs 3.62), although their 12-month readmission rates were similar to men (1.46 vs 1.50).
Conclusions: These findings support the literature on the telescoping effect, evidenced by women's older age and a similar number of readmissions despite a more precarious social situation and greater psychiatric comorbidities. Notably, although women were a minority among readmissions, their proportion exceeded the expected prevalence rate (30%/70% vs 15%/85%). This highlights the necessity of personalised therapeutic approaches that address the unique factors perpetuating AUD in women.

Numbing the Pain: How Alcohol Use for Chronic Pain Relief Leads to Dependency – Review and Case Study

Â. Ferreira[1]*, I. Pereira[2], A. Falcão[2] and J. Teixeira[2]
[1]São Bernardo Hospital, Setúbal and [2]Júlio de Matos Hospital, Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.947

Introduction: Chronic pain is a debilitating condition affecting 20% to 30% of adults globally, with prevalence rates rising to 19% to 38% in Europe. It is often linked to self-medication, particularly through alcohol consumption, due to alcohol's short-term analgesic properties, which act on the opioid system. However, continued alcohol use for pain relief can lead to alcohol use disorder (AUD), worsening the pain and causing physical and mental health issues.
Objectives: This study explores the relationship between alcohol use in chronic pain management and the development of AUD through a literature review and a clinical case.
Methods: A narrative literature review was conducted using PubMed with the terms "alcohol use disorder" and "chronic pain." English and Portuguese articles from the last 10 years were included, yielding 85 results. A clinical case involving a patient with chronic pain and alcohol dependence illustrates the issue.
Results: The review shows that 28% to 35% of chronic pain patients use alcohol for symptomatic relief. While alcohol may provide initial pain relief, prolonged use leads to tolerance, increased consumption,

and a significant risk of AUD. Approximately 18% to 25% of patients meet the criteria for AUD, with men being more commonly affected. The clinical case describes a 56-year-old man with family history of AUD, who developed chronic pain after a work accident resulting in multiple trauma. The patient began consuming alcohol daily for pain relief, which escalated to an AUD diagnosis and worsened pain due to alcohol-induced hyperalgesia.
Conclusions: Alcohol use is prevalent among chronic pain patients, often as a form of self-medication. However, this practice is frequently counterproductive, as increased consumption to counteract tolerance can lead to serious complications, including hyperalgesia, psychiatric disorders, and significant difficulties in managing both pain and alcohol use disorder (AUD). The clinical case highlights these issues and reinforces the need for a multidisciplinary approach that addresses both pain management and alcohol dependence.
Early detection of problematic alcohol use is essential to prevent the development of AUD. A comprehensive treatment plan, incorporating strategies for pain control and addiction management, is crucial for improving the overall health and well-being of patients dealing with chronic pain.

Hellenic National Observatory for Internet and Gaming Addiction

G. Floros[1]*, K. Siomos[2] and N. Christodoulou[2]

[1]2nd Department of Psychiatry, Medical School, Aristotle University of Thessaloniki, Thessaloniki and [2]Department of Psychiatry, Medical School, University of Thessaly, Larisa, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.948

Introduction: The Greek National Observatory for Internet and Gaming Addiction (NOIAD) is a state-sponsored organization that will be setup in the University of Thessaly during this year following its inclusion in the Greek National Health Plan for Mental Health 2021-2030.
Objectives: In this presentation of the setup and goals of NOIAD, a case will be brought forward for scientific collaboration across the European continent that could culminate in similar centers in different countries.
Methods: The main publication that NOIAD intends to produce annually will have the role of a national report or at least an update of the national situation. In addition to this report, the observatory is expected to prepare a number of studies or reports on individual problems or in response to questions from state institutions (eg Parliament, ministries). Implementation of an online platform (portal) of specialized but also popular knowledge that will aim to inform health professionals and the general population (parents, pupils/students, adults with an addiction problem) with different information profiles for each population. Information lectures, educational activities for minor students, organization of an annual interdisciplinary conference.
Results: NOIAD's principal goal is the planning and implementation of actions to address digital addictions through the collection of objective, reliable and valid information about the state of Internet and Gaming addiction prevalence and related research and clinical practice in Greece. NOIAD will provide a state-of-the-nation annual report and disseminate the relevant information and conclusions to health professionals, government bodies and the wider population. Furthermore, NOIAD will plan and provide local preventative actions in the wider area of Thessaly, especially regarding the high-school and university student population; these actions will serve as blueprints for similar activities across Greece.
Conclusions: Setting up a national center to provide with a complete picture of Internet Addiction and Gaming Disorder, pool together research output and coordinate preventative actions will assist with a fragmented research landscape and make better use of limited resources.

Sexwork and transactional sex in chemsex: results of an anonymous online study

M. Gertzen[1]*, D. Dubrovin Leao[1], N. Khorikian-Ghazari[1], T. Halms[1], A.-M. Strasser[1], A. Rabenstein[2], T. Rüther[2] and A. Hasan[1]

[1]Psychiatry and Psychotherapy, Faculty of Medicine University of Augsburg, Augsburg and [2]Psychiatry and Psychotherapy, LMU Klinikum, München, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.949

Introduction: Sex work and transactional sex (SWTS), along with Chemsex, are linked to high-risk sexual behaviors and poorer health outcomes. Chemsex is the use of methamphetamine, GHB/GBL and mephedrone in a sexual context especially among men who have sex with men (MSM). Transactional sex (TS) is the exchange of sexual services for other services or things in a non professional way. Sexwork (SW) means having sex with people in exchange for money in a professional way.
Objectives: The aim of our study was to determine the prevalence rates of sex work and transactional sex (SWTS) among chemsex users and to answer the question of whether the combination of the two leads to an increased risk profile of those affected in terms of sexual health.
Methods: To achieve this, we conducted an online survey across three European German-speaking countries, targeting MSM. The survey gathered data on participants' substance use patterns, sexual behaviors, and health outcomes, with a particular focus on their engagement in SWTS. SWTS was defined as the exchange of sexual favors for money, drugs, or other material goods, which has been shown to be associated with higher risk behaviors, including unprotected sex and multiple sexual partners.
Results: A total of 399 sexually active MSM were included, categorized into three sub-groups: 129 engaging in Chemsex (MSM-CX), 128 in sexualized substance use with non-Chemsex substances (MSM-SSU), and 142 not engaging in sexualized substance use (MSM-NSU). MSM-CX reported significantly higher rates of SWTS compared to both MSM-SSU ($p=.032$) and MSM-NSU ($p<.001$), indicating that Chemsex use is strongly linked to transactional sex. Both Chemsex and SWTS were associated with higher HIV ($p<.001$, $p=.042$) and STI ($p<.001$, $p=.023$) prevalence, but no cumulative effect was found. Among MSM-CX engaging in SWTS, participants were younger ($p=.006$), had more sexual partners ($p=.029$), and reported higher substance use, including methamphetamine, mephedrone, and GHB/GBL. These factors may contribute to the increased vulnerability to HIV and STIs.

Conclusions: The results highlight the need for targeted prevention and intervention measures addressing the risks of Chemsex and SWTS among MSM. Public health campaigns should consider the socio-behavioral traits of Chemsex users, such as their younger age, higher number of sexual partners, and frequent substance use. These efforts should also reduce stigma, encourage help-seeking, and promote safer sex practices. Prevention should focus on regular HIV/STI testing and accessible harm reduction strategies. In conclusion, this study underscores the importance of tailored, evidence-based interventions to improve health outcomes for MSM-CX engaging in Chemsex and SWTS.

Behind the Screens : Exploring the phenomenon of Binge-Watching behaviour among Tunisian Adolescents

R. Ayoub[1,2], F. Jemil[1], N. Fleh[1], I. Gouia[1], H. Ben Abid[1,2] and A. Guedria[1,2]*

[1]Child and Adolescent Psychiatry Departement, Fattouma Bourguiba Hospital and [2]University of Monastir, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.950

Introduction: In recent years, the rise of streaming platforms has given adolescents unprecedented access to vast libraries of series and films, often leading to hours of continuous viewing, a phenomenon known as binge watching. This emerging trend is reshaping how adolescents engage with media, often affecting their social behaviors, routines, and overall well-being. Understanding these factors is crucial for developing preventive interventions.
Objectives: This study aims to explore binge-watching behavior among Tunisian adolescents and the key factors influencing this trend.
Methods: We conducted a descriptive and analytical cross-sectional study among Tunisian adolescents aged between 12 to 18 years old. Data were collected using an online questionnaire spread throughout social media (Facebook), using the Google Forms® platform in September 2024. We evaluated the epidemiological and social characteristics of the participants, as well as the binge watching behaviour , using Binge-Watching Addiction Questionnaire (BWAQ).
Results: Eighty-two adolescents participated in our study, with a mean age of 16.02 ± 1.65 years and a sex ratio of 0.82. Our resultas showed that 86.5% of our population lived in urban areas, 13.4% in rural areas, and 18.3% did not live with both parents. Our results showed that 15.9% of our population reported low grades, 23.2% had repeated a grade, and 27.7% had issues with teachers or administration. Additionally, 21.5% had experienced bullying, 30.5% faced domestic violence, and 31.7% reported conflicts with parents. Regarding binge-watching, 41.5% of participants engaged in it more than once per week, 43.1% spent over two hours daily on school days, and 29.3% watched more than five episodes in one sitting. The most preferred content included drama series (56.1%), movies (24.4%), and sports shows (19.6%).The mean score on the Binge-Watching Addiction Questionnaire (BWAQ) was 39.43, with 27.7% showing moderate and 7.7% showing highly problematic binge-watching, with no sex difference. Highly problematic binge-watching was significantly associated with conflicts with parents ($p = 0.01$), peers ($p = 0.02$), school staff ($p = 0.42$), and poor academic performance, including grade repetition ($p < 0.01$).
Conclusions: These results highlight the potential negative impact of excessive media consumption on adolescents' social interactions and and academic performance, underscoring the need to implement targeted interventions that not only raise awareness about the risks of excessive media consumption but also provide practical strategies to help adolescents manage their screen time.

EPV0049

Research of personality anxiety and anxiety disorders in patients receiving opioid agonist maintenance therapy (OAMT)

N. Halytska-Pasichnyk

OAMT, Municipal Enterprise "Dnipropetrovsk multiprofile clinical hospital for provision of psychiatric care" Dnipropetrovsk regional council", Dnipro, Ukraine
doi: 10.1192/j.eurpsy.2025.951

Introduction: Increased levels of anxiety in patients with opioid dependence is a common problem that requires a comprehensive approach to treatment. They can manifest as GAD, panic attacks, social anxiety, and other forms of anxiety. The level of personal distress in patients on methadone therapy can be significant, as these patients often face a complex of psychological and social problems related to addiction and treatment.
Objectives: The causes of anxiety disorders can be: 1) biological factors - changes in the neurochemistry of the brain associated with the use of opioids, which can affect the regulation of emotions and cause anxiety; 2) psychological factors – trauma in the anamnesis, stressful situations or negative experiences can contribute to the development of anxiety disorders; 3) social factors – relationship problems, social isolation and economic hardship can increase anxiety. Factors affecting the level of personal anxiety include both medical and social aspects - a) changes in life; b) concomitant mental disorders; c) attitude toward therapy; d) social support.
Methods: In the course of the study, 150 patients aged 26 to 64 years with a diagnosis of opioid dependence, who receive methadone hydrochloride as OAMT, were examined. The Psychopathological Symptom Severity Questionnaire (SCL-90-R, Derogatis, Lipman, Covi) and the Hamilton Anxiety Rating Scale (HAM-A/HARS) were used to assess the level of personal anxiety and existing anxiety disorders.
Results: According to the levels of interpersonal anxiety (very low, low, medium, high), the indicators were distributed as follows: in the control group - 10 (20.4%), 32 (65.3%), 7 (14.3%), 0 (0 .0%); in the main group - 28 (27.7%), 59 (58.4%), 13 (12.9%), 1 (1.0%), respectively ($p=0.685$).
The degree of clinical anxiety according to the Hamilton scale (mild, moderate, severe, strong) in the main group was distributed as follows: 60 (59.41%), 23 (22.77%), 15 (14.85%) and 3 (2.97%); in the control group - 31 (63.27%), 10 (20.41%), 6 (12.24%), 2 (4.08%), respectively ($p=0.930$).
The level of anxiety according to the SCL-90 scale (very low, low, medium, elevated, high) was determined in 19 (38.78%), 22 (44.90%), 6 (12.24%), 2 (4.08%) and 0 (0.00 %) of persons, respectively, in the control group; 39 (38.61%), 46 (45.54%), 15 (14.85%), 1 (0.99%) and 0 (0.00%) - in the primary ($p=0.628$).

Conclusions: The results of the study showed that receiving substitution maintenance therapy did not significantly increase the level of personal anxiety and the risk of anxiety disorders in patients on methadone therapy, the vast majority of patients showed very low, low and mild levels of manifestations. However, the level of personal anxiety may vary, but it is important to provide a comprehensive approach to treatment, including psychological support and social integration, to improve patients' quality of life and reduce anxiety.

Characteristics of gambling among Tunisian students

R. Jbir[1]*, R. Masmoudi[1], F. Cherif[1], M. Abdelkefi[1], I. Feki[1], I. Baati[1] and J. Masmoudi[1]

[1]psychiatry 'A' department, Hedi Chaker university hospital, sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.952

Introduction: Nowadays, gambling has become a common form of entertainment for many young people. Gambling is essentially divided into dice games, card games (especially poker), casino games, sports betting, lotteries and, in recent years, online gambling. As a result, gambling has become a major international business, especially among young students.
Objectives: Evaluate the practice of gambling in a population of young students and describe its characteristics.
Methods: We conducted a descriptive and analytical cross-sectional study among university students.
This survey involved a population of Tunisian students recruited through students' Facebook groups.
A questionnaire was designed to collect information related to participants' background characteristics and gambling-related details.
DSM-5 criteria were used to screen for pathological gamblers.
Results: A total of 151 students responded to our questionnaire. Gambling was found in 29.1% of the students in our study (n=44). Thirty players (68.4%) were occasional players. The lottery (54.5%), followed by sports betting (29.5%) and blackjack (27.3%) were the most reported gambling games by students.
Among the players, nineteen (43.2%) experienced a Big Win. The average amount of money spent on gambling per month was 107.14 ± 123.58 TND, with extremes of 4 and 600 TND.
The majority (77.3%; N=34) played online. Among players, 61.4% (N=27) were used to play with friends.
Almost the half of gamblers (45.5%) have started gambling for less than a year and 6.8% have been gambling for 4 to 5 years.
Pathological gamblers represented 13.9% (n=21) of the students in our population.
Conclusions: Our study highlights the prevalence and characteristics of gambling among university students in Tunisia. With nearly 30% of participants engaging in various forms of gambling. These findings suggest a need for targeted awareness and prevention strategies to address potential risks associated with gambling among young adults, particularly in educational settings. Further researches are essential to explore the long-term implications of gambling behaviors on student well-being and academic performance.

Chronotype in individuals with exercise addiction – preliminary analysis

M. J. Kania[1]*, A. J. Krupa[2], A. Chrobak[3] and M. Siwek[2]

[1]Clinical Department of Adult Psychiatry, University Hospital in Krakow; [2]Department of Affective Disorders and [3]Department of Adult Psychiatry, Jagiellonian University Medical College, Krakow, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.953

Introduction: Exercise addiction (EA) is conceptualized as the uncontrolled practice of physical activity, with repetition of that behavior despite the negative effects on the individual [Khazaal et al. Rev Med Suisse. 2024; 20(882):1354-1359]. According to current systems, EA is included in the group of behavioral addictions [Martyniak et al. Psychiatr Pol 2021;55(6):1357-1372]. The prevalence of EA is understudies, with data from athlete samples ranging from 5-17% [Weinstein et al. Dialogues Clin Neurosci. 2023; 25(1): 1–13]. No prior studies investigatedthe links between chronotype and EA.
Objectives: This work aimed to assess the relationship between EA and chronotype.
Methods: This is a preliminary analysis of data from a larger online survey that assessed the links between behavioral addictions and psychopathology in an online community sample. The inclusion criteria were 1) age ≥18-35 and 2) consent to participate. A local bioethical committee approved the study. Responders completed self-report questionnaires to assess EA: EAI (Exercise Addiction Inventory-Short Form), and chronotype Composite Scale of Morningness (CSM). The participants were divided into subgroups based on their EAI scores: 1) with negative EA screen (EA [-]) [scores ≤12], 2) with positive EA screen (EA [+]) [scores >12]. EA[-] and EA [+] were compared in terms of general characteristics and chronotype (continuous measure). The quantitative data were evaluated with a T-test. The qualitative data were analyzed using the X2 test.
Results: 183 subjects were EA [-] and 99 were EA [+]. There were no significant differences between the groups regarding the mean age: EA [-] 27.36±10.74 years; EA [+] 25,55±7.47 years [t (2, 262) =1.661, p< 0.09]. EA [+] were more likely to be male (40.4%) than EA [-] (27.3%) (X2=5.060, df=1, p=0.026). There were no differences in the levels of education (primary/secondary/ college student/ university student/ completed higher education) in the studied groups (X2=1.78, df=4, p=0.786). EA [+] showed a higher level of morningness measured with the CSM total score (34.13 ±6.48) than EA [-] (30.62±8.63)[t (2, 251.8) = 3.855, p< 0.001).
Conclusions: EA was linked to male sex in the studied sample. Individuals with positive exercise addiction screen present higher levels of morningness.

Attachment style and food addiction: Exploring psychological links

A. Karmous[1]*, H. Ghabi[2], M. Karoui[2], H. Nefzi[2], R. Kammoun[2] and F. Ellouze[2]

[1]emergency and outpatient department and [2]Department G, Razi hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.954

Introduction: Behavioral addiction is well-established for gambling but still debatable for other pleasurable behaviors such as eating. Attachment style is defined as a psychological concept describing the dynamics of human interpersonal interactions. Studies investigating the influence of attachment style on food addiction are rare.
Objectives: The aim of the study was to evaluate the association between food addiction and the quality of attachment
Methods: A cross-sectional study was conducted online with a non-clinical population. All participants completed an anonymous e-questionnaire containing sociodemographic data, background, substance use and self-reported weight and height. Attachment style was assessed with the Relationship Scale Questionnaire (RSQ). Food addiction was screened with modified Yale food addiction scale questionnaire (mYFAS 2.0).
Results: A total of 114 individuals had fully responded to the questionnaire. The mean age was 32.28 ± 9.32 years with a sex ratio of 0.48. The mean BMI was 23.7 kg/m2 ± 5.5. Most of participants (64%) had an insecure attachment style and 36% had a secure one. The results of the mYFAS 2.0 showed that 11.4% of participants had a food addiction and 8.8% had a severe form. BMI was significantly associated with food addiction which was more common in participants who had a BMI greater than 22.2 kg/m2. A statically significant association between insecure attachment style and food addiction was found.
Conclusions: Our study showed the importance of studying attachment style in food addiction. More research is needed to prove the association between food addiction and different attachment styles.

Patients with alcohol use disorder clustering based on definition of alcohol withdrawal syndrome

V. Karpyak[1]*, A. M.-C. Ho[1], B. J. Coombes[2], V. M. Pazdernik[2], J. A. Frank[2] and J. M. Biernacka[2]

[1]Psychiatry and Psychology and [2]Computational biology, Mayo Clinic, Rochester, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.955

Introduction: Alcohol withdrawal syndrome (AWS) is among the most severe components of alcohol dependence (AD). Severe AWS, especially complicated with seizures and delirium, was a common reason for medical complications and death. The introduction of benzodiazepines decreased but did not eliminate those risks. The definition of AWS evolved in different versions of Diagnostic and Statistical Manual for Mental Disorders (DSM) from having hand tremor plus one or more other symptoms in DSM-III-R to any two or more symptoms in DSM-IV, which was retained in the current version of DSM-5.
Objectives: Comparing subgroups of individuals with AUD based on AWS symptoms profile to define phenotypes for investigation of biological underpinnings of AWS phenomenology and treatment response.
Methods: Treatment-seeking individuals diagnosed with DSM-IV alcohol dependence (AD; n=473; 35.5% females) were assessed with Psychiatric Research Interview for Substance and Mental Disorders (PRISM), Timeline Follow back (past 90 days) alcohol consumption, Penn Alcohol Craving Scale (PACS), Pittsburgh Sleep Quality Index (PSQI), Patient Health Questionnaire-9 (PHQ9), and General Anxiety Disorder-7 (GAD-7). Latent class analysis was used to classify subjects according to lifetime prevalence of AWS symptoms according to DSM-III-R or DSM-IV/5 . Demographic and other clinical variables were compared among clusters by linear model ANOVA and chi-squared test.
Results: Four clusters were identified: subjects with (1) no history of meeting any AWS criteria (n=50); (4) with complete number of AWS symptoms, meeting both DSM definitions (n=259); and two clusters of subjects with smaller number of AWS symptoms: (3) those meeting only DSM-IV/5 criteria (n=94) and (2) those also meeting DSM-III-R criteria (n=70). Compared to cluster 2, the Cluster 3 members had higher frequency of anxiety, insomnia, and restlessness during withdrawal. The clusters also differed in the total number of drinks (p=0.021), average drinks per drinking days (p=0.013), history of anxiety disorder (p=0.006), substance-induced depression (p=0.019), and higher scores of PSQI (p<0.001), PHQ9 (p<0.001), and GAD-7 (p<0.001) with a relative increase in frequency between clusters as follows 1<2<3<4. Group 4 also had the highest percentages of subjects with history of seizure, delirium or hallucinations.
Conclusions: Different definitions of AWS capture clusters of AD patients with different symptomatology, comorbidity and consumption patterns. Understanding of biological underpinnings behind those differences may guide improvement in personalized treatment selection.

Addiction to Ultra -Processed Foods In the general population

N. Kissa[1]*, N. Ait Bensaid[1], A. Korchi[1], F. Laboudi[2] and A. Ouanass[2]

[1]University psychiatric hospital Arrazi and [2]University Psychiatric Hospital Arrazi of Salé Faculty of Medicine and Pharmacy – Mohammed V University of Rabat, Salé, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.956

Introduction: IIn recent decades, the global rise in obesity and related diseases has led researchers to investigate factors like ultra-processed foods (UPF), known for promoting overconsumption due to their low cost and hyper-palatable design. Studies link UPF to obesity, cardiovascular diseases, and type 2 diabetes, while the concept of food addiction to UPF has emerged to explain compulsive eating. Although not yet officially recognized, UPF addiction calls for urgent public health strategies to regulate their production and consumption.
Objectives: We aim to assess addiction to ultra-processed foods in the general population, its effects on mental and physical health, and explore the factors influencing these eating behaviors to propose intervention approaches for preventing and treating this form of addiction.

Methods: A questionnaire assessed ultra-processed food addiction in the general population, along with its health effects and factors influencing this behavior. A multivariate analysis, including a logistic regression model, measured the impact of different variables on this addiction.
Results: Using the YFAS 2.0 scale, 16.2% of participants show dependence on ultra-processed foods, mostly in mild to moderate forms. Logistic regression reveals that addiction is associated with being female, overweight or obese, and having low perceived well-being, increasing the risk by 6.8, 4.9, and 7.6 times, respectively. These findings suggest that food addiction is influenced by both biological (e.g., BMI) and psychological (e.g., well-being) factors.
Conclusions: The literature shows that addiction to ultra-processed foods, though not officially recognized, is associated with overconsumption behaviors and various health issues, including obesity and cardiovascular diseases. These foods, designed to be highly palatable, activate the brain's reward circuits. Public health strategies, such as regulation and labeling, are essential to prevent negative health impacts.

Everyday Financial Functioning of People with Alcohol Use Disorder

A.-M. Ariesen[1], L. Tucha[2], A. Hope[2], A. B. Fuermaier[1], O. Tucha[2,3] and J. Koerts[1]*

[1]Clinical and Developmental Neuropsychology, University of Groningen, Groningen, Netherlands; [2]Psychiatry and Psychotherapy, University Medical Center Rostock, Rostock, Germany and [3]Psychology, National University of Ireland, Maynooth, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.957

Introduction: Alcohol Use Disorder (AUD) and its comorbidities can have a tremendous negative impact on various activities of daily living, including the capability to manage one's finances. Adequate financial functioning is essential for an individual's health and well-being and is key to leading an autonomous and independent life. Problems with financial functioning can have far-reaching personal and legal consequences, and may lead to financial insecurity or poverty, financial victimisation, placement under guardianship, and reduced opportunities for social and societal participation.
Objectives: To evaluate the financial situation and the strengths and weaknesses in the everyday financial functioning of individuals with AUD.
Methods: The financial situation and financial performance of an AUD group (n = 52) were compared to a control group (CG) (n = 95), using the Financial Performance Scale (FiPS). In addition, associations between financial performance and everyday contextual factors (i.e., income, depressive symptoms (i.e., Beck Depression Scale - II), social support (i.e., Brief Perceived Social Support Questionnaire)) were explored.
Results: As compared to the CG, the AUD group reported to have a significantly poorer financial situation, including lower income levels, more frequent debts, and fewer savings. Furthermore, the AUD group reported a significantly poorer overall financial performance (FiPS total score) than the CG, and significant group differences were observed for relatively complex financial tasks, such as financial goal setting and doing tax returns. The difficulties in financial performance of the AUD group were, however, considered as relatively mild, since most aspects of financial performance (i.e., FiPS item scores) did not differ between groups. In the total sample, a better financial performance was significantly associated with a higher income, more perceived social support, and fewer depressive symptoms.
Conclusions: Individuals with AUD reported a poorer financial situation and more difficulties with performing complex financial tasks compared to controls. These reported weaknesses may stem from cognitive and affective impairments associated with AUD, as well as from a scarcity of financial resources. Since a vicious cycle may exist between financial problems and AUD symptoms, it is relevant to enhance the financial well-being of those individuals with AUD who experience financial difficulties.

Evaluation of the use of anxiolytics among students from Gabes Institute of Nursing Sciences

S. Kolsi[1]*, W. Abbes[1], S. Nouili[1], A. Bouaziz[1] and K. Medhaffar[1]

[1]Psychiatry, University Hospital, Gabes, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.958

Introduction: The use of anxiolytics is a complex phenomenon, increasingly affecting the student population. Inappropriate use of this type of treatment can lead to abuse and even dependence.
Objectives: To study the prevalence of dependence on anxiolytics, particularly benzodiazepines BZD in this population and to identify its associated factors.
Methods: This was a cross-sectional descriptive study carried out among students from Gabes institute of nursing sciences, for a period of two months(March to May 2024).
Data were collected using an online anonymous questionnaire from Google form that we distributed via Messenger social network.
We used the Benzodiazepine Attachment Cognitive Scale (BACS) to study BZD dependence.
A score ≥ 6 enables to differentiate between dependent and non-dependent patients.
Results: We collected data from 135 students. Our sample included only 33 students.
The mean age of our population was 21.30 ±1.51 years and the sex ratio (M/F) was 0.65.
Consumption of psychoactive substances (PAS) was reported by 21 students (63.63%): tobacco by 21.2%, coffee by 12.2% and alcohol by 12.2%.
All students reported having taken benzodiazepines BZD.
In our study, 13 students (39.4%)reported having used BZDs 1 or 2 times in their lives (for experimental purposes). Daily use of BZDs was not reported.
The mean score of the ECAB scale was 6.93, with extremes of[3-10]. According to our results, dependence on BZD was clearly predominant, found in 28 students (84.8%). No correlation was found between the socio-demographic characteristics and the presence of anxiolytic dependence.
BZD dependence (assessed by the ECAB scale) was correlated with coffee consumption (p=0.03), unlike for other substances (tobacco, alcohol, cannabis).

Conclusions: The study highlighted the high level of dependence on anxiolytics, particularly BZD and identified individuals who were at higher risk. Specific interventions were necessary to deal with the problem of addiction.

Disclosure of Interest: None Declared

EPV0062

Relationsheep between anxiolytic dependence, anxiety and depression among students from Gabes Institute of Nursing Sciences

S. Kolsi[1]*, S. Nouili[1], W. Abbes[1], W. Ben Flah[1], A. Bouaziz[1], K. Medhaffar[1] and W. Abbes[1]

[1]Psychiatry, University Hospital, Gabes, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.959

Introduction: Access to university marks a crucial stage in the lives of young adults. This transition can generate high levels of stress and anxiety, influencing their mental and emotional well-being.
To overcome these challenges, some students may resort to the increasingly common use of psychotropic drugs, particularly anxiolytics, to ease their distress.
Objectives: To determine the relationship between anxiolytic dependence, anxiety and depression in students.
Methods: This was a cross-sectional, descriptive and analytical study conducted on Gabes institute of nursing sciences, for a period of two months(March to May 2024).
We used:

- Benzodiazepine Attachment Cognitive Scale (BACS) : to study BZD dependence.

A score above 6 indicates dependance to BZD.

- Hospital and anxiety depression scale (HAD): to assess the severity of anxiety and depressive symptoms. Seven questions relate to anxiety (total A) and seven to depression (total D), giving two scores (maximum score for each = 21).

Results: The sample comprised 33 students. The mean age of our population was 21.30 ±1.51 years and the sex ratio (M/F) was 0.65.
The mean score of the ECAB scale was 6.93, with extremes of [3-10].
According to our results, dependence on BZDs was clearly predominant, found in 28 students (84.8%).
According to the HAD scale, 82% of students showed anxiety symptoms and 24.2% were depressed.
According to our study, we found that BZD dependence in students was strongly correlated with anxiety with p=0.007.
Similarly, we found that those dependent on BZDs were more likely to develop depressive symptoms compared with non-dependents, with a significant difference (p=0.04).
Conclusions: Our findings suggest that the greater the dependence on anxiolytics, the greater the risk of developing anxiety and depressive symptoms.

Breaking Free from Nicotine Gum Dependence: Two Unique Paths to Recovery with Psychosocial Support

J. Kosor Ljoka[1]*, I. Rojnić Palavra[1], R. Krčelić[1], D. Bodor[1,2], V. Grošić[1,2] and I. Filipčić[1,2,3]

[1]University Psychiatric Hospital Sveti Ivan, Zagreb; [2]Faculty of Dental Medicine and Health Osijek, Osijek and [3]University of Zagreb School of Medicine, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.960

Introduction: Nicotine replacement therapy, particularly nicotine gum, is an effective tool for smoking cessation but may lead to dependence in 6-9% of long-term users. This report presents two patients with prolonged nicotine gum dependence, exploring individualized treatment strategies and their outcomes.
Objectives: To evaluate two personalized treatments for nicotine gum dependence: one using transdermal nicotine patches with psychosocial support, and the other using bupropion with psychosocial support.
Methods: Patient A, a 67-year-old retired technician with a history of anxiety, depression, and past alcohol and benzodiazepine dependence (both in remission), began smoking at 16 (20 cigarettes a day) and quit at 35 due to Leriche Syndrome, switching to 20 pieces of 2 mg nicotine gum daily. In a four-week program, he transitioned to nicotine patches with a gradual dose reduction, alongside psychosocial support. Patient B, a 61-year-old social worker with a history of depression, smoked 40 cigarettes daily until quitting at 51 due to COPD, then developed a long-term dependence on 30 pieces of 4 mg gum. Fifteen days before admission, she abruptly discontinued using nicotine gum. She presented to the program seeking support and strategies for managing cravings, and her treatment focused on psychosocial interventions and medication adjustments.
Results: Both patients successfully achieved abstinence and improved functioning. Patient A transitioned from nicotine gum to nicotine patches, starting at 40 mg daily, reducing to 25 mg after six weeks, and then to 15 mg before discontinuation. Throughout the treatment period, the patient successfully maintained abstinence. Psychological assessments showed stable mood and satisfactory remission. One week into the treatment, patient B reported difficulties in maintaining abstinence after abruptly stopping nicotine gum during a COVID-19 infection. She began experiencing increased depressive symptoms and nervousness, leading to an increase in bupropion (which she used prior to enrolling in the program) dose from 150 mg to 300 mg daily. Active participation in group therapy helped her manage cravings and control anxiety, preventing relapse.
Conclusions: Two distinct approaches, one using nicotine patches and the other pharmacological support, both highlighted the importance of psychosocial support in achieving nicotine gum dependence cessation. Nicotine patches, with their slower absorption, are less rewarding and reduce long-term dependence risk. Despite patient B's initial struggles after abrupt cessation, the combination of increased bupropion and active therapy participation helped manage cravings and anxiety. Both cases highlight the importance of individualized care and comprehensive psychosocial interventions for sustained nicotine abstinence.

EPV0064

Sociodemographic, medical and COVID-19 factors associated with relapse in alcohol-dependent patients: preliminary results

L. Kozina[1]*, D. Blažev[2], D. Žakić-Milas[1], K. Brozić[1] and Z. Kovačić Petrović[1,3]

[1]University Psychiatric Hospital Vrapče; [2]Independent researcher and [3]School of Medicine, University of Zagreb, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.961

Introduction: Abstinence is crucial in the rehabilitation of alcohol-dependent (AD) patients, yet relapse rates remain high. Despite extensive research on relapse predictors, various sociodemographic and medical factors are still overlooked. The COVID-19 pandemic has presented numerous challenges in preserving mental health, but little is known about how recovery from symptomatic COVID-19 impacts relapse in AD patients.
Objectives: To examine the associations and differences in sociodemographic, medical, and COVID-19 factors between AD patients who relapsed and those who maintained abstinence. We assessed changes in these differences over time at two assessment points.
Methods: This study, part of a larger project on COVID-19 recovery and psychiatric symptoms in AD patients, runs from March 2023 to March 2025 with assessments at inclusion and after six months. Eighty treatment-seeking AD patients, without severe comorbid mental illness or other substance use, are included. Data cover sociodemographic and medical info, COVID-19 recovery details (number of episodes, time since last episode, treatment, vaccination, symptoms), and AD history (age of drinking onset, binge onset, age at first treatment, alcohol-related issues, commonly consumed type of alcohol, liver disease presence, abstinence duration, and relapse status at the second assessment). The Alcohol Use Disorders Identification Test (AUDIT), CAGE questionnaire for alcohol screening, and Alcohol Timeline Follow Back (TLFB) are used to assess relapse severity. A two-way repeated-measures ANOVA was used to examine sociodemographic, medical, and COVID-19 factor differences between patients who relapsed and those who did not.
Results: Preliminary data indicate differences in occupational and marital status, psychiatric and physical comorbidities, inpatient AD treatment, regular drinking patterns, alcohol-related data, heavy liquor consumption, age of excessive drinking, and prior hospitalizations between patients who relapsed and those who did not. Some variable changes over time were also noted in both groups.
Conclusions: Differences in multiple sociodemographic and medical factors between relapsed and non-relapsed AD patients should be addressed in AD treatment. COVID-related factors show no strong association with relapse, likely due to mild disease forms in most participants.

Disclosure of Interest: None Declared

EPV0065

Residential Treatment for Adolescents with Substance Use Disorders in Slovenia: A Six-Month Retrospective Preliminary Evaluation

L. Podnar Sernec[1] and I. Kruljac[1]*

[1]Center for Treatment of Drug Addiction, University Psychiatric Clinic Ljubljana, Ljubljana, Slovenia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.962

Introduction: Adolescence is a critical period for the development of substance use disorders (SUD), with psychoactive substance (PAS) use posing significant mental and physical health risks. In Slovenia, the absence of specific residential treatment options for adolescents has historically limited care mostly to outpatient settings, often inadequate for severe cases. In December 2023, the University Psychiatric Clinic Ljubljana opened Slovenia's first inpatient ward for adolescents with SUD, offering a comprehensive, structured program addressing both the psychological and physiological aspects of addiction.
Objectives: The primary objectives of this study are to present the inpatient ward for adolescents with SUD program in Slovenia and to conduct an analysis of data from the first six months of the program.
Methods: The program utilized a multidisciplinary approach, incorporating individual therapy, group therapy, psychoeducation, pharmacotherapy, family involvement and a range of structured therapeutic activities such as music therapy, film therapy and educational groups. A retrospective analysis of patient data from December 2023 to June 2024 was conducted. Key outcome measures included length of stay, abstinence rates, readmission rates and factors influencing premature discharge. Motivation and adherence to the therapeutic agreement were also assessed.
Results: During the six-month period, 20 adolescents were admitted to the ward, resulting in a total of 32 hospitalizations, reflecting a significant rate of readmissions. The average age of the patients was 17.16 years. The length of stay varied considerably, with an average duration of 45 days. Readmissions accounted for 37.5% of total hospitalizations, often due to relapse or behavioral challenges. Motivation for treatment and adherence to the therapeutic agreement were critical factors affecting the length of hospitalization and the risk of early discharge.
Conclusions: The introduction of Slovenia's first residential treatment program for adolescents with SUD marks a significant development in the country's healthcare system. The program offers a structured environment conducive to improving abstinence rates and addressing the complexities of adolescent substance use. However, the high rate of readmissions and the ongoing challenge of maintaining abstinence post-discharge highlight the need for refined treatment strategies, particularly regarding patient motivation and long-term relapse prevention. Future efforts should focus on optimizing the length of stay and enhancing post-discharge support to improve long-term outcomes.

Disclosure of Interest: None Declared

EPV0066

Internet and Mobile Phone Addiction in Individuals Aged 15-50 Years

E. Szreder[1] and K. Krysta[2]*

[1]Clinical Psychiatric Hospital SPZOZ in Rybnik, Rybnik and [2]Department of Rehabilitation Psychiatry, Medical University of Silesia, Katowice, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.963

Introduction: Mobile phone addiction is a behavioral disorder characterized by the inability to function in daily life without a smartphone, most often with unlimited access to the internet. "Phone addicts" perceive their mobile phone as the most important tool for daily contact with others.
Objectives: The aim of our study was to examine internet and mobile phone addiction in individuals aged 15-50 years.
Methods: The study involved 107 participants who regularly use mobile phones and access the internet. The participants completed an online survey as part of the study. The Kimberly Young test was used to assess internet addiction. The test consisted of 7 questions with "yes" or "no" responses. A score of ≥4 points was considered indicative of addiction. To assess mobile phone addiction, a test consisting of 10 questions was used. The questions concerned attitudes towards SMS messages, phone calls, mobile network operator promotions, and mobile phone use. Each question had 3 possible answers. Providing answers marked with point "c" to 5 or more questions was considered indicative of mobile phone addiction. The only inclusion criteria were: being over 14 years old and owning a mobile phone with internet access.
Results: The study involved 71 women, accounting for 66.4% of the respondents, and 36 men, accounting for 33.6% of the respondents. The age of the participants ranged from 16 to 50 years, with the average age being approximately 22.8 years. Among the study participants, 35.5% had higher education, 43.9% had secondary education, and 20.6% had primary education. 54.2% of the respondents lived in urban areas, while 45.8% lived in rural areas.
The questionnaire included a question regarding the amount of time spent online each day. According to the respondents' answers, the average time spent online was approximately 358 minutes. The next question concerned the time spent on phone calls or text messages. The average time spent on this was approximately 75 minutes.
The results of the study indicated that 20 individuals, or 18.7% of the respondents, were addicted to the internet. Six individuals, or 5.6%, were addicted to their phones. Two respondents, or 1.9%, were addicted to both the internet and their phones. The data obtained were subjected to statistical analysis using Statistica software.
A statistically significant correlation was found between the degree of mobile phone addiction and the amount of time spent using the phone. The longer the time spent on the phone, the greater the degree of mobile phone addiction.
Conclusions: Age significantly affects the degree of internet addiction. Among older individuals, the level of internet addiction is lower. The amount of time spent using the internet does not affect the degree of addiction. As the duration of mobile phone use increases, the intensity of mobile phone addiction also increases. Age does not affect the degree of mobile phone addiction.

The hidden cost of connectivity: Social media addiction among medical students

A. Karmous[1], H. Ktari[2]*, H. Ghabi[3], A. Hajri[1], E. Khelifa[1], A. Maamri[1] and H. Zalila[1]

[1]Emergency and outpatient department, Razi hospital, Manouba; [2]Psychiatry department, Tahar Maamouri hospital, Nabeul and [3]Department G, Razi hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.964

Introduction: Social media addiction (SMA) had not been formally recognized by medical organizations such as the American Psychiatric Association. However, it is an increasing problem especially among young adults. Little is known about medical students' use of social media and the potential existence of this addiction among them.
Objectives: The aim of the study was to investigate SMA among medical students and to determine the related factors.
Methods: A cross-sectional study was conducted from February to March 2024 in the faculty medicine of Tunis (Tunisia). Full-time students, from the first to the fifth grade, who accepted to take part in the study were invited to respond to a questionnaire. Self-report questionnaires, comprising sociodemographic status, lifestyle habits, social media usage behavior, the Patient Health Questionnaire (PHQ-9), the Bergen Social media addiction scale (BSMAS) were filled by the participants.
Results: A total of 60 individuals had fully responded to the questionnaire. The mean age was 21.98 ± 2.97 years. Eighty percent were female. Instagram was the most social media used with 96.6 % of participants followed by Facebook with 90 %. The mean number of hours spent on social media per day was 2.6 ± 1.96. According to the PHQ-9, 21.6 % (n=13) were suffering from depressive symptoms. The mean BSMAS was 16.6 ± 4.96 and 36.6 % (n=22) had SMA. SMA was more common among students in first years of medical school, not practicing a regular physical activity, posting regularly on social networks and having depressive symptoms.
Conclusions: This study suggested that SMA is common among Tunisian medical students. An early intervention appears to be necessary to preserve their mental health and academic performance.

The role of dopamine D3 receptor and cariprazine in substance use disorders: a systematic review

B. A. Lázár[1]*, A. Anand[1], J. Hevesi[1], J. Gajdics[1], O. Bagi[1], F. F. Farkas[1] and B. K. Kádár[1]

[1]Department of Psychiatry, University of Szeged, Szeged, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.965

Introduction: In recent years, dopamine D3 receptor (DRD3) has gained extensive attention in substance use disorders (SUDs) in terms of their anatomical localization and role in drug-related processes. Animal studies have shown that DRD3 agonists modulate addictive behaviour. In addition, cariprazine (CAR), a novel antipsychotic with a partial agonist effect on DRD3, may be a

treatment option for patients diagnosed with schizophrenia (SCZ) with comorbid SUD.
Objectives: Therefore, the main goal of the present work was to summarize literature data about DRD3 and CAR in SUDs.
Methods: A systematic review was conducted in August 2024. The full-text search was performed without filtering from four databases (PubMed, ScienceDirect, Web of Science, Cochrane Registry). In the first search "dopamine receptor D3" AND "substance use" OR "addiction" OR "dependence" OR "misuse" were used as the key search terms, and in the second search "cariprazine" AND "substance use" OR "addiction" OR "dependence" OR "misuse" were used. Duplicated studies, non-relevant articles, review articles, and animal and cell studies were excluded.
Results: In the first search, 40 articles were identified; however, 15 were excluded. In the second search, 21 articles were identified; however, 12 were excluded. Findings based on the 25 included articles show that DRD3 modulators, which are mostly agonists of the receptors, may have a positive effect on both psychotic symptoms and substance use frequency- and drug-seeking behavioral reduction. Our findings based 9 included articles demonstrate that CAR is a more effective and safe medication for SCZ with comorbid SUD than other atypical antipsychotics. It could also be suggested that in other psychiatric conditions where substance abuse is occurring CAR is also a good treatment option.
Conclusions: Based on past and current research, it's crucial to systematically evaluate the role of DRD3 for developing new therapeutic perspectives in SUDs, though more research is needed to confirm the efficacy and safety of DRD3 modulators and CAR as medications for SUDs. Furthermore, the present review suggests that CAR may be the optimal antipsychotic for treating SCZ with comorbid SUDs.

Peer victimisation and drug use in sexual minorities

R. S. C. Lee[1]* and A. Curley[1]

[1]Melbourne School of Psychological Sciences, The University of Melbourne, Melbourne, Australia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.966

Introduction: Adversity in adolescence, including peer victimisation, is associated with substance misuse in young adults, particularly in vulnerable individuals like sexual minorities. However, the potential developmental mechanisms underlying this association are yet to be fully understood.
Objectives: This study will empirically investigate the relationship between childhood adversity and addictive behaviours in young adulthood (i.e., drug use). In particular, we will examine the possible moderating role of sexual identity and orientation on drug use problems.
Methods: A total of 329 adults (aged 18 to 35 years old) were recruited into the study and included in the final analysis. Of the 329 participants, 93 identified as being a sexual minority (26.16%). A large majority of participants were women (N = 278 / 78.1%) with a mean age of 20.3 years old (SD = 3.5) and a diverse distribution of ethnicities reflective of metropolitan Australia. All participants completed an online battery of demographic, self-report, and behavioural measures. A multiple regression using Hayes' PROCESS macro for SPSS was conducted.
Results: Overall, both identifying as being a sexual minority (b = .51, p < . 05) and reporting greater peer victimisation during childhood (b = .17, p < . 01) predicted greater levels of drug use in adulthood. Over and above the independent effects of sexual orientation and peer victimisation, being a sexual minority who also experienced a high level of peer victimisation were together predictive of more pronounced drug use in adulthood (b = .25, p < . 05).
Conclusions: Identifying as being a sexual minority as well as reporting greater peer victimisation in childhood were independently predictive of potential risky drug use in adulthood. This is in keeping with theories of the role of chronic stress in the development of potentially harmful behavioural, coping mechanisms. Consistent with our hypothesis, these effects were magnified when they occurred in combination, such that sexual minorities were more susceptible to the effects of peer victimisation on later drug use. Findings from the current study contribute to the identification of a possible modifiable adolescent risk factors – that is, peer victimisation - in driving increased substance misuse in sexual minority groups, which have significant implications for targeted public health strategies for these vulnerable individuals.

Pentazocine dependence in a 57-year-old female patient

G. P. Leonte[1]*, R. M. Rusu-Andron[1], H. G. Coman[1] and M. M. Manea[1]

[1]Psihiatrie, Spitalul Clinic Județean de Urgență, Cluj Napoca, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.967

Introduction: Pentazocine dependence, although rare, poses serious risks in patients with chronic pain, especially after surgical interventions. Misuse of prescribed opioid analgesics, such as Pentazocine, can lead to a wide range of medical and psychiatric complications. This case study explores the long-term effects of Pentazocine dependence in a patient with coexisting psychiatric conditions and chronic medical illnesses.
Objectives: MAM, a 57-yer-old female patient, was first introduced to Pantozocine following pancreatic surgery in 1999 for Wirsung duct calcifications, a hereditary condition. Initially prescribed for pain relief, the patient increased her dose to 14-20 vials/day over six months. Psychiatric issues, including suicidal ideation and financial distress, emerged shortly after her addiction took hold.
Methods: Between 2002 and 2024, the patient was admitted to psychiatric wards approximately 55 times. In 2003, after an accidental burn injury to her lower limbs, she began injecting Pentazocine directly into the wounds, as intramuscular administration no longer produced the desired effects. Her conditionworsened with multiple suicide attempts, including an overdose of 22 vials of Pentazocine, which she survived. During her hospitalizations, she presented with complications such as insulin dependent diabetes mellitus, mixed tissue disease, cervical spondylosis, and Raynaud's syndrome. Multiple reconstructive surgeries were performed for the wounds caused by repeated injections.

Results: Meanwhile, the patient followed methadone substitution treatment until 2008, later and until now she only requiring antidepressant treatment for recurrent depressive disorder, her current diagnosis.
Conclusions: This case highlights the significant risks associated long-term opioid dependence, particularly in patients with medical conditions and psychiatric comorbities. Managing Pentazocine dependence requires careful monitoring of pain medication, early psychiatric intervention, and long-term follow-up. Comprehensive care, including psychological support and substitution therapies, is essential for improving prognosis in such cases.

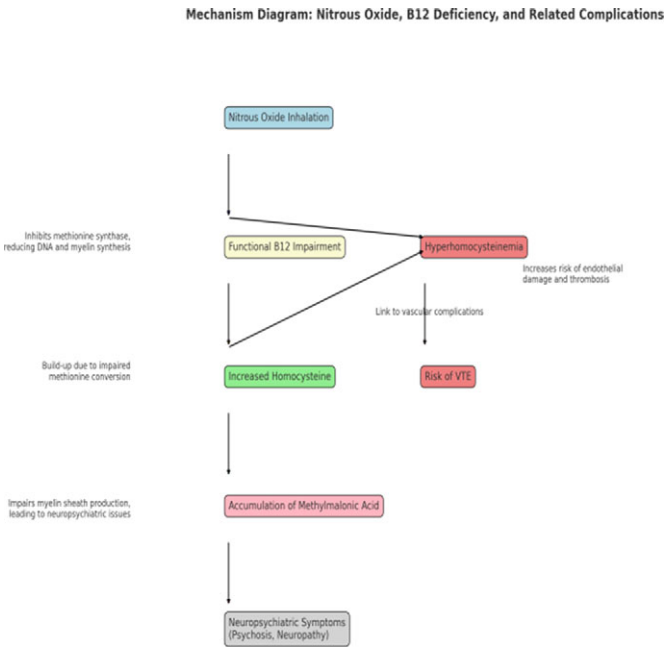
Neuropsychiatric and Hematologic Manifestations in Nitrous Oxide Psychosis: A Case Report and Scoping Review

S. Liaqat[1]*, F. Rizwan Bhatti[2] and A. Deka[1]



[1]Psychiatry, RUSH University Medical Center, Chicago, United States and [2]Psychiatry, Pakistan Institute of Medical Sciences, Islamabad, Pakistan
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.968

Introduction: Nitrous Oxide (N2O) has recently emerged as a global public health threat, particularly in young adults resulting in neuropsychiatric and hematologic sequelae.
Objectives: This study aims to highlight a case of N2O-induced psychosis with a review of literature on neuropsychiatric and hematologic complications with N2O use in patients presenting with psychosis, with elucidation of mechanisms, clinical presentations and management.
Methods: Case was reviewed, and findings were contextualized with existing literature. Relevant keywords yielded 253 studies; after title and abstract screening, 14 studies were reviewed.
Results: A 33-year old male with no known comorbidities presented with bizarre behaviors with paranoia, persecutory delusions, delusion of control, ideas of reference, Cotard delusion, and hallucinations. He reported taking daily B12 supplements because he was aware of the effects of N2O on B12 metabolism. Collateral information revealed N2O use for >5 years with recent escalation. Labs revealed high homocysteine (93.45 µmol/L), despite normal B12 and MMA level. Syphilis was negative. Neurological examination showed intact proprioception, vibration and gait, and a negative Romberg sign. MRI indicated nonspecific FLAIR hyperintensities. He was admitted to the inpatient psychiatric unit where he initially remained disorganized, paranoid, and attempting to elope, requiring PRN medications. Risperidone was uptitrated to 0.5 mg QAM and 1 mg QHS, while continuing B12 supplementation. On discharge, psychosis had resolved. He was provided psychoeducation regarding the complications of N2O use, he demonstrated understanding, however, remained in pre-contemplation stage.
Literature review (Fig 1) highlights significant neuropsychiatric and hematological effects. B12 deficiency resulting in sensorimotor polyneuropathy and axonal degeneration, with MRI often showing symmetrical cervical spinal cord abnormalities has been reported in multiple studies. EMG tests reveal peripheral nerve damage. Hematologically, it is linked to cerebral venous sinus thrombosis and DVT, with elevated homocysteine raising thrombosis risk (Fig 2). Psychiatrically, nitrous oxide can cause transient psychosis and suicidal behavior, although cases of subsequent primary psychotic illness have been reported. Management includes cessation of use, B12 supplementation; occasional use of antipsychotics has also been reported.

Mohammed et al., 2024	25/F	Bizarre behavior, delusions, hallucinations	Low (135 pmol/L)	High	High	Normal	Not reported	IM B12 Supplementation, Risperidone 4 mg, Diazepam 30 mg daily
Lundin et al., 2019	21/M	Double vision, lower extremity weakness with difficulty ambulating, psychiatric symptoms	Low (78 pg/mL)	High	High	Normal	Not reported	IM B12 Supplementation, Physical therapy
Mancke et al., 2016	35/M	Numbness, difficulty walking, psychiatric symptoms (depression, anxiety)	Low (110 pmol/L)	High	High	MRI: T2 hyperintensity in posterior columns of cervical spinal cord	Not reported	IM B12 Supplementation, Physical therapy, Methionine supplementation

Image 2:

Conclusions: The patient's presentation underscores the complexity of N2O-induced neuropsychiatric and hematologic conditions. The findings emphasize the need for thorough clinical evaluations, including psychiatric and neurologic assessments, and laboratory testing when N2O use is suspected. Future research should focus on early recognition and intervention, optimizing management strategies, and understanding the long-term prognosis of patients with N2O-induced psychosis and associated sequelae.

EPV0074

Efficacy of Topiramate in Treating Methamphetamine Use Disorder: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

M. L. Geremias[1], I. Borja De Oliveira[2], A. L. Balduino de Souza[3], F. Bandeira de Melo Guimarães[4] and D. Soler Lopes[5]*

[1]Medicine, University of Joinville Region (UNIVILLE), Joinville; [2]Medicine, University of São Paulo, São Paulo; [3]Medicine, Evangelical University of Goias, Anapolis; [4]Medicine, Federal University of Rio de Janeiro (UFRJ), Rio de Janeiro, Brazil and [5]Medicine, Lancaster University, Lancaster, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.969

Introduction: Methamphetamine use disorder poses a significant public health challenge, with few effective pharmacological treatments. Topiramate, an anticonvulsant, shows potential for treating various substance use disorders. This meta-analysis evaluates topiramate's efficacy in treating methamphetamine use disorder, focusing on abstinence rates and depressive symptoms.
Objectives: This review aims to assess the efficacy of topiramate in treating methamphetamine use disorder, specifically its impact on abstinence rates measured by negative urine tests for methamphetamine. Additionally, it evaluates topiramate's effects on depressive symptoms, quantified by Beck Depression Inventory scores.
Methods: A systematic search was conducted in Scopus, Web of Science, and PsycINFO in September 2024, following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Included studies were peer-reviewed randomized controlled trials (RCTs) assessing topiramate's effects on individuals with methamphetamine use disorder. The analysis utilized a random-effects model, with the primary outcome being abstinence assessed through negative urine tests and the secondary outcome being depression scores from the Beck Depression Inventory.
Results: Three studies (n = 249) were included, comparing topiramate to placebo. The pooled risk ratio (RR) for the common effect model was 1.00 (95% CI: 0.94-1.07), indicating no significant difference between topiramate and placebo. Heterogeneity was low (I^2 = 2%, p = 0.36). Individual study risk ratios ranged from 0.43 to 1.09, with the largest study (n = 140) showing no effect (RR 1.00, 95% CI: 0.93-1.07). Two studies (n = 109) reported that topiramate tended to improve depressive symptoms relative to placebo, though not reaching statistical significance (mean difference = -2.52 (95% CI: -5.31 to 0.26).
Conclusions: For patients with methamphetamine use disorder, topiramate did not increase abstinence rates when compared to placebo, but showed a trend towards improving depressive symptoms. Although no statistically significant effects were observed, the trends provide a foundation for future research. Larger sample sizes, extended follow-up periods, and standardized outcome measures are needed to better evaluate topiramate's efficacy. Future studies should also explore dose-response relationships, combination therapies, and identify patient subgroups likely to benefit from topiramate, which may reveal clinically meaningful effects and enhance treatment options for methamphetamine use disorder.

Effects of the anticonvulsant Galonal during long-term alcohol exposure

E. Markova[1]*, I. Savkin[1] and M. Knyazheva[1]

[1]Neuroimmunology Laboratory, State Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.970

Introduction: Galonal increases gamma-aminobutyric acid (GABA) neurotransmission in the brain by having a modulatory effect on neuronal GABAA-receptors (GABAA-R). The presence of functional GABAA-R on the surface of immune cells, in particular T-lymphocytes, which mediate modulation of the cell's functional activity has also been described. Chronic alcohol use is associated with significant T-lymphocytes dysregulation within the adaptive immune system. It suggests that synthetic GABAA-R ligand Galonal, similar to its effects on neuronal cells, may cause modulation of the functional activity of the lymphocytes, thereby influencing the intensity of the immune response.
Objectives: Considering the fact that GABAA-R proved to be the molecular targets of ethanol on the immune and nervous cells, we investigated behavior and immunomodulatory effects of the artificial GABA receptor ligand Galonal during long-term alcohol exposure to find new perspective pharmacological substances in the treatment of alcoholism.
Methods: Galonal (100 mg/kg) was administered in mice with 6-month 10% ethanol exposure (suspension of 1% starch mucus intragastrically) for 10 days, after which animal's alcohol consumption, behavior and immune parameters were estimated.
Results: After the course of Galonal administration a decrease in alcohol motivation and stimulation of exploratory behavior have been established in long-term alcoholized mice. An increase in the humoral immune response was also recorded, assessed by the absolute and relative numbers of AFC, to a level characteristic of healthy animals of the corresponding age. Significant stimulation of the cellular immune response, estimated by the DTH reaction and lymphocytes proliferative activity was also registered.
Conclusions: Galonal demonstrated positive neuroimmunomodulation effect during long-term alcohol exposure, therefore, its promising for clinical use in the treatment of alcoholism.

Treatment challenges in co-occurring substance use and gambling disorder: A case report

E. Medved[1]* and M. Delić[1]

[1]University psychiatric clinic Ljubljana, Ljubljana, Slovenia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.971

Introduction: Gambling disorder was previously classified as an impulse control disorder in the DSM-IV, but with the introduction of DSM-5, it has been redefined as a behavioural addiction. This reclassification reflects a growing understanding of how gambling shares many characteristics with substance use disorders, including the compulsive nature of the behaviour, its neurological underpinnings, and the significant consequences it has on an individual's life. The shift from an impulse disorder to an addiction framework highlights the chronic, relapsing nature of the condition and underscores the need for more comprehensive treatment approaches. Gambling disorder is now recognized as one of the major public health issue due to its association with significant psychological, social, and financial harm. Furthermore, it frequently co-occurs with other psychiatric conditions, particularly mood disorders and substance use disorders, making treatment and recovery more complex. This dual diagnosis often results in overlapping symptoms that reinforce each other, complicating the course of treatment and decreasing the likelihood of sustained abstinence. Addressing the multifaceted nature of gambling disorder is critical to improving therapeutic outcomes, particularly in individuals with comorbid conditions.
Objectives: This case report aims to examine the challenges in maintaining abstinence in individuals with co-occurring substance use and gambling disorders, focusing on the role of impulsivity and motivational instability. It also seeks to explore effective treatment strategies to improve long-term recovery outcomes.
Methods: A case report approach was employed, following a 23-year-old male patient with a history of multiple psychiatric hospitalizations due to substance use and gambling disorders. The patient's treatment journey was analysed, with particular attention to his motivation, therapeutic engagement, and relapse patterns.
Results: The patient struggled with maintaining long-term abstinence due to impulsivity, frustration intolerance, and repeated relapses, exacerbated by non-compliance with treatment. Although initial motivation for recovery was present, it deteriorated over time, resulting in premature termination of treatment programs. Persistent gambling and substance use led to significant personal and financial consequences.
Conclusions: Effective treatment for co-occurring gambling and substance use disorders must prioritize enhancing frustration tolerance, impulse control, and stable motivation. Comprehensive therapeutic interventions, continuous support, and realistic goal-setting are crucial for improving abstinence and preventing relapse. Understanding the interconnectedness of gambling and substance use is key to tailoring effective treatments.

The nightmare of scratch tickets: a case report on Gambling Disorder

F. Jarmela de Pina[1], N. Monteiro[1]*, I. Faria[1,2], F. Sola[1] and C. Silva[1,2]

[1]Centro de Responsabilidade Integrada de Psiquiatria, Centro Hospitalar e Universitário de Coimbra and [2]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.972

Introduction: Gambling disorder (GD) can be defined as the maintenance of gambling behavior despite its negative impact both on the health, social, work and financial aspects of one's life, with growing importance over other interests, loss of control over this behavior and an intense need of maintaining it. In the last decades, the prevalence of GD has been increasing, while it remains an underdiagnosed and undertreated disorder. Regarding scratch tickets (ST), Portugal is the European country with the biggest per capita spending, more than doubling the European average, with 150€ spent annually.
Objectives: We report the case of a woman with GD and aim to briefly discuss the most recent evidence on this subject.
Methods: Description of clinical case and brief review of the literature on the subject.
Results: G. is a caucasian 66-year-old woman without past psychiatric history. Her first contact with ST happened in 2016, when she started working at a kiosk and spent around 1€/day. In 2017, after going through a divorce, her gambling habits worsened, spending around 70€/day. She spent most of her income on gambling and started developing depressive symptoms. By the end of 2020, she is put in a medical leave of absence and starts seeing a therapist. To better control her spendings, her daughter is appointed as her bank account holder, but the patient relapses a week after returning to work, having contracted a loan to keep up with her addiction. She maintains this behavior until 2023 when she is referenced to a Psychiatry appointment and starts treatment, including individual psychotherapy sessions and weekly Gambling Anonymous meetings. In January 2024, G. joins an in-hospital patient group for gambling addicts and decides to retire, to distance herself from the environment that potentiates her addiction. She is now in remission and has been abstinent from gambling for over a year. She still has occasional thoughts about gambling as well as craving to gamble, but all other psychiatric symptoms have resolved, and she has been discharged from Psychiatry appointments.
Conclusions: The average ST gambler is middle aged, plays weekly and earns less than minimum wage, with the chance of gambling decreasing drastically if monthly wage is >1500€. Additionally, service workers are 55% more likely to gamble ST when compared to their counterparts. With the lack of regulation, growth in publicity and the possibility of anonymity, the prevalence of GD is growing, becoming essential that we detect this disorder promptly so that a multidisciplinary treatment can be implemented.

Cannabinoid Hyperemesis Syndrome: The challenge of diagnosis and management – A case report

C. P. Murta[1]*, F. Silva[1] and L. Kobayashi[1]
[1]Psychiatry, ULS Algarve, Faro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.973

Introduction: Cannabinoid Hyperemesis Syndrome (CHS) is a condition associated with long-term cannabis use, marked by recurrent episodes of nausea, vomiting and abdominal pain, typically relieved by hot showers—a nearly pathognomonic feature. It often develops after years of heavy cannabis use, with symptoms recurring cyclically every few weeks to months while the individual continues to use cannabis. Symptom resolution is generally observed after cessation. Though cannabis is commonly used to relieve nausea (as in chemotherapy-induced vomiting), in susceptible individuals, prolonged use paradoxically induces these symptoms, presenting a diagnostic and therapeutic challenge. Recognizing CHS is increasingly important as global cannabis consumption rises.
Objectives: The aim of this study is to review the clinical presentation of CHS, highlighting key diagnostic features, current management strategies and treatment.
Methods: A comprehensive case report of a 27-year-old female with a history of heavy cannabis use was conducted. She presented with severe nausea and vomiting for two weeks following reported cannabis cessation. A thorough clinical evaluation was undertaken to better understand the clinical presentation of CHS. Additionally, a literature review was performed using PubMed to gather relevant clinical articles on CHS.
Results: The patient exhibited hallmark features of CHS, including a prolonged history of cannabis use beginning in adolescence, recurrent episodes of severe nausea, vomiting, abdominal pain, the typical compulsive use of hot showers for symptom relief and lack of response to conventional antiemetic treatments. These features, combined with the patient's lack of motivation to discontinue cannabis despite symptom recurrence, strongly support the diagnosis of CHS. Although she had a history of an eating disorder and presented with the Russell sign and dental damage consistent with chronic vomiting, no psychiatric comorbidities or body image disturbances were identified.
Conclusions: CHS remains an under-recognized condition that poses diagnostic challenges. This case reinforces the need to inquire about cannabis use in patients presenting with cyclic vomiting, abdominal pain and weight loss. CHS symptoms and pathophysiological mechanisms can mimic other important diseases, such as eating disorders or gastrointestinal pathologies. Challenges in managing CHS include patient skepticism regarding the role of cannabis as a cause of symptoms, perceived benefits of cannabis and a lack of other effective therapies. Management of CHS involves both acute symptomatic treatment and long-term cessation of cannabis use. Acute interventions may include fluid resuscitation, haloperidol administration, and topical capsaicin application. However, the only definitive treatment is complete abstinence from cannabis, which leads to symptom resolution in the vast majority of cases.

EPV0082

Ekbom Syndrome in the context of psychotic depression and cocaine use: A case report

C. P. Murta[1]*, F. Silva[1] and L. Kobayashi[1]
[1]Psychiatry, ULS Algarve, Faro, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.974

Introduction: Ekbom syndrome, also known as delusional infestation (DI), is a rare mono-symptomatic psychosis in which the patient has the firm and unshakable belief that one's body, mainly their skin, is infested by parasites or bugs. DI primarily affects middle-aged women and it can be classified as primary or secondary, often associated with other psychiatric conditions like psychotic depression, or induced by substances such as cocaine or amphetamines. Understanding that DI may not represent a single, uniform disease or diagnostic entity and can have various underlying causes is essential for accurate diagnosis and effective treatment.
Objectives: This study aims to examine the clinical presentation, etiology and therapeutic approach for a patient presenting with DI while comparing approaches for different DI etiologies.
Methods: A case report was conducted on a 61-year-old woman presenting with delusion of infestation, skin lesions, depressive symptoms and a toxicology screening positive for cocaine. Addicionally, a literature review using the PubMed database was performed to identify relevant clinical articles on DI.
Results: In evaluating the patient's condition, the initial differential diagnosis included formication, a condition where patients experience sensations such as stinging or crawling on the skin without developing fixed delusions. Formication can arise from multiple neurological or systemic causes, including exposure to substances. A unique subtype of formication, known as "cocaine bugs," is seen in cocaine users and produces similar tactile sensations. Cocaine-induced formication is often part of a broader cocaine-related delirium that involves hallucinations and ideas of contamination. For these patients, detoxification is a priority in treatment, addressing the substance use disorder directly. In cases where delusions develop alongside these sensations, particularly in individuals with pre-existing psychiatric conditions such as schizophrenia or depressive disorder, the diagnostic focus shifts.
Conclusions: Delirium of infestation can occur in individuals with cocaine use and those with psychotic depression. More than half of the patients with DI have a history of depression and both conditions often coexist. There are individuals for whom DI appears to cause depression and patients for whom depression appears to precipitate DI. This case highlights the complexity in diagnosing and treating DI, particularly when cocaine use and psychotic depression co-occur. The patient's symptoms reflect overlapping etiologies, with cocaine use likely exacerbating formication, while psychotic depression contributed to fixed beliefs of infestation. Given the frequent co-occurrence of DI and depressive symptoms, further research is needed to refine neurobiological insights and treatment strategies for DI across these patient groups.

Internet Addiction among Students: cross-sectional study

Z. Nesrine[1]*, I. Gassara[2], R. Feki[2], N. Smaoui[2], N. Charfi[2], J. Ben Thabet[2], L. Zouari[2], M. Maalej[2], S. Omri[2] and M. Maalej[2]

[1]pédopsychiatrie and [2]psychiatrie C, hopital hedi chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.975

Introduction: Conceptually, the internet has transformed the Earth into a vast information network village, significantly enhancing human experience through unprecedented availability and exchange of information. However, the potential adverse effects of internet addiction on human health have emerged as a major global concern.
Objectives: This study aimed to estimate the prevalence of internet addiction among students.
Methods: A cross-sectional, descriptive, and analytical study was conducted between October 2022 and January 2023 among students from various faculties in Sfax. Data were collected through a self-administered electronic questionnaire accessible online, created using the Google Forms application. The questionnaire explored sociodemographic and relational data. Internet addiction was assessed using the Internet Addiction Scale (IAS).
Results: The average age of the students was 25,62 ± 3,29 years, with a sex ratio of 1/5. Among the participants, 96% resided in urban areas, and 81,9% lived with their families. Nearly half of the students were from the Sfax Faculty of Medicine, and 64,4% were in the third cycle of their studies. The study found a mean total score of 74,27 +/- 21,25 on the IAS, indicating an estimated prevalence of internet addiction at 24,2%. Factors correlated with internet addiction included excessive internet use by family members (p=0,004) and poor adaptation to the faculty (p=0,03).
Conclusions: Internet addiction was prevalent in our student population. Exploring the characteristics associated with this addiction would undoubtedly assist in identifying the risks our students might face.

Ketamine Treatment for Alcohol Use Disorder: A Review

B. Peixoto[1]*, M. Cruz[1] and V. Ustares[1]

[1]Psychiatry, Hospital do Divino Espírito Santo, Ponta Delgada, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.976

Introduction: Alcohol Use Disorder (AUD) is a pervasive condition with substantial psychological, social, and physical consequences. Traditional treatment approaches often struggle with high relapse rates, highlighting the need for more effective interventions. Recently, ketamine, an N-methyl-D-aspartate (NMDA) receptor antagonist, has emerged as a potential treatment for AUD due to its unique pharmacological properties.
Objectives: The aim of this study is to evaluate the current evidence of ketamine treatment for alcohol use disorder and its efficacy.
Methods: The authors did a non-systematic review of the current literature.
Results: The results suggest that ketamine combined with psychotherapy reduces alcohol consumption and prolongs abstinence in AUD patients. The mechanism is hypothesized to involve ketamine's ability to enhance neuroplasticity and modulate glutamatergic pathways, which may improve motivation and cognitive control. Additionally, ketamine's rapid antidepressant effects could address comorbid conditions like depression and anxiety, often observed in AUD patients, thereby reducing the overall risk of relapse.
Conclusions: Ketamine presents a promising adjunct to existing therapies for AUD, offering benefits that extend beyond traditional treatment approaches. However, while preliminary findings are encouraging, further research is necessary to confirm the long-term safety and efficacy of ketamine in treating AUD, particularly concerning optimal dosing strategies and the integration with psychotherapeutic interventions.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.977

Introduction: Substance Use Disorders (SUDs) are highly prevalent and substantially contribute to the global burden of disease, negatively impacting individuals' health, well-being, and social functioning. While SUD treatments have demonstrated effectiveness in reducing substance use and related behaviors, there has been a growing emphasis on including subjective outcome measures, recognizing the importance of patients' perspectives on their well-being. This shift has driven the development of Patient-Reported Outcome Measures (PROMs), which are progressively being integrated in healthcare to enhance patient-centered care, patient-provider communication and shared decision-making.
Objectives: This study aims to develop a PROMs Digital Health Intervention (PROMs-DHI) with the potential to improve the quality and effectiveness of outpatient addiction treatment services.
Methods: PROMs-DHI includes the electronic adaptation of ICHOM's standardized set for addictions using REDCap software and feedback created by Tableau on individual PROMs scores for patients and clinicians. PROMs-DHI will be assessed through mixed methods following a patient-centered design. Quantitative data will be collected using the System Usability Scale (Brooke, 1986), while qualitative data will be gathered through 5 focus groups with patients and 5 with healthcare professionals from collaborating addiction treatment centers. This strategy will yield valuable insights into the experiences and perspectives of both

groups in utilizing the PROMs-DHI, offering a deeper understanding of their interactions and outcomes.
Results: It is expected that patients will perceive a positive effect of the usage of the PROMs-DHI, gaining insights into their progress, reinforcing communication with clinicians, and enhancing self-management. Clinicians are expected to find the PROMs-DHI beneficial for managing patient care, profiting from the ability to monitor patient outcomes in real-time, receive notifications when values exceed critical thresholds, and access detailed reporting tools to inform their treatment decisions. This would enable them to provide more targeted and effective care, ultimately leading to improved patient outcomes.
Conclusions: Implementing the PROMs-DHI in addiction care could facilitate outcome comparisons, guide service improvement, and ultimately increase the effectiveness and quality of interventions, contributing to a stronger and more sustained recovery for patients undergoing treatment. Providing patients with regular feedback on their outcomes may also have a therapeutic effect in itself, promoting self-awareness, motivation and empowerment to manage their recovery. Furthermore, PROMs can support healthcare professionals in making well-informed treatment decisions that are tailored to each patient's needs, thereby strengthening the impact and sustainability of addiction interventions.

Affective Disorder in Addictology -Salus Hospital

T. Pengili[1]*, E. LEKLI[1], J. Draci[1] and M. KAMBO[1]
[1]Psichiatry, Salus Hospital, Tirana, Albania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.978

Introduction: AFFECTIVE DISORDERS IN ADDICTOLOGY
In recent years, the number of substance users has increased globally. Referring to a study conducted in Albania by the Youth Risky Behavioral Survey, it results that: 5.4% of young people aged 14-18 have an experience with cannabis, 4% with ecstasy, 1.4% with heroin and 1.6% with cocaine. From the data published by Our World (2019) it results that the number of deaths from drug and alcohol consumption has doubled, especially in the last three decades. From studies it results that 50 thousand individuals in Albania (1.8% of the population are drug users.
From a 3-year study carried out in the Addictology pavilion at Salus Hospital, where a sample of 133 patients with addiction to substances was examined. It turned out that 118 people were men (88.7%) and 15 women (11.3%). Over 50% of patients are in the 18-33 age group and 40% are in the 30-40 age group. Referring to the place of residence, most of the patients are from Tirana and this is influenced by the number of the population (32% of the population of Albania).Education is another important data of this study as it turns out that more than 50% of them have a secondary education and only 1/3 of them have a higher education. Referring to the married/single status, the ratio is respectively 46.97/48.48%. After analyzing the years of abuse,from 1-5 years addiction constitute 29 % of the total,6-10 years constitute 37 % and from 10-20 years constitute 21 %.If we refer to substances, it turns out that cocaine occupies 74% of the championship, followed by Cannabis, 14% and Alcohol, 12%. If we consider the psychiatric pathologies from which this study is referred, it turns out that Affective Disorders make up the largest part with 69% of followed by Psychotic Disorder with 28% of patients. Over 50% of patients manifested symptoms similar to Bipolar Disorder and over 30% of them symptoms of an Uspecified Affective Disorder.
Objectives: Place occupied by mood disorders in addictology
Methods: Quantitative research
Results: Referring to the married/single status,the ratio is respectively 46.97/48.48%.After analyzing the years of abuse, from 1-5 years addiction constitute 29 % of the total,6-10 years constitute 37 % and from 10-20 years constitute 21 %.If we refer to substances,it turns out that cocaine occupies 74% of the championship,followed by Cannabis,14% and Alcohol,12%.If we consider the psychiatric pathologies from which this study is referred,it turns out that Affective Disorders make up the largest part with 69% of followed by Psychotic Disorder with 28% of patients.Over 50% of patients manifested symptoms similar to Bipolar Disorder and over 30% of them symptoms of an Uspecified Affective Disorder
Conclusions: Affective Disorders make up the largest part with 69% of followed by Psychotic Disorder with 28% of patients.Over 50% of patients manifested symptoms similar to Bipolar Disorder and over 30% of them symptoms of an Uspecified Affective Disorder.

Adverse Childhood Experiences, Gender Identity and Substance Misuse: Challenges in Addiction Psychiatry – A Case Report

M. D. Pereira[1]* and P. Carriço[2]
[1]Psiquiatria da Infância e da Adolescência , Unidade Local de Saúde de Coimbra and [2]Centro de Respostas Integradas de Coimbra, ICAD, Coimbra, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.979

Introduction: Adverse Childhood Experiences, referring to potentially traumatic events such as sexual abuse, rejection, and family dysfunction, are strongly associated with the development of psychiatric disorders, including anxiety, depression, and substance misuse. Peer victimization related to sexual orientation and gender identity or expression has been linked to higher rates of depressive symptoms, disrupted educational paths, trauma, and increased use of substances such as alcohol and drugs. Gender-diverse youth are particularly vulnerable to substance misuse, especially in environments with limited support and prevalent discrimination.
Objectives: To emphasize the complex interactions between substance use, early trauma, and gender identity struggles, while highlighting the importance of a multidisciplinary therapeutic approach.
Methods: This case report was developed through detailed psychiatric interviews and assessments conducted during the patient's follow-up in an outpatient addiction treatment unit. The case description is supported by a focused literature review on PubMed using the keywords "Adverse Childhood Experiences", "Substance Use Disorder" and "Gender Identity".
Results: The patient is a young adult with a history of polysubstance use, starting in adolescence. His substance use was closely associated to early trauma, including childhood sexual abuse and rejection by family and peers after disclosing his sexual orientation.

These events led to dropping out of school, running away from home, and experiencing homelessness. As a result, he developed long-standing anxiety, depressive symptoms, and emotional instability. Internal struggles with gender identity, alongside ongoing familial conflict and unstable romantic relationships, further worsened his psychopathology. After a multidisciplinary intervention involving psychiatry, psychology, and social services, he showed significant improvements in emotional regulation, anxiety management and has remained abstinent since starting treatment.
Conclusions: Personal experiences, especially during childhood and adolescence, profoundly influence mental health and behaviors in adulthood. This case underscores the interaction between adverse childhood experiences, substance misuse, and discrimination related to sexual orientation, illustrating how these factors collectively impact psychiatric health. The patient's journey through addiction, identity struggles, and mental health challenges reflects the deep influence of both personal trauma and systemic issues. This case highlights the need for multifaceted therapeutic approaches that address the psychological, social, and familial factors underlying the patient's condition.

Needs and Barriers of Mental Health Professionals in Promoting Smoking Cessation

L. Pérez De Lucia Bové[1]*, S. Ravelo[1], C. Bountzas[2] and Y. Khazaal[1]
[1]CHUV, Lausanne and [2]CNP, Neuchâtel, Switzerland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.980

Introduction: Various studies have shown that individuals with mental health disorders are significantly more likely to smoke compared to the general population. Additionally, they tend to exhibit more severe tobacco dependence. For these populations, smoking is associated with increased morbidity, mortality, and healthcare costs. Despite the significance of this issue and its impact on health, quality of life, and financial well- being, smoking cessation interventions are rarely implemented in mental health services.
Objectives: The STEN project (alleviate Stigma, Train, Enhance smoking cessation interventions, rely on a specialized Network), funded by the Tobacco Prevention Fund in Switzerland, aims to promote smoking cessation among individuals with mental health disorders. The project seeks to strengthen the competencies of mental health professionals, encourage the utilization of available resources, and shift healthcare professionals' beliefs about smoking in individuals with mental disorders.
Methods: The first phase of the STEN project focuses on identifying the needs and perceptions of mental health professionals regarding smoking cessation. This phase involves a qualitative opinion survey exploring the perceived barriers and needs related to treating tobacco dependence in people with mental health disorders. The survey was conducted through focus groups held between December 2023 and April 2024, involving about 80 professionals from various linguistic regions of Switzerland, representing different professional bodies and both private and public addiction and psychiatry services. Data collection was facilitated and standardized using a structured response document.
Results: The analysis of the focus group discussions revealed:
Barriers: The main barriers to implementing tobacco dependence treatment among mental health professionals included a lack of knowledge, the misconception that addressing tobacco use is not part of their mission, and false beliefs about patients' willingness to quit.
Needs: There is a strong interest among mental health professionals in digital training, accompanied by opportunities for practice-sharing.
Conclusions: This phase will culminate in the development of a training and digital support concept tailored to the needs and perceptions of mental health professionals in Switzerland.

Evaluation of addiction interventions: follow up after discharge

M. Perez Lopez[1]* and J. Chicharro[1]
[1]SGA. Adicciones, Madrid-Salud. Ayuntamiento de Madrid, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.981

Introduction: Addiction treatments are complex, and their goals have changed over time. In the past, abstinence was the main objective. Nowadays, treatments focus on people and their recovery. They are developed to act in many areas of life, therefore appropriate measures are needed that really show the results achieved. One of the variables that has been shown to be appropriate for measuring the results of interventions is quality of life.
Objectives: Our main objective was to evaluate the results of the intervention carried out on people who have been discharged, with an instrument that includes data on quality of life. Another objective was to standardize the measurement of results, establishing reliable criteria that include the diversity of people in treatment for addictions.
Methods: A computer-assisted telephone survey was conducted, with 575 people, between May 2023 and June 2024. They had been for 3 or 6 months on therapeutic or voluntary discharge.
Criteria for therapeutic discharge, voluntary discharge, and abandonment were established. They included results in different areas: substance use, health and self-care, mental health, social/family integration and educational/work.
The World Health Organization Quality of Life BREF (WHOQOL BREF) questionnaire was used. Psychosocial and drug use questions were added to the evaluation.
Results: At discharge, around 75% of people considered that they were in better health than before starting treatment, 60% believed that their quality of life was good or very good, 72% considered that their life had a lot or some meaning and 75% maintained abstinence from the substance for which they were in treatment.
Regarding quality of life (WHOQOL BREF) in people with discharge from treatment, the domain with the lowest score was the one of personal relationships.
Opiate patients were the ones with the lowest scores, with physical health values being highlighted. In terms of gender, women scored worse than men, especially in psychological health.
Conclusions: The results obtained indicate that the biopsychosocial and interdisciplinary treatment of addictions at the Addictions Institute of Madrid City Council improves the overall quality of life

and the perception of health. These changes are largely maintained over time, including abstinence.

Addiction Hospital Emergency Department: A Five-Year Performance Review

R. Peric[1]*, E. Novakovic[2], O. Sbutega Filipović[1], M. Radusin Čkautović[1] and D. Raketić[1]

[1]Special Hospital for Addiction Disorders and [2]Dr Laza Lazarevic Clinic for Mental Disorders, Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.982

Introduction: Addictive disorders are chronic, highly recurrent conditions that often require long-term treatment and a multidisciplinary approach. Exacerbation of a chronic disorders presents a special challenge and requires a quick response from the medical team. Emergency services implement life-saving interventions on a daily basis.
Objectives: The objective of this study is to point out the importance of the Emergency Service and the provision of adequate medical care to people who need emergency intervention due to the abuse of psychoactive substances.
Methods: This retrospective study was conductet from January 2018 to January 2023 and included 4337 persons. Data was collected from the Special hospital for addiction disorders in Belgrade, Serbia, using a sociodemographic questionnaire and medical documentation. All included participents were users of the Emergency services. Unknown persons were excluded from the research.
Results: Out of a total of 4337 participants, 76% were male with an average age of 37.71 ± 9.94, while 24% were female with an average age of 37.89 ± 11.42. Opiate withdrawal syndrome was the most common reason for presentation in both sexes. However, it should be noted that the incidence of occurrence in men is significantly higher (68%), while in women it is slightly lower (close to 50%). Statistically significantly more women appear due to symptoms of acute alcohol intoxication ($p<0.05$), as well as intoxication with hypnotics and withdrawal symptoms from the anxiety-depressive spectrum. Comparing the reasons for reporting throughout the monitoring period of 5 years, with the exception of 2022, the trend of reporting did not change significantly. Opiate withdrawal syndrome is the most common, followed by acute alcohol intoxication, polytoxicomania and marijuana use.
Conclusions: The Emergency Service is of great importance because a large number of patients are cared for on an annual basis due to various symptoms of addiction. In addition to the training and readiness of the medical team, joint work and coordination of other emergency service institutions is also needed for the most efficient care.

Psychosocial functioning of individuals at risk of developing compulsive buying disorder

K. Rachubińska[1]*, A. M. Cybulska[1], D. Schneider-Matyka[1], M. Stanisławska[1] and E. Grochans[1]

[1]Department of Nursing, Pomeranian Medical University, Szczecin, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.983

Introduction: Personality-related correlates are significant factors associated with compulsive buying. The Big Five personality traits can be a risk factor or a protective factor for addiction.
Objectives: This study aimed to establish the connection between depressiveness, workaholism, eating disorders, and personality traits, according to the five-point model called the Big Five, in women with a risk of compulsive buying disorder.
Methods: The study was conducted on 556 Polish women from the West Pomeranian Voivodeship. The study employed the diagnostic survey method using a questionnaire technique including Personality Inventory NEO-FFI, the Buying Behaviour Scale, the Beck Depression Inventory I-II, the Three-Factor Eating Questionnaire, and a self-questionnaire.
Results: The analysis revealed the risk of compulsive buying being accompanied by a higher median score for depressiveness, neuroticism, Cognitive Restraint of Eating, Uncontrolled Eating, and a risk of workaholism. A lower score in the respondents in the compulsive buying risk group was observed in an assessment of agreeableness and conscientiousness. Work addiction was exhibited by 26% of people with compulsive buying disorder vs. 12% of people without it.

Table 1. Descriptive statistics for selected scales with respect to the risk of the compulsive buying disorder.

Selected Scales	Total (n = 556)	Norm (n = 483) Group 1	Risk of Compulsive Buying (n = 73) Group 2	*p*
BDI I-II Me (Q1–Q3)	4.5 (1.0–10.0)	4.0 (1.0–9.0)	8.0 (1.0–15.0)	0.021
Neuroticism acc. to NEO-FFI, Me (Q1–Q3)	21.0 (15.0–28.0)	21.0 (15.0–28.0)	24.0 (20.0–32.0)	0.003
Openness to experience acc. to NEO-FFI, Me (Q1–Q3)	26.0 (23.0–31.0)	26.0 (23.0 -31.0)	26.0 (23.0–30.0)	0.774
Agreeableness acc. to NEO-FFI, Me (Q1–Q3)	30.0 (27.0–34.0)	31.0 (27.0 -34.0)	27.0 (24.0–32.0)	<0.001
Conscientiousness acc. to NEO-FFI, Me (Q1–Q3)	34.0 (29.0–38.0)	34 (30.0–39.0)	30.0 (25.0–38.0)	0.028
Cognitive Restraint of Eating acc. to TFEQ-13, Me (Q1–Q3)	6.0 (4.0–8.0)	6.0 (4.0–8.0)	7.0 (5.0 -9.0)	0.004
Uncontrolled Eating acc. to TFEQ-13, Me (Q1–Q3)	5.5 (4.0–7.0)	5.0 (4.0–7.0)	7.0 (5.0 -8.0)	0.019
WART, Me (Q1–Q3)	53.0 (45.0–62.0)	51.0 (44.0–61.0)	60.0 (51.0–66.0)	<0.001
Addiction to work acc. to WART, n (%)	79	60 (12.42%)	19 (26.03%)	<0.001

BDI I-II—Beck Depression Inventory, NEO-FFI—Personality Inventory NEO-FFI, TFEQ-13—Three-Factor Eating Questionnaire, WART—Work Addiction Risk Test, Me—median, Q1—quartile first, Q3—quartile third, n—number of patients, *p*—statistic
Conclusions: This study found that a high risk of compulsive buying disorder is accompanied by a high risk of moderate depressiveness, neuroticism, Cognitive Restraint of Eating, Uncontrolled Eating, and workaholism. It also confirmed the view that compulsive buying is a behavioural addiction which is a consequence of ineffective coping and being dissatisfied with one's social life.

EPV0095

Management of Subutex Addiction: A Case Report in a tunisian psychiatry unit

A. Rami[1]

[1]Razi Hospital, Manouba, Tunisia
doi: 10.1192/j.eurpsy.2025.984

Introduction: Subutex abuse in Tunisia is a phenomenon that is becoming more and more frequent and the management of which is not obvious due to the development of this substance in parallel markets.
Objectives: Our objective was to assess the patient's Subutex use and initially assist with withdrawal, followed by achieving abstinence.
Methods: We followed the case of a patient in the psychiatric unit B at the Razi hospital, for depressive symptoms and having a problem of misuse of Subutex for 4 years, in a difficult family and social context.
Results: Patient follow-up was done over a one-year period with weekly consultation sessions at the beginning to assess the situation. Although withdrawal was done after a few weeks, it was essential to maintain this abstinence, using psychotherapy based on CBT done over 7 sessions.
During the study period, the patient violated abstinence only once in a family conflict.
Conclusions: The patient's response to our management has reinforced the hope of being able to treat addiction to Subutex despite the severity of his condition and family and social instability.

Perception of Electronic cigarette among young doctors

A. Hrairi[1], N. Rmadi[1]*, A. Kchaou[1], A. Chhaider[2], F. Dhouib[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupational medicine department, Hedi chaker university hospital, University of Sfax and [2]Family medicine department, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.985

Introduction: The electronic cigarette (EC), invented in 2006, represents a recent phenomenon that is increasingly discussed especially in healthcare environment. Beliefs regarding this form of consumption are very diverse.
Objectives: This study aims to assess the perception of young doctors towards EC consumption.
Methods: An online survey had been conducted inspired from the French health barometer (2017). Data were collected through an anonymous questionnaire using Google Forms. The recruitment of participants was based on social media platforms combining young doctors.
Results: A total of 203 young doctors had responded to the questionnaire. Most of participants were female (71%) with a mean age of 25.64 ± 2.64 years. More than half (60%) were resident doctors. Non-smokers represent 79.3% of our population. At the time of the survey, only 14 subjects (6.9%) had used EC or experienced vaping. The evaluation of perceptions with regard to vaping had showed that 30% of participants disagreed with the fact that EC consumption represents a measure to promote the cessation of tobacco use and 82% hadn't recommended it to their patients. A proportion of 47.3% thought that vaping is as harmful as smoking and 60% agreed that e-cigarettes may contain toxic chemicals. More than half (51.6%) almost agreed that vaping may encourage ex-smokers to become nicotine addicts.
Conclusions: We may conclude that EC represents for young doctors an emerging form of consumption that is not a safe or healthy alternative to smoking.

Addiction to smartphones and social media among young doctors

N. Rmadi[1]*, A. Hrairi[1], I. Ben Hnia[1], R. Affes[2], O. walha[2], F. Dhouib[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupational medicine department, Hedi chaker university hospital, University of Sfax and [2]Family medicine department, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.986

Introduction: Smartphones and social media have become increasingly common in recent years. However, uncontrolled use can have negative effects on physical and mental health.
Objectives: To evaluate the prevalence of social media and smartphone addiction in a group of young doctors
Methods: Descriptive cross-sectional study of a population of young doctors. Socio-professional and medical data were collected using a self-administered questionnaire on Google Forms. The Bergen Social Media Addiction Scale (BSMAS) was used for screening social media addiction, with a score of ≥24 indicating problematic use. The Smartphone Addiction Scale Short Version (SAS-SV) was adopted to determine the degree of smartphone addiction, where a very high score of >40 suggests severe smartphone addiction.
Results: Our population consisted of 64 young doctors. Among them, 63.8% were female. BSMAS and SAS-SV means were respectively 16.14 ± 5.54 and 28.91 ± 7.62. A social media problematic use was assessed in 13% of cases. We identified severe smartphone addiction in 6.7% of cases. In bivariate analysis, female sex was associated with a higher BSMAS score (p=0.046) and younger age was associated with severe smartphone addiction (p=0.049). Moreover, strong correlation was found between smartphone and social media addiction (p=0.00, r=0.79).

Conclusions: Given the potential negative impacts on mental and physical health, it is crucial for healthcare institutions to implement strategies that promote balanced technology use and raise awareness about the risks associated with addiction. Addressing these issues can ultimately enhance the well-being of medical professionals, fostering a healthier work environment conducive to effective patient care.

EPV0101

The prevalence of Internet addiction and its relationship with sociodemographic characteristics

M. RMILI[1]*, S. BOULBAROUD[2], M. EL AYACHI[1], A. CHAKIR LAMRANI[1], H. HAMI[1] and F.-Z. AZZAOUI[1]

[1]Laboratory of Biology and Health, Faculty of Sciences, Ibn Tofail University , Kenitra, Morocco and [2]Unit of Biotechnology and Sustainable Development of Natural Resources, Polydisciplinary Faculty, Sultan My. Slimane University, Beni Mellal, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.987

Introduction: The increasing integration of the Internet into daily life has raised numerous concerns, including the risk of addiction. This addiction may be influenced by sociodemographic factors.
Objectives: Determinate the prevalence of Internet addiction among adolescents and examine the effect of sociodemographic factors on Internet addiction.
Methods: This is a cross-sectional study with a descriptive and analytical aim in the Oued eddahab high school in the city of Tiflet of the Khemisset provincial direction, including 378 students (239 girls and 139 boys), the average age of the participants is 17.0.8±1.28 years. The Students were asked to complete a sociodemographic questionnaire and an internet addiction test (IAT) consisting of 20 items to determine the level of addiction.
Results: The prevalence of Internet addiction among students is 55.6%. The addiction of these students is highly significantly related ($\chi2=22.893$, $p<0.001$) to conflicts with their mothers. While conflicts with their fathers are highly significantly related ($\chi2=12.961$, $p<0.01$) to Internet addiction. However, conflicts between parents have a highly significant relationship ($\chi2=9.421$, $p<0.01$) with Internet addiction. Parents' control of Internet access has a highly significant influence ($\chi2=10.473$, $p<0.01$) on Internet addiction.
Conclusions: Students who experience conflicts with their mothers, fathers, or between their parents are more likely to develop Internet addiction. Parental control over Internet access helps reduce the risk of addiction.

Posttraumatic Stress Disorder and Co-occurring Addictions: A Narrative review focusing on approach and therapeutic challenges

C. A. Romano[1]*, C. P. Osório[1] and J. M. Paupério[2]

[1]Psychiatry and Mental Health, Tâmega e Sousa Hospital Centre and [2]Psychiatry and Mental Health, São João, Oporto, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.988

Introduction: Posttraumatic Stress Disorder (PTSD) and substance use disorders (SUD) frequently co-occur, and their combination presents significant challenges in diagnosis and treatment due to the complex interaction between trauma-related symptoms and substance misuse behaviors.
Objectives: This review aims to explore the pharmacological and psychosocial interventions conducted in comorbid PTSD and SUDs. It specifically focuses on which interventions are effective in addressing substance use as opposed to post-traumatic symptoms in patients with these concurrent conditions.
Methods: Narrative literature review by performing a search on MedLine for English-written articles. The following search terms were used: ((“posttraumatic stress disorder”) AND (“substance use disorder” OR “alcohol use” OR “cannabis use” OR “cocaine use” OR “opioids use”) AND ((“treatment”) OR (“adherence”))).
Results: Studies show that 46,4% of individuals meeting the criteria for PTSD also meet the criteria for an SUD, with an additional correlation between PTSD symptomatology and an increased substance use frequency and associated heightened risk of other mental health concerns, suicidality, mortality, and functional impairment. Within treatment-seeking samples, patients with PTSD are approximately 14 times more likely to meet the criteria for a SUD than patients without PTSD, with alcohol and cannabis as the most frequent substances involved. In clinical settings, management involves employing treatment strategies effective for each condition independently. The literature is not uniform regarding the impact of substance consumption in the treatment of PTSD, although it suggests a greater impact of alcohol when compared to other substances, in which studies are relatively uniform in highlighting a minor effect. Despite this minor effect, literature advances neurocognitive impairments and higher psychosocial stressors (legal issues, financial challenges, unemployment, housing instability, and a decline in social support) as potential causes leading to poorer outcomes. Despite this, there seems to be consensus on the fact that SUD was associated with the highest rate of discontinuation from both psychotherapy and medication treatment for PTSD.
Conclusions: Concurrent PTSD and SUD present complex clinical challenges requiring integrated treatment approaches addressing both trauma-related symptoms and substance use behaviors. This narrative review underscores the importance of comprehensive assessment, evidence-based interventions, and multidisciplinary collaboration in facilitating recovery and improving functional outcomes.

EPV0104

Characteristics of Stimulant-Induced Psychoses and Schizophrenia Symptoms: A Comparative Analysis Using the PANSS

N. Sakels[1]

[1]Department of Psychiatry and Narcology, Rīga Stradiņš University, Riga, Latvia
doi: 10.1192/j.eurpsy.2025.989

Introduction: The use of stimulants such as amphetamines, cocaine, and methylenedioxymethamphetamine is associated with various mental disorders, including psychoses. These psychotic states can closely resemble the symptoms of schizophrenia, leading to potential misdiagnosis, incorrect treatment, and the assignment of disability status for perceived schizophrenia.
Research indicates that stimulant use can trigger psychoses with characteristics similar to those seen in schizophrenia, including hallucinations, delusions, and disorganized thinking.
Objectives: Investigate the clinical characteristics of stimulant-induced psychoses among patients with stimulant-positive rapid urine test (cocaine, amphetamine, methamphetamine, methylenedioxymethamphetamine, cathinone group) in the Daugavpils Psychoneurological Hospital and the narcology ward of the Daugavpils Regional Hospital.
Assess the clinical presentation of these psychoses in comparison to schizophrenia using the Positive and Negative Syndrome Scale (PANSS), as a validated instrument for evaluating schizophrenia symptoms.
Analyze the data from cases with stimulant-positive rapid urine test and PANSS compare with other research PANSS data in pure schizophrenia psychosis cases.
Methods: 1. Data Collection: The study involve participants diagnosed with stimulant-induced psychosis. Data collection will include gathering medical histories with positive stimulant induced psychosis of schizophrenia and stimulant use diagnosis (by ICD-10 F14.5, F15.5, F20+F14/F15) conducting new patient clinical interviews using PANSS, and performing rapid drug urine tests. The Positive and Negative Syndrome Scale will be utilized to quantitatively assess the severity and nature of the participants' symptoms.
PANSS Scale
Clinically available rapid urine test (MultiDrug Test ect.).
Data Analysis: Clinical data comparisons will be performed using statistical methods.
Results: The comparison of PANSS scores between patients with stimulant-induced psychosis (n=46) and schizophrenia (n=80) is expected to reveal distinct patterns. Patients with stimulant-induced psychosis are likely to exhibit higher scores on the positive symptoms subscale (84%) than in negative (31%), reflecting the more pronounced acute psychotic symptoms triggered by substance use.
In contrast, patients with schizophrenia may exhibit a more balanced profile, with significant impairments in both positive (72%) and negative symptoms (80%).
Conclusions: The clinical presentation of stimulant-induced psychoses can closely resemble that of schizophrenia, leading to diagnostic and therapeutic challenges. This study highlights the differences in PANSS profiles between the two conditions, which can aid clinicians in the differential diagnosis and improve patient outcomes. As well it uncovers the significant impact of rapid urine drug tests in clinical routine.

doi: 10.1192/j.eurpsy.2025.990

Introduction: Research suggests that the gender gap in alcohol (Alc.) consumption may be narrowing, with increasing consumption by the female population. For women, the equivalent of 20-25 grams/day is considered harmful consumption. Many of the harmful effects of alcohol consumption occur more rapidly and more severely in women, yet the majority do not seek treatment
Objectives: To describe the prevalence of harmful use of alcohol in women admitted to hospital for other mental illness.
Methods: Retrospective observational study of six months duration. Data was collected from all patients admitted to the hospital during the period of study, with no specific exclusion criteria. Descriptive statistics were performed.
Results: During the study period, 312 patients were admitted to the hospital, 52.8% of whom were women, 21.8% of whom had a harmful use of Alc. The prevalence of harmful Alc. use in the different mental illnesses was: 22.2% in schizophrenia or other psychoses, 13.9% in bipolar affective disorder, 11.1% in depressive disorder, 13.9% in personality disorder, 19.4% in substance use disorder, 13.9% for other diagnoses and a prevalence of 5.56% for those of unknown diagnosis
Conclusions: In recent years, it has been shown that the overall prevalence of harmful alcohol use and alcohol use disorder has increased in women. They tend to seek care in settings where their alcohol problems may not be recognised. They have lower social support for treatment participation and greater barriers to accessing treatment, resulting in even higher rates of co-occurring medical and mental health problems. Prevention strategies and intervention programmes should be adapted to the specific needs of women, taking into account both individual risk factors and socio-cultural contexts

High-Dose Levomethadone in Opioid Dependence: Case Study Exploring Pharmacogenetics and Management of Benzodiazepine Withdrawal

M. F. Melloni[1], P. Boldrini Parravicini Persia[2], F. Cappella[1], F. Odorizzi[1] and R. P. Sant'Angelo[2]*

[1]Psychiatry, University of Bologna, Bologna and [2]Mental Health Department, Ausl Romagna, Cesena, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.991

Introduction: Methadone is typically administered as a racemic mixture of two enantiomers (50% Dextro, 50% Levo methadone) and is used for chronic pain management and as maintenance therapy for opioid dependence. Levomethadone, when used alone, shows similar efficacy but with fewer side effects, particularly a safer cardiac profile with less QTc prolongation. In maintenance therapy for heroin dependence, the effective dosage of levomethadone ranges from 40 to 70 mg per day.
Objectives: Our case concerns a 42-year-old patient who has struggled with substance abuse since the age of 17. Admitted to

the Psychiatric Unit of Cesena Hospital for a reduction of Lormetazepam (previously consuming 80-100 mg/day), he was found to be taking 200 mg of levomethadone daily. This dosage is typically administered for pain management rather than as maintenance therapy for heroin dependence. Although the man was consistently consuming high doses of psychoactive medications, exceeding the ranges commonly reported in the literature, he did not exhibit significant adverse effects or signs of sedation during his hospital stay. This observation led us to consider the possibility of a genetic alteration in cytochrome enzymes that could enable ultra-rapid drug metabolism.

Methods: During the hospital stay, it was possible to safely reduce the benzodiazepine therapy by switching from oral lormetazepam to intravenous diazepam and subsequently to oral diazepam.The patient also underwent a pharmacogenetic test that analyzes the polymorphisms of 60 different enzymes using cells obtained from saliva.

Results: In the reported case, the use of L-Methadone has allowed over the years a full control of withdrawal symptoms and cravings from opioid drugs, a greater compliance with treatment and a lower risk of general and cardiological side effects than racemic methadone administered in equivalent therapeutic doses in past years.

It has also been made possible, through in-patient treatment, to carry out a progressive withdrawal from Lormetazepam in total safety.

Pharmacogenetic testing targeting CYP3A4 and CYP2B6 enzymes did not reveal significant alterations, contradicting our initial hypothesis.

Conclusions: The originality of this case is basically due to the lack in the literature about clinical cases treated with such a high dose of Levomethadone (200 mg/day) as substitution therapy for opioid addiction and to the investigation of the salivary pharmacogenetic testing to eventually support the hypothesis that the patient could be a rapid or ultrarapid metabolizer.

Moreover, we have sought to clarify the correct use of levomethadone in individuals at high risk of death due to conditions that may increase the risk of Torsades de Pointes.

The pharmacogenetic analysis excluded rapid metabolism, suggesting a role for P-glycoprotein (PGP) in influencing the absorption of methadone and the variability of plasma concentration.

Injectables and implants in consideration of opioid use disorder treatment: Patient perspectives from India

S. Sarkar[1]*, N. Seth[1], M. K. Brar[1], A. Verma[2], S. Singh[1] and A. Dhawan[1]

[1]National Drug Dependence Treatment Centre and [2]Department of Psychiatry, All India Institute of Medical Sciences, New Delhi, India
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.992

Introduction: Implants and injectable medications have been utilized frequently in the treatment of opioid use disorder, along with other treatment approaches like orally consumed opioid agonist treatment or antagonist treatment, and psychotherapeutic interventions. The overall use of implants and injectable medications in the Indian healthcare landscape is low.

Objectives: The study aimed to assess the acceptability of implants and injectable among treatment options among patients with opioid use disorders.

Methods: A cross sectional survey was conducted among patients with opioid use disorders. They were shown a pre-recorded video explaining the various treatment options for opioid use disorder, and their acceptability of treatment was recorded.

Results: Among the 150 included patients, 26 (17.3%) were willing for naltrexone depots, 11 (7.3%) were willing for naltrexone implants, and 10 (6.7%) were willing for buprenorphine injection. Compared to this, patients were more willing for buprenorphine sublingual (n = 105, 70%), tramadol oral (n = 89, 59.3%), and naltrexone oral (n = 43, 28.7%) formulations. Willingness for counselling or psychotherapy was expressed by 34 patients (22.7%), and for engagement with narcotics anonymous by 20 patients (13.3%).

Conclusions: While implants and injectable may be a viable option for many patients with opioid use disorder, it may have limited acceptability among the range of therapeutic options available. Collaborative decision making may be useful considering patient's preferences for aligning goals of treatment team and the patient.

Screening for smoking and chronic obstructive pulmonary disease among employees of an electricity and gas company

I. Sellami[1]*, A. Abbes[1], R. Gargouri[2], R. Khemakhem[2], A. Feki[3], W. Feki[2], N. Bahloul[2], S. Kammoun[2], M. L. Masmoudi[1], M. Hajjaji[1], H. Ayadi[2] and K. Jmal Hammami[1]

[1]Occupationnal medecine; [2]Pneumology and [3]Rheumatology, CHU Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.993

Introduction: Chronic obstructive pulmonary disease (COPD) is a common and under-diagnosed disease. Screening for this disease and assessing smoking behaviour are essential to tobacco control measures.

Objectives: Our study aims to screen for smoking and COPD among employees of an electricity and gas company.

Methods: We conducted a descriptive, analytical, cross-sectional survey to screen for smoking and COPD among employees of an electricity and gas company. The survey was carried out during a COPD screening day, using a two-part questionnaire. Nicotine dependence was assessed using the Fagerström test. COPD screening was carried out using a COPD screening self-questionnaire from the French National Authority for Health.

Results: Our population comprised 28 male participants. Active smoking was reported by 87.7% of participants. Nicotine dependence assessed by the Fagerström test was moderate to high in 54.7% of smokers. We found that 11 participants (39.2%), were identified as being "at risk" of developing COPD. Bivariate analysis showed that the COPD self-screening questionnaire score was associated with smoking and nicotine dependence.

Conclusions: COPD and smoking among workers are prevalent in the electricity and gas company. Through this awareness-raising day, an action plan had prioritized anti-smoking programs directed

at smoking employees to ensure their comprehensive care and prevent the onset of COPD.

Disclosure of Interest: None Declared

EPV0111

The effect of chronic obstructive pulmonary disease on quality of life in smoking electrical technicians

I. Sellami[1]*, A. Abbes[1], R. Gargouri[2], R. Khemakhem[2], A. Feki[3], W. Feki[2], N. Bahloul[2], S. Kammoun[2], M. L. Masmoudi[1], M. Hajjaji[1], H. Ayadi[2] and K. Jmal Hammami[1]

[1]Occupationnal medecine; [2]Pneumology and [3]Rheumatology, CHU Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.994

Introduction: Chronic obstructive pulmonary disease (COPD) is an under-diagnosed disease. Screening for this disease, assessing quality of life and combating smoking are key factors in the overall management of this pathology.
Objectives: Our study aims to assess the effect of COPD on quality of life in smoking electrical technicians and their motivation to quit smoking.
Methods: We conducted a descriptive, analytical, cross-sectional survey to assess the impact of COPD on quality of life among smoking electrical technicians and their motivation to quit smoking. A questionnaire was administered during a COPD screening day. Smoking cessation motivation was assessed using the Richmond questionnaire. COPD screening was carried out using COPD screening self-questionnaire from the French National Authority for Health. The COPD Assessment Test (CAT) was used to determine the presence and severity of respiratory symptoms.
Results: Our population comprised 24 male smokers. Motivation to quit smoking was low in half of the participants. Eleven participants (45.8%) were identified as being "at risk" of developing COPD. Cough, sputum and chest tightness were more frequent in participants at risk of developing COPD than in those not at risk, with a significant difference. The mean CAT score in participants at risk of developing COPD was 12.2 ± 9.7. The impact on quality of life in participants at risk of developing COPD was low and moderate to high in 45.5% and 54.6% of participants respectively. Bivariate analysis showed that motivation to quit smoking was not correlated with either the COPD self-screening score or participants' quality of life.
Conclusions: COPD impairs the quality of life of workers at the electricity and gas company. Training sessions on breathing and anti-smoking actions in the electricity and gas company must be directed towards smoking employees by ensuring comprehensive management will serve to prevent the onset of COPD.

EPV0112

Smoking and job satisfaction among electrical technicians

A. Abbes[1], I. Sellami[1]*, A. Feki[2], M. A. Ghrab[1], M. Hajjaji[1], S. Baklouti[2], M. L. Masmoudi[1] and K. Jmal Hammami[1]

[1]Occupationnal medecine and [2]Rheumatology, CHU Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.995

Introduction: To ensure the health of employees, maintaining a smoke-free workplace is essential. Understanding the relationship between smoking and work is crucial for implementing effective smoking cessation interventions.
Objectives: Our study aims to determine the prevalence of smoking and its relationship with job satisfaction among electrical technicians.
Methods: We conducted a descriptive, analytical and cross-sectional survey among electrical technicians. Data collection was carried out using a self-completed questionnaire. We collected socio-professional data. Nicotine dependence was assessed using the Fagerström test, while job satisfaction was evaluated using the single-item measure of job satisfaction.
Results: Our study population was exclusively male, including 70 electrical technicians. The mean age of participants was 38.1 ±10.2 years. The mean of the tenure of job was 14.5±11.1 years. Active smoking was reported by 45.1% of participants. Using the Fagerström test, nicotine dependence was low and moderate to high respectively in 13.4% and 28.9% of smokers. Median job satisfaction was 4, with extreme values ranging from 1 to 5. We found that nicotine dependence was negatively correlated with job satisfaction ($p = 0.02$, $r = -0.3$).
Conclusions: Smoking is a prevalent issue among electrical technicians. Our findings highlight the urgent need for smoking cessation interventions among these workers. The association of smoking with low job satisfaction underscores the importance of preventive measures to reduce work-related stress in order to promote greater job satisfaction and smoking cessation.

Pathological Gambling: A Neurobiological Approach Through a Literature Review

N. Sghaier[1]*, A. Ben Haouala[2], I. Zariat[1], N. Romdhane[3] and H. Ben Garouia[1]

[1]Psychiatry Departement, Ibn Jazzar Hospital, Kairouan; [2]Psychiatry Departement and [3]Child Psychiatry Departement, Fattouma Bourguiba Hospital, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.996

Introduction: Gambling is an increasingly widespread practice worldwide. Currently, gambling disorder (also known as pathological gambling) is recognized as a behavioral addiction in the DSM-5 due to its numerous similarities with substance addiction. Consequently, several neurobiological hypotheses have been tested in recent years.
Objectives: To illustrate, through a literature review, the neurobiological basis of pathological gambling.
Methods: We conducted a systematic review of the literature in the "PubMed" database, following PRISMA guidelines, using the following keywords: "Neurobiology," "Gambling Disorder," "Pathological Gambling," and "Gambling."

Results: Our study included 27 articles, comprising 15 articles addressing pathological gambling from a neuroimaging perspective, 7 articles focusing on neurochemistry, and 5 articles discussing the therapeutic implications of neurobiological mechanisms. Literature studies reveal that the primary neurobiological mechanisms explaining pathological gambling involve dysfunctions in the brain circuits of the "reward system," particularly in the striatum and ventromedial prefrontal cortex. The studies also highlighted the central role of dopamine and dopaminergic receptors, as well as the involvement of other noradrenergic, serotonergic, glutamatergic, and opioid systems in the disorder's development, with preliminary evidence suggesting the effectiveness of medications that alter these neurotransmitters.
Conclusions: Pathological gambling is an increasingly common psychiatric disorder that remains underestimated to this day. Therefore, it is important to clarify the neurobiological mechanisms involved in the etiology of this disorder to develop targeted intervention strategies.

Alcohol addiction, trichotillomania, and trauma: is there a secret link? A case report

M. Štracak[1], A. Boban[2], A. Krešo[2], M. Škarić[2] and I. Todorić laidlaw[3]*

[1]Psychiatry, "Ivo Pedišić" General Hospital, Sisak; [2]Psychiatry, "Dr. Ivan Barbot" Neuropsychiatry hospital, Popovača and [3]Psychiatry, "Vrapče" Universitiy Psychiatric hospital, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.997

Introduction: Interpersonal traumas affect women's ability to rely on their social network to cope, which increases their reliance on maladaptive avoidance coping strategies such as drinking. According to psychodynamic models of trichotillomania hair pulling is a manifestation of unresolved sexual conflicts, disordered attachment, and dissociation from traumatic memories. (Houghton, D. C., Mathew, A. S., Twohig, M. P., Saunders, S. M., Franklin, M. E., Compton, S. N., Neal-Barnett, A. M., & Woods, D. W. (2016). Trauma and trichotillomania: A tenuous relationship. *Journal of Obsessive-Compulsive and Related Disorders*, *11*, 91-95.)
Objectives: Evidence suggests that rather than making hair pulling worse, alcohol is often used to avoid negative affect related to hair pulling. It slows the nervous system's activity and may also be used to reduce the urge to hair-pull. (Grant, J.E., Collins, M., Chesivoir, E. *et al.* Hazardous Alcohol Use in Trichotillomania. *Psychiatr Q* **94**, 361–369 (2023))
Methods: We present a 43-year-old patient who has been hospitalized several times due to alcohol addiction. She is divorced, has no children, is unemployed, and finished elementary school. The patient reported that she started drinking at high school during weekend parties and gradually her drinking became more frequent. Now she is drinking a liter of vodka a day. Her last hospitalization was after she left a domestic violence shelter for women where she escaped because her partner abused her. After she was placed in the alcoholism ward, the initial psychic examination discovered alopecia. Childhood anamnesis showed sexual trauma at a young age, and she reported that she started to pull her eyelashes in kindergarten after two members of a family sexually abused her. Now she is wearing a wig and she reported that there are areas on her scalp where hair doesn't grow anymore because she pulled it while she was in a shelter. As she described, pulling her hair gave her a sense of relief from anxiety.
Results: During hospitalization, her pharmacotherapy was corrected and titrated. She was included in psychotherapy, family therapy, group, and individual psychotherapy. The therapeutic procedures applied have improved her mental condition. She has been advised to continue outpatient psychiatric treatment, to regularly use pharmacotherapy, and to attend family therapy and rehabilitation club.
Conclusions: There is a clear need for future clinical studies not only in the area of trichotillomania's relationship to substance use disorders but also in trauma coping mechanisms so we can truly understand how people adapt to and recover from trauma.

EPV0118

Motivation for Sustained Substance Use in Patients with Psychotic Disorders

C. Tapoi[1]

[1]Addictions Department, Alexandru Obregia Clinical Psychiatry Hospital, Bucharest, Romania
doi: 10.1192/j.eurpsy.2025.998

Introduction: Substance use is a prevalent issue in individuals with psychotic disorders and has major implications for the course of the disease. Substance use is associated with treatment noncompliance, more positive symptoms and increased risk of relapse. However, reasons for substance use in people diagnosed with psychotic disorders are insufficiently understood.
Objectives: This study seeks to explore the specific reasons for substance use among patients diagnosed with psychotic disorder, while aiming to identify subgroups of patients that may benefit from targeted interventions to reduce drug use.
Methods: We investigated the reasons for maintaining substance use in patients with a dual diagnosis of psychotic disorder and substance use disorder that were admitted to Alexandru Obregia Clinical Psychiatric Hospital, Addictions Department, Bucharest, Romania, between October 2024 and March 2025. Patients were evaluated through a semi-structured interview developed for this study.
Results: The results of the study will be available and presented during the EPA 2025 Congress.
Conclusions: Understanding the underlying motivations for substance use is crucial for developing targeted interventions that address the unique needs of patients with psychotic disorders, ultimately improving treatment outcomes and promoting long-term recovery.

Psychiatric characteristics of pregnant crack users admitted to a referral center in Southern Brazil

M. B. Terra[1]*, J. V. E. Santos[1], N. A. F. da Silva[1], L. M. A. Sartes[2], J. B. Schuch[3] and F. H. P. Kessler[3]

[1]Department of Internal Medicine, Federal University of Health Sciences of Porto Alegre, Porto Alegre; [2]Department of Psychology, Federal University of Juiz de Fora, Juiz de Fora and [3]Department of Psychiatry and Legal Medicine, Federal University of Rio Grande do Sul - Graduate Program in Psychiatry and Behavioral Sciences, Porto Alegre, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.999

Introduction: Psychoactive substance use among pregnant women has reached alarmingly high rates and is considered a public health problem. Pregnancy is a period in which women become more sensitive and concerned about their well-being, in view of how that will affect their baby. Therefore, pregnancy becomes a favorable period for therapeutic intervention, especially with regard to drug use. Despite this, there is still a small number of studies that address the issue of female drug users in Brazil, especially due to stigma and prejudice.
Objectives: Our main aim was to characterize the clinical and psychiatric profile of pregnant crack users in Brazil, with a focus on comorbidities, the severity of crack use, and the use of other substances.
Methods: This was a cross-sectional study of 24 pregnant crack users admitted to a referral hospital for psychiatric disorders in pregnant women, in Porto Alegre, Brazil, over three years. Most women tend to remain hospitalized for a long time, often months, until giving birth. This scenario directly influenced the sample size of this study. The following instruments were applied: a clinical-obstetric questionnaire; the condensed version of the Addiction Severity Index; a diagnostic interview for psychoactive substance use based on DSM-5; the Mini International Neuropsychiatric Interview for DSM-IV; and the Semi-Structured Clinical Interview for DSM-IV Axis II Personality Disorders (SCID-II).
Results: Most patients had severe crack dependence and used other substances, such as tobacco, cannabis, and alcohol. The median duration of crack use was three years, ranging between three and 12 years. Most women subsisted from illegal or informal activities; a fifth had previously been arrested and often had relationship problems. Twenty percent had HIV (n = 5), and 37.5% (n = 9) had syphilis. Borderline personality disorder was the most prevalent mental condition (62.5%), followed by suicidal tendencies (45.8%), hypomanic episodes due to substance use (37.5%), and past major depressive episodes (33.3%).
Conclusions: This is one of the few studies exploring and characterizing social, economic and health aspects of pregnant crack users in Brazil. An alarmingly high prevalence of consumption of other drugs, psychiatric disorders, and difficult-to-treat personality disorders was observed in our study. Investigating the psychiatric profile of women who use substances is essential to minimize the impacts on the mother and child, optimize therapeutic approaches to comorbidities, and enable more effective relapse prevention.

Disclosure of Interest: None Declared

EPV0122

Dual pathology and Takotsubo syndrome. A case report

M. Valverde Barea[1]*, A. Jurado Arevalo[1], I. Contreras Pérez[1] and M. P. Vargas Melero[1]

[1]H. U. Jaén, Jaén, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1000

Introduction: Cocaine use is a significant health problem, since its abuse constitutes a substance use disorder and can produce cardiovascular symptoms, including acute coronary syndrome (ACS). Tako-tsubo syndrome (TTS) is a transient dysfunction of the apical left ventricle that can manifest with intense chest pain and alterations in the electrocardiogram. TTS can be triggered by physical stressors (hyperthyroidism, cocaine or amphetamine abuse) or psychological stressors (grief or reaction to acute stress).
Objectives: The objective is to present the case of a patient who developed tako-tsubo syndrome after harmful cocaine use.
Methods: A 50-year-old woman, under psychiatric follow-up, diagnosed with mixed personality disorder, with a medical history of hypothyroidism. The patient has been presenting for 2 months after mourning the death of her husband with anxiety-depressive symptoms with a great behavioral impact with episodes of hetero-aggression and begins with abusive consumption of cannabis and cocaine toxins. The patient presents an episode of psychomotor agitation after acute consumption of cocaine, presenting psychotic symptoms. During the study in the emergency area, she verbalizes chest pain and complementary studies are performed with elevated cardiac enzymes and alterations in the electrocardiogram. Cardiology is contacted and after hospital admission and complementary studies, the diagnosis of acute coronary syndrome is reached, filiating it with Takotsubo syndrome triggered by cocaine consumption. The diagnoses presented by the patient with dual pathology would be a psychotic disorder due to toxins, a borderline personality disorder and harmful consumption of cocaine.
Results: Dual pathology in patients with personality disorder with toxin abuse such as in this case cocaine is very frequent.The situation of grief is an acute stressful situation that leads to greater emotional instability and, together with the toxic effects of cocaine, can trigger Takotsubo syndrome in patients. Therefore, when approaching patients with substance use, it is very important to always take into account the possible somatic complications that can be triggered.The treatment chosen to treat the psychotic symptoms that the patient presented was lurasidone, since it has a tolerability and cardiological safety profile.
Conclusions: In patients with dual pathology, it is very important to address all possible complications, both somatic and psychiatric, for proper therapeutic management.

EPV0123

New psychoactive substances and mental health-Practical challenges for psychiatrists

V. A. Voicu[1,2,3]*, O. Vasiliu[1,4] and A. Ciobanu[1,5]

[1]Carol Davila University of Medicine and Pharmacy; [2]Romanian Academy of Medical Sciences; [3]Romanian Academy; [4]Psychiatry Dept., Dr. Carol Davila University Emergency Central Military Hospital and [5]"Prof. Al. Obregia" Psychiatry Clinical Hospital, Bucharest, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1001

Introduction: New psychoactive substances (NPS) are a heterogeneous group of new drugs that are not controlled by the United Nations drugs conventions but may represent public health threats of largely the same impact as substances listed in the respective

conventions, according to the European Union Drugs Agency (EUDA). The history of NPS encompasses approximately two decades, but this category of substances is continually expanding.
Objectives: To review the literature for data regarding the practical challenges the use of NPS raises for mental health specialists, in order to help clinicians in the construction of an adequate case management plan for these patients.
Methods: A literature review was conducted in three electronic databases (PubMed, Cochrane, and Web of Science/Clarivate) to find primary and secondary sources published between January 2000 and September 2024. The keywords used were „novel psychoactive drugs", „synthetic cathinone", „cannabimimetics", „synthetic cannabinoids", „synthetic stimulants", „phenethylamines", „legal highs", „designer drugs", „emergency", „intoxication", „case management", and „challenge". There was no restriction regarding the age of participants, but only sources published in English were selected.
Results: Based on the 27 sources retained for detailed analysis, six main clinically focused challenges related to NPS use were identified. The lack of characteristic clinical manifestations of NPS intoxication is provocative, especially for the presentations in the emergency rooms (ER), where a rapid differential diagnosis is needed. The second challenge detected was polydrug use, with studies reporting more than 50% of the users combining different NPS or NPS with conventional drugs of abuse. The third difficulty is related to the difficulty of detecting the NPS in the consumers due to the continuously changing structures by designers, who are trying to avoid the current legislation. The fourth aspect is related to the high costs of screening for NPS and the need, despite these costs, to apply such screening in the psychiatric population, which is considered vulnerable to the use of these drugs, according to epidemiological studies. The fifth challenge is related to the lack of specific treatments in the case of NPS intoxication, with management strategies being limited to supportive and symptomatic care. The sixth aspect refers to the need to hospitalize patients with NPS intoxication in ICU departments due to their unpredictable evolution, need for monitoring, cardiovascular and neuropsychiatric toxicity, polydrug use, etc.
Conclusions: There is an acute need for routine screening for NPS in the ER whenever a drug intoxication is suspected and especially in psychiatric populations where the anamnesis could be difficult. Case management requires ICU hospitalization, intensive monitoring, supportive care, and a post-ICU psychiatric evaluation and treatment for relapse prevention.

Disclosure of Interest: None Declared

EPV0124

Evaluation of the quality of life in patients with substance use disorders – A suggested algorithm

V. A. Voicu[1,2,3]* and O. Vasiliu[1,4]

[1]Carol Davila University of Medicine and Pharmacy; [2]Romanian Academy of Medical Sciences; [3]Romanian Academy and [4]Psychiatry Dept., Dr. Carol Davila University Emergency Central Military Hospital, Bucharest, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1002

Introduction: Assessment of the quality of life (QoL) in patients diagnosed with substance use disorders (SUDs) is important due to the need to explore potential ways of improving the prognosis and evolution of these patients towards recovery and prolonged abstinence. The impact of SUDs on the QoL is often difficult to determine in the absence of structured methods because of the multiple factors that may moderate the results, including misperceptions of the patients on the effects of the drugs of abuse (DOA), stigmatization, countertransference aspects of the therapeutic relationships, etc.
Objectives: To assess the most validated psychometric tools dedicated to the evaluation of QoL in patients with SUDs.
Methods: A literature review was conducted in three electronic databases (PubMed, Google Scholar, and Clarivate/Web of Science) to find clinical reports published between January 2000 and September 2024 regarding the QoL instruments in patients with SUD. The keywords used were "substance use disorders", "quality of life", "health-related quality of life", "scales", "inventories", and "questionnaires". There was no restriction regarding the age of participants, and only sources published in English were selected.
Results: The most frequently reported scales used for the purpose of monitoring the QoL in patients with SUDs were the Short-Form Health Survey (SF-36) and EuroQoL (EQ) 5D 5L. Also, WHOQOL-BREF, which is associated with the WHO International Classification of Diseases system, is a comprehensive and useful instrument that may be applied in patients with SUDs. Health-related Quality of Life for Drug Abusers (HRQOLDA) and Injection Drug Use Quality of Life Scale (IDUQOL) may be used in this specific population because they refer more exactly to daily life aspects of the patients with SUD that interfere with their QoL, but these instruments are less known and applied by clinicians.
Conclusions: General instruments, like surveys or inventories, targeting the evaluation of QoL and, also, more specific instruments focused on the quality of the daily life of patients with SUDs need to be administered in case management because these may highlight important areas of therapeutic intervention. The inclusion of such instruments is expected to have multiple benefits, such as better treatment adherence through the improvement of the therapeutic relationship, more targeted interventions for the meeds of this population, etc.

EPV0125

Moving towards new targets in the pharmacological treatment of substance use disorders

V. A. Voicu[1,2,3]*, O. Vasiliu[1,4] and A. Ciobanu[1,5]

[1]Carol Davila University of Medicine and Pharmacy; [2]Romanian Academy of Medical Sciences; [3]Romanian Academy; [4]Psychiatry Dept., Dr. Carol Davila University Emergency Central Military Hospital and [5]"Prof. Al. Obregia" Psychiatry Clinical Hospital, Bucharest, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1003

Introduction: Substance use disorders (SUDs) are a highly prevalent and complex class of psychiatric illnesses that lead to increased rates of mortality and morbidity, societal costs, low quality of life, and difficulties in all important areas of personal functioning. Although SUDs are constantly explored from a therapeutic perspective, there are very few validated treatments available for these disorders.

Objectives: To review the evidence supporting new targets for the psychopharmacological management of patients diagnosed with SUDs.
Methods: A literature review was conducted in three electronic databases (PubMed, Cochrane, and Clarivate/Web of Science) and the US National Library of Medicine database for clinical trials (www.clinicaltrials.gov) to find clinical and preclinical sources published between January 2000 and September 2024. The keywords used were „substance use disorders", „drug dependence", „drug addiction", „new treatments", „drugs in pipeline", and „pharmacological treatment". There was no restriction regarding the age of participants, and only sources published in English were selected.
Results: Based on 12 sources identified for detailed analysis, the main directions of research in the field of new treatments for SUDs are modulators of glutamatergic and GABA-ergic systems, neurokinin-1 receptors, alpha-2 adrenergic agonists, G-protein signaling-biased μ-opioid receptor agonists, serotonin modulators, cannabinoid agonists or partial agonists, N-acetylcysteine, and monoclonal antibodies. These agents are explored for cocaine, opioids, nicotine, psychostimulants, and cannabis use disorder. Examples of investigational products from these emergent classes are SR-170189 (a biased mu-opioid receptor agonist without evidence of tolerance in preclinical studies), dexmedetomidine (BXCL501, an alpha-2 preferring agonist explored for opioid withdrawal), guanfacine (another alpha-2 agonist explored in cannabis use disorder-CUD), lorcaserin (a selective 5HT2C receptor agonist also explored for CUD), oxytocin (explored for alcohol use disorder- AUD and as add-on to methadone for comorbid opioid and cocaine use disorder), N-acetylcysteine (investigated for AUD and nicotine use disorder), NT-814 (neurokinin-1 and -3 receptor antagonist, investigated for opioid use disorder), memantine (a noncompetitive N-methyl-D-aspartate antagonist explored in patients with AUD), baclofen (a GABA-B receptor agonist explored for AUD, opioid withdrawal, and psychostimulants use disorder) and various biological therapies for NUD and cocaine use disorder.
Conclusions: There are hopes related to an extensive number of investigational products that undergo different stages of clinical research for a large variety of SUDs, targeting multiple neurotransmitters and hormonal pathways, and even biological therapies that could block the action of the drugs of abuse before reaching their targets.

Gender Sensitive Depression in Male Patients with Alcohol and Substance Addiction: A Pilot Study

I. G. Yilmaz-Karaman[1]*, T. Gündüz[1], B. Bağcı[2], E. Doğaneroğlu[3] and G. Güleç[1]

[1]Psychiatry, Eskişehir Osmangazi University, Eskişehir; [2]Psychiatry, İzmir Atatürk Training and Research Hospital and [3]Psychiatry, İzmir Katip Çelebi University Atatürk Training and Research Hospital, İzmir, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1004

Introduction: Women are diagnosed with depression twice as often as men. Although depression is more common in women, men have higher suicide rates. Instead of seeking help, men tend to use various coping mechanisms that can be considered dysfunctional. These behaviors include risk-taking behaviors, aggressive behaviors, and alcohol and substance use. In addition, men's failure to seek mental health services may be related to their beliefs about gender and masculinity. That symptom cluster is called a male depressive syndrome and can be seen in both sexes.
Objectives: The present study aimed to measure depression with a widely used scale and a gender-sensitive scale among men with addiction disorders. Additionally, the study aimed to evaluate relations between addiction severity, depression and masculinity.
Methods: Fifty-one male patients with alcohol and substance addiction participated in the present study. BAPİRT-alcohol and BAPİRT-drug questionnaires, Beck Depression Scale, Gender Sensitive Depression Scale, and Precarious Manhood Beliefs.
Results: The mean age of the patients was 40.56 ± 12.35, and most were single (64.7%). Regarding the cut-off scores of BAPİRT scales, 45.9% of patients screened as high risk for substance addiction, and 86.27% screened as high risk for alcohol addiction. Depression scores were evaluated using the cut-off values. Both the Beck Depression Scale and the Gender Sensitive Depression Scale determined a depression prevalence of 60.8%, with diverse participants. Table 1 shows the intersection of the depression screening with the two scales.

Depression scores		Beck Depression Scale (>16)	
		Positive	Negative
Gender Sensitive Depression Scale (>49.5)	Positive	22 (43.1%)	9 (17.6%)
	Negative	9 (17.6%)	11 (21.6%)

Conclusions: Male patients with addiction showed a high prevalence of depression (%60.8). Gender-sensitive depression was related to substance addiction severity.
Male patients with addiction may experience depression with a specific symptom cluster, which includes irritability.

doi: 10.1192/j.eurpsy.2025.1005

Introduction: Tobacco and alcohol use are two of the main risk factors for most of the non-communicable diseases and causes of death worldwide. Healthcare professionals can play an important role in helping patients to quit smoking and alcohol consumption, but this role is undermined if they themselves have the same addictions.

Objectives: The aim of this study was to study the effect of smoking and alcohol use on healthcare professionals' quality of life. In addition we aimed to identify any demographic and occupational factors that affect quality of life.
Methods: The research sample of the present cross-sectional study consisted of 200 health professionals. The Demographic Questionnaire, the Smoking Addiction Inventory (Fagerstrom), the Alcohol Addiction Inventory, and the Quality of Life Inventory (EQ-5D) were used. The statistical analysis was performed using the statistical package IBM Spss v.27
Results: Among the sample, the 46.5% stated that were smokers. The mean score of alcohol dependence was found to be 3.61 (±3.29), while the corresponding mean value of Fagerstrom was calculated to be 3.96 (±2.27). The EQ-5D quality of life score was found to be 0.93. Finally, the EQ-Vas score was found to be 7.95 (± 1.57).
Conclusions: A particularly high prevalence of smoking was found among the healthcare professionals in the study, while alcohol consumption was moderate. The results showed that tobacco and alcohol consumption negatively affects the quality of life of healthcare professionals.

doi: 10.1192/j.eurpsy.2025.1006

Introduction: Illness Anxiety Disorder denotes an excessive fear of becoming critically ill. Even when a medical exam does not indicate a significant medical problem, people may have no physical symptoms or think that familiar body sensations or minor symptoms are symptoms of a dangerous sickness.
Objectives: We aimed to estimate and compare the prevalence of illness anxiety disorder among health colleges students at King Saud University. Also, we examined whether the prevalence of illness anxiety disorder is influenced by the specific field of study within the medical disciplines and whether the disorder manifests differently among students based on their chosen area of specialization.
Methods: This was an observational cross-sectional study. Data were collected through an online self-administered questionnaire called The Short Health Anxiety Inventory (SHAI) and was analyzed using SPSS 23rd version.
Results: The prevalence of IAD in this study was found to be 5.8% (n=325). with a significant relation to gender, college, the presence of psychiatric disorders, and being subjected to abuse or neglect.
Conclusions: This study found that the prevalence of illness anxiety disorder was low compared to other studies published in the past.

A cross-sectional evaluation of binge-eating behavior and its correlation with anxiety disorders among adolescents in Northern Saudi Arabia: Implications for future generations

A. M. Alhuwaydi[1]

[1]department of medicine , Jouf university, sakaka, Saudi Arabia
doi: 10.1192/j.eurpsy.2025.1007

Introduction: Binge-eating behavior and anxiety disorders pose a significant public health issue worldwide, as it has severe implications for both the physical and mental health of the adolescent population. The present study evaluated the prevalence of binge-eating behavior, anxiety disorders, and associated factors among the northern Saudi adolescent population.
Objectives: Assessed the correlation between binge eating and anxiety.
Methods: The present population-based cross-sectional study was carried out among adolescents in the Aljouf region of Saudi Arabia from June 2023 to December 2023. A total of 384 eligible participants were selected using the convenience sampling method. The present study used a pretested Arabic version of the binge eating scale (BES) and Hamilton Anxiety Scale (HAM-A) to assess the binge-eating behavior and anxiety disorders among the target population. The Spearman correlation test determined the strength and direction of the correlation between BES and HAM-A scores. Furthermore, logistic regression analysis was applied to find the associated factors for binge-eating behavior among the study participants.
Results: Of the 384 participants, moderate and severe binge-eating behaviors were found among 11.2% and 8.3% of the respondents, respectively. Regarding the severity of anxiety as assessed by the HAM-A scale, mild, moderate, and severe anxiety were shown among 12.8%, 9.6%, and 7.5% of the participants, respectively. Also, the study found a positive correlation between binge eating and anxiety scores, with a correlation coefficient of 0.26 and a p-value of 0.001. Furthermore, being female ($p = 0.001$), moderate ($p = 0.004$), and severe anxiety ($P = 0.001$) were significantly associated with binge-eating behavior.
Conclusions: The present research findings advocate for the implementation of targeted interventions and support services aimed at decreasing binge-eating behavior and anxiety, thereby promoting the overall well-being of adolescents and building stronger future generations. Moreover, it is recommended that optional courses about binge eating be incorporated into the curricula of schools and universities.

Social Anxiety Disorder in The Visually Impaired Versus Healthy Control: Saudi Arabian Samples

S. Alsubaie[1]

[1]Psychiatry, AFHSR, Khamees Mushait, Saudi Arabia
doi: 10.1192/j.eurpsy.2025.1009

Introduction: While the relationship between social anxiety disorder SAD and various sociodemographic factors has been explored, there is a notable gap in research examining the prevalence of SAD in visually impaired individuals. Vision loss could influence social interactions and thus may alter the typical presentation or severity of social anxiety.
Objectives: This study aims to compare self-esteem and social anxiety disorder (SAD) levels between visually impaired and sighted individuals and to explore the relationship between social anxiety and various sociodemographic factors.
Methods: A case-control study was conducted from March to June 2017 in Riyadh, Saudi Arabia, involving 62 participants (24 visually impaired and 38 sighted). Participants completed a demographic form, the Liebowitz Social Anxiety Scale (LSAS), and the Rosenberg Self-Esteem Scale (RSES). Data analysis included descriptive statistics, t-tests, and ANOVA to compare psychological outcomes between groups.
Results: The mean age of visually impaired participants was significantly higher than that of sighted participants (24±2.8 vs. 22.4 ±2.2 years, p=0.013). No significant differences were observed between the two groups in terms of gender, marital status, or education level. The RSES scores indicated no significant difference in self-esteem between visually impaired and sighted individuals (18.13±2.66 vs. 17.42±2.04, p=0.244). Similarly, LSAS scores did not significantly differ between the two groups (32.63±24.19 vs. 36.68±22.68, p=0.506).
Conclusions: The findings suggest that visually impaired individuals do not have significantly different levels of self-esteem or social anxiety compared to their sighted peers, indicating that visual impairment may not directly contribute to lower self-esteem or higher social anxiety. Future research should involve larger, more diverse samples and longitudinal studies to further explore these relationships.

Vicarious trauma in Child and adolescent psychiatry residents in Tunisia

G. Amira[1]*, S. Bourgou[1] and F. Charfi[1]

[1]Child psychiatry Department, Mongi Slim Hospital, La Marsa, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1010

Introduction: Vicarious trauma can significantly affect the physical and mental health of mental health professionals, as well as their ability to provide quality of care, particularly in the population of child and adolescent psychiatry residents who frequently encounter traumatic narratives.
Objectives: This study aims to determine the prevalence of vicarious trauma in child and adolescent psychiatry residents.
Methods: This is a cross-sectional study conducted from 19 august to 16 september 2024. An anonymous Google Forms questionnaire was sent to child psychiatry residents via the college email and private groups. We used the Compassion Fatigue Questionnaire to measure levels of vicarious trauma.
Results: A total of 48 child psychiatry resident out of 70 participated in the study. The sex ratio was 1:8,6. The mean age was 28,8 years. The residents were married in 33,4% of cases, in a romantic relationship in 29,1% and single in 37,5% . We found that 54,1% of residents practiced a leisure activity, 22,9% had history of psychiatric disorder and 14,5% had addictive behaviours. We found that 74% of the residents exhibited a high to very high risk of vicarious trauma. The mean score of Compassion Fatigue Questionnaire was 44,18.
Conclusions: This study underscores the need to recognize and address vicarious trauma among child and adolescent psychiatry residents in Tunisia, as its effects can detrimentally influence both clinician well-being and patient care. By fostering an awareness of this often-overlooked issue and integrating supportive measures into residency training, it can help residents develop healthier coping strategies and resilience.

Excessive preoccupation of having a serious illness in medicine residents

A. Mhalla[1], A. Ben Haouala[1]*, I. Betbout[1], A. Haj Salah[1], B. Amamou[1] and F. Zaafrane[1]

[1]Laboratory research LR05ES10, University of Monastir, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1011

Introduction: Excessive preoccupation of having a serious illness (EPHSI) or illness anxiety disorder is frequently reported by doctors and medical students
Objectives: Our objectives were to estimate the frequency of EPHSI in a population of medicine residents in Tunisia and to determine the factors associated with this pathology.
Methods: This was a cross-sectional study via internet, carried out among 404 medicine residents practicing in Tunisia during the period of November and December 2020 and January 2021.
The information was collected using a pre-designed questionnaire, edited using the Google site and disseminated via social networks. This questionnaire was inspired by the Health Anxiety Questionnaire, the MSD score, and the DSM-5 criteria for illness anxiety disorder
Results: In the end of the study period, 404 medicine residents responded to the questionnaire. The mean age was 27.4 years, the sex ratio was 0.47. Residents who fulfilled the DSM5 criteria of anxiety illness disorder represented 33.7% of the total group.
The most preoccupying diseases were neoplastic diseases (40.8%), neurodegenerative disorders (14.3%), and psychiatric disorders (10%).
EPHSI was associated to several sociodemographic, anamnestic and psychological factors
Conclusions: The establishment of psychological support systems for students, emphasizing coping and stress management techniques, should be implemented to prevent the EPHSI.

Anxiety and its effect on foreign medical students

N. Bouattour[1]*, F. Guermazi[1], R. Jbir[1], D. Mnif[1], M. Lalaoui Rhali[1], I. Baâti[1] and J. Masmoudi[1]

[1]Psychiatry A, Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1012

Introduction: Nowadays thousands of students choose to get into medical universities in foreign countries for a plethora of reasons. Tunisia represents one of these destinations, thanks to its geographic localization, weather, biological diversity as well as its ethnical and cultural background.
Objectives: To determine the effect of anxiety and psychological distress on the motivation of studies in foreign students in Tunisia.
Methods: We conducted a cross-sectional, descriptive and analytical study, carried out between July and September 2023 among foreign students at the Sfax Faculty of Medicine. Data collection was carried out using an anonymous self-questionnaire via "Google Forms shared via social media. Psychological distress was assessed using the "DASS-21" Depression, Anxiety and Stress Scale. Motivation was assessed using the French version of the "SMMS-R-FR" Study Motivational Strength Questionnaire.
Results: Seventy-two foreign medical students completed the survey. The average age was 25 ± 3.45 years. The majority of students were male (57%). Coffee and tobacco were the most consumed substance by the students (88.9%, and 47.2% respectively). The mean score for score anxiety score was 6.59, 7.2 for depression and 7.83 for stress. The mean score for the strength of motivation was 42.4. We found a negative statistical association between the anxiety dimension and the strength of motivation (p=0.011, r= -0.29). We found no statistical association with the depressive symptoms dimension nor with the stress dimension.Smoking was correlated with anxiety and depression in our foreign students (p=0.02 and p=0.027 respectively).
Conclusions: Identifying psychological distress and screening for them can help prevent the deterioration of mental health of foreign students and therefore the deterioration their academic performance.

EPV0144

Examining the Relationship Between Cyberchondria and Health Anxiety in Clinical Medical Students

N. Boussaid[1]*, R. Feki[1], S. Omri[1], I. Ben Ayed[1], I. Gassara[1], N. Charfi[1], J. Ben Thabet[1], M. Maalej[1], M. Maalej[1], N. Smaoui[1] and L. Zouari[1]

[1]Psychiatry C, Hedi Chaker university hospital center, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1013

Introduction: Cyberchondria refers to the phenomenon where individuals experience increased health anxiety due to excessive health-related information-seeking on the internet. This behavior can lead to increased worry, symptom misinterpretation, and the belief that one may be suffering from a serious illness. While internet health-seeking is common, it can become maladaptive and contribute to clinically significant anxiety.
Objectives: The aim of this study was to investigate the prevalence and severity of cyberchondria among medical students, and to explore the relationship between online health-seeking behaviors and health anxiety.
Methods: A cross-sectional survey was conducted among clinical medical students using the **Cyberchondria Severity Scale (CSS)** and the **Short Health Anxiety Inventory (HAI-18).** The CSS is a 12-item self-report questionnaire that assesses the frequency of online health searches, the distress caused by those searches, and the misinterpretation of symptoms. The HAI-18 evaluates the frequency and intensity of health-related worries and behaviors over the past six months. Participants were asked to report their online health-searching habits, emotional responses, and overall health anxiety levels.
Results: A total of 169 clinical students participated in the study, with a predominance of females (74%). The mean age of participants was 23 ± 1.5 years. Regarding family medical history, 62.1% of participants reported a familial history of medical conditions, while 26% had a familial history of psychiatric disorders. Additionally, 39.6% of participants reported that their family members had been hospitalized for a serious illness. A personal medical history was

reported by 23.7% of participants, and 21.3% had a documented history of psychiatric disorders. Health-related anxiety was observed in 21.9% of participants and was significantly associated with a history of family member hospitalization for a serious illness ($p < 0.05$). Regarding cyberchondria, 35.5% of participants reported low levels, 43.2% moderate levels, 20.1% high levels, and 1.2% very high levels. High levels of cyberchondria were significantly associated with higher health anxiety scores ($p < 0.001$).
Conclusions: The findings suggest a moderate to high prevalence of cyberchondria among clinical medical students, with a strong association between higher cyberchondria scores and increased health-related anxiety. Interventions to reduce cyberchondria should focus on managing health anxiety and mitigating the negative impact of online health information

Disclosure of Interest: None Declared

Suppressing Health-Related Thoughts: A Pathway to Increased Anxiety?

N. Boussaid[1]*, R. Feki[1], I. Gassara[1], H. E. Mhiri[1], S. Omri[1], N. Charfi[1], J. Ben Thabet[1], M. Maalej[1], N. Smaoui[1], M. Maalej[1] and L. Zouari[1]

[1]Psychiatry C, Hedi Chaker university hospital center, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1014

Introduction: Health-related anxiety, characterized by excessive worry about one's health, often leads to significant distress and impairment. Thought suppression, the conscious attempt to control or avoid unwanted thoughts, is frequently associated with various psychological conditions, including anxiety disorders. Research suggests that individuals with anxiety may attempt to suppress thoughts related to their fears, potentially exacerbating symptoms.
Objectives: The present study investigates the relationship between thought suppression and health-related anxiety, exploring how the tendency to suppress intrusive thoughts may influence health anxiety levels.
Methods: A cross-sectional survey design was employed, with participants drawn from a sample of medical students. The White Bear Suppression Inventory (WBSI) was used to assess the extent to which participants tend to suppress intrusive thoughts, while the Health Anxiety Inventory (HAI-18) was used to measure health-related anxiety. The HAI-18 evaluates the frequency and intensity of health-related worries and behaviors over the past six months.
Results: The study recruited 213 medical students, of which 74.2% were female. The mean age of participants was 22.11 ± 2 years. Among the sample, 22.1% had a personal medical history, and 20.2% had a documented history of psychiatric disorders. Regarding family medical history, 59.6% of participants reported a familial history of medical conditions, and 21.6% reported a familial history of psychiatric disorders. Additionally, 39% of participants had family members who had been hospitalized for serious illness.
Health-related anxiety was observed in 26.3% of participants. A significant positive correlation was found between WBSI scores (thought suppression) and HAI scores (health-related anxiety) ($r = 0.301$, $p < 0.001$), suggesting that participants who reported higher levels of thought suppression were more likely to experience health-related intrusive thoughts and heightened anxiety about their health. Furthermore, individuals with higher health anxiety tended to have a stronger inclination to suppress thoughts, compared to those with lower levels of health anxiety.
Conclusions: The findings indicate a positive relationship between thought suppression and health-related anxiety among medical students. Specifically, students who engage in higher levels of thought suppression tend to report more frequent intrusive thoughts related to health and greater anxiety about their well-being. Future research could explore interventions aimed at reducing thought suppression as a potential strategy for alleviating health anxiety.

Disclosure of Interest: None Declared

EPV0146

The Impact of Thought Suppression on Cyberchondria

N. Boussaid[1]*, R. Feki[1], I. Gassara[1], H. E. Mhiri[1], N. Smaoui[1], N. Charfi[1], J. Ben Thabet[1], M. Maalej[1], M. Maalej[1], S. Omri[1] and L. Zouari[1]

[1]Psychiatry C, Hedi Chaker university hospital center, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1015

Introduction: Cyberchondria, defined as excessive and anxiety-driven health-related internet searching, has become an increasingly significant issue in the digital age, where easy access to online health information can contribute to heightened health anxiety. Recent studies suggest that cognitive avoidance strategies, such as thought suppression, may worsen anxiety-related behaviors, including health-related internet searching.
Objectives: The objective of this study was to investigate how the tendency to suppress thoughts (thought suppression) influences the development and intensity of cyberchondria in a sample of medical students.
Methods: A cross-sectional study design was employed, involving a sample of 213 medical students. The White Bear Suppression Inventory (WBSI) was used to assess participants' tendency to suppress health-related thoughts. The Cyberchondria Severity Scale (CSS) was used to measure the extent and severity of health-related internet searching behaviors. Participants also provided information about their medical history, family medical history, and psychiatric background.
Results: The sample consisted predominantly of females (74.2%), with a mean age of 22.11 ± 2 years. Among the 213 participants, 22.1% reported a personal medical history, and 20.2% had a documented history of psychiatric disorders. Regarding family medical history, 59.6% of participants reported a familial history of medical conditions, and 21.6% reported a familial history of psychiatric disorders. Additionally, 39% of participants reported that family members had been hospitalized for serious illness.
The levels of cyberchondria among participants were as follows: 36.6% of participants reported low levels of cyberchondria, 41.8% reported moderate levels, 20.7% reported high levels, and 0.9% reported very high levels of cyberchondria.
A significant positive correlation was found between WBSI scores (measuring thought suppression) and Cyberchondria Severity Scale (CSS) scores (measuring health-related internet searching) ($r = 0.4$, $p=0.02$). This suggests that medical students who engaged in higher levels of thought suppression were more likely to experience intrusive health-related thoughts and engage in heightened online health searching behaviors.

Conclusions: The findings of this study suggest that there is a positive relationship between thought suppression and the intensity of cyberchondria among medical students. These results highlight the importance of addressing cognitive avoidance strategies, such as thought suppression, in the management of health anxiety. Future research could explore interventions that aim to reduce thought suppression, such as cognitive-behavioral therapy (CBT) or mindfulness-based techniques, as potential strategies for alleviating cyberchondria and its associated health anxiety.

Health Anxiety in Medical Students: A Hidden Challenge in Medical Education

N. Boussaid[1]*, R. Feki[1], I. Ben Ayed[1], N. Smaoui[1], I. Gassara[1], N. Charfi[1], J. Ben Thabet[1], M. Maalej[1], M. Maalej[1], S. Omri[1] and L. Zouari[1]

[1]Psychiatry C, Hedi Chaker university hospital center, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1016

Introduction: It is well-established that medical students often experience health-related anxiety, a phenomenon commonly referred to as "medical student syndrome" in the literature. This condition is believed to arise from exposure to life-threatening diseases during medical training.
Health anxiety is characterized by excessive worry about having a serious illness, often leading to heightened distress and maladaptive health-related behaviors.
Objectives: The aim of this study was to explore and compare health anxiety levels between preclinical and clinical medical students.
Methods: A cross-sectional, descriptive, and analytical study was conducted at the Sfax Medical School from March to June 2024. Medical students were invited to voluntarily complete a self-administered questionnaire, which collected socio-demographic data, lifestyle-related factors (such as substance use, physical activity, and medical history), and the Short Health Anxiety Inventory (HAI-18). The HAI-18 assesses the frequency and intensity of health-related worries and behaviors experienced over the past six months. The total score ranges from 0 to 54 and includes two subscales: the Health Anxiety subscale (items 1–14, range 0–42) and the Negative Consequences of Illness subscale (items 15–18, range 0–12). A score of 18 or higher on the Health Anxiety subscale indicates significant health anxiety.
Results: A total of 285 students participated in the study, with a predominance of females (73.7%).
The mean age was 21.96 ± 2.05 years. Preclinical students constituted 31.9% of the sample, while clinical students comprised 68.1%. Most participants (91.9%) resided in urban areas, and 82.1% reported a moderate socioeconomic status. Additionally, 69.5% of participants were living with their families. A medical history was reported by 21.8% of the participants, while 17.2% had a history of psychiatric difficulties. Among these students, 5% had been hospitalized for a serious illness, for a prolonged duration or on multiple occasions.
Health-related anxiety was observed in 24.6% of participants. It was significantly associated with female gender ($p = 0.045$), a history of psychiatric difficulties ($p = 0.004$), and being a clinical medical student ($p = 0.04$). These factors were identified as key predictors of increased health-related anxiety levels.

Conclusions: Female gender, a history of psychiatric difficulties, and clinical medical training were identified as significant risk factors for health-related anxiety among medical students. These findings suggest the need for targeted interventions to address and alleviate anxiety in these high-risk groups, potentially improving both mental health and academic performance within medical training environments.

doi: 10.1192/j.eurpsy.2025.1017

Introduction: Severe asthma (SA), often associated with chronic rhinosinusitis with nasal polyps (CRSwNP), contributes significantly to global disability and mortality. A personalized treatment approach, including addressing treatable traits like mental health, is crucial for improving outcomes. The impact of panic disorder (PD) on asthma symptoms and outcomes requires investigation due to their epidemiological association.
Objectives: To cross-sectionally compare the clinical presentation of outpatients with SA and/or CRSwNP, with and without PD, treated at the Personalized Medicine Asthma and Allergy Clinic, Humanitas Research Hospital.
Methods: Participants were consecutively recruited among outpatients attending follow-up visits to treat SA and/or CRSwNP from February to March 2024. All were previously enrolled in the SANI (Severe Asthma Network Italy) or RINET (Rhinosinusitis Italian Network) registries. Participants completed a comprehensive self-report survey on sociodemographic, lifestyle, medical, and psychiatric information, along with validated questionnaires assessing asthma control, severity of nasal obstruction, burden and emotional responses to physical symptoms, psychophysical well-being, and the PD module from the Patient Health Questionnaire (PHQ) screening tool, to identify provisional diagnoses for current or past PD. Data were analyzed using the Kruskal-Wallis, post-hoc Dunn's, and Fisher's exact tests, with Holm's adjustment for multiple comparisons. The significance level was set at 0.05.
Results: Seventy-nine patients, 46 women (58.2%) and 33 men (41.8%), participated in this study. Thirty patients (38%) had SA only, 44 (55.7%) had both SA and CRSwNP, and 5 (6.3%) CRSwNP only. Current PD was identified in 7 outpatients (8.9%), while 12 (15.2%) had past PD. Compared to patients who have never experienced PD, those with current PD had significantly worse asthma control, more severe nasal obstruction, greater dyspnea and physical symptom burden, as well as greater proneness to catastrophizing about asthma, heightened attentional focus on internal bodily

sensations, and lower quality of life. Patients with past PD had greater dyspnea and physical symptom burden, swallowing difficulty, and reduced quality of life compared to those without PD. No significant differences were found between current and past PD groups.
Conclusions: The prevalence of current or past PD among patients with SA and/or CRSwNP was approximately three times higher than in the general population, corroborating previous epidemiological findings. PD was associated with poorer asthma and nasal symptom control, along with a higher burden and sensitivity to respiratory and physical symptoms. Our preliminary results suggest a need for PD screening and targeted interventions for these patients. Further studies with psychiatric interviews and objective respiratory measures are warranted.

Living with 20 Medications, Attempting Suicide with 15: A Critical Perspective on the Healthcare System through a Somatization Disorder Case Report

M. E. Çelik[1]* and F. Ekici[1]

[1]Psychiatry, Selcuk University, Konya, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1018

Introduction: Patients with somatization disorder frequently seek medical evaluations for unexplained symptoms, strongly believing they are physically ill and often rejecting psychosocial explanations. In Turkey, easy and low-cost access to healthcare and medications via the General Health Insurance system encourages frequent hospital visits. High patient loads and short consultation times hinder thorough assessments, complicating diagnoses like somatization disorder. Consequently, physicians may practice "defensive medicine," over-ordering tests and medications to minimize risks. These practices reinforce patients' beliefs in having an organic illness and increase the risk of polypharmacy.
Objectives: This case discusses a patient with somatization disorder experiencing multiple hospital admissions and polypharmacy due to the dynamics of the Turkish healthcare system.
Methods: A 31-year-old woman was admitted after a suicide attempt, exhibiting depressive symptoms and psychosomatic complaints. Detailed examinations of her socio-demographic data, medical and psychiatric history, current complaints, medication use, and past hospitalizations were conducted.
Results: Since age 16, the patient frequently presented with fainting, convulsions, nausea, and vomiting, undergoing extensive evaluations. She repeatedly visited emergency services for chest pain radiating to her left arm and jaw; coronary angiography found no cardiac pathology. Despite no organic cause, she was prescribed 15 different medications by various specialties, reaching 20 tablets daily, covering cardiovascular, gastrointestinal, endocrine, and respiratory systems. Due to family issues, divorce processes, and social stressors, she exhibited depressive and psychosomatic symptoms, attempted suicide 7 times, and was hospitalized in psychiatric wards 12 times. In her latest attempt, she ingested 15 fluoxetine tablets. Psychiatric evaluation revealed ongoing somatic complaints, and polypharmacy was adversely affecting her health. After consultations, unnecessary non-psychiatric medications were discontinued. Her treatment was adjusted to venlafaxine 300 mg/day, clozapine 50 mg/day, and mirtazapine 30 mg/day.
Conclusions: This case illustrates how structural issues in the healthcare system adversely affect patients with somatization disorder, increasing polypharmacy risk. Unnecessary tests and treatments reinforce beliefs in organic illness and complicate management. Healthcare professionals should approach such patients carefully, avoid defensive medicine practices, and consider early psychiatric evaluation. Policy-level changes are needed for the healthcare system to better address these patients' needs.

The Impact of Psychiatric conditions on Functional Gastrointestinal Symptoms

K. Imen[1], R. Nakhli[2], M. Bouhoula[1], L. S. Chaibi[3]*, O. Ajmi[4], N. Belhadj[5], A. Aloui[1] and M. Kahloul[6]

[1]Occupational Medicine Department, University of Sousse, Faculty of Medicine Ibn Al Jazzar; [2]Occupational Medicine Department (LR19SP03), Faculty of Medicine of Sousse, Farhat Hached University Hospital, University of Sousse, Sousse; [3]D Psychiatric Department, Razi Hospital, Tunis; [4]Psychiatry Department, Psychiatry Department, Farhat Hached University Hospital Medicine Department, Sahloul University Hospital; [5]Occupational Medicine Department, Occupational Medicine Department, Sahloul University Hospital and [6]4. Anesthesia and Intensive Care Department, Sahloul University Hospital, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1019

Introduction: Functional gastrointestinal disorders (FGIDs) represent a significant global health burden, affecting approximately 15-20% of the population. These disorders can significantly impair quality of life, particularly in individuals facing high levels of psychological stress, such as medical students.
Objectives: To study the association between psychiatric factors, specifically anxiety and depressive disorders, and the prevalence of FGIDs among medical students in Tunisia.
Methods: A cross-sectional study was conducted among second-year medical students at the Faculty of Medicine, Sousse, from March 2023 to February 2024. Data were collected using a self-administered questionnaire designed to assess gastrointestinal symptoms such as abdominal pain, bloating, diarrhea, constipation, and heartburn. Psychiatric conditions were assed using validated screening tools.
Results: The study included 206 students, with a strong female predominance (80.1%). Among them, 46.1% (n=95) reported experiencing between 1 and 4 digestive disorders, primarily abdominal pain and bloating (66%). Psychiatrically, univariate analysis revealed a significant association between FGIDs and several psychological factors: female gender ($p<0.01$), a tendency towards anger in daily life ($p<0.01$), anticipatory anxiety ($p<0.01$), and the presence of panic attacks ($p<0.01$).
Conclusions: Functional gastrointestinal disorders (FGIDs) are prevalent among medical students and are often linked to anxiety and depressive disorders. Preventive measures focused on stress management and mental health could significantly improve the quality of life of these students and prevent digestive complications.

Neuroprotective effects of EDTA on manganese-induced neuroaffective disorders: Implications for anxiety and depressive disorders

H. Harifi[1]*, H. Hami[1] and L. Bikjdaouene[1]

[1]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1020

Introduction: Manganese (Mn), an essential yet potentially toxic metal found naturally in the environment, has been implicated in various neurodegenerative and neuroaffective disorders due to its propensity for chronic intoxication.
Objectives: This study explores the neuroprotective effects of Ethylenediaminetetraacetic acid (EDTA) against Mn-induced toxicity, with a specific focus on its potential to mitigate anxiety and depressive disorders.
Methods: Three groups of male Wistar rats were used: one group was injected with 25 mg/kg Mn, another with 25 mg/kg Mn plus 4 mg/kg EDTA, and the control group received NaCl. Injections were administered intraperitoneally daily for 12 weeks. Rat weights were monitored weekly, and following the exposure period, rats underwent a series of neurobehavioral tests to assess anxiety and depressive behaviors.
Results: Rats receiving the 25 mg/kg Mn dose alone exhibited increased immobility in the forced swimming test (FST) and anhedonia in the sucrose preference test, indicative of depressive behaviors. In contrast, rats treated with Mn and EDTA displayed significantly reduced immobility times and maintained normal sucrose water consumption. Behavioral tests, including the open field test (OFT) and elevated plus maze (EPM), indicated increased anxiety in Mn-exposed rats, which was mitigated by EDTA treatment.
Conclusions: Mn exposure induces anxiety and depressive disorders in rats, but coadministration of EDTA significantly mitigates these effects, suggesting its potential as a neuroprotective agent against Mn toxicity.

Eye movements predict treatment response in children and adolescents with social anxiety disorder

J. L. Kleberg[1]*, M. Cervin[2], M. Nord[3], E. Serlachius[2] and J. Högström[4]

[1]Department of Psychology, Stockholm University, Stockholm; [2]Department of Clinical Sciences, Lund University, Lund; [3]Department of Public Global Health and [4]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1021

Introduction: Response to treatment in pediatric social anxiety disorder (SAD) is highly variable. Atypical face processing has been suggested as a maintaining factor. A previous study reported that youth with SAD scan a more restricted area of faces than healthy controls during emotion recognition, potentially interfering with social cognition.
Objectives: The current study examined whether visual scanning and arousal (pupil dilation) also predicts treatment response and changes as a function of successful treatment.
Methods: Youth with SAD (n = 55) were assessed prior to treatment with internet-delivered cognitive behavioral therapy (ICBT) or supportive therapy (ISUPPORT) and three and twelve months after treatment.
Results: Restricted scanning of faces predicted worse treatment outcome, most consistently for youth receiving ICBT. No evidence for a change in social attention after treatment was found. Instead, visual social attention measures showed moderate to high stability. Children whose arousal decreased from baseline to three months follow up were most likely to benefit from ICBT rather than ISUPPORT, pointing to a role of arousal in treatment response.
Conclusions: Restricted scanning of faces may interfere with social interaction, thereby interfering with treatment. These results have implications for our understanding of social information processing in SAD.

Formation model of anxiety disorders in internally displaced persons in war context in Ukraine

H. Kozhyna[1]*, K. Zelenska[1], L. Gaichuk[1], S. Isaenko[2] and A. Nartova[1]

[1]Department of Psychiatry, Narcology, Medical Psychology and Social Work, Kharkiv National Medical University, Kharkiv and [2]Mental Health Clinic by Dr.Isaenko, Kyiv, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1022

Introduction: Since the beginning of the full-scale war with Russia, 7.7 million Ukrainians have been forcibly displaced from their homes and are currently living in internally displaced persons (IDP) camps. According to the International Organization for Migration (IOM), the proportion of IDPs in Ukraine's total population has reached 17.5%, indicating that one in six individuals has been displaced.
Objectives: The purpose of the study is to investigate the clinical, psychological and pathological patterns of anxiety disorders of psychogenic genesis. The main group consisted of 93 IDP patients with anxiety disorders, both sexes, aged 20-55 years.
Methods: SCL-90-R; HAM-A, HAM-D; Spielberger-Khanin Scale and Questionnaire of neuropsychological stress by T.A. Nemchin.
Results: It has been established that the clinical structure of anxiety disorders in the examined patients is represented by a mixed anxiety-depressive reaction (28.2±1.2% of the examined), panic disorder (36.4±1.3%) and generalised anxiety disorder (35.4±1.3%). At the same time, in the clinical structure of anxiety disorders in IDPs, along with the dominance of anxiety symptoms, there is a high severity of depressive manifestations. Based on data obtained in the course of our research, a multifactorial model of formation of anxiety disorders in IDPs was developed. The catalyst for anxiety disorders is the very fact of forced displacement, uncertainty of future, situations of loss, effects of combat stress, information stress and situations of increased responsibility.
High levels of anxiety, somatisation, depression, obsessive-compulsive disorders, interpersonal sensitivity, and phobic anxiety according to SCL-90-R scale are prognostically significant in formation of anxiety

disorders; severe depressive and anxiety episodes according to the Hamilton Anxiety and Depression Scales; high levels of personal and situational anxiety according to the Spielberger-Khanin Scale and excessive levels of neuropsychological stress.
Conclusions: The basis for the formation of anxiety disorders in IDPs is a low level of resilience, which entails a high level of social frustration in this cohort. We have developed and tested a comprehensive personalised system for treatment of anxiety disorders in IDPs with differentiated use of psychopharmacotherapy, psychotherapy and psychoeducation.

Are medical students more prone to symptoms of anxiety and depression?

S. Kucukalic[1]*, M. Arnautovic Tahirovic[2], A. Ganibegovic[3], M. Bubenik[3] and A. Tahirovic[1]

[1]Psychiatric clinic, Clinical centre university of Sarajevo; [2]Psychiatric hospital of Canton Sarajevo and [3]Faculty of Medicine University of Sarajevo, Sarajevo, Bosnia and Herzegovina
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1023

Introduction: Faculty of Medicine is often recognized as one of the most laborious. Student workload, constant exposure to stressful situations, fear of failure, pressure from parents, exposure to death and human suffering are some of the many factors associated with increasing levels of anxiety and depression among medical students.
Objectives: The aim of this study was to estimate the severity of anxiety and depression disorders among medical students.
Methods: In this cross-sectional study, self-report anonymous online survey was distributed to the students of all six years of the Faculty of Medicine, University of Sarajevo. In this survey, which consisted of 33 questions, we gathered general information and the Beck's Anxiety and Depression Inventory were used to assess the severity of anxiety and depression, whereby respondents received points by answering each question, and after scoring, they were categorized in different groups based on the severity of anxiety and depression.
Results: 129 students completed the survey. Considering the Beck's Anxiety Inventory, 56% scored for the "Low anxiety" group, 33% scored for the "Moderate Anxiety" group, 11% scored for the "Potentially concerning levels of anxiety". Considering the Beck's Depression Inventory, 43% of the students scored for the group "These ups and downs are considered normal", 21% scored for "Mild mood disturbances", 9% for the "Borderline clinical depression", 19% for "Moderate depression", 6% for "Severe depression", 2% for "Extreme depression".
Conclusions: Psychiatric morbidity found needs to be identified and treated at the earliest, because it can lead to suicidal ideation. Medical students should be encouraged to seek help and adequate facilities should be available to all of them.

Features of cognitive impairment in affective disorders

E. Markova[1]*, I. Goldina[1] and B. Goldin[2]

[1]Neuroimmunology Lab, State Research Institute of Fundamental and Clinical Immunology and [2]Department of Psychiatry, Narcology, Psychotherapy and Clinical Psychology, Novosibirsk State Medical University, Novosibirsk, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1024

Introduction: Iimpaired cognitive functions are an urgent problem of modern neurology and psychiatry. Cognitive failure appears to be as etiologically heterogeneous syndrome, characterized by a decrease in memory indicators below the age norm, with unimpaired intellectual functioning and well-preserved activity. The wide prevalence of affective disorders and the leading role of the cognitive component in the process of personal self-development determine the undoubted relevance of studying the frequency and severity of cognitive impairment in affective disorders.
Objectives: The purpose of this work was to study the cognitive impairment frequency and features in patients with generalized anxiety disorder (GAD) or panic disorder with agoraphobia (PDA).
Methods: The study included 25 patients with an established diagnosis of GAD and 20 patients PDA. The control group consisted of 20 conditionally healthy volunteers. Cognitive function was assessed based on complaints, a study of visual-constructive skills, naming, memory, attention, praxis, speech, abstraction, orientation, using the Mini-mental State Examination scale and the Montreal Cognitive Function Rating Scale. The severity of anxiety disorders symptoms was determined during a clinical interview by a psychiatrist, as well as using the Hamilton Anxiety Scale (HDRS), Beck Anxiety Scale (BAI).
Results: All patients in contrast to the healthy participants showed signs of cognitive impairment of varying severity. When studying cognitive function, the following was found:

patients with PDA were characterized by mild non-dementia cognitive impairment and showed signs of rumination - a tendency to think through the same stressful event over and over again. No memory or attention impairments were identified;
in patients with GAD moderate cognitive impairment was observed, the severity of which was obvious to both patients and their relatives in the form of impaired attention and memory, also in the absence of signs of dementia. The spectrum of cognitive impairment manifestations included impaired attention, executive functions and memory disorders. These patients were characterized by perfectionism, decreased confidence in their own memory, anxious doubts and double-checks.
Conclusions: Our data indicate that in all patients with affective disorders impaired cognitive functions are detected. GAD is characterized by a greater severity of cognitive deficits compared to those in PDA.

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1025

Introduction: Functional neurological disorder (FND) is a core neuropsychiatric condition that includes both physical and mental symptoms. Recently, a validated clinical phenotype termed neuroconnective endophenotype (NEP), which includes several physical and psychological characteristics together with joint hypermobility (hypermobility spectrum disorders), was found at a significantly higher frequency among patients with anxiety (Bulbena A *et al.* Adv Psychosom Med 2015; 34:143–157).

Objectives: The purpose of the present study was to examine the presence of the NEP among patients with FND.

Methods: A multicenter case-control study was conducted comprising 27 FND patients and 27 healthy control participants (matched by sex and age) ages 13 to 58 years. Eight questionnaires were administered. Proportional differences were examined with Student's t tests, one-way analyses of variance, and chi-square tests.

Results: Differences between FND patients and control participants were observed. As presented on tables 1 and 2, FND patients had higher sensory sensitivity, increased prevalence of hypermobility features (including relevant physical signs and symptoms), greater frequency of polarized behaviors and an increase in the characteristics and sensations typical of anxiety. FND patients also presented a greater number of comorbidities, both psychiatric (generalized anxiety disorder or panic attacks (63%); phobias, including social anxiety, agoraphobia, and specific phobias (52%); and depression (44%)) and physical (migraine (59%), irritable bowel syndrome (48%), drug intolerances (44%), dark sclerae (41%), and chronic fatigue syndrome (41%)). Particularly striking was the presence of the hypermobility spectrum in more than 75% of FND patients compared with 15% among control participants (Table 3).

Neuroconnective endophenotype questionnaire subscale	FND patients (N=27) Mean	SD	95% CI	Healthy control participants (N=27) Mean	SD	95% CI	F	p
Sensory sensitivity	41.15	12.44	36.34, 45.95	14.63	12.44	9.83, 19.43	61.34	<0.001
Physical signs and symptoms	11.07	3.46	9.74, 12.41	4.22	3.46	2.89, 5.56	52.94	<0.001
Pain intensity	3.01	1.29	2.51, 3.51	1.29	1.29	0.79, 1.79	23.88	<0.001
Pain locations	2.33	1.10	1.91, 2.76	1.04	1.10	0.61, 1.46	18.74	<0.001
Behavioral polarized dimensions	3.41	1.48	2.84, 3.98	1.78	1.48	1.21, 2.35	16.47	0.002
Psychopathological characteristics and sensations	53.63	14.68	47.96, 59.3	26.70	14.68	21.04, 32.37	45.44	<0.001
Psychiatric diagnoses	3.44	1.20	2.98, 3.91	0.00	1.20	−0.46, 0.46	111.54	<0.001
Somatic disorders	4.78	2.27	3.9, 5.66	1.37	2.27	0.49, 2.25	30.31	<0.001

[a] Comparison of subscale scores and their significance are reported. Data for the Hypermobility Evaluation Guideline and Beighton scoring system are not included. F values were obtained with one-way analysis of variance.

Image 3:

TABLE 3. Hypermobility spectrum disorder assessment of patients with functional neurological disorder (FND) and healthy control participants[a]

Hypermobility spectrum disorders questionnaire	Cutoff point	FND patients (N=27) N	%	Mean	SD	95% CI	Healthy control participants (N=27) N	%	Mean	SD	95% CI	F	p
SQ-CH	≥4	21	78	4.7	1.69	4.05, 5.36	4	15	1.70	1.69	1.04, 2.36	42.33	<0.001
HLX9	≥5	21	78	6.19	2.40	5.26, 7.11	8	30	3.59	2.40	2.67, 4.52	15.80	0.002
Beighton	≥5	21	78	6.22	2.64	5.2, 7.24	10	37	3.56	2.64	2.54, 4.57	13.82	0.005

[a] N and % values represent participants in each group over the cutoff value. For the Beighton scoring system, possible scores range from 0 to 9, with higher scores indicating greater hypermobility. HLX9=Hypermobility Evaluation Guideline (scores range from 0 to 9, with higher scores indicating greater hypermobility); SQ-CH=Screening Questionnaire for the Assessment of Joint Hypermobility Syndrome (scores range from 0 to 10, with higher scores indicating greater hypermobility). F values were obtained with one-way analysis of variance.

Conclusions: FND patients presented higher scores in all five dimensions included in the NEP. Thus, this phenotype, solidifying the original association between anxiety and the hypermobility spectrum, could help to identify an FND subtype when evaluating and managing FND patients, because it provides a new global view of patients' physical and mental symptoms. Limitations in this study included small sample size, possible selection and recall biases and lack of data on socioeconomic factors and education.

Post-Colectomy Cacosmia: The Role of Anxiety and Sensory Distortion in Postoperative Recovery

Y. Mashayekhi[1]*, M. Marudkar[1] and R. Sherrat[1]

[1]Mental health liaison service, Leicester Royal infirmary, Leicester, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1026

Introduction: Cacosmia, the perception of neutral odors as foul, is an unusual and distressing postoperative complication. This case focuses on a 66-year-old female who experienced cacosmia after a colectomy, raising questions about the role of anxiety in postoperative sensory distortions. While colectomy is commonly associated with physiological complications, emerging research indicates that psychological factors, particularly anxiety, may influence sensory processing. Addressing these interactions is crucial for improving outcomes in patients with psychiatric comorbidities undergoing surgery.
Objectives:
1. To examine the influence of pre-existing anxiety on the development of sensory distortions, specifically cacosmia, following colectomy.
2. To investigate the relationship between the gut-brain axis and psychological factors, including anxiety, in the context of postoperative recovery.
3. To highlight the gaps in the literature regarding sensory distortions in surgical patients and to propose potential areas for future research.

Methods: Patient: A 66-year-old female with a history of anxiety disorder developed cacosmia two weeks after undergoing colectomy. **Symptoms:** She reported that food smelled like feces despite normal postoperative recovery and the absence of physical abnormalities. **Literature Review: a** search was conducted using databases such as PubMed and Scopus with terms like *cacosmia*, *postoperative sensory distortion*, *anxiety and surgery*, and *gut-brain axis.* Articles exploring the relationship between anxiety and sensory distortions in surgical patients were included.
Results: Gut-Brain Axis: The gut-brain axis is essential in regulating emotions and sensory processing. Disruptions from surgery can affect neurotransmitters, contributing to both anxiety and sensory misinterpretations like cacosmia. **Anxiety's Role:** Anxiety is known to heighten sensory perception. The patient's pre-existing anxiety likely amplified her awareness of sensory stimuli, leading to distorted odor perceptions.
Literature Gap: While the role of anxiety in surgical recovery is recognized, there is a lack of research specifically addressing sensory distortions like cacosmia in the postoperative period.
Conclusions: This case underscores the importance of considering psychological factors, especially anxiety, in postoperative sensory distortions like cacosmia. The interaction between the gut-brain axis and sensory perception in anxious patients highlights the need for a more comprehensive, multidisciplinary approach to postoperative care. Current gaps in the literature suggest a need for future research on how anxiety and sensory processing intersect after surgery. Investigating preoperative interventions such as cognitive-behavioral therapy (CBT) or pharmacotherapy may help mitigate sensory distortions and improve postoperative recovery outcomes in patients with anxiety.

A Case of Emetophobia Responding to Selective Serotonin Reuptake Inhibitors: Implications for Treatment

R. A. Moreira[1]*, H. J. Gomes[1], E. Maldonado[1], I. Machado[1] and J. M. Justo[1]

[1]Psiquiatria, Unidade Local de Saúde do Nordeste, Bragança, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1027

Introduction: Emetophobia, an intense and disproportionate fear of vomiting, is a chronic and debilitating condition characterized by the avoidance of situations or activities that may increase the perceived risk of vomiting. It is often accompanied by an overwhelming fear of losing control, becoming severely ill, or being perceived as repulsive by others. Treating emetophobia is particularly challenging, primarily due to the difficulties in implementing exposure-based interventions effectively. Data on the pharmacological management of emetophobia is limited, with only a few case reports in the literature suggesting potential benefits from selective serotonin reuptake inhibitors (SSRIs).
Objectives: With this case report we aim to describe a case of emetophobia treated with an SSRI.
Methods: Description of a clinical case of a patient with emetophobia observed in a psychiatric outpatient consultation.
Results: We present the case of a 21-year-old male with a one-year history of emetophobia. At the time of consultation, he was unemployed, having recently completed a computer engineering degree. He had no relevant past medical history and was not on any regular medication. The patient was referred for psychiatric evaluation after three years of psychotherapeutic treatment for generalized anxiety disorder. His anxiety symptoms worsened one year prior after an episode of vomiting, which triggered a fear of recurrence. This fear led to restrictive eating, resulting in a 10 kg weight loss over the preceding year (current weight: 63 kg), and significant social avoidance due to the fear of vomiting in public. Physical and neurological examinations revealed no abnormalities. Routine blood tests, urinalysis, and urine drug screening showed normal results. Given the limited efficacy of prior psychotherapeutic interventions, pharmacotherapy with escitalopram 10 mg daily was initiated. After one year of follow-up, the patient reported substantial improvement in anxiety symptoms and avoidance behaviors related to his fear of vomiting. He was able to resume normal eating patterns and gained 5 kg during this period.
Conclusions: This case highlights the potential efficacy of SSRIs, specifically escitalopram, in the treatment of emetophobia. After one year, the patient showed significant improvement, with the return of normal eating patterns and weight gain. While exposure-based interventions remain a cornerstone of treatment for specific phobias, pharmacological options like SSRIs can serve as a valuable adjunct, especially in cases with comorbid anxiety disorders. Further research is needed to better understand SSRIs' role in managing emetophobia and refine treatment strategies for this complex condition.

EPV0167

Psychological Resilience in Fibromyalgia: The Impact of Mental Health on Clinical Progression

T. Mutlu Topal[1]*, H. Ertekin[1] and H. Reşorlu[2]

[1]Psychiatry and [2]Physical Therapy and Rehabilitation, Çanakkale Onsekiz Mart University, Çanakkale, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1028

Introduction: Fibromyalgia (FM) is a chronic condition characterized by widespread muscle pain,with an unclear etiology. Pain-related behaviors are often closely tied to the individual's mental state. This has made FM a significant area of psychiatric research, highlighting the need to understand the psychological factors that influence disease progression.
Objectives: We aim to explore differences in psychological resilience between FM patients and healthy controls and its relationship with depression,anxiety,and fibromyalgia symptoms. Specifically,we seek to understand how resilience may influence disease development and progression. By examining these factors, the study aims to clarify the underlying causes of fibromyalgia,is closely linked to psychiatric factors and remains poorly understood in terms of etiology.
Methods: The study included FM patients treated at the Department of Physical Medicine and Rehabilitation at Çanakkale 18 Mart University and a control group of healthy volunteers matched for demographic factors. Pain intensity was measured using the Visual Analog Scale(VAS) and functional disability was assessed with the Fibromyalgia Impact Questionnaire(FIQ). Participants completed sociodemographic forms, the Beck Anxiety Inventory(BAI), the Beck Depression Inventory(BDI), and the Psychological Resilience Scale(PRS).
Results: The study involved 40 female patients with FM and 35 healthy controls. No significant differences were found between the two groups in terms of demographic factors. The FM group showed significantly higher scores for BDI,BAI and PRS compared to controls ($p<0.001$ for BDI and BAI; $p =0.04$ for PRS). Correlation analysis revealed significant negative correlations between pain intensity and both PRS total and PRS dedication scores ($r=-0.34$, $p=0.02$; $r =-0.35$, $p =0.02$). Additionally,FIQ scores were negatively correlated with PRS dedication scores($r=-0.37$, $p=0.01$). (Table 1).

Table 1: Psychological Status and Performance Scales (BDI, BAI, PRS, etc.)

Variable	FM (n, %) & mean ± SD	Control (n, %) & mean ± SD	Statistics	p
BDI	20.20 ± 11.54	7.77 ± 6.79	5.58	<0.001
BAI	24.90 ± 13.14	9.0 ± 6.97	6.40	<0.001
PRS Total	54.92 ± 10.67	59.08 ± 10.27	-1.71	0.09
Challenge	21.22 ± 5.82	21.11 ± 5.50	0.08	0.93
Dedication	17.75 ± 5.14	19.54 ± 4.24	-1.63	0.10
Control	16.25 ± 5.01	18.38 ± 3.70	-2.05	**0.04**

BMI: Body Mass Index, BDI: Beck Depression Inventory, BAI: Beck Anxiety Inventory, PRS: Psychological Resilience Scale

Conclusions: This study highlights the complex interplay between psychological resilience,depression,anxiety and pain in FM patients. Psychological resilience was not significantly lower in FM patients compared to healthy individuals,but higher levels of depression and anxiety were inversely related to resilience.These findings underscore the need for treatment approaches that not only address physical symptoms but also aim to enhance psychological resilience in order to improve the overall quality of life in FM patients.

Muscles Flexed, Minds Relaxed: Investigating the association between strength training and anxiety

S. Ben Aissa[1]*, C. Najar[1], K. Razki[1], M. Cheour[1] and F. Fekih-Romdhane[1,2]

[1]Razi Hospital, La Manouba and [2]Faculty of Medicine of Tunis, Tunis El Manar University, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1029

Introduction: Strength training approaches have seen a significant increase in popularity in the fitness and wellness industries in recent years. This rise is fueled not only by the desire for physical prowess and muscle development, but also by a growing awareness of its potential impact on mental health. While the traditional focus of research on strength training has primarily been on its physical benefits, there exists a developing enthusiasm within the scientific community to explore deeper into its implications for mental health, particularly with anxiety levels.
Objectives: The purpose of this study is to examine the link between strength training intensity and anxiety levels among active gym-goers in Tunisia.
Methods: This is a cross-sectional study, conducted from February to March 2024. Participants were recruited online through social media platforms (Tunisian facebook groups and fitness forums) using a posted survey link. We've included respondents who are 18 years of age or older who have been active in strength training with a gym membership for 1 month or more. The respondents were required to answer a questionnaire that included socio-demographic questions and to provide strength training intensity related details (sessions frequency, duration, perceived overall intensity using likert scale). Anxiety levels were evaluated using the Generalized Anxiety Disorder 7 (GAD-7) scale.
Results: The overall number of participants was 72, with 86% being male. The majority of responders (n=65, 90.2%) indicated that they performed strength training exercises at least three times per week, with an average session length of 45 minutes. In terms of strength training intensity, 38.8% (n= 28) of participants reported high-intensity sessions, 48.6%(n=35) moderate-intensity sessions, and the remaining participants reported low-intensity sessions.
Analysis showed a mean anxiety score of 6.1 (SD = 3.8) on the GAD-7 scale, indicating absent to mild anxiety symptoms among respondents.
Further analysis revealed a negative association between strength training intensity and anxiety levels ($r = -0.59$, $p = 0.026$), implying that higher intensity sessions were linked with lower anxiety scores.
Conclusions: In conclusion, this study provides insight into the level of anxiety of Tunisian gym-goers who participate in strength training, emphasising the potential of exercise interventions to improve mental health in this society. Moving forward, these findings can help to shape targeted interventions and wellness

efforts, promoting holistic approaches to well-being that prioritise both physical and psychological health.

Anxiety levels among medical students and healthcare workers during Covid-19 pandemic: Bulgaria sample

E. Papazov[1,2], P. Marinov[1,2,3] and A. Chankov[1]*

[1]Mental Health Center Prof. N. Shipkovenski; [2]SOFIA UNIVERSITY ST. KLIMENT OHRIDSKI, Sofia and [3]Trakia University, Stara Zagora, Bulgaria
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1030

Introduction: The Covid-19 pandemic has been an integral part of our lives since late 2019, bringing significant changes to the way we live. These changes have brought with them a wave of pandemic-related psychological distress including fear, anxiety, feelings of threat. The Covid-19 pandemic presented several global challenges to the functioning of the health system in general and to medical personnel in particular. Unfortunately, the discussion on how staff in health facilities deal with pandemic-associated distress has remained in the background.
Objectives: The main aim of our study was to investigate the impact of the COVID-19 pandemic on the mental health of healthcare workers and trainees and specifically on the development of anxiety symptoms. We aimed to track levels of anxiety among physicians, health care professionals, and medical students, and their relationship to various sociodemographic indicators-gender, age, marital status, education and occupation, familial predisposition to anxiety disorders, and previous consultation with a psychologist/psychiatrist.
Methods: The study was led among fifth and sixth year medical students in Sofia university and Trakia university and also doctors and nurses working in hospitals in Sofia and Stara Zagora - MHC "Prof. H. Shipkovensky", University Hospital "N.I Pirogov", University Hospital "Prof. Dr. Stoyan Kirkovich". The study used a questionnaire created by the researchers and the Coronavirus Anxiety Scale by Lee and the Covid-19 anxiety syndrome scale by Nikcevic and Spada.
Results: The mean age of the study participants was 28.21 ±10.11 years ranging from 22 to 68. Majority of the study participants (72.3%) were students followed by doctors with 19.8% and nurses with 5.6%. After statistical analysis of the data, there was a linear relationship between having a close friend or relative who had died or had a serious illness due to Covid-19 infection and having marked anxiety and fear for the health of loved ones. In this group frequent checking for coronavirus symptoms, both in the respondents themselves and by them to their friends and relatives was observed more often. Pre-pandemic visits to a psychologist/psychiatrist for anxiety symptoms appeared to be a predictor of avoidance behaviour in respondents e.g.not using public transport to reduce the risk of infection.
Conclusions: Having a close friend or relative who had a severe infection with Covid-19 and pre-pandemic visits to a mental health professional were predictors of increased pandemic-related anxiety and avoidance behavior among health care professionals and medical students. Due to the high prevalence of this mental health problem among medical students and frontline health workers, it is suggested that healthcare institutions provide mental health services for these working groups in order to appropriately manage anxiety.

Differentiating PNES from Epilepsy- a case report

I. Rakos[1]* and D. Lucijanic[1]

[1]University Hospital Dubrava, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1031

Introduction: PNEA- Psychogenic Non-Epileptic seizures resemble epileptic seizures, have no electrophysiological correlate or clinical evidence for epilepsy, whereas there is positive evidence for psychogenic factors that may have caused the seizure. The clinical presentation usually includes convulsive movements, tremor of the whole body, or just some of the parts, loss of awareness, unresponsiveness and sometimes amnesia. (N.M.G. Bodde, J.L. Brooks, G.A. Baker, P.A.J.M. Boon, J.G.M. Hendriksen, O.G. Mulder, A.P. Aldenkamp, Psychogenic non-epileptic seizures—Definition, etiology, treatment and prognostic issues: A critical review, Seizure, Volume 18, Issue 8, 2009, Pages 543-553, ISSN 1059-1311, https://doi.org/10.1016/j.seizure.2009.06.006.). We were called for a psychiatric consultation for a 35 year old female patient who presented to the Emergency service of our hospital with a history of severe headache unresponsive to painkillers, seizures and a panic attack. A few days prior to this visit she was hospitalized in the Department of Neurology of a different hospital under suspicion of hydrocephalus.
Objectives: The objective of our psychiatric consult was to determine whether the clinical presentation of seizures and headache could be caused by underlying psychological disturbances, rather than by somatic symptoms.
Methods: We reviewed the patient history and previous medical findings and treatment. Additionally, the patient underwent a series of diagnostic tests, with the most important one being video EEG monitoring.
Results: On the MINI diagnostic questionnaire, she met the criteria for Mixed anxiety and depressive disorder and Dissociative and conversion disorder. Psychological testing confirmed a tendency to somatization, and development of secondary psychiatric symptoms on top of the existing physical symptoms. Also, continuous EEG recording for the duration of four days detected only functional seizures, and with other non-pathological findings, among others, through MR of the brain and MR angiography, confirmed the working diagnosis of PNEA.
Conclusions: The mutual cooperation between neurology specialists and liaison psychiatrists is vital in cases like this when there is an unclear cause of the symptoms. Accurate determination of the underlying cause of disturbances enables adequate treatment of the patient.

Screening for psychoaffective disorders in night-shift nurses : a cross sectional study

N. Rmadi[1]*, A. Hrairi[1], F. Bouzid[2], A. Kchaou[1], N. Kotti[1], M. Hajjaji[1] and K. Jmal Hammami[1]

[1]Occupational medicine department, Hedi chaker university hospital, University of Sfax and [2]Family medicine department, University of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1032

Introduction: Night shift work disrupts the natural circadian rhythms, leading to significant sleep disturbances that can adversely affect mental health. Nurses working these shifts often report higher levels of stress, anxiety, and depression compared to their day-shift counterparts.
Objectives: This study aims to assess the prevalence of psychoaffective disorders among night-shift nurses.
Methods: Data were collected from a cross sectional study in the university hospitals of Sfax. We used a questionnaire exploring sociodemographic, professional data and pathological history. We evaluated absenteeism based on the number of days absent over the past year. Psychoaffective disorders were screened using the validated Arabic version of the Depression, Anxiety, and Stress Scale: DASS-21.
Results: Our study included 114 nurses, with 65% being female. The mean age was 33.8 ans ± 7 years. Severe to very severe symptoms of depression, anxiety, and stress were found in 14%, 21%, and 18% of our participants, respectively. Among our workers, 58% reported being moderately satisfied at work. During the last 12 months, 68 nurses (59.6%) were absent for an average of 27.21 days ± 72.73 days. Significant associations were found between job satisfaction and severity of depression (p= 0.000), anxiety (p=0.027) and stress (p = 0.000). Absenteeism was significantly associated to depression (p=0.009, r=0.24), anxiety (p=0.014, r=0.23) and stress (p=0.35, r=0.19).
Conclusions: Psychoaffective disorders are common among paramedical staff working shifts in hospitals. It is essential to conduct screening consultations in occupational medicine to identify these disorders early on.

Interwoven Pathologies: The Complex Interplay of Social Anxiety Disorder, Body Dysmorphic Disorder, and Neuropathic Pain Post-Surgical Intervention

V. H. Santos[1,2]*, F. M. Santos[3], P. Coelho[3], R. P. Andrade[4], I. A. Silva[5], T. Carvalhão[1] and S. Fontes[1]

[1]Department of Psychiatry and Mental Health, Cova da Beira Local Health Unit; [2]Faculty of Health Sciences, University of Beira Interior, Covilhã; [3]Department of Psychiatry and Mental Health, Médio Tejo Local Health Unit, Tomar; [4]Department of Psychiatry and Mental Health, Viseu Dão-Lafões Local Health Unit, Viseu and [5]Department of Psychiatry and Mental Health, Norte Alentejano Local Health Unit, Portalegre, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1033
Introduction: Social anxiety disorder (SAD) and body dysmorphic disorder (BDD) share a unique and intricate relationship, often presenting with overlapping yet distinct anxieties about social evaluation. In patients who have undergone repeated surgical interventions, the added dimension of neuropathic pain further complicates the clinical picture, as seen in this 48-year-old male. His preoccupation with his perceived nasal and upper lip deformities, coupled with neuropathic pain from multiple reconstructive surgeries, underscored a profound interplay of psychological and somatic symptoms, warranting a multidimensional therapeutic approach.
Objectives: To elucidate the diagnostic overlap between SAD and BDD in a patient with neuropathic pain post-surgery, to explore the off-label use of pregabalin in addressing both anxiety and neuropathic pain symptoms, and to highlight the subtle clinical distinctions between social phobia related to perceived physical flaws (BDD) versus the broader fear of negative evaluation in social contexts (SAD).
Methods: The patient's history includes five reconstructive surgeries to correct perceived nasal and upper lip deformities, which resulted in significant spastic neuropathic pain. This pain was exacerbated by the patient's intense anxiety regarding his physical appearance, manifesting as avoidance behaviors, fear of negative social evaluation, and repetitive self-evaluative behaviors typical of BDD. Initial treatment involved clonazepam and mirtazapine combined with psychotherapy. Despite partial relief of anxiety symptoms, neuropathic pain persisted, exacerbating his body image concerns. Pregabalin was introduced under the assumption that neuropathic pain was worsening his BDD-related distress and social anxiety symptoms.
Results: Following the introduction of pregabalin, the patient demonstrated marked clinical improvements. The dual efficacy of pregabalin, particularly in its off-label role for social anxiety, contributed to a reduction in the fear of social situations, previously fueled by BDD-related preoccupations. The remission of neuropathic pain, in conjunction with improved social functioning, underscores the utility of pregabalin in addressing the complex somatopsychic interactions in patients with comorbid psychiatric and neuropathic conditions.
Conclusions: This case highlights the intricate diagnostic and therapeutic complexities in managing co-occurring social anxiety and body dysmorphic disorder, where psychosomatic pain further distorts the clinical picture. The addition of pregabalin, despite its off-label status for SAD, proved to be a pivotal intervention, addressing both the patient's physical and psychological distress, incorporating psychopharmacology, pain management, and psychosocial interventions to effectively restore function and quality of life.

The study to identify the psychological factors that influence anxiety in mine workers

P. Sarantuya[1]*, B. Purev[1], M. Dashdondov[2], B. Dashdorj[1] and A. Altantsetseg[1]

[1]Medical department and [2]Basic Medical Department, Etugen University, Ulaanbaatar, Mongolia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1034

Introduction: If stress, insomnia, anxiety, and depression persist for a long time and occur more than normal, it can become a serious illness. Based on the data from 263 mountain work reports

submitted to the Department of Mining, Production, and Technology and the Coal Research Department of the Mineral Oil Department in 2018, a human resource survey of the industry was conducted. There are 56,635 registered workers in the mining sector, 96% of whom are Mongolian and 4% are foreign experts. 90% of all employees working in the mining industry are men, and 10% are women. In our country, there is a lack of research on the psychological health of mine workers and the factors affecting it, so this study is the reason for conducting this research.
Objectives: To identify the anxiety of mine workers and to study some correlations and effects.
Methods: The survey was conducted from March 26, 2024, to April 5, 2024, by the employees of "TiTiGiViSiOu LLC," located in Tsogtsetsii Sum, Umnugobi Province, according to GAD7, SRQ20, issued by WHO for doctors of primary health care institutions. Survey data were collected from mining workers using the PHQ9, 18 sleep disturbance questionnaires, and 10 general information questionnaires. IBM SPSS-26 software was used to analyze the research.
Results: 66.0% of the study participants had no anxiety, 23.3% had mild anxiety, 6.8% had moderate anxiety, and 3.9% had severe anxiety. Also, 70.9% work in the night shift, while 24.3% do not work in the night shift. However, 4.8% answered that they sometimes work the night shift. The majority of night shift workers are male workers. 66.0% of the respondents had no anxiety, 23.3% had mild anxiety, 6.8% had moderate anxiety, and 3.9% had severe anxiety. Anxiety has a strong direct correlation with stress (r = 0.7**, p = 0.00), depression (r = 0.87**, p = 0.00), and sleep disturbance (r = 0.58**, p = 0.00). degree was directly related. In univariate regression analysis, a one-point increase in stress score was associated with a 71% increase in anxiety. The depression score increased by 80% per unit increase, and the sleep disturbance score increased by 87% per unit increase. Multivariate linear regression analysis revealed that anxiety increased by 18.6% when the stress score increased by one and depression increased by 66.2% when the depression score increased by one.
Conclusions: Anxiety is strongly associated with stress, depression and sleep disturbances. An increase in stress, depression, and sleep disturbance scores leads to an increase in anxiety. Multivariate linear regression analysis reveals these relationships.

EPV0182

The Effect Of Pet Therapy On Anxiety In Anxiety Disorders: A Systematic Review

M. T. SİNAN[1]*, C. H. AYHAN[1], M. C. AKTAŞ[1] and H. AKBULUT[1]

[1]Mental Health And Pschiatric Nursig, Van Yuzuncu Yil University, VAN, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1035

Introduction: Observation of the potential benefits of human-animal interaction is evident. Pet therapy is used to treat anxiety as it significantly reduces self-reported anxiety in many age groups. Most studies of pet therapy involve dogs, but cats and horses have also been studied. Pet therapy is becoming increasingly popular and is used in a variety of diverse ways, from promoting communication in older adults to improving the wellbeing of those with serious mental illness. Studies have also found mental health inpatients with mood and psychotic disorders to display significant reductions in anxiety on the State-Trait Anxiety Inventory.
Objectives: This study aims to measure the effect of pet therapy (especially therapy with pets such as dogs or cats) in individuals with anxiety disorders. It is aimed to examine how pet therapy affects anxiety levels, whether it reduces anxiety symptoms and its contribution to overall quality of life.
Methods: The study will be conducted between November 2024 and January 2025 in 3 databases (PubMed, Cochrane Library, Science Direct) using the keywords "anxiety disorders", "anxiety", "pet therapy". These databases were preferred because they contain a significant amount of evidence-based literature in biomedical sciences and psychology. Studies conducted between 2015 and 2024, whose full texts were accessed and written in Turkish and English were included in the study.
Results: There are 20 national and international research articles on the subject and the literature review is ongoing. When the literature review is completed, all study results will be presented together.
Conclusions: This study provides an overview of the positive effects of pet therapy in reducing anxiety symptoms and improving quality of life in individuals with anxiety disorders. In the studies reviewed, it was found that therapy with pets, especially dogs and cats, led to significant reductions in anxiety levels and improved individuals' overall mental health. Many of the participants felt calmer, less stressed and had higher levels of satisfaction with the therapy. The findings suggest that pet therapy not only reduces anxiety levels, but also increases social communication, reduces feelings of loneliness and improves functioning in daily life. Pet therapies can be considered as a complementary method for anxiety reduction.

Insomnia in the third trimester and its association with postpartum anxiety

J. V. Stojanov[1]

[1]Forensic Psychiatry, Special Hospital for Psychiatric Disorders "GornjaToponica", Serbia; Medical faculty Nis, University of Nis, Serbia;, Nis, Serbia
doi: 10.1192/j.eurpsy.2025.1036

Introduction: Postnatal anxiety (PNA) in recent years, has become increasingly recognized as an important issue, as it affects a substantial number of women. Data from non-perinatal populations indicate that insomnia has a bidirectional association with anxiety.
Objectives: Here we aimed to explore the association between insomnia in third trimester and PNA.
Methods: We analyzed data from the hospital's birth records and questionnaire responses from pregnancy week 32 and postnatal week 4 (n=225). Postnatal anxiety symptoms were measured using the Beck Anxiety Inventory (BAI). Anxiety disorder measurements were based on questions from the Mini-International Neuropsychiatric Interview. Insomnia was measured using the Insomnia Severity Index.
Results: Among postnatal women, 8.7 % reported symptoms of at least one anxiety disorder. The observed prevalence of obsessive-compulsive disorder after delivery was 3.7%, and for social anxiety disorder 2%. Multiple regression analysis, with adjustment for several psychosocial and reproductive variables, indicated that insomnia in third trimester was significantly associated with postpartum anxiety symptoms.

Conclusions: Our results suggest that anxiety disorders are prevalent in postnatal period. Healthcare professionals should be aware that women with insomnia in third trimester may have an increased risk of postnatal anxiety disorders.

EPV0185

Diagnosis and therapeutic challenges in the exploration of cyberchondria

O. Vasiliu[1,2*] and A. M. Ciobanu[1,3]

[1]Neuroscience Department, "Carol Davila" University of Medicine; [2]Psychiatry Department, "Dr. Carol Davila" University Emergency Central Military Hospital and [3]Psychiatry Department, „Prof. Dr. Alexandru Obregia" Clinical Hospital of Psychiatry, Bucharest, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1037

Introduction: Cyberchondria is usually defined by health-related worries and repeated searches on the Internet for data on health conditions, although this behavior is associated with significant discomfort, distress, or anxiety. However, no consensus on a definition exists, and the nosography of this disorder is still uncertain, as it is not recognized by any of the currently available classifications of mental disorders. Still, cyberchondria has been associated with a negative impact on the quality of life and comorbid anxiety-depressive clinical manifestations (Ambrosini et al. *Heliyon* 2022;8 (5) e09437), thus highlighting the need for early detection and treatment of this disorder.
Objectives: This review aimed to assess the data supporting the diagnosis and therapeutic management of cyberchondria and to identify areas for further research in this field.
Methods: The review included three databases (Google Scholar, PubMed, and EMBASE), explored from their inception to June 2024, for papers published in English using the keywords "cyberchondria," and "diagnosis," "clinical scales," or "treatment."
Results: According to data extracted from 34 primary and secondary sources, health anxiety (HA) was positively correlated with seeking online information about health and with cyberchondria. Studies exploring the overlap between HA and cyberchondria have found the two conditions were distinct on multiple measures, including functional impairment and healthcare resources use. The construct of cyberchondria has several dimensions, such as "compulsion," "distress," "excessiveness," "reassurance," "mistrust," "illness-related Internet use," and "metacognitive beliefs," which are explored by specific structured methods. Two questionnaires have been created for this purpose, i.e., the Cyberchondria Severity Scale (CSS) (McElroy & Shevlin *J Anxiety Disord* 2014;28(2) 259-65) and the Online Health-related Beliefs and Behaviours Inventory (Singh & Brown *Anx Stress Coping* 2014;27(5) 542-54). Prevention should target Internet users' expectations (avoiding self-diagnosis, verifying data on the Internet with a health specialist, and searching for low-quality information on unofficial sites). Group cognitive-behavior therapy delivered by the Internet was associated with favorable results, based on the CSS scores, but there is a need for further, larger group studies to confirm these observations.
Conclusions: Cyberchondria still needs extensive explorations to be defined as a nosographic stable condition, although dimensions of this concept have begun to be explored in a systematic manner, and studies investigating psychotherapeutic approaches for this disorder have been initiated. Due to the continually increasing access of the general population to medical data online, the exploration of HA and cyberchondria is expected to attract more interest from mental health specialists in the near future.

doi: 10.1192/j.eurpsy.2025.1038

Introduction: Hypochondriasis was included in DSM-III up to DSM-IV TR in the category of „somatoform disorders," and ICD-10 concurred with this classification. However, in the last editions of the DSM (i.e., 5 and 5TR), this entity has been transformed into „illness anxiety disorder" (IAD) based on its main clinical feature- the fear of having or contracting a serious disease, although no medical evidence to support such an assumption exists. ICD-11 preserves the term „hypochondriasis" but places it between „obsessive-compulsive or related disorders." Approaching patients with hypochondria or IAD is reputedly difficult due to the difficulty of maintaining a therapeutic relationship, the sensitivity of these patients to medical data that deny their assumptions of being somatically ill, and their tendency to continuously search the information that validates their belief about their own health.
Objectives: To conduct a literature search to assess the efficacy of psychotherapeutic interventions for patients with IAD.
Methods: This review included three databases (Google Scholar, PubMed, and Web of Science/Clarivate) that were searched from their inception until June 2024 for papers published in English corresponding to the keywords "hypochondriasis," or illness anxiety disorder," and "psychotherapy*."
Results: Cognitive-behavioral therapy (CBT) was used successfully in case reports of IAD when integrated into case management. In a clinical trial, CBT plus fluoxetine led to better results than either intervention alone after 24 weeks. Systematic reviews and meta-analyses showed CBT, cognitive therapy, behavioral therapy and behavioral stress management may significantly reduce hypochondriacal symptoms versus waiting list. The therapeutic approach for IAD was focused on restructuring the catastrophic anticipations, exposure to feared stimuli, and learning relaxation techniques, replacing avoidance and reassurance-seeking with adaptive coping skills and problem-solving techniques. Mindfulness-oriented therapy, group therapies, and acceptance and commitment therapies have also been explored in this population, but the level of quality is low.
Conclusions: CBT remains the only psychotherapy that proved efficacious for patients with IAD, but most of the data retrieved is derived from case reports and small trials. Changes in the terminology

and conceptualization of hypochondriasis/IAD may negatively interfere with the possibility of selecting homogenous groups for clinical studies.

Emotional awareness and expression therapy vs cognitive behavioural therapy in patients with chronic pain: Systematic review and Meta Analysis

N. Farid[1]*, S. Reza[2], K. Marvin[3], R. Sabloak[4], N. Belhayne[5], R. Jabbar[6] and I. Teohar[7]

[1]Medicine, Mohiuddin Islamic medical College, Mirpur, Pakistan; [2]Upszilla health complax, Sitakundo, Bangladesh; [3]Azerbaijan Medical University, Baku, Azerbaijan; [4]Faculty of medicine,Sriwijaya University, Palembang, Indonesia; [5]Faculty of rehabilitationsciences and health techniques, Universiapolis University, Agadir, Morocco; [6]Fatima Memorial Hospital, FMHCMD, Lahore, Pakistan and [7]Department of Physical and Rehabilitation Medicine, The Clinical Rehabilitation Hospital of Cluj-Napoca, Cluj Napoca, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.376

Introduction: Emotional awareness and expression therapy (EAET) is a newer approach that focuses on identifying and expressing repressed emotions.While cognitive behavioural therapy (CBT) has ample evidence supporting its efficacy, the benefits provided by EAET are still unknown.
Objectives: We aimed to compare the efficacy of EAET versus CBT in treating chronic pain and stress-related conditions.
Methods: We systematically searched PubMed, Embase, Cochrane and Web of Science databases for randomized controlled trials (RCTs) comparing EAET with CBT in patients with chronic pain. Statistical analysis was performed using Review Manager 8.1.1 (Cochrane Collaboration). Heterogeneity was assessed by I^2. We pooled mean differences (MD) with 95% confidence intervals (CI) . Reduction in pain severity was assessed using brief pain inventory (BPI), anxiety by PROMIS anxiety short form 7a ,sleep disturbances by PROMIS sleep disturbances short form 8a and satisfaction with life by NIH toolbox general life satisfaction fixed form B.
Results: Three RCTs reporting data on 333 patients were included. Among them, 173 (52%) received EAET and 160 (48%) received CBT. Follow-up ranged from 3 to 6 months. The mean age of patients between studies ranged from 48 to 75 years. EAET significantly reduced pain severity (MD -0.93 points; 95% CI -1.63 to -0.23 ; p=0.009; I^2 = 81%) compared with CBT. There were no differences in anxiety (MD -1.62 points; 95% CI -4.30 to 1.05 ; p=0.23; I^2 = 91%), Sleep disturbance (MD -0.21 points; 95% CI -0.55 to 0.12; p=0.22; I^2 = 55%) and satisfaction with life (MD 0.71 points; 95% CI -0.24 to 1.65 ; p=0.14; I^2=94%).
Conclusions: In patients with chronic pain, EAET was associated with a greater reduction in pain severity compared with CBT.

Assessment of suicide risk in stabilized bipolar patients

M. Abdelkefi[1]*, S. Ellouze[1], I. Chaari[1], N. Bouattour[1], R. Jbir[1], N. Halouani[1], M. Turki[1] and J. Aloulou[1]

[1]Psychiatry B, Hedi Chaker university hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1039

Introduction: Suicide risk is a significant concern in bipolar disorder, with a notably higher rate of suicidal behaviors compared to the general population. Stabilized bipolar patients, while in remission, remain at risk due to the chronic nature of the illness and its associated mood dysregulation.
Objectives: This study aims to evaluate the prevalence and characteristics of suicide risk in a sample of stabilized bipolar patients.
Methods: We approached 107 stabilized bipolar patients attending the psychiatry outpatient unit at the Hedi Chaker University Hospital in Sfax. Ninety-three patients agreed to participate in the study. We collected their sociodemographic and clinical data. Suicide risk was assessed using the Mini International Neuropsychiatric Interview (MINI).
Results: The mean age of the participants was 41.49±12.33 years, with a predominance of males (72%). Among the patients, 58.1% were married, 47.3% were unemployed, and 44.1% reported low income. Medical comorbidities were reported by 35.5% of patients, while 11.8% had psychiatric comorbidities in addition to bipolar disorder.
Lifestyle factors revealed that 49.5% of the participants were smokers, 11.8% consumed alcohol, and 2.2% used cannabis.
Most of the patients were diagnosed with type I BD (74.2%), and 18 patients (19.4%) had a history of attempted suicide.
At the time of the study, 19.4% of the patients were assessed as being at risk of suicide with 17.2% presenting low risk and 2.2% exhibiting moderate risk.
Conclusions: This study reveals that a significant portion of stabilized bipolar patients remain at risk for suicide, with nearly one in five participants showing some level of suicide risk despite their clinical stabilization. While most were categorized as low risk, the findings underscore the necessity for continuous suicide risk assessments and preventive strategies, even during periods of mood stability.

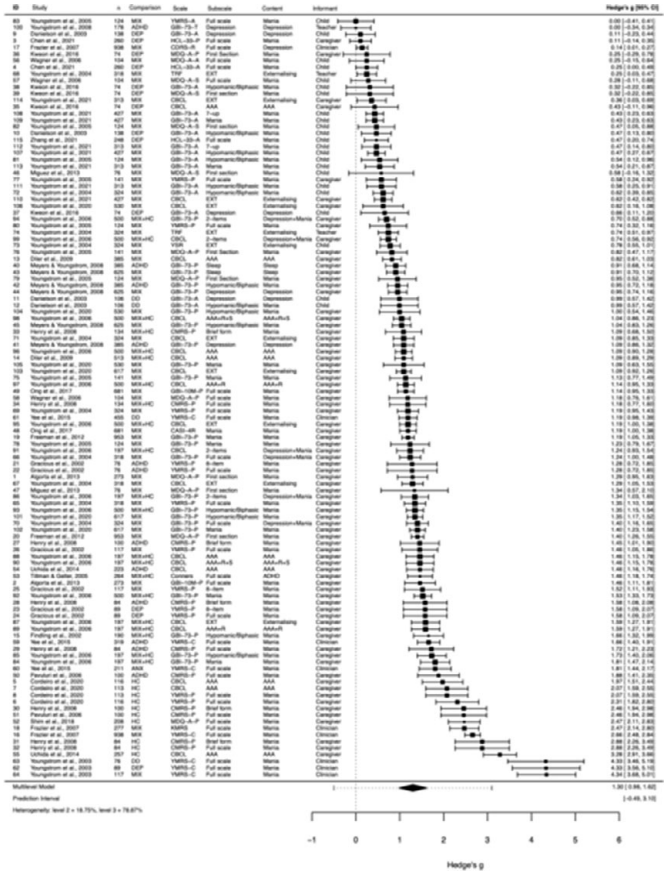
EPV0190

Early detection of pediatric bipolar disorders: a systematic review and meta-analysis



C. Alcaino[1]

[1]University of Edinburgh, Edinburgh, United Kingdom
doi: 10.1192/j.eurpsy.2025.1040

Introduction: Bipolar disorders (BD) are among the most impairing of pediatric psychiatric disorders. Even though BD symptoms may begin in adolescence, they are frequently not diagnosed until adulthood. BD screening tests could aid diagnostic assessment in paediatric populations and are supported by The International Society for Paediatric Bipolar Disorders Task Force and empirical evidence.

Objectives: This review synthesizes the evidence on the accuracy of BD symptom screening tests in distinguishing bipolar disorders from other psychiatric conditions or healthy cases in pediatric populations. Additionally, it examines a wide range of potential moderators that may influence diagnostic accuracy.
Methods: A systematic search was conducted across three databases (1980–2022), supplemented by searches of grey literature, citation chaining, and author contact. Data from relevant studies were combined using meta-analysis. A multilevel model was used to account for nested effect sizes, with 31 potential moderators tested in both univariate and multivariate models.
Results: 2,281 records were identified; 1712 titles-and-abstracts records were screened; 114 records were full-text screened; and 28 studies were included. The meta-analysis was based on all s=28 studies, 40 independent samples, k=115 effect sizes, and n=11,464 participants. Meta-analytic results showed that BD symptom index tests have high diagnostic accuracy in pediatric populations (g = 1.300; 95% CI: 0.982 - 1.619; p < .001) (see Fig. 1). Accuracy varied based on the comparison group, test content, test informant, and the specific scale or subscale used.

Image:

Conclusions: Screening tests focusing on mania-related symptoms, caregiver reports, and psychiatric comparison groups demonstrate clinical value in identifying pediatric BD. Also, other informants and symptom content combinations may not reliably identify pediatric BD. Importantly, tests derived from studies using psychiatric comparison groups, represent BD symptom non-specificity and BD symptom overlap with other disorders (eg. ADHD and depression), providing external validity and clinical utility. Screening tests with high accuracy and clinically useful are the GBI-73-P, MDQ-A-P and the YMRS-P.

EPV0191

First Manic Episode After a Loss Experience: A Case of Funeral Mania

U. Altunoez[1]*, B. Wolff[1], I. B. Guevercin[1] and A.-C. Hergott[1]
[1]Department of General Psychiatry and Psychotherapy, KRH Wunstorf Psychiatric Hospital, Wunstorf, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1041

Introduction: There is a paucity of research on the relationship between bereavement and the onset of bipolar disorder, especially in connection with manic episodes. While some case reports delivered preliminary data, they are insufficient to determine whether the stress response to a loss triggers the first signs of the disorder, or if manic symptoms arise in individuals with pre-existing mood instabilities. Overall, the predictors and prodromal characteristics for the development of a manic episode following a loss remain unclear. Moreover, there are no follow-up case studies to evaluate the long-term outcomes of these patients after the first manic episode.
Objectives: In this presentation, we will discuss the case of a woman who experienced her first manic episode immediately after the death of her son and present the one-year follow-up process to provide some experience in the psychopharmacological and psychotherapeutic treatment of these patients.
Methods: Here we will present a case from a psychiatric-psychotherapeutic hospital in Lower Saxony, Germany, in a comprehensive way.
Results: A 43-year-old woman was referred to the psychiatric department three weeks after the sudden death of her 15-year-old son due to an undiscovered congenital heart defect. She presented with chest pain, anxiety, sleep disorders, and referential psychotic thoughts. In the intensive psychiatric ward, she exhibited mood swings, sexual disinhibition, agitation, and aggressive behaviors towards staff. She engaged in excessive spending and refused to take her medications, Risperidone and Quetiapine. Her history included one depressive episode, successfully treated with psychotherapy and medication, but no previous manic episodes. Additionally, one brother had committed suicide, and another brother and her father had died from congenital heart conditions. We applied an intensive dynamic, systemic approach involving her family members to create a supportive environment for processing grief while managing her manic symptoms. After insisting on discharge after one month, she stopped her medication, leading to another intensive ward treatment due to aggression. During this phase, we resumed the same medications and intensive psychotherapy, resulting in stabilization. She later entered a psychosomatic treatment program, where she discontinued her antipsychotic medication and focused on her grief. Six months after this treatment, just before the anniversary of her son's death, she fell into a deep depression with suicidal thoughts and was referred to an open ward, where she was successfully treated with lithium and supportive psychotherapy. All somatic examinations and brain MRI scans were normal.

Conclusions: Bereavement can manifest in various ways, and in a small number of patients, it can trigger the first manic episode of bipolar disorder. Further detailed follow-up research is needed to optimize the diagnostic and treatment processes for these patients.

Real-World Trends in Benzodiazepine Prescribing for Maintenance Treatment of Bipolar Disorders

S. Andric Petrovic[1,2*], D. Jankovic[2], V. Mandic Maravic[1,2], D. Pesic[1,2], I. Ristic[1,2] and N. P. Maric[1,2]

[1]University of Belgrade, Faculty of Medicine and [2]Institute of Mental Health, Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1042

Introduction: Bipolar disorders (BD) are highly recurrent, necessitating effective long-term treatment to prevent negative outcomes. Current guidelines recommend maintenance treatment with mood stabilizers (MS) and/or antipsychotics (AP), emphasizing monotherapy after successful acute treatment. Despite limited evidence supporting polypharmacy, real-world prescribing often involves the use of multiple psychotropic drugs when monotherapy fails to adequately manage symptoms. The use of benzodiazepines (BDZ) in BD remains controversial due to potential for misuse and the exacerbation of existing substance use disorders, which are common in this population. Moreover, BDZ use may be linked to an increased risk of mood episode recurrence and could indicate a more severe course of BD.
Objectives: To examine real-world prescribing patterns in BD outpatients, with a specific focus on BDZ use.
Methods: This cross-sectional study included BD outpatients treated at the outpatient department and day hospital at the Institute of mental health in Belgrade during a one-month index period (November 2021). Besides the diagnosis, inclusion criteria were: age 18-65 years, regularly managed medical record established at least three months prior, and a consistent prescription pattern for at least one month. Basic socio-demographic and clinical data, along with information on regularly prescribed medications (MS, AP, antidepressants (AD) and BDZ), were extracted from medical records.
Results: Data from 107 clinically stable BD outpatients (75.7% female, age 44.8±11.7 years) were analyzed. Monotherapy was prescribed to 8.4% of patients, with six receiving only MS and three only AP. The majority (91.6%) were prescribed multiple psychotropic medications, predominantly the combination of MS (87.9%) and AP (80.4%). AD, mainly SSRI, were prescribed to 50.5% of the sample. Additionally, 54.2% were prescribed BDZ daily as part of their maintenance therapy, with a mean daily dose of 3.4 mg lorazepam equivalents (SD=2.5, range 0.5-12.0 mg). Patients prescribed with BDZ, compared to the those without, were significantly older (p=0.002, r=0.300), had a longer psychiatric history (p=0.042, r=0.197), and were less likely to have a comorbid personality disorder (p=0.021, Cramer's V=0.223).
Conclusions: This study illustrates prescribing practices in a university psychiatric clinic in the Western Balkans, an underresearched region. Our findings, similar to those from other regions, indicate that real-world prescribing for BD maintenance often deviates from guidelines, with most patients receiveing polypharmacy, including BDZ in over half of the cases. These results underscore the need for further research into the role of GABAergic mechanisms in the pathophysiology of BD and for randomized studies to assess the efficacy and safety of adjunctive BDZ use in BD management.

Automated Speech Analysis in Bipolar Disorder: The CALIBER Study

G. Anmella[1*], M. De Prisco[1], J. B. Joyce[2], C. Valenzuela-Pascual[1], G. Chatzisofroniou[2], D. Hidalgo-Mazzei[1] and E. Vieta[1]

[1]Bipolar and Depressive Disorders Unit, Hospital Clinic of Barcelona, Barcelona, Spain and [2]School of Graduate Medical Education, Mayo Clinic, Rochester, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1043

Introduction: Background: Bipolar disorder (BD) is marked by dramatic mood and energy shifts, often mirrored in speech. Traditional diagnosis and monitoring largely rely on subjective clinical assessments. However, advancements in natural language processing (NLP) present an opportunity for more objective speech pattern analysis.
Objectives: Aims: This study aims to (i) identify correlations between speech features and BD symptom severity, (ii) create predictive models for diagnostic and treatment outcomes, and (iii) pinpoint significant speech features and optimal tasks for analysis.
Methods: The CALIBER study is a longitudinal, observational project collecting audio from BD patients during euthymia, acute manic or depressive episodes, and recovery phases. Patients engaged in clinical interviews, cognitive assessments, standard readings, and storytelling (**Figure 1**). Automatic diarization and transcription enabled the extraction of speech features, including acoustic properties, linguistic content, formality, and emotionality. Analyses include (i) correlation of speech features with clinical scales, (ii) predictive modeling using lasso logistic regression, and (iii) feature importance identification.
Results: Preliminary data from 76 patients (24 manic, 21 depressed, 31 euthymic) were analyzed. The cohort had a mean age of 46.0 ± 14.4 years, 63.2% female. Mean YMRS scores dropped from 22.9 ± 7.1 to 5.3 ± 5.3 post-mania, and HDRS-17 scores in depressed patients fell from 17.1 ± 4.4 to 3.3 ± 2.8 post-recovery. Euthymic patients showed lower baseline scores.
Conclusions: Automated speech analysis in BD can provide objective biomarkers for diagnosis and monitoring, highlighting subtle pre-relapse changes and informing treatment strategies. Establishing standardized protocols is vital for developing a global speech database to support collaborative research and enhance BD management.

Psychological outcomes of patients with bipolar disorder during the perinatal period

S. Arsova[1,2*], S. Mitrovska[1], M. Milutinovic[1], S. Kocoska[1], V. Isjanovski[3], S. Bajraktarov[1] and M. Stankovic[1]

[1]Day Hospital; [2]Head of University Clinic of Psychiatry, University Clinic of Psychiatry and [3]PHCI Psychiatric Hospital "Skopje", Skopje, North Macedonia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1044

Introduction: Women with bipolar disorder (BD) face a high risk of adverse mental health outcomes during the perinatal period, including a high prevalence of affective episodes and postpartum psychosis. The challenge of management BD in this period includes balancing maternal stability while securing fetal safety, given the teratogenic risks of mood-stabilizing medications.
Objectives: To evaluate the course of BD during the perinatal period, assess the impact of risk factors, and examine the effectiveness of therapeutic interventions.
Methods: This prospective cohort study included 23 patients with various sociodemographic characteristics, diagnosed with BD (ICD-10 criteria). They were monitored over the course of 6 months utilizing EPDS (Edinburgh Postnatal Depression Scale), and the Young Mania Rating Scale at baseline, 3 – months and 6-months follow up, in addition to a clinically guided interview, non-standardized sociodemographic and risk factors questionnaire. The patients were treated with a combined approach in a specialized unit for mothers, including individual and group therapy, along with pharmacological treatment. Nearly all patients were switched to atypical antipsychotics with stabilizing effects while valproate was excluded due to teratogenic risks.
Results: The cohort comprised mostly of women over 30 (69.6%, $p = 0.006$), married (78.3%, $p = 0.000$), with stable socioeconomic status (69.6%, $p = 0.008$). Combined treatment (inpatient and outpatient) was predominant (82.6%, $p = 0.000$), with antipsychotics either alone (21.7%) or in combination with other medications as the most common treatment (91.3%, $p = 0.000$). All participants reported risk factors, including history of affective episodes (95.6%), traumatic events, intimate-partner violence (34.8%), substance abuse (26.1%), and unplanned pregnancy (21.7%).The EPDS scores showed a low likelihood of depression at baseline, 3, and 6 months (56.5%, 69.6%, 69.6%; $p < 0.05$), with mean scores decreasing from baseline to three months and slightly increasing at six months ($p = 0.81$). The YMRS scale indicated a significant reduction in mania from baseline to six months ($p = 0.038$). There was no significant correlation between risk factors and postnatal depression ($p > 0.05$).
Conclusions: The study confirms that BD women are at high risk for affective destabilization during the perinatal period. While continuous treatment mitigates severe mood deterioration, BD women remain vulnerable, necessitating long-term monitoring. One or more risk factors were registered in all of the participants. Although no direct significant correlation was observed in this study, existing literature suggests that risk factors such as unplanned pregnancy, abrupt medication changes, and intimate-partner violence are associated with adverse outcomes in BD women during the perinatal period. Understanding and managing these risks is essential for comprehensive BD care.

Bipolar Disorder and Fitness for Work: A Study of 17 Cases

E. Bechrifa[1*], J. Hsinet[1], E. Baraketi[1], S. Ismail[1], A. Dallagi[1], N. Ellili[1], S. Ernez[1], N. Khouja[1] and A. Benzarti[1]

[1]Occupational Medicine Department, Rabta University Hospital, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1045

Introduction: The impact of bipolar disorder on occupational health and work ability has garnered increasing attention, as it significantly influences individuals' professional functioning
Objectives: To examine the socio-professional characteristics of workers diagnosed with bipolar disorder and evaluate their fitness for work.
Methods: Retrospective descriptive study of patients with psychiatric disorders seeking medical assessments at the occupational pathology department between January 2011 and January 2024.
Results: A total of 17 patients with bipolar disorder were included, with a mean age of 36.3±8.6 years and a sex ratio of 0.42. The average professional seniority was 10.8±7.7 years. In terms of marital status, 37.5% were married, and 62.5% were single. Regarding educational level, 37.5% had completed secondary education, while 58.8% had a higher education degree, and 50% reported a family history of psychiatric disorders. Concerning lifestyle habits, 37.5% of patients were smokers, and 6.3% consumed alcohol. The most common sectors of activity were telecommunications (31.3%), transportation (18.8%), healthcare (18.8%), and cleaning and maintenance (12.5%). Workplace exposures included solvents (12.5%), noise (43.8%), imposed work pace (35.3%), lack of autonomy (35.3%), and conflicts with hierarchical superiors (62.5%). Work schedules varied, with night shifts (43.8%), alternating shifts (24.9%), and fixed hours (31.3%). Reported challenges included irritability (94.1%), sadness (93.8%), sleep disturbances (81.3%), appetite changes (43.8%), concentration difficulties (31.3%), and suicidal thoughts (25%). The disorder impacted work performance in 66.7% of cases, and 53% of patients required sick leave with an average duration of 7.4 months; 75% reported improvement under treatment. Medical assessments for work ability found that 18.8% were fit for work, 12.5% were permanently unfit, and 6.3% were temporarily unfit, while 56.3% required workplace adjustments, including avoidance of answering phone calls (12.7%), fixed work hours (23.5%), exclusion from night shifts (11.8%), and avoidance of public contact (17.6%); 6.3% underwent job reassignment.
Conclusions: Bipolar disorder has a substantial impact on work ability, highlighting the need for customized interventions and job accommodations to ensure that workers can maintain their roles and productivity.

Real clinical experience of inhaled esketamine in bipolar depression. A retrospective study

S. Benavente López[1]*, A. Lara Fernández[1], E. Toro Carrasco[1], I. Pedrero Torrejon[1], A. Parra González[1], M. Mejia Quiterio[1], A. Viñas Arboleda[1], E. Losantos Ucha[1] and E. Baca García[1]

[1]Department of Psychiatry, Hospital Universitario Infanta Elena, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1046

Introduction: Bipolar depression is a severe type of depression that poses a clinical challenge when treating it, as it can often be resistant to treatment and there is also the possibility that when treated with antidepressants the patient may switch to a manic episode. In addition, there are few medications indicated for the depressive phase of bipolar depression, which reduces the therapeutic possibilities and makes the treatment of these patients even more complicated. Bipolar depression is associated with high rates of dysfunctionality and suicide, being a serious condition that can cause severe damage to the patient. Treatment with inhaled esketamine has been shown to be safe and effective in patients with bipolar depression.
The present study shows the response in a series of cases with bipolar depression treated with inhaled esketamine, showing their evolution through the Montgomery-Asberg Depression Rating Scale (MADRS) as main outcome.
Objectives: The main objective of this study is to describe the use of inhaled esketamine in patients with bipolar depression in real clinical practice, using the MADRS as main outcome to show the evolution.
Methods: Retrospective descriptive study with a sample selected by non-probabilistic consecutive sampling, retrospective type, in a time interval of 2 years. The patients selected were those who completed treatment with inhaled esketamine and had a diagnosis of bipolar depression at Hospital Universitario Infanta Elena. A descriptive analysis was performed. Mean and standard deviation were calculated for quantitative variables and N and percentage for categorical variables.
Results: A total of 3 patients diagnosed with bipolar depression were included in the study (n: 3). Treatment with intranasal esketamine showed a clear improvement in the 3 patients with bipolar depression included in the study (100% response), greatly improving the MADRS score and restoring functionality to the patients. In addition, the treatment was well tolerated and no serious adverse effects occurred, with no switch to mania occurring in any of the patients.
Conclusions: This study shows that inhaled esktemina may be a useful drug in the treatment of bipolar depression, showing high efficacy and good tolerability. No switch to mania was observed in any of the patients in this study. Longitudinal studies must be carried out to confirm this hypothesis.

The connection between alexithymia and attachment style in the bipolar pathology

C. Bredicean[1,2]*, D. Onita[3], Z. Popovici[3], F. Calota[2], A. Danciu[2], S. Ursoniu[4] and C. Giurgi-Oncu[1]

[1]Neuroscience, University of Medicine and Pharmacy Timisoara; [2]Psychiatry, Dr. Victor Popescu Emergency Military Clinical Hospital, Timisoara; [3]Psychiatry, The mental health center, Arad and [4]Functional Sciences, University of Medicine and Pharmacy Timisoara, Timisoara, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1047

Introduction: Difficulties in identifying and expressing one's emotions, known as alexithymia, may influence the development of bipolar disorder. Attachment style reflects how a person forms and maintains interpersonal relationships
Objectives: The aim of the study is to analyze the connection between alexithymia, attachment style and the clinical evolution of bipolar disorder.
Methods: The study was conducted on a sample of 31 subjects diagnosed with bipolar affective disorder, with a longitudinal evolution of at least 10 years. Sociodemographic parameters, alexithymia (Toronto Alexithymia Scale), and attachment style (Adult Attachment Scale) were evaluated. Data were collected and analyzed to identify potential correlations between levels of alexithymia and attachment styles, as well as their impact on the number of illness episodes.
Results: There is no correlation between alexithymia and attachment style ($r = -0.044$, $p > 0.05$). A strong and significant correlation was observed between the level of alexithymia and the number of bipolar episodes ($r= 0.907$, $p < 0.05$). Attachment style did not have a significant influence on the course of illness. The educational level correlated inversely with alexithymia, but without being statistically significant ($r=- 0.344$, $p > 0.05$).
Conclusions: Alexithymia has an important role in the evolution of bipolar disorder, as it appears to be associated with an increased frequency in the number of illness episodes. The development of psychotherapy interventions to reduce alexithymia are essential to ensure a satisfactory quality of life for patients.

EPV0202

Antidepressant use in bipolar disorder, a case report

R. M. Brito Rey[1]* and R. Diler[2]

[1]Psychiatry, Complejo Asistencial Universitario de Salamanca, Salamanca, Spain and [2]Psychiatry, UPMC, CABS, Pittsburgh, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1048

Introduction: Pediatric bipolar disorder is a severe and disabling condition that affects around 1–3% of youth worldwide. The typical clinical course consists of alternating episodes of depressed or elevated mood, with intervals of well-being. Studies have shown that the onset of bipolar disorder is frequently of depressive polarity, and the long-term affective morbidity is primarily depressive, even in patients who have received treatment. This indicates that

achieving an adequate response to these mood states remains a challenge.
Objectives: In relation to a case of a patient with pediatric bipolar disorder who received treatment with SSRIs in the CABS program, we reviewed the existing literature regarding the efficacy, safety, and tolerability of antidepressant medications in the pediatric population with bipolar disorder.
Methods: We conducted a literature review of studies published in the past five years. We searched PubMed using the keywords "antidepressant," "pediatric bipolar depression," and "bipolar disorder." We discuss the case of a 17-year-old patient undergoing treatment in the CABS program with a diagnosis of bipolar I disorder.
Results: Studies have found that antidepressants are generally safe and well-tolerated. However, in bipolar disorders, antidepressants should be used in combination with mood stabilizers to reduce the risk of manic or hypomanic switching, especially in bipolar I disorder. The combination of olanzapine and fluoxetine has been found to be effective and has been approved by the FDA for both adults and adolescents with bipolar depression. SSRIs have shown effectiveness for pediatric bipolar depression in some studies, although the level of evidence is low. They are mainly used in cases of bipolar depression with comorbid anxiety. Bupropion is used off-label for ADHD in both pediatric and adult populations and is often prescribed for depression associated with bipolar disorder in adults. It is considered to have a lower risk of manic or hypomanic switch. Evidence for the use of ketamine in bipolar depression in adults remains unclear, particularly regarding long-term effects.
We present the case of a 17-year-old male with a diagnosis of bipolar I disorder who is undergoing treatment in the CABS program. He has a history of two hospitalizations and is currently being treated with aripiprazole. Escitalopram was added after he reported anxiety symptoms that aripiprazole was not addressing, resulting in a favorable response with no reported side effects.
Conclusions: Antidepressants may play a role in some cases of pediatric bipolar depression, especially when anxiety symptoms are also present and do not respond to psychotherapeutic approaches. It is important to balance the risks and benefits of using antidepressants in this population. Close monitoring is recommended to assess response and possible side effects. Further research regarding the treatment of pediatric bipolar depression is needed.

Exploring the relationship between seasonal changes and bipolar disorder relapses

A. Nunes[1]*, M. Almeida e Silva[1], J. Fonseca Barbosa[1], J. Fernandes Fontes[1] and M. Andrade[1]

[1]Psychiatry, Hospital Júlio de Matos - ULS São José, Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1049

Introduction: Bipolar disorder (BD) is a mental health disorder characterized by episodes of mania or hypomania alternating with depression, and it is known that seasonal changes can have an impact on the risk of relapse. Circadian rhythm - which works as an internal biological clock that regulates sleep-wake cycles, hormone production and mood stability -, plays a crucial role in the course of the disease, and it is likely that it influences relapse during seasonal changes, through mechanisms not entirely understood.
Objectives: Review the relationship between seasonal changes and bipolar disorder relapse, focusing on circadian rhythm disruption, including possible pathophysiological pathways and treatment options.
Methods: Narrative review of articles published on Pubmed's database using the following keywords and their combinations: *bipolar disorder*, *circadian rhythms*, *seasonal* and *sleep disturbances*, screening for relevance.
Results: Several studies show us that manic episodes are associated with transition into spring and summer and depressive ones with transition into autumn and winter. Seasonal changes result in alterations in daylight exposure, which in turn, through the cardinal role of the suprachiasmatic nuclei in the hypothalamus, lead to disruptions in sleep-wake cycles, impacting melatonin and cortisol levels, which can contribute to mood instability. These hormones are also subjected to changes by other shifts in biological rhythms such as body temperature regulation, that come with seasonal transitions. On the other hand, light exposure also influences neurotransmission, particularly of serotonin and dopamine, with consequences on energy, mood and reward processing and arousal. There might also be a role for genetic polymorphisms like CLOCK, BMAL1 and PER, that influence sleep patterns and hormonal regulation, and therefore can predispose some people to mood disorders. Furthermore, there are important social factors related to seasonal changes, such as increases or decreases in social activities, that can impact mood. Therapeutic approaches that target circadian rhythm, such as light therapy and chronotherapy (including options like sleep deprivation and phase advance therapies), can be useful in decreasing relapse episodes. Additionally, simple psychoeducation on the matter, regarding maintenance of regular sleep schedules and social activities, might be helpful in preventing or, at the very least, decreasing relapses.
Conclusions: Seasonal changes play a relevant role in both manic and depressive relapses in BD through their role in circadian rhythm disruption, by way of a myriad of mechanisms. Future investigation should focus on these mechanisms and others that might possibly be involved, allowing us to reach more targeted treatment and even preventative measures to diminish relapse episodes in BD.

Treating Bipolar II Depression: a preliminary open-label investigation of a five-day, accelerated repetitive Transcranial Magnetic Stimulation (rTMS) protocol

C. Cavallotto[1], G. d'Andrea[1,2], A. D'Attilio[1], G. Mammarella[1], O. Di Marco[1], L. P. Padula[1], L. De Risio[3], F. Zoratto[4], G. Di Lorenzo[5], M. Pettorruso[1,2] and G. Martinotti[1,2,6]*

[1]Department of Neurosciences, Imaging and Clinical Sciences, Università degli Studi G. D'Annunzio; [2]Department of Mental Health, ASL 2 Abruzzo Lanciano-Vasto-Chieti, Chieti; [3]Department of Mental Health and Addiction, ASL Roma 5; [4]Centre for Behavioural Sciences and Mental Health, Istituto Superiore di Sanità; [5]Department of Systems Medicine, University of Rome Tor Vergata, Roma, Italy and [6]Psychopharmacology, Drug Misuse and Novel Psychoactive Substances Research Unit, School of Life and Medical Sciences, University of Hertfordshire, Hatfield, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1050

Introduction: Bipolar disorder is a complex psychiatric condition marked by severe mood swings, including prolonged depressive episodes that constitute approximately 50% of the illness duration. While there is substantial evidence supporting interventions for manic and hypomanic episodes, therapeutic options for bipolar depression remain insufficient and often ineffective. Accelerated repetitive transcranial magnetic stimulation (arTMS) has emerged as a promising treatment modality with the potential to address these gaps. arTMS offers rapid antidepressant effects comparable to traditional repetitive transcranial magnetic stimulation (rTMS) protocols while maintaining a favorable safety and tolerability profile.
Objectives: This prospective, open-label, multicenter study investigates the efficacy and safety of arTMS in treating bipolar II disorder during depressive phases.
Methods: The study enrolled 20 patients who underwent a five-day, four-times-daily arTMS protocol targeting the left dorsolateral prefrontal cortex (DLPFC). The primary outcome measure was the Montgomery–Åsberg Depression Rating Scale (MADRS), assessed at baseline, immediately post-treatment, and at one- and three-month follow-ups. Secondary outcomes included safety and tolerability, with a focus on the risk of manic or hypomanic switches as measured by the Young Mania Rating Scale (YMRS).
Results: Results indicated a significant reduction in MADRS scores from baseline to immediately post-treatment, with a mean difference of -9.80 (Cohen's d=1.065, p<0.001). Continued improvements were observed at one month (-15.60, d=1.695, p<0.001) and three months (-19.70, d=2.140, p<0.001), with response rates increasing from 15% immediately after treatment to 60% at three months, and remission rates rising from 5% to 55% over the same period. Importantly, arTMS did not result in any significant increase in YMRS scores, indicating no emergence of manic symptoms, and no hypomanic switches were reported.
Conclusions: The findings underscore the rapid onset and sustained effectiveness of arTMS for bipolar depression, with improvements observed immediately after treatment and continuing over the subsequent months. The progressive rise in response and remission rates suggests that therapeutic benefits may become more pronounced over time, highlighting the importance of considering delayed treatment responses. Moreover, the lack of adverse effects on mood polarity supports arTMS as a safer alternative compared to traditional pharmacological treatments, which are often associated with a risk of manic episodes. Future research should include larger, randomized, sham-controlled trials to validate these findings and further explore the neurobiological mechanisms underlying arTMS's rapid antidepressant effects.

On Being and Having: A Qualitative Study of Self-Perceptions in Bipolar Disorder

A. L. Chang[1]*, M. Ponticiello[1], R. J. Chang[1], S. Mirza[1] and A. Martin[1,2]

[1]Yale School of Medicine and [2]Yale Child Study Center, New Haven, CT, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1051

Introduction: Bipolar disorder (BD) is a chronic and often severe mental illness. Yet despite the well-documented complexities in its diagnosis and treatment, little research has been dedicated to understanding the complex inner landscape experienced by those living with BD. Even as qualitative research has explored the lived experience of BD across a variety of perspectives, i.e., what BD *looks like*, there is a lack of research exploring what BD *means* to those living with the condition.
Objectives: We aimed to understand how people with BD perceive their condition, construct the meaning of their illness, and view BD in relation to their sense of self.
Methods: We conducted individual, semi-structured interviews with 20 adults with clinically stable BD. We coded the transcripts according to the principles of thematic analysis and analyzed the data using an interpretative phenomenological analysis approach.
Results: We identified three overarching domains: (1) *Benefit or burden:* a dialectic through which participants weighed the valence of their illness over time; (2) *Self or other*: the internal or external locus through which they experienced BD; and (3) *From ineffability to meaning making:* the process of naming, understanding, and incorporating BD into their life's whole. Within each domain, themes and subthemes outline nuanced and often conflicting perspectives of participants' illness experiences.
Conclusions: Our work provides a framework of three domains central to the inner reality of lived bipolar experience. Thoughtful understanding of patients' experiences, perspectives, and desires within these three domains may aid clinicians and loved ones alike in more sensitively and effectively addressing the unique individual needs of those living with BD. By exploring patients' perspectives in each of the three domains we identified, those caring for people with BD may be better positioned to help identify the inner work and practical interventions needed to achieve a rich, meaningful life with BD.

EPV0206

Seasonality in bipolar disorder, analysis of an inpatient unit

M. I. Chaves[1]*, J. Garcês Marques[1], F. Varino[1], C. Siopa[1] and A. I. Duarte[1]

[1]Psychiatry, ULS Santa Maria, Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1052

Introduction: Bipolar disorder is a chronic mental health condition characterized by alternating periods of mania, depression, and mixed states. The timing and recurrence of these mood episodes may be influenced by external factors, including seasonal variations. Previous research has highlighted potential seasonal patterns in the onset of manic episodes, with environmental factors such as changes in light exposure, temperature, and circadian rhythms playing a role. Comprehending these temporal patterns is paramount, as they provide critical insights into the underlying mechanisms of mood dysregulation and can inform the development of more targeted and effective clinical interventions for individuals with bipolar disorder.
Objectives: The primary objective of this study is to determine whether manic and mixed episodes in bipolar disorder show a

seasonal pattern. Specifically, this study aims to investigate whether specific times of the year are associated with a heightened incidence of hospitalizations for manic or mixed episodes.
Methods: A retrospective analysis was conducted on patient records from an inpatient psychiatric unit over four years. Inclusion criteria were a primary diagnosis of bipolar disorder and admission due to a manic or mixed episode. Data were categorized by month and season of hospitalization, and statistical analyses were performed to assess for significant seasonal variations.
Results: Our study revealed a significant increase in hospitalizations for manic episodes during the spring and summer months, with 58% of manic episodes occurring during this period, and a secondary peak in autumn. Mixed episodes demonstrated less pronounced but still observable seasonal variation. Statistical analysis confirmed the presence of seasonality, with manic episodes more likely to occur during periods of increased daylight, while mixed episodes appeared more distributed across the year.
Conclusions: The findings indicate that manic episodes in bipolar disorder follow a distinct seasonal pattern, peaking in spring and summer. Although mixed episodes are less strongly correlated with seasonality, some seasonal trends were observed. These results highlight the significance of considering environmental and seasonal factors in the management of bipolar disorder. Further investigation into the underlying mechanisms of these patterns could improve preventative care and inform the development of personalized treatment strategies.

Manic episodes triggered by weight loss in a patient with bipolar disorder: the importance of integrated lifestyle interventions in psychiatric care

D. De Francesco[1]*, S. Cipolla[1], P. Catapano[1], D. Vozza[1], R. Monda[1], M. C. Della Corte[1], R. Murolo[1], V. De Santis[1], F. Perris[1] and F. Catapano[1]

[1]Department of Psychiatry, University of Campania "Luigi Vanvitelli", Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1053

Introduction: Worldwide, obesity has become a major public health issue, affecting over 650 million people, and individuals with severe mental disorders (SMD) are disproportionately affected by higher rates of obesity and metabolic syndrome (MetS). These patients often face significant barriers to improving their lifestyle, including the metabolic side effects of psychiatric medications, which are associated with weight gain, insulin resistance, and dyslipidemia. Moreover, psychiatric patients frequently encounter challenges when seeking care, often due to the stigma surrounding mental illness. This can lead to inadequate medical attention for physical health issues, further exacerbating the vicious cycle between physical and mental health. For these reasons, attention to the physical health of patients with SMD has been increasing in the recent years. However, the attempts to improve physical health can be a trigger by the exacerbation of psychiatric symptoms in more vulnerable patients.
Objectives: The report aims to highlight the reciprocal influence between psychiatric symptoms and physical health, emphasizing the importance of lifestyle interventions in patients with severe mental disorders.
Methods: In this case report, we present a 57-years-old patient with Bipolar I Disorder and class 3 obesity (BMI: 47.689) who experienced recurrent manic episodes triggered by past weight loss attempts, including one involving the use of liraglutide, a glucagon-like peptide-1 (GLP-1) receptor agonist.
Results: To prevent a new manic episode, the patient was admitted to our in-patient ward after he started to take orally liraglutide, a novel drug to treat obesity. As we expected, during hospitalization the patient experienced a manic episode and dysphoric mood, tachypsychia, and sleep disturbance emerged. After a treatment with a combination of valproic acid, risperidone, and gabapentin, the manic episode resolved at time of discharge, but despite the administration of liraglutide, no significant change in body weight was observed.
Conclusions: This case emphasizes the need for a tailored, integrated approach to lifestyle interventions in psychiatric care, in alignment with the "One Health" concept, which highlights the interconnection between physical and mental well-being. However, some patients may require the assistance of a mental health professional while attempting to change their lifestyle during their lifestyle improvement and weight loss attempts, as even modern pharmacological interventions for obesity can act as a psychopathological trigger.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1054

Introduction: Maniform symptoms for the first time after the age of 50 are not common, although we can find it in our clinical practice due to the increasing aging of the world's population.
Objectives: We present a clinical case of a patient with manifest behavioral symptoms where a differential diagnosis is made between Late-onset bipolar disorder vs Frontotemporal dementia with a behavioral profile (FTD)
Methods: 62-year-old male with a history of type II diabetes, hypertension and L4-L5 disc herniation. Psychiatric history of recurrent depressive disorder and dysfunctional personality. Treated with venlafaxine 150 mg and gabapentin 600 mg DMD. He was on sick leave from his company due to lower back pain. Married with two children, dysfunctional relationship with them. He was admitted to Psychiatry for the first time in February 2024 due to behavioral disturbances of 5 days' duration. He was verbose, irritable and described "being better than ever". A few days earlier he took a Tadalafil tablet, an event that he related to the onset of the condition. Since then, there has been an increase in psychomotor activity, disinhibition and exalted mood. He reported having contact with high-ranking political figures. Upon discharge from hospital, he was diagnosed with an Unspecified Manic Episode and was

prescribed Lithium 800mg DMD and Risperidone extended release 75 mg monthly. The symptoms did not improve, he abandoned the treatment and was admitted for the second time in April 2024 where Valproic 1000 mg DMD, Olanzapine 20mg DMD and Risperidone 6 DMD were prescribed.
Results: He has a poor outpatient evolution with loss of autonomy, physical deterioration, hyperfamiliarity, behavioral disinhibition and no awareness of the disease. Given the suspicion of an organic condition, he was referred to Neurology consultations where a cranial magnetic resonance imaging was performed. with results of punctate and hyperintense images in T2 localized in subcortical white matter of nonspecific character and Mini-ACEII test: 22/30. Waiting for PET-CT and with a diagnosis of possible Frontal Release Syndrome to rule out behavioral variant FTD.
Conclusions: Within the differential diagnosis of the condition we find Late-onset bipolar affective disorder and behavioral variant FTD. The first presents with inappropriate, repetitive and stereotyped behavior, as well as a progressive and gradual deterioration. While late bipolar disorder presents with self-limiting episodes and more manifest symptoms. In a PET-CT suggestive of FTD it is likely to find areas of hypoperfusion in frontal and temporal regions. The differential diagnosis between both is a challenge in clinical practice.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1055

Introduction: Lifestyle factors are being increasingly studied in bipolar disorder (BD) due to their possible effects on both course of disease and physical health.
Objectives: The aim of this study was to jointly describe and explore the interrelations between diet patterns, exercise, pharmacological treatment with course of disease and metabolic profile in BD.
Methods: The sample consisted of 66 euthymic or mild depressive individuals with BD. Clinical and metabolic outcomes were assessed, as well as pharmacological treatment or lifestyle habits (diet and exercise). Correlations were explored for different interrelations and a factor analysis of dietary patterns was performed.
Results: Adherence to the Mediterranean diet was low, seen in 37.9% of the patients and was positively associated with perceived quality of life. The amount of exercise was negatively associated with cholesterol levels, with 32.8% of participants rated as low active by International Physical Activity Questionnaire. There was a high prevalence of obesity (40.6%) and metabolic syndrome (29.7%). Users of lithium showed the best metabolic profile. Interestingly, three dietary patterns were identified: "vegetarian," "omnivore" and "Western." The key finding was the overall positive impact of the "vegetarian" pattern in BD, which was associated with reduced depression scores, better psychosocial functioning, and perceived quality of life, decreased body mass index, cholesterol, LDL and diastolic blood pressure. Nuts consumption was associated with a better metabolic profile.
Conclusions: A vegetarian diet pattern was associated with both, better clinical and metabolic parameters, in patients with BD. Future studies should prioritize prospective and randomized designs to determine causal relationships, and potentially inform clinical recommendations.

Cardiovascular disease risk in female patients with mood disorder symptoms

A. Hadj Ali[1]*, I. Chaari[1], N. Messedi[1], G. Chakchouk[1], F. Charfeddine[1], L. Aribi[1] and J. Aloulou[1]

[1]Psychiatric department "B", Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1056

Introduction: Patients with bipolar disorder (BD) and major depressive disorder (MDD) face an elevated risk of early mortality from various physical illnesses, particularly cardiovascular disease (CVD). However, it remains uncertain whether depressive or manic symptoms contribute more significantly to CVD outcomes.
Objectives: This study aimed to assess the association between manic and depressive symptoms and long-term CVD risk factors.
Methods: A retrospective study was conducted on patients hospitalized in the female unit of psychiatric department "B" in Sfax, Tunisia, between January and June 2023. Sociodemographic, clinical, and CVD risk factor data were collected from medical records to calculate Framingham Scores. The relationships between mood symptoms (depressive and manic) and Framingham scores, as well as individual CVD risk factors (lipids, blood pressure, BMI, smoking, and fasting glucose), were analyzed.
Results: The study included 50 female patients with a mean age of 45 years (SD = 9.9). Of the patients, 18% were diagnosed with MDD, while 82% were diagnosed with BD; 64% were admitted for manic symptoms, and 36% for depressive symptoms. Clinical obesity was observed in 64% of patients, with 60% diagnosed with hyperlipidemia, 34% with hypertension, and 26% with type 2 diabetes. Notably, 12% of patients had a Framingham score of ≥ 10%, indicating a moderate to high 10-year risk of CVD. Bivariate analysis revealed that patients with manic symptoms had a significantly higher CVD risk than those with depressive symptoms ($p=0.034$). Manic symptoms were also significantly associated with elevated BMI ($p=0.034$), fasting glucose ($p=0.039$), and blood pressure ($p<0.001$).
Conclusions: This study demonstrates a strong association between manic symptoms and long-term CVD risk in patients with mood disorders, particularly with elevated blood pressure, glucose levels, and BMI. These findings underscore the importance of specific monitoring and intervention programs for CVD risk factors in patients with mood disorders, especially those with BD.

Performance-based assessments and their correlations with self-reports and informant judgments of cognitive and social cognitive impairments in patients with Schizophrenia and Bipolar Disorder

J. Henry[1]*, C. A. Depp[2], P. D. Harvey[1], A. E. Pinkham[3] and R. C. Moore[2]

[1]University of Miami Miller School of Medicine, Miami; [2]UCSD Medical Center, San Diego and [3]UT Dallas, Dallas, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1057

Introduction: Cognitive impairment in serious mental illness (SMI) is a major determinant of disability across employment, independence, and social outcomes. However, performance-based assessments are commonly unavailable in clinical settings. The remaining choices are self-report vs. clinician impressions and it is not clear across SMI how much clinician vs self-reports are related to objective performance.
Objectives: In this study, we examine performance-based assessments and their correlations with self-reports and informant judgments of cognitive and social cognitive impairments.
Methods: Participants with bipolar disorder (BPl; n=114) and schizophrenia (SCZ; n=126) participated in a comprehensive study of cognition and functioning, including clinical (MADRS), performance-based assessments, self-reports, and observer ratings of cognitive and social cognitive functioning following a 30-day Ecological Momentary Assessment (EMA) assessment period daily assessments of Positive (PA) and Negative (NA) Affect were collected.
Results: In participants with schizophrenia, self-reports of cognitive functioning were uncorrelated with objective data (r=-.02) and with clinician ratings assessments(r-.00), but were correlated with clinician ratings of depression (r=.41) and EMA reports of momentary NA (r=.37). Interestingly, clinician ratings of cognitive performance were correlated with performance data (r= .41) and MADRS (r=.35) but not self-reported cognitive ability (r=-.08). In participants with bipolar disorder, self-reports of performance ability was correlated with performance-based data (r=.43) and clinicians' ratings of cognitive ability (r=.51). Both MADRS ratings and EMA-based momentary NA ratings were also correlated with self-reported cognitive performance (r>.44), but not objective cognitive performance (r=.14).
Conclusions: There are clear differences in the ability to self-report cognitive performance in schizophrenia and bipolar disorder. However, clinicians appear to be equivalently able to index cognitive impairment across BPI and SCZ. Participants with BPI appear to be much more able to identify their impairments than those with SCZ, but the correlation between clinician ratings and objective performance seems similar across conditions. These data suggest that reliance on self-reports of impairment may require adjustments based on diagnosis or other factors, but that clinician impressions of cognitive impairment converge with cognitive data.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1058

Introduction: Cariprazine is indicated for the treatment of Schizophrenia in adult patients. Its therapeutic action is dual: as a blocker of D2 dopamine receptors, as a partial agonist at D2 and D3 dopamine receptors, and as a partial antagonist at 5HT2B and 5HT2A receptors of serotonin, as well as a blocker of histamine H1 receptors.
Objectives: The objective of this paper is to highlight the treatment of Emotional Disorders.
Methods: 30 patients (n=30) of the Outpatient Psychiatric Clinics of the Department of Psychiatry were studied, of which 15 men and 15 women, who suffered from Bipolar Disorder Type I. All patients were given the YMRS (Young Mania Related Scale) questionnaire, before starting treatment and 30 days after starting treatment with Cariprazine 6 mg, in combination with sodium valproate 1000 mg daily.
Results: Of the 30 patients, 25 presented a clear decrease in the YMRS Scale (percentage 75%), of which 13 were women and 12 were men, respectively. In the present study no superiority in response to treatment was found for either men or women.
Conclusions: Cariprazine is a new therapy in the treatment of Bipolar Disorder Type I. It is of course necessary to complete the study with a larger pool of patients.

Exploring Functioning Impairment in Clinical Course of Illness in Early and Mid-Life Onset Bipolar Disorder in Mexican Patients

H. L. Juarez[1]*, A. B. Cuellar[1,2], S. Luna[1] and M. S. Gonzalez[1]

[1]Psychiatry, Universidad Autonoma de Nuevo Leon, Monterrey, Mexico and [2]Psychiatry, Mayo Clinic, Rochester, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1059

Introduction: Bipolar disorder (BD) is a chronic illness that can lead to severe functioning impairment, which can disrupt daily life. This study aims to compare overall functioning and clinical presentation associated with early onset (EO) and mid-life onset (MO) BD.
Objectives: The objective of this study is to be able to predict the cognitive and functional impairment evolution of bipolar disorder based on the onset.

Methods: A total of 154 BD patients (81 in euthymia and 51 in a depressive episode) participated in this cross-sectional study. We selected two groups of subjects based on age at onset of the first mood episode (EO: 0-20 years, n=117; MO: 20-40 years, n=37) and compared socio-demographic, clinical variables and functional impairment assessed by the World Health Organization Disability Assessment Schedule (WHODAS 2.0).
Results: 75.2% of the patients with an EO were female, they had higher psychiatric comorbidities prevalence (76.1% vs. 43.2%; p<.001), being personality disorders the most significant (30.2% vs. 5.4%; p=.001), more suicide attempts (51.3% vs. 16.2%; p<.001), mood episodes (mdn=12, iqr=17 vs. mdn=6, iqr=9.5; p=.001), childhood abuse (93.5% vs. 73.9%; p=.014), being verbal (78.0% vs. 52.2%; p=.015) and physical abuse (51.6% vs. 21.7%; p=.009) higher compared to MO. Functionality was also affected, with higher dysfunction percentages in EO (mdn=47, iqr=34.7 vs. mdn=24, iqr=12.5; p<.001) affecting cognition (mdn=8.5, iqr=6 vs. mdn=4, iqr=7; p<.001), self-care (mdn=2, iqr=5 vs. mdn=0, iqr=1; p<.001), daily activities (mdn=12, iqr=13 vs. mdn=4, iqr=10; p<.001) and community participation (mdn=13, iqr=8.7 vs. mdn=8, iqr=7; p<.001).
EO depressed patients (n=38; F: 30; M: 8), had more personality disorders (42.1% vs. 0%; p=.010), suicide attempts (60.5% vs. 0%; p<.001), mood episodes (mdn=12, iqr=12 vs. mdn=5.5, iqr=4.7; p=.001), lower overall functionality (mdn=57, iqr=41.5 vs. mdn=35, iqr=38.3; p=.009), cognition (mdn=10, iqr=6.5 vs. mdn=4, iqr=9; p=.023), self-care (mdn=4, iqr=6.2 vs. mdn=0, iqr=3; p=.008), oneself care (mdn=9, iqr =7 vs. mdn=5, iqr=8.5; p=.025), daily activities (mdn=15.5, iqr=14 vs. mdn=11, iqr=12.7; p=.037) and community participation (mdn= 15.5, iqr=8.2 vs. mdn=11.5, iqr=5.7; p=.030).
EO euthymic patients (n=59; F: 42; M: 17) had more psychiatric comorbidities (74.6% vs. 33.3%; p=.001), physical abuse history (51.2% vs. 0%; p= .002), and lower functionality (mdn=7, iqr=7 vs. mdn=2, iqr=7; p=.004), cognition (mdn=7.5, iqr=7 vs. mdn=4, iqr=7; p=.033), daily activities (mdn=9, iqr=11 vs. mdn=3, iqr=8.5; p=.005) and community participation (mdn=10, iqr=9 vs. mdn= 7, iqr=7; p=.031).
Conclusions: Results suggest that patients with an EO are more associated with severe psychosocial functioning impairment. Future studies are needed to clarify a more severe illness prediction between EO and MO.

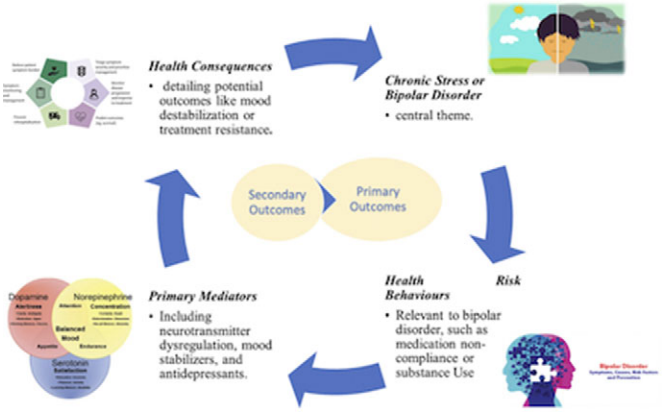
Exploring the Efficacy and Safety of Antidepressants in Bipolar Disorder: A Comprehensive Review

M. Juhlin[1]* and D. Adedeji[2,3]

[1]Solna Sundbyberg General Psychiatry department, Karolinska Institutet, Stockholm, Sweden; [2]General Psychiatry, Helgeland Hospital, Mosjøen, Norway and [3]Division of Clinical Geriatrics, Department of Neurobiology, Care Sciences, and Society, Karolinska Institutet, Stockholm, Sweden
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1060

Introduction: Bipolar disorder (BD) is a complex mental health condition characterized by alternating periods of depression and mania, affecting millions worldwide. Despite its prevalence, the use of antidepressants, widely prescribed for unipolar depression, remains debated in the context of bipolar depression due to concerns about mood destabilization, mania induction, rapid cycling, and long-term efficacy and safety. This ambiguity underscores the critical need for a comprehensive analysis to guide clinical practice. This review aims to evaluate the efficacy, safety, and long-term outcomes of antidepressant use in bipolar disorder.
Objectives: Assess the safety and efficacy of antidepressants in bipolar disorder. Optimize treatment options to help reduce the global burden of bipolar disorder and address a major gap in understanding regarding the role of antidepressants in treating bipolar disorder.
Methods: A systematic review of 35 studies, including 18 randomized controlled trials (RCTs), 14 cohort studies, and 3 meta-analyses published between 2010 and 2023, was conducted. Studies were selected based on predefined inclusion and exclusion criteria, focusing on antidepressant efficacy, safety, and long-term effects in BD patients. Data extraction and synthesis followed rigorous methodological protocols. The extracted data were then analyzed to identify trends, themes, and contradictions in the literature.
Results: The use of antidepressants in bipolar disorder should be highly individualized, balancing potential benefits against risks. Clinicians must exercise caution, particularly regarding the risk of mania induction. This review found that antidepressants, especially when combined with mood stabilizers, demonstrated moderate efficacy in treating bipolar depression. Outcomes varied significantly across studies; while some patients benefited from antidepressant use, others experienced increased risks, such as rapid cycling and mania induction. There is a lack of conclusive long-term safety data, highlighting the need for personalized treatment approaches to mitigate risks.

Image:



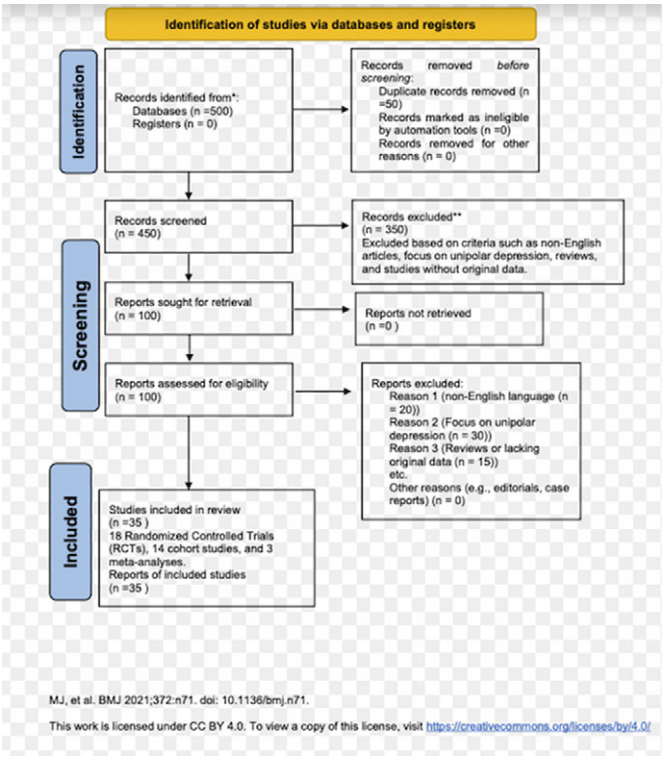


Image 2:

Conclusions: The role of antidepressants in bipolar disorder treatment remains contentious due to variability in outcomes and safety concerns. A personalized treatment approach, incorporating mood stabilizers, is recommended. This literature review concluded it is essential to balance the benefits and risks. Therefore, a combined treatment regimen with mood stabilizers is recommended. Further research, particularly longitudinal studies, is necessary to establish more definitive, evidence-based guidelines for treating bipolar depression with antidepressants.

Enhancing Accuracy in Distinguishing Bipolar and Unipolar Disorders: Using MDQ Subscales and BSDS

K. Kim[1,2*], H. Lim[1] and E. Moon[2,3]

[1]Department of Psychiatry and Biomedical Research Institute, Pusan National University Hospital, Busan; [2]Department of Psychiatry, Pusan National University School of Medicine, Yangsan and [3]Department of Psychiatry and Biomedical Research Institute, Pusan National University Hospital, Pusan, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1061

Introduction: Distinguishing between bipolar and unipolar disorder is essential for effective treatment, yet accurate diagnosis remains challenging despite extensive research. The MDQ (Mood Disorder Questionnaire) and BSDS (Bipolar Spectrum Diagnostic Scale) are widely used self-assessment tools, each offering unique advantages. However, these tools are typically used based on total scores, potentially overlooking valuable information within individual items.
Objectives: This study aims to employ clustering analysis on the MDQ and BSDS, utilizing subscales derived from factor analysis, to better differentiate patients with bipolar and unipolar disorders.
Methods: The study included patients diagnosed with bipolar and bipolar depression, with diagnoses confirmed by a psychiatrist according to DSM-IV-TR criteria. A total of 299 patients with bipolar depression and 142 with unipolar depression completed the MDQ and BSDS. Based on prior factor analysis, the MDQ was divided into two subscales: the positive activation subscale (items 3, 4, 8, 9) and the negative activation subscale (items 1, 2, 6, 7, 12, 13). K-means clustering was performed twice: once using the total scores from the MDQ and BSDS (two scores), and using the positive activation subscale, negative activation subscale from the MDQ, and the total score from the BSDS (three scores). The analysis was iterated 1000 times to avoid overfitting.
Results: The analysis identified an optimal solution with K=2. Cluster 1, characterized by high scores on both questionnaires, predominantly comprised bipolar patients. In contrast, Cluster 2, with lower scores, was primarily composed of unipolar patients. Using the total scores from both the MDQ and BSDS for clustering yielded an accuracy of 67.88%. In the second analysis using the MDQ subscales and the BSDS total score, the accuracy improved to 77.55%.
Conclusions: Clustering based on the MDQ and BSDS achieved a 77.55% accuracy in distinguishing bipolarity when using MDQ subscales alongside the BSDS score, demonstrating a promising level of precision with self-report questionnaires. Importantly, segmenting the MDQ into positive and negative activation subscales resulted in a nearly 10% increase in accuracy compared to using total scores alone. This suggests that increasing the dimensionality of the data by incorporating disorder-specific subscales can improve clustering accuracy. These findings highlight the potential of using high-dimensional psychiatric data to develop more effective classification models.

Linguistic features of Bipolar Disorder and Approaches: Scoping Review

S. Lee[1*], S. Choi[1] and Y. Lee[2]

[1]Psychology, Duksung Women's University, Seoul and [2]Psychotherapy, Dankook University, Cheonan-si, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1062

Introduction: A linguistic feature is a common characteristic associated with various mental disorders. In particular, bipolar disorder is one of the disorders in which verbal abnormalities as symptoms can be prominent. As technology advances and big data processing becomes easier, studies on the linguistic characteristics of bipolar disorder are increasing. However, the results of previous generations, who studied the linguistic features of bipolar disorder without computer-based methods are not considered, and have not been integrated with current research findings. It is necessary to review what methodologies can be used and what limitations should be considered to explore the linguistic characteristics of bipolar disorder.

Objectives: This scoping review aims to explore how we can analyze linguistic features of bipolar disorder by using textual language. It reviewes the approaches and results of the studies can explain bipolar disorder appropriately.
Methods: The study protocol follows the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines. Research papers for this review were collected by 3 electronic databases: Google Scholar, PubMed, Web of Science Using inclusion and exclusion criteria, all investigators screened the abstracts and full texts of the articles and extracted the data independently.
Results: We identified 315 potential studies from 3 databases. After screening the abstracts and full texts of articles, 17 (5.3%) articles met our inclusion criteria. We extracted elements such as results, and methodology from the above articles. The purpose of investigating linguistic features is mostly to predict and classify bipolar disorder, and to characterize the linguistic feautres of patients with bipolar disorder and other disorders. The most commonly used methodology is computer-based language analysis, such as natural language processing and learning models. Non-computer based articles, some of them adopted qualitative analysis. We confirmed the following results regarding the linguistic characteristics of bipolar disorder: a reduction in lexical variety, a higher rate of coordinate phrases, words related to power and achievement, and themes of humor and anger. In the narrative description of this, we include discussions on ethical issues.
Conclusions: This scoping study synthesizes a study analyzing the linguistic characteristics of patients with bipolar disorder for the purpose of classification and discrimination. Past and present study uses various collection targets such as letters and web-based data, and adopts various methodologies including computer-based methods and qualitative analysis. In this study, we review the points to consider in order to interpret and apply the results of these studies from a clinical point of view. Additionally, the focus is presented to researchers who analyze the linguistic characteristics of bipolar disorder.

Energy drinks and psychotic symptoms. A case report

D. Mancho Gragera[1]*, C. A. Díez de los Ríos[2], M. S.[2] and S. O. Molina[2]

[1]Psiquiatría y Salud Mental, Hospital Universitario Ramón y Cajal and [2]Psiquiatría y Salud Mental, Hospital Universitario Infanta Leonor, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1063

Introduction: This is a 26-year-old male patient, diagnosed with bipolar disorder, admitted to a medium-stay unit for two months due to lack of awareness of the disease, after several admissions to the acute unit for manic decompensation with psychotic symptoms after abandoning psychopharmacological treatment and cannabis use.
The patient, who was stable since the beginning of the medium-stay admission after being referred directly from an acute unit, began to show strange behavior that became more pronounced over the days.
Objectives: To study the relationship between energy drinks and the development of psychotic symptoms in the existing literature, based on a clinical case.
Methods: Description of the clinical case. Bibliographic review related to the topic.
Results: The difficulty in this case was to find out the cause of the psychotic symptoms that the patient was presenting, since he was taking the psychopharmacological treatment well and the urine tests that were carried out every time he returned from the street were negative. He had not had any stressful events either. On one of the outings that he made, an assistant saw that he was drinking a can of Monster. When asked, the patient commented that he usually drank between one and two cans a day. Olanzapine 10 mg (0-0-1) and clonazepam 2 mg (1-0-1) were added to the patient that he was taking. In addition, his outing permits will be withdrawn until clinical stabilization is achieved.
Conclusions: In the acute appearance of psychotic symptoms in patients with a previous history, possible causes must always be investigated, the most frequent being the following: abandonment of psychopharmacological treatment, consumption of toxic substances and stressful events. Although it is true that there are not many studies that support this, cases have been reported in which energy drinks, due to their high caffeine content, could also be one of the triggers.

Biological Markers of Cognitive Dysfunction In Bipolar Disorder Type 1: A Systematic Review And Meta-Analysis

A. Melillo[1]*, C. Recano[1], M. Allegretta[1], A. Ambroselli[1], E. Caporusso[1], L. Giuliani[1], A. Perrottelli[1], P. Pezzella[1], G. M. Giordano[1], P. Bucci[1], A. Mucci[1] and S. Galderisi[1]

[1]Deparment of Physical and Mental Health and Preventive Medicine, University of Campania "L. Vanvitelli", Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1064

Introduction: Bipolar disorder (BD) has a lifetime prevalence of approximately 2% and is one of the 17 most disabling diseases worldwide. Multiple factors, beyond the impact of acute mood episodes, contribute to the burden of the disease. BD is also characterized by cognitive impairment (CI), which affects between 30% and 57% of patients during euthymic phases [1]. The most impacted cognitive domains are memory, attention, processing speed, and executive function [1]. CI plays a critical role in the diminished psychosocial functioning observed in BD patients [2, 3]. However, cognitive profiles in BD are heterogeneous, and the underlying causes of CI are likely multifactorial, involving more than just the effects of acute mood episodes.
In recent years, growing evidence on the biomarkers associated with BD has expanded our understanding of various molecular pathways—such as inflammatory, oxidative stress, and dysmetabolic pathways—which have been linked to CI. These pathways not only affect cognitive function but also contribute to an increased risk of metabolic and inflammatory comorbidities, further exacerbating CI and the overall burden of the illness [4, 5]. As a result, further research into biomarkers of CI is essential, as it may enhance our knowledge of the molecular mechanisms involved and help identify potential pharmaceutical targets.
Despite recent systematic reviews on the topic, most have focused on individual pathways [2, 6], and there is a need for a more

comprehensive review of the current evidence regarding biomarkers linked to CI in BD.
Objectives: The goal of the present review is to examine the relationship between peripheral biomarkers (e.g., blood, saliva, urine) and impairments across specific cognitive domains in individuals with BD in euthymic state.
Methods: Inclusion/exclusion criteria: we included studies that assessed patients in euthymic states at the time of both cognitive evaluation and biomarker collection, and we excluded studies employing more invasive techniques (e.g., spinal puncture). Study quality will be assessed using the Joanna Briggs Institute Critical Appraisal tools.
Results: A database search (PubMed, Scopus, PsychInfo) identified 6,767 records after duplicate removal. Following title, abstract, and full-text screening, as well as manual reference list checks, a total of 52 studies were included. Data extraction is currently ongoing and includes publication year, country of origin, study design, sample size, sociodemographic and clinical characteristics, cognitive assessment tools, biomarkers investigated, and study outcomes.
Conclusions: Conclusions will be drawn at the end of the systematic review process. Further research into biomarkers of CI in BD is essential, as it may enhance our knowledge of the molecular mechanisms involved and help identify potential pharmaceutical targets.

EPV0226

From "unhappy" to "happy" with vortioxetine: how effective psychoeducation, illness awareness, and safe medications can provide patients with a degree of autonomy in managing their condition. A case report

M. Menendez Munoz[1]*, H.-B. J. MIN KIM[2] and E. LOPEZ BARDON[1]

[1]SERVICIO DE PSIQUIATRIA, COMPLEJO ASISTENCIAL UNIVERSITARIO DE LEON, LEON and [2]SERVICIO DE PSIQUIATRÍA, COMPLEJO ASISTENCIAL UNIVERSITARIO DE LEÓN, LEÓN, SPAIN
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1065

Introduction: We present the case of a 61-year-old retired woman with hypothyroidism and rheumatoid arthritis who was diagnosed with bipolar disorder in 2006 after a manic episode. Her initial treatment included venlafaxine, valproic acid, quetiapine, zolpidem, and lormetazepam. She had several manic episodes over the years, some requiring hospitalization. In 2017, venlafaxine was replaced with vortioxetine, which she now introduces when detecting depressive phases, under psychiatric supervision but with some autonomy. She has remained stable, with occasional manic or hypomanic episodes triggered by stress, but none requiring hospitalization.
Figures 1 and 2 illustrate the patient's self-perception changes with vortioxetine treatment. Figure 1 shows her as unhappy during the depressive phase (top) and happy after recovery (bottom). Figure 2 depicts her self-image during the depressive phase (left) and after recovery (right).
Objectives:
- To assess the effectiveness, safety and risk of mood swings of vortioxetine in a patient with bipolar disorder during depressive phases.
- To determine if effective psychoeducation allows patients to manage some of their medications safely under specialist supervision.

Methods: The patient mantains treatment with vortioxetine 20 mg daily, valproic acid 500 mg every 12 hours, quetiapine extended release 400 mg at dinner, zolpidem 15 mg, and lormetazepam 2 mg at bedtime during depressive phases. In manic episodes, quetiapine 300 mg is added, vortioxetine is discontinued, and the dosage of hypnotics is doubled. Intensive psychological support has improved her disease awareness and treatment adherence, allowing her to adjust vortioxetine (but not other medications) as needed under medical supervision. She has not reported any adverse effects from vortioxetine.
Results: Vortioxetine 20 mg could effectively treat depressive phases without causing mania. Though research on its use in bipolar disorder is limited, it shows potential when combined with a mood stabilizer, with a response time of about nine weeks and a low risk of hypomania/mania. It may also help with cognitive decline and brain inflammation related to bipolar disorder, improving cognitive performance and reducing inflammatory markers. Vortioxetine is noted for its effectiveness, tolerability, and low dropout rate.

Image 1:

Image 2:

Conclusions: Vortioxetine 20 mg may be effective for treating depressive phases in bipolar disorder with a lower risk of manic episodes compared to other antidepressants. Its procognitive and potentially anti-inflammatory effects could also support stability in non-psychiatric comorbidities. For this patient, good psychoeducation has facilitated a degree of independence in managing the medication, which is aided by vortioxetine's safety and ease of use for both professionals and patients.

In the context of a case: Aripiprazole to resume habits

A. B. Mulero García[1]*, E. S. Martinez[1], C. Lopez Morillo[1] and G. Perez Guerrero[1]

[1]Hospital Regional Universitario de Málaga, Málaga, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1066

Introduction: A 43-year-old male with a diagnosis of Bipolar Disorder associated with substance use is admitted to the mental health unit due to a psychotic decompensation. The patient has had an unfavorable progression requiring multiple admissions to mental health services. He suffers from dyslipidemia, hypertension, and poorly controlled diabetes. He has had some occasional work but is currently unemployed. He does not engage in leisure or sports activities, which he attributes to being highly sedated by the medication. He is currently being treated with clozapine, valproic acid, quetiapine, and various benzodiazepines.
Objectives: Achieve stabilization of the psychopathological condition without producing additional side effects such as sedation.
Methods: During the hospital stay, Quetiapina is slowly reduced over one week, and Aripiprazole is introduced at a moderate oral dose (Aripiprazole 10 mg). It is then gradually increased to 30 mg/day. After 3 weeks, it is switched to Aripiprazole 400 mg /28 days intramuscularly. At the start of Aripiprazole introduction, there is a good response and a tolerance.
With the combination of Clozapine and Aripirazole 400 mg/28 days intramuscularly, there is a noticeable reduction in psychotic symptoms, allowing for the discontinuation of both Quetiapine and benzodiazepines from the patient's treatment.
Results: At present, reviewing the outpatient follow-ups the patient has had after hospital discharge, he continues with Aripiprazole 400 mg /28 days intramuscularly, showing overall improvement in functioning. Due to the reduction in sedation, the patient has begun participating in sports and educational activities, which provide him significant personal satisfaction.
Conclusions: Introducing Aripiprazole in combination with Clozapine significantly reduces psychotic symptoms by controlling positive symptoms, which means the patient does not need to rely on benzodiazepines, allowing for their discontinuation. The reduced level of sedation has enabled the patient to engage in sports and other activities that he previously felt hindered from due to medication. It is indeed very important for any patient to resume leisure and sports activities, but in this specific case, the patient had grade III obesity with associated dyslipidemia.

Cannabis Withdrawal Induced Mania. A two year observational study of Hospital admissions from 2015 to 2019

I. Ochandiano Recio[1]*, I. Pacchiarotti[1], A. Gimenez Palomo[1], H. Andreu Gracia[1], S. Salmerón Morales[1], J. I. Mena[1], E. Cesari[1], T. Fernandez-Plaza[1], L. Olivier[1] and O. De Juan Viladegut[1]

[1]Instituto de Neurociencias, Servicio de Psiquiatría y Salud Mental, Hospital Clinic de Barcelona, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1067

Introduction: Bipolar disorder (BD) is a recurrent psychiatric illness characterized by manic, hypo-manic, depressive and mixed episodes. The endocannabinoid system (ECS) is a vast network of chemical signals and cellular receptors that are densely packed throughout the brain. It is involved in most critical central nervous

system functions, such as learning and memory, but also mood regulation. Despite this, there is only anecdotal evidence on the potencial role of the ECS in the pathophysiology of BD.
Objectives: This study aims to retrospectively assess clinical and sociodemographic variables of patients whose manic episode is temporally associated with the suspension of cannabis use, compared with the rest of a sample of manic patients admitted to an acude psychiatry ward. The objective of the study is to investigate the presence of a specific group of BD patients, with potential clinical and therapeutic implications.
Methods: We retrospectively analysed all admitted patients to the acute psychiatry unit at Hospital Clinic of Barcelona from 2015 to 2019 and hospitalized for a manic episode. Patients with core manic symptoms started after cannabis withdrawal were included in the study. Cannabis Withdrawal Induced Mania (CWIM) group (n=20) was compared with the rest of bipolar manic patients in our sample according to several clinical and sociodemographic variables. Univariate and multivariate logistic regression models were performed.
Results: between 2015 and 2019, 315 patients were admitted to the acute psychiatry unit with diagnosis of manic episode. In 282 of the cases, the history of cannabis use was documented. 20 of them meet criteria for CWIM. CWIM group patients were significantly more frequently men (p=0.015) and younger (p<0.001), were not married or in a relationship (p = 0.018) and less frequently had somatic illnesses (p=0.41). Patients with CWIM debuted with a first manic episode and had their first psychiatry admission at a significantly younger age (p=0.008 and p=0.004, respectively). Previous treatment with antipsychotic medication was significantly less frequent in the CWIM group (p=0.022). According to follow-up, there were no significant differences in relapse after three years (p=0.936).
Conclusions: This study found a new clinical profile of patients, who are more suggestive to have a manic episode in context of cannabis withdrawal.

Emotion dysregulation in bipolar disorder according to predominant polarity

V. Oliva[1,2], M. De Prisco[1,2]*, M. Bort[1,2], C. Sommerhoff[1,2], T. Fernández-Plaza[1,2], L. Montejo[1,2], V. Ruiz[1,2], M. Y. Rivas[1,2], E. Vieta[1,2], A. Murru[1,2] and G. Fico[1,2]

[1]Department of Medicine, Faculty of Medicine and Health Sciences, University of Barcelona (UB) and [2]Bipolar and Depressive Disorders Unit, Institute of Neuroscience, Hospital Clinic, IDIBAPS, CIBERSAM, University of Barcelona (UB), Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1068

Introduction: Emotion dysregulation (ED) is a core feature of bipolar disorder (BD), impacting patients' ability to manage intense emotional responses and maintain mood stability. Predominant polarity (PP) is a clinical specifier in BD with important implications for prognosis, treatment planning, and outcomes. PP categorizes patients based on the mood episode type they experience most frequently: depressive PP (DPP), manic PP (MPP), or undetermined PP (UPP) when no episode type prevails. Given that PP reflects the types of symptoms most commonly experienced by patients, and that ED is closely linked to mood symptoms in BD, it remains unclear whether ED differs across PP subgroups.
Objectives: We aimed to compare overall levels of ED and specific emotion regulation (ER) domains across patients with BD and DPP, MPP, and UPP.
Methods: We analyzed data from patients with BD enrolled in the Bipolar Exposome-Gene Interaction Naturalistic (BEGIN) study. ED and ER strategy alterations were assessed using the Difficulties in Emotion Regulation Scale (DERS-28) and its subscales: Lack of Control, Non-Acceptance, Interference, Inattention, and Confusion. PP was defined based on the Barcelona proposal. Due to non-normal DERS score distributions (Shapiro-Wilk $p < 0.05$), the Kruskal-Wallis test was applied to compare DERS total and subscale scores across PP groups, followed by Dunn's test with Bonferroni correction for pairwise comparisons.
Results: The sample included 64 patients with BD (mean age=51 ±12.5; 46.9% female). Of these, 17 had DPP, 7 had MPP, and 40 had UPP. Significant differences across PP groups were observed in overall ED (p=0.04), with the UPP group showing higher total DERS scores than the MPP group (Z=2.55, p=0.03). In the Lack of Control subscale, both the DPP and UPP groups scored higher than the MPP group (Z=2.43, p=0.04 and Z=3.14, p=0.01, respectively). No other significant differences were found.
Conclusions: These findings indicate that ED varies across PP groups, emphasizing the potential advantages of tailored interventions within a precision psychiatry framework. Personalized approaches to managing ED may improve long-term outcomes and decrease the risk of recurrence across mood states in BD.

Profiles of affective temperaments can support differentiation of bipolar I disorder, bipolar II disorder, and major depressive disorder

M. Cho[1] and C. H. K. Park[2]*

[1]Psychology, Seoul National University and [2]Psychiatry, Asan Medical Center, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1069

Introduction: Differentiating bipolar I, bipolar II, and major depressive disorders is essential; therefore, the relationship between affective temperaments and mood disorder diagnoses has garnered considerable attention.
Objectives: The current study aimed to explore the representative types of Temperament Evaluation of Memphis, Pisa, Paris, and San Diego-Autoquestionnaire (TEMPS-A) profiles observed in the actual clinical setting using a data-driven approach and verify the relationship between TEMPS-A profiles and the proportions of three mood disorders (bipolar I, bipolar II, and major depressive disorders). Through this research, we intend to enhance the utility and applicability of affective temperament assessment based on the TEMPS-A when differentiating among mood disorders in clinical practice.

Methods: Psychiatric outpatients diagnosed with bipolar I, bipolar II, or major depressive disorder and aged ≥18 years were analyzed. Latent profile analysis was conducted using TEMPS-A scores, and each patient was classified into a subgroup according to their TEMPS-A scores. After that, multinomial logistic regression was conducted to verify the relationship between TEMPS-A profiles and mood disorder diagnoses.
Results: The findings indicate that seven types of TEMPS-A profiles are the most appropriate (Table 1). The depressive profile did not significantly increase the likelihood of being diagnosed with both bipolar II disorder and bipolar I disorder. The cyclothymic profile and anxious, cyclothymic and depressive profiles significantly increased the likelihood of the diagnosis of bipolar II disorder but did not significantly increase the likelihood of the diagnosis of bipolar I disorder. Furthermore, the cyclothymic and hyperthymic profile; cyclothymic, depressive and irritable profile; and anxious, cyclothymic, hyperthymic and irritable profiles significantly augmented the likelihood of being diagnosed with both bipolar II disorder and bipolar I disorder (Tables 2 and 3).

Notes. *B* = unstandardized coefficient; *SE* = standard error; OR = odd ratio; CI = confidence interval; Profile 2: *Depressive;* Profile 3: *Cyclothymic;* Profile 4: *Anxious, cyclothymic and depressive;* Profile 5: *Cyclothymic and hyperthymic;* Profile 6: *Cyclothymic, depressive and irritable;* Profile 7: *Anxious, cyclothymic, hyperthymic and irritable*
Latent profiles are dummy-coded, and profile 1 (*flat profile*) was set as the reference category.
[b] Significant findings of $p < .050$ are in **bold**.
[c] Female = 0, male = 1.

Conclusions: Our findings show that certain affective temperaments are closely correlated with one another, and cyclothymic temperament can act as a crucial risk factor for bipolarity. Moreover, our findings suggest the possibility that hyperthymic or irritable temperaments can help differentiate between bipolar I disorder and bipolar II disorder. Further studies using reliable clinical interview schedules are needed, and studies focusing on patients with other mood disorders would be helpful.

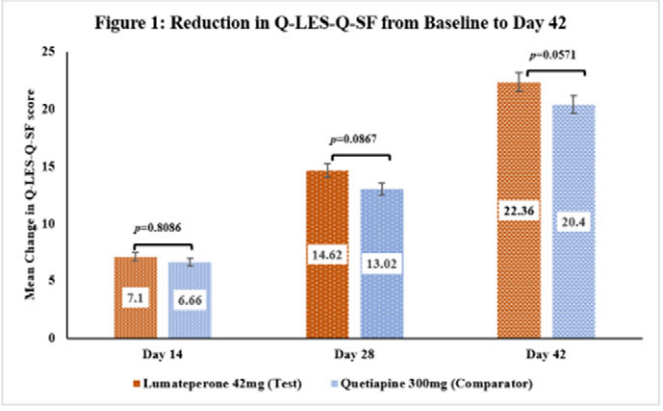
Introduction: Lumateperone, an atypical antipsychotic drug approved for Bipolar II depression in 2021, has a dual mechanism of action by combination of activity at central serotonin (5-HT2A) and dopamine (D2) receptors.
Objectives: This post-hoc analysis of an Indian Phase 3 study was conducted to evaluate the impact of Lumateperone 42mg compared to Quetiapine 300mg on quality of life of patients with Bipolar II depression assessed via Quality-of-life enjoyment and satisfaction-short form questionnaire (Q-LES-Q-SF).
Methods: The phase-III, randomized, multi-centric, assessor-blind, parallel-group, active-controlled, comparative, non-inferiority study included patients with Bipolar II depression with moderate severity having a Montgomery-Asberg depression rating scale (MADRS) score ≥20 and Clinical global impression–bipolar version–severity (CGI-BP-S) score ≥4. The study was conducted after receiving regulatory and ethics committee approvals. The patients were randomized (1:1) to either receive Lumateperone 42mg [Test] or Quetiapine 300mg [Comparator] for 6 weeks. This post-hoc analysis evaluated Q-LES-Q-SF total score and individual item scores [Physical health(1), Mood(2), Work(3), Household activities(4), Social relationships(5), Family relationships(6), Leisure time activities(7), Ability to function in daily life(8), Sexual drive, interest and/or performance(9), Economic status(10), Living/housing situation(11), Ability to get around physically(12), Ability to do work(13), Overall sense of wellbeing(14), and Overall life satisfaction and contentment(16)] for efficacy outcomes and for safety outcomes treatment emergent adverse events (TEAEs) were assessed. [Clinical trial registration: CTRI/2023/10/058583]
Results: This post-hoc analysis included 462 patients [231 each in Test and Comparator]. The baseline demographic characteristics were comparable in between treatment arms. The improvement in Q-LES-Q-SF (total score and individual item scores) is significant from baseline to Day 42 in both treatment arms and comparable [Figure 1 and Figure 2 respectively]. Statistically significant improvement in Test over Comparator was observed for Item 7 (Leisure time activities) and Item 14 (Overall sense of wellbeing) [Figure 2]. The incidence of TEAEs were similar in both treatment arms [Test: 34.6%; Comparator: 35.5%] and no serious adverse events were reported.

Image 1:



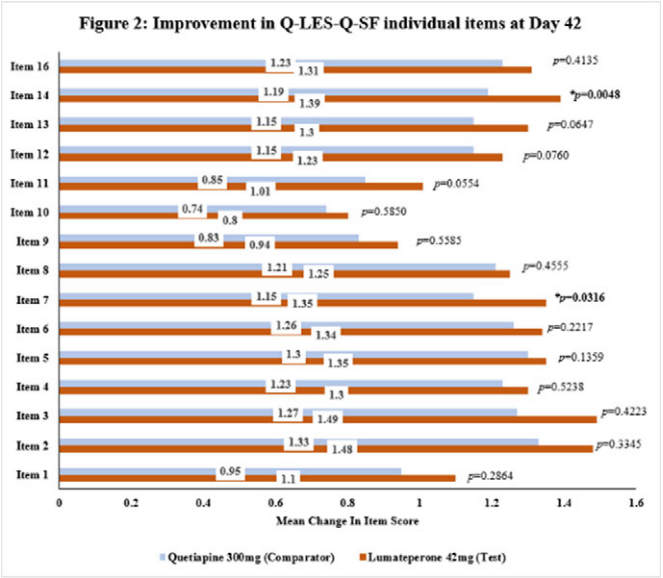


Image 2:

Conclusions: This post-hoc analysis demonstrated that Lumateperone 42mg is comparable to Quetiapine 300mg in treatment of Bipolar II depression as assessed via Q-LES-Q-SF score from baseline to Day 42, and both treatments were found to be well tolerated.

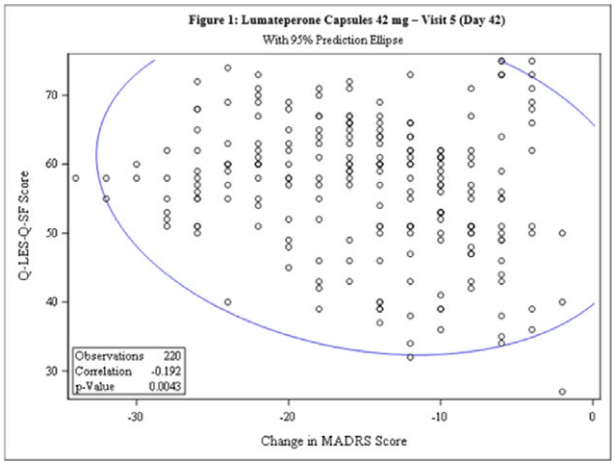
Introduction: Lumateperone, an atypical antipsychotic drug approved in 2021 for bipolar depression, has a dual mechanism of action by combination of activity at central serotonin (5-HT2A) and dopamine (D2) receptors. In India, Quetiapine is one of the approved drugs for use in depressive episodes for bipolar disorder.
Objectives: This post-hoc analysis of an Indian Phase 3 study was conducted to evaluate the correlation of severity of depression assessed via Montgomery-Asberg depression rating scale (MADRS) and quality of life assessed via Quality-of-life enjoyment and satisfaction-short form questionnaire (Q-LES-Q-SF) when treated with Lumateperone 42mg or Quetiapine 300mg.
Methods: The phase-III, randomized, multi-centric, assessor-blind, parallel-group, active-controlled, comparative, non-inferiority study included patients with Bipolar II depression with moderate severity having a MADRS score ≥20 and Clinical global impression–bipolar version–severity (CGI-BP-S) score ≥4. The study was conducted after receiving regulatory and ethics committee approvals. The patients were randomized (1:1) to either receive Lumateperone 42mg [Test] or Quetiapine 300mg [Comparator] for 6 weeks. In this post-hoc analysis, correlation between MADRS and Q-LES-Q-SF were evaluated and for safety outcomes treatment emergent adverse events (TEAEs) were assessed. [Clinical trial registration: CTRI/2023/10/058583]
Results: This post-hoc analysis included 462 patients [231 each in Test and Comparator]. The baseline demographic characteristics were comparable in between treatment arms. The Pearson's correlation coefficient between change from baseline in MADRS score and Q-LES-Q-SF score was statistically significant for both treatment arms at Day 42 [Test: -0.192, p=0.0043; Comparator: -0.299, p<0.0001] and the linear regression between 2 arms was not statistically significant (p=0.0853), indicating weak negative correlation between the 2 scales [Figure 1 and Figure 2]. The incidence of TEAEs were similar in both treatment arms [Test: 34.6%; Comparator: 35.5%] and no serious adverse events were reported.

Image 1:



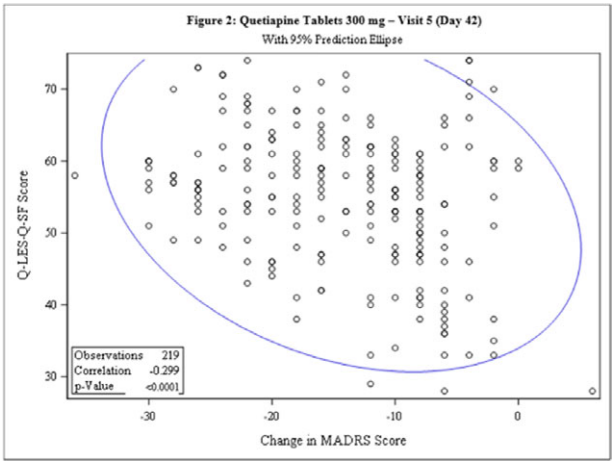


Image 2:

Conclusions: This post-hoc analysis demonstrated that patient with Bipolar II depression when treated with Lumateperone 42mg or Quetiapine 300mg, the reduction in MADRS score is inversely proportional to Q-LES-Q-SF score.

Neuropsychiatric Symptoms in Multiple Sclerosis: A Case Report

A. Picallo Vieito[1]*, S. Buyo Lagares[1], M. Pardal Iglesias[1], M. Grueiro Cao[1], A. Lagoa Pego[1], C. Ramil López[1], C. Fernández Ovies[1], A. Parada Barcia[1], P. Piñeiro Magro[1], L. González Pereira[1], J. Ricoy Chaín[1] and R. Prieto Perez[1]

[1]Psychiatry, Hospital Universitario A Coruña, A Coruña, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1073

Introduction: The relationship between bipolar disorder (BD) and multiple sclerosis (MS) has gained increasing attention due to the complex interplay between neurological and psychiatric symptoms in affected individuals. BD can significantly impair quality of life, and its prevalence in MS patients remains a critical area of investigation.
We present the case of a a 42 year-old woman. She was admitted to the Psychiatric Hospitalization Unit due to a manic episode with psychotic symptoms. Her psychiatric history includes a visit to the Mental Health Unit one year prior for anxiety-depressive symptoms. Notably, she has a diagnosis of Multiple Sclerosis from 2022.
Objectives: Based on the described clinical case, we aim to review the available literature on the relationship between bipolar disorder and multiple sclerosis.
Methods: A systematic review of the literature was conducted using databases such as PubMed, Scopus, and PsycINFO. Studies published up to 2023 that reported on the prevalence and clinical characteristics of BD in MS patients were included. Data were extracted and synthesized to provide a comprehensive overview.
Results: The review identified 20 relevant studies, with pooled data indicating a prevalence of BD in MS patients ranging from 5% to 20%. Key factors influencing prevalence included demographic variables, such as age and sex, as well as the presence of other psychiatric comorbidities. The literature suggests that inflammatory processes and neurobiological changes in MS may contribute to the development of mood disorders, including BD.
Conclusions: There is significant evidence linking bipolar disorder with multiple sclerosis, highlighting the importance of comprehensive mental health assessments in MS patients. Future research should focus on understanding the pathophysiological mechanisms behind this association and developing tailored interventions to improve overall patient outcomes.

Melanopsin-Mediated Pupillary Responses in Bipolar Disorder: A Non-Systematic Review

M. O. Pires[1]*, H. J. Gomes[2], R. M. Freitas[3], C. Freitas[3] and M. Albuquerque[3]

[1]Department of Psychiatry and Mental Health, Guarda Local Health Unit, Guarda; [2]Department of Psychiatry and Mental Health, Nordeste Local Health Unit, Bragança and [3]Integrated Responsability Center - Mental Health, Hospital Pedro Hispano, Matosinhos, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1074

Introduction: Melanopsin-expressing intrinsically photosensitive retinal ganglion cells (ipRGCs) are critical regulators of circadian rhythms and various non-image-forming visual functions, such as the pupillary light reflex (PLR), which adjusts the amount of light entering the eye. ipRGCs, through their direct responsiveness to circadian light, influence both circadian entrainment and neurophysiological processes that affect mood regulation. Emerging evidence suggests that melanopsin-mediated PLR may be disrupted in mood disorders, including bipolar disorder (BD) and even patients with increased bipolar disorder-traits. Given the well-documented association between circadian dysregulation and BD pathophysiology, it is hypothesized that changes in ipRGC function may contribute to the neurobiological mechanisms underlying BD.
Objectives: The primary aim of this review is to synthesize and evaluate the existing body of literature on melanopsin-mediated pupillary responses in individuals with bipolar disorder. Specifically, this review seeks to assess the extent to which these responses are altered in BD and to explore the potential utility of melanopsin-driven PLR as a biomarker for mood dysregulation and circadian disruption in this patient population.
Methods: A non-systematic review of the literature on the melanopsin-mediated pupillary light reflex in patients with bipolar disorder, through a targeted search of databases.
Results: The reviewed studies demonstrate consistent alterations in melanopsin-mediated pupillary responses in individuals with BD. Several investigations report reduced PLR amplitude and delayed latency in BD patients, with variability depending on mood state. Manic and depressive episodes appear to be associated with distinct patterns of dysregulation, suggesting that melanopsin signaling may be differentially affected by the phase of illness. One study also shows a variation in ipRGCs responses in remitted BD patients, suggesting an alteration of this system throughout the disease. (Madsen *et al.* Int J Bipolar Disord 2021;9,7) These findings align with circadian disruptions commonly observed in BD, further supporting a mechanistic link between ipRGC dysfunction and mood regulation.
Conclusions: Melanopsin-mediated pupillary responses have emerged as a promising avenue of investigation for identifying biomarkers of bipolar disorder, particularly concerning circadian rhythm and mood dysregulation. Despite encouraging preliminary findings, the current literature is limited by methodological heterogeneity and small sample sizes. Future research should standardize assessment protocols and investigate how ipRGC dysfunction contributes to BD pathophysiology, potentially leading to novel treatments targeting circadian regulation and improving clinical outcomes.

Quetiapine-Induced Mania and Hypomania: A Case Study and Literature Review

S. Prasad[1], S. Das[2] and S. Gunturu[1]*

[1]Psychiatry, BronxCare Health System, New York, United States and [2]Psychiatry, Western Health, Melbourne, Australia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1075

Introduction: In the realm of mental health treatment, quetiapine, is a commonly prescribed for various conditions like schizophrenia, acute manic episodes, anxiety disorder, and major depressive disorder. Its pharmacological profile includes serotonin, dopamine, histamine, and adrenergic receptor antagonism, with a higher affinity for 5-HT2A receptors compared to D2 receptors. Quetiapine's unique receptor interactions and low risk of side effects make it a versatile option for clinicians.
Objectives: This case report aims to shed light on the potential for quetiapine, an atypical antipsychotic, to induce or exacerbate manic or hypomanic symptoms in patients with bipolar affective disorder. By presenting a real-world case study and reviewing existing literature, we seek to contribute to the understanding of how quetiapine dosage can influence mood symptomatology and inform clinical decision-making regarding treatment strategies in bipolar disorder.
Methods: This investigation was conducted following SANRA guidelines for case reports, and involved performing a search in PubMed to compile evidence on how quetiapine impacts mood symptoms, particularly at different dosage levels, in individuals with bipolar affective disorder.
Results: In our case involving a 26-year-old male with bipolar affective disorder, he experienced a manic episode when starting quetiapine at 200 mg/day, with symptom resolution after discontinuation of the medication. Patients ranged from 21 to 66 years old, with males being more prevalent (11 out of 15 cases). The most common diagnoses were paranoid schizophrenia (8 cases) and bipolar disorder (4 cases), with two bipolar patients experiencing worsened hypomanic symptoms. Dosages of quetiapine varied from 100 mg/day to 600 mg/day, with symptoms appearing between the 2nd day and 7th week of starting treatment. Most cases (13 out of 15) were managed by stopping quetiapine, while one patient's dose was increased to 800 mg/day and another reduced to 100 mg/day. Discontinuing quetiapine in the studied patient led to symptom improvement within two weeks, aligning with similar outcomes in other cases.Alternative antipsychotics were effective if quetiapine worsened symptoms. Various theories explain quetiapine's impact, with poor metabolizers potentially needing higher doses for relief.
Conclusions: Despite the risk of inducing hypomanic/manic symptoms at lower doses of quetiapine, findings suggest that in randomized placebo-controlled studies on bipolar patients treated for depressive episodes, quetiapine has shown a lower likelihood of causing a manic or hypomanic switch compared to a placebo. Clinicians should cautiously monitor patients during the initial dose titration period but can consider quetiapine as a management option for bipolar disorder.

Age at menarche and its implications for the mood-psychosis continuum

M. Puric[1,2]*, M. Nesic[1,2], M. Gostiljac[1], S. Dodic[1,2], I. Minic[1], B. Velickovic[3], B. Dunjic Kostic[2,4], M. Ivkovic[2,3] and M. Pantovic Stefanovic[1,2]

[1]Department for Bipolar Disorders, Clinic of Psychiatry, University Clinical Centre of Serbia; [2]University of Belgrade, School of Medicine; [3]Department of Organic Mental Disorders, Clinic of Psychiatry, University Clinical Centre of Serbia and [4]Department for Forensic Psychiatry, Institute of Mental Health, Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1076

Introduction: Earlier age at menarche has been associated with an increased risk of affective disorders, but also a later onset of schizophrenia in women, indicating a complex relationship between hormonal changes and mental health. This interplay highlights the importance of understanding how pubertal timing and estrogen exposure can influence both mood disorders and psychotic conditions throughout a person's life.
Objectives: Our study aimed to explore the relationship between age at menarche and severity of clinical presentation of patients pertaining to mood-psychosis continuum.
Methods: The study group consisted of a total of 109 female patients, 71 diagnosed with bipolar disorder and 38 diagnosed with schizophrenia. The dimensional assessment of psychosis and affective symptoms was done using the Schizo-Bipolar Scale (SBS), together with the severity of the symptom domains measured by the Brief Psychiatric Rating Scale (BPRS).
Results: Age at menarche significantly correlated to score on SBS scale (r= 0.257,p=0.028), after controlling for confounders (age and body mass index). Other clinical characteristics or psychometric properties were not related to age at menarche in the group of BD and SCH patients perceived as a unified group, possibly pertaining to one continuum.
Conclusions: Pubertal timing may play a role in the severity of symptoms associated with bipolar disorder and schizophrenia. Further research is needed to elucidate the specific pathways linking age at menarche to symptom severity and to explore the potential implications for early intervention and treatment strategies targeting the interplay between hormonal factors and mental health outcomes in individuals with bipolar disorder and schizophrenia.

Metabolic syndrome and its influence on clinical characteristics in bipolar disorder type 1: a cross-sectional study

S. Ben Aissa[1]*, K. Razki[1], C. Najar[1], A. Larnaout[1] and W. melki[1]

[1]Psychiatry, Razi hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1077

Introduction: Metabolic syndrome (MS) is a prevalent condition in individuals with bipolar disorder (BD) and may influence the expression of psychiatric symptoms. Factors contributing to this

association include limited access to physical healthcare, lifestyle influences related to psychiatric symptoms, and adverse effects of psychotropic medications.
Objectives: To compare the clinical characteristics of patients with Bipolar Disorder Type 1 (BD-1) with and without metabolic syndrome (MS).
Methods: This was a cross-sectional descriptive study conducted over a three-month period from August to October 2023 at the Psychiatric Service D of Razi Hospital in Tunisia. Patients diagnosed with Bipolar Disorder Type 1 according to the diagnostic criteria of the DSM-5, aged 18 years or older, and in a euthymic phase (confirmed by Hamilton Depression Rating Scale (HDRS) score <8 and Young Mania Rating Scale score <13) were included. Sociodemographic data, clinical features, and treatment information were initially collected from medical records and then verified and completed through direct interviews using a predefined information sheet and psychometric assessments. Metabolic syndrome was diagnosed according to the criteria of the International Diabetes Federation.
All participants provided informed consent before enrollment, and confidentiality of their personal and medical information was strictly maintained. The study protocol was approved by the Institutional Review Board (IRB) of Razi Hospital, ensuring that the research was conducted in accordance with ethical guidelines and principles of patient autonomy, beneficence, and non-maleficence. Participants were informed about the voluntary nature of their participation and their right to withdraw at any time without consequences. Data collection and storage adhered to strict privacy regulations to protect participants' rights and ensure data security.
Results: Forty patients were included in the study, of whom 28 had MS and 12 did not. The mean age of patients was 34.5 ± 8.2 years in the MS group and 32.1 ± 6.5 years in the non-MS group. Participants with MS had a significantly younger mean age of disorder onset (22.6 ± 8.25 years) compared to those without MS (27.9 ± 4.86 years) ($p = 0.02$). We found that the mean number of suicide attempts was significantly higher in the MS group (2.8) compared to the non-MS group (1.6) ($p = 0.001$). Anxiety comorbidity was significantly higher in patients with MS compared to those without MS (57% vs 35%, p < 10^-3).
Conclusions: Our study underscore the importance of addressing metabolic syndrome in the management of patients with BD-1. Given the higher prevalence of metabolic syndrome in this population and its impact on clinical outcomes, interventions aimed at preventing and managing metabolic syndrome components such as obesity, diabetes, and dyslipidemia are crucial.

First manic episodes triggered by the nuptial context: A case series from Tunisia

Y. Rebei[1]*, H. Ghabi[1,2], S. Aouadi[1], M. Karoui[1,2], H. Nefzi[1,2], R. Kammoun[1,2] and F. Ellouze[1,2]

[1]Psychiatry G, Razi hospital and [2]Faculty of Medicine of Tunis, El Manar University, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1078

Introduction: Manic episodes, a defining feature of bipolar disorder, are often triggered by significant psychosocial stressors. In Tunisia, marriage carries deep religious, societal, and familial significance, creating considerable pressure that may act as a precipitating factor for the onset of bipolar disorder. This case series presents three patients who experienced their first manic episode in the immediate aftermath of their wedding.
Objectives: To highlight the role of marriage as a significant trigger for the first manic episodes in patients with no previous psychiatric history, within the specific socio-cultural context of Tunisia.
Methods: These case reports were compiled through clinical observations and interviews with the patients and their families. All three cases involved newlywed males who developed manic symptoms shortly after marriage, requiring hospitalization.
Results:

- **Case 1:** A 30-year-old male with no personal or familial psychiatric history presented with manic symptoms 5 days after his wedding. Symptoms included expansive mood, irritability, insomnia, grandiose and persecutory delusions, hyperactivity, and logorrhea. He was hospitalized and treated with lithium and risperidone. After 3 weeks, he was discharged and has remained symptom-free for 1 month.
- **Case 2:** A 33-year-old male with a paternal history of schizoaffective disorder developed mania the day after his wedding, following alcohol use and sleep deprivation. His symptoms included psychomotor agitation, destruction of objects, verbal aggression, logorrhea, tachyphemia, delusions of grandeur and persecution, insomnia, and hyperactivity. He was treated with clonazepam, lithium and haloperidol. Clonazepam was discontinued before discharge, and haloperidol after 3 months. He had been episode-free for 3 years, then he had a manic episode and was hospitalized for 2 weeks. Now he's been symptom-free for 2 months
- **Case 3:** A 31-year-old male with no personal or familial psychiatric history presented with manic symptoms 7 days after his wedding, including insomnia, expansive mood, grandiose delusions with auditory hallucinations (he believed God told him to have a son who would be the next prophet), hyperactivity, and logorrhea. He was treated with diazepam, lithium, and risperidone. He was discharged after 4 weeks, with diazepam discontinued before discharge and risperidone after 6 months. He has remained episode-free for 1 year.

Conclusions: These cases highlight the significant cultural pressures surrounding marriage in Tunisia, which can serve as a potent trigger for manic episodes in individuals without prior psychiatric history. Early identification and intervention with antipsychotics and mood stabilizers proved effective in all cases. These findings emphasize the importance of psychiatric vigilance in similar sociocultural settings to manage the onset of bipolar disorder in response to life stressors.

Effectiveness of bright light therapy in patients suffering from unipolar or bipolar depression; a naturalistic study

M. A. Riedinger[1,2]*, G. E. van Son[3], N. J. van der Wee[1], E. J. Giltay[1,4] and M. de Leeuw[1,5]

[1]Psychiatry, Leiden University Medical Center; [2]Outpatient clinic for mental disability and psychiatry; [3]Department of Care and Quality, GGZ Rivierduinen, Leiden; [4]Public Health & Primary Care, Health Campus The Hague, The Hague and [5]Outpatient clinic for bipolar disorder, GGZ Rivierduinen, Leiden, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1079

Introduction: Depressive disorders, both unipolar (MDD) and bipolar (BD), impact patients and society greatly. In bipolar depression and seasonal affective disorder the episodic nature and periodicity relate to changes in circadian rhythms. Bright light therapy (BLT) is thought to ameliorate symptoms of depression through its influence on circadian rhythms. Effectiveness of BLT has not been thoroughly established in real-world clinical samples.
Objectives: To assess effectiveness of BLT in a real-world patients with BD or MDD and assess effect on individual symptoms of depression.
Methods: For seventy-four patients with depression Inventory of Depressive Symptoms – Self Rated (IDS-SR) scores were available through Routine Outcome Monitoring (ROM) used in BLT in the outpatient clinic for mood disorders. Patients received one or two weeks of BLT as usual care. Patients suffering from MDD (n=33, 60.6% female, mean age 36.1±11.5 years) were compared to patients suffering from BD (n=41, 70.7% female, mean age 45.0±14.5 years) and changes in individual symptoms were analyzed for these two groups as well as the whole cohort.
Results: IDS-SR scores decreased significantly in both groups of patients and did not differ in effect size between the groups. Explorative analyses of the effects on individual items of the IDS-SR showed that items related to core symptoms of depression such a as mood, concentration and energy level showed the largest improvements.

Image:

Conclusions: Self-report depressive symptoms in patients suffering from either MDD or BD decreased in this naturalistic cohort after receiving BLT.

Emotion Regulation Strategies and Persistence of Mood Symptoms in Response to Positive Events: A Follow-Up Study Among Hypomanic Personality Traits, Depressed, and Normal Individuals

E. Ryu* and S. Choi

Duksung Women's University, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1080

Introduction: Despite the clinical insight that bipolar disorder is associated with specific mood regulation strategies (e.g., positive rumination), this relationship has rarely been confirmed through empirical research. Previous recall-based studies have failed to establish significant links due to potential memory distortion and recall bias. This study addresses these limitations by using a prospective approach to track the direct effects of emotion regulation strategies on mood symptoms in real time and to assess their persistence.
Objectives: The study aimed to: (1) identify differences in emotion regulation strategies in response to positive events among individuals with Hypomanic Personality Traits, depression, and normal controls; and (2) examine how these strategies impact the persistence of mood symptoms over a one-week period.
Methods: 90 participants were divided into three groups based on the Hypomanic Personality Scale (HPS) and the Centre for Epidemiological Studies Depression Rating Scale (K-CESD-R): a hypomanic personality trait group (HPS ≥ 29), a depressed group (K-CESD-R > 13), and a healthy control group (HPS ≤ 21, K-CESD-R ≤ 13). Participants completed an initial online survey to assess emotion regulation strategies immediately following positive social and goal-related events. To assess the moderating effect of emotion regulation strategies on mood persistence, participants were asked to complete follow-up surveys at regular intervals over the course of one week to track the sustained emotional impact of the positive event. The nature of each event was pre-classified, and differences in emotion regulation strategies between groups were analyzed. The moderating role of emotion regulation strategies in the relationship between the initial positive mood response and its persistence over time was analyzed using repeated measures analysis of covariance (ANCOVA).
Results: Emotion regulation strategies significantly moderated the relationship between positive events and mood symptoms. The Hypomanic Personality Traits Group predominantly engaged in maladaptive strategies, such as positive rumination, which led to more pronounced positive mood symptoms over time. The Depressed Group used mood dampening strategies, resulting in minimal improvement in mood. Conversely, the Healthy Control Group employed adaptive strategies, such as savoring, which contributed to stable mood.
Conclusions: This study underscores the critical role of emotion regulation strategies in the persistence of mood symptoms. It highlights the negative impact of maladaptive strategies on mood,

particularly for individuals with hypomanic traits or depression, suggesting a need for targeted therapeutic interventions. Future research should focus on refining these interventions and exploring their efficacy in diverse populations.

EPV0244

Impact of insight on treatment adherence in bipolar disorder

F. Sahnoun[1]*, F. Cherif[1], D. Mnif[1], F. Guermazi[1], I. Baati[1], I. Feki[1], R. Masmoudi[1] and J. Masmoudi[1]

[1]Psychiatry A Department, Hedi Chaker University hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1081

Introduction: Extreme mood swings are a hallmark of bipolar disorder (BD). Consistent treatment adherence, including medication and regular attendance at outpatient care, is usually necessary for the effective management of BD. However, many individuals with BD struggle with treatment engagement, which is often influenced by several factors, including insight.
Objectives: This study aims to explore the relationship between patients' level of insight into their condition and their attendance at scheduled treatments
Methods: It was a cross-sectional, descriptive, and analytical study conducted on bipolar disorder patients from the Psychiatry "A" Department, Hedi Chaker University Hospital. Clinical and sociodemographic data were collected from March to September 2023 using a questionnaire along with Medication Adherence Rating Scale (MARS) for assessing treatment adherence and the Birchwood Insight Scale (BIS) to evaluate insight
Results: A total of 37 patients with BD completed the questionnaire. The mean age was 45.4 ± 13.9 years, with a sex ratio (M/F) of 1.46.
In our study, 73% of patients were with BD type I and 27% were with BD type II.
The mean MARS score was 7.14 ± 2.13, and 37.8% of our population were non-adherent to medication.
The mean BIS score was 8.58 ± 2.35, and 56.8% of patients had good insight.
Mean scores of awareness of illness, re-labeling of symptoms, and need for treatment subscales of BIS were respectively 2.86, 2.73, and 2.86.
The MARS score was positively correlated with the BIS score ($p = 0.002$, $r = 0.40$).
The MARS score was also positively correlated with both the *awareness of illness* subscale of the BIS ($p = 0.035$, $r = 0.34$) and the *re-labeling of symptoms* subscale of the BIS ($p = 0.41$, $r = 0.33$).
Conclusions: This study demonstrates that certain aspects of insight are significantly associated with treatment adherence in bipolar disorder. Specifically, a*wareness of illness* and *re-labeling of symptoms* suggest that the ability to reinterpret and understand symptoms may enhance engagement with care. In contrast, the *Need for Treatment* subscale did not show a significant correlation with attendance, indicating that simply recognizing the need for treatment alone may not be sufficient to ensure consistent participation in care.

Subjective cognitive impairment in bipolar disorder patients: prevalence and associated factors

F. Sahnoun[1]*, F. Cherif[1], D. Mnif[1], F. Guermazi[1], I. Baati[1], I. Feki[1], R. Masmoudi[1] and J. Masmoudi[1]

[1]Psychiatry A Department, Hedi Chaker University hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1082

Introduction: Over the last decade, there has been a growing recognition of the importance of identifying and treating cognitive impairment associated with bipolar disorder, as it persists during remission periods. Evidence suggests that neurocognitive dysfunction may significantly influence patients' psychosocial outcomes. An increasing body of research aims to improve understanding of potential moderators contributing to cognitive impairment in bipolar disorder in order to develop prevention strategies and effective treatments
Objectives: The aim of this study is to explore the prevalence of cognitive impairment among bipolar disorder patients and identify related factors.
Methods: It was a cross-sectional, descriptive, and analytical study conducted on bipolar disorder patients from the Psychiatry "A" Department, Hedi Chaker University Hospital. Clinical and sociodemographic data were collected from March to September 2023 through a questionnaire along with The Cognitive Complaints in Bipolar Disorder Rating Assessment (COBRA) for evaluation of subjective cognitive impairment
Results: A total of 37 patients with BD completed the questionnaire. The mean age was 45.4 ± 13.9 years, with a sex ratio (M/F) of 1.46.
Our results showed that 73 % of patients were with BD type I and 27% were with BD type II.
The mean score of COBRA was 12.54 ± 7.62 and 32.4% of participants presented subjective cognitive disorder.
Subjective cognitive disorder was significantly associated with the number of relapses, hospitalizations and suicide attempts, with respectively $p< 0.001$, $p= 0.02$ and $p= 0.05$
Female patients and patients with poor income presented significantly more subjective cognitive disorders ($p = 0.01$ and $p = 0.02$, respectively).
The COBRA score was positively correlated with the number of relapses ($p<0.001$, $r = 0.67$).
Conclusions: Our findings indicate that a significant proportion of individuals with bipolar disorder report cognitive difficulties, which may impact their daily functioning and quality of life. Key factors such as poor income, female sex, and the number of relapses and suicide attempts were associated with higher levels of perceived cognitive dysfunction. These results highlight the need for greater attention to cognitive symptoms in the clinical management of bipolar disorder.

Treatment adherence in bipolar disorder: related factors

F. Sahnoun[1]*, F. Cherif[1], D. Mnif[1], F. Guermazi[1], I. Baati[1], I. Feki[1], R. Masmoudi[1] and J. Masmoudi[1]

[1]Psychiatry A Department, Hedi Chaker University hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1083

Introduction: It is well established that user behavior does not align with clinical recommendations regarding using medication in psychotic disorders, particularly bipolar disorder (BD). Nonadherence to treatment carries a high risk of relapse due to the recurrent nature of the illness and is influenced by multiple factors
Objectives: The aim of this study is to investigate the prevalence of medication adherence among BD patients and to explore the various factors contributing to poor adherence.
Methods: This cross-sectional, descriptive, and analytical study was conducted with patient diagnosed with bipolar disorder at the Psychiatry "A" Department of Hedi Chaker University Hospital. Data on clinical and sociodemographic variables were collected between March and September 2023 using a questionnaire, alongside the Medication Adherence Rating Scale (MARS) to evaluate treatment adherence.
Results: A total of 37 patients with BD completed the questionnaire. The mean age was 45.4 ± 13.9 years, with a sex ratio (M/F) of 1.46. In this study, 73 % of patients had BD type I and 27% had BD type II. The mean MARS score was 7.14 ± 2.13 and 62.2% were adherent to their treatment.
Only 16.2% of bipolar patients discontinued their medication due to side effects, while 51.4% present unintentional poor adherence. A significant association was found between treatment adherence and socio-economic status ($p = 0.05$).
The MARS score was negatively correlated with the number of hospitalizations ($p = 0.05$, $r = -0.315$)
Conclusions: This study highlights that treatment adherence in bipolar disorder is influenced by various factors, with socio-economic status being a significant determinant. The negative correlation between MARS scores and the number of hospitalizations suggests that better adherence is associated with fewer hospitalizations. Improving treatment compliance is crucial to reducing the risk of recurrence and hospitalization in BD.

From fire to ashes. A six-month follow-up prospective study of manic patients after acute inward hospitalisation

S. Salmeron[1]*, J. I. Mena[1], E. Cesari[1], H. Andreu[1], L. Olivier[1], O. de Juan[1], B. Serra[1], I. Ochandiano[1], A. Giménez-Palomo[1,2] and I. Pacchiarotti[1,2]

[1]Psychiatry and Psychology Service, Hopsital Clínic de Barcelona and [2]Institut de Recerca Biomèdica August Pi i Sunyer (IDIBAPS), Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1084

Introduction: Although manic episodes are the most characteristic and diagnostic, depressive episodes and subsyndromal depressive symptoms are most prevalent through bipolar patients lifetime and are most related to functional impairment. Manic episodes are still more frequently psychiatrically identified and managed and represent for many patients the first contact with mental health professional and the beginning of an adequate follow-up. They are, however, frequently followed by depressive states. For these reasons, post-episodic constitutes an important psychiatric task for monitoring and follow-up, with little evidence supporting its risks and needs.
Objectives: To elucidate the sociodemographic and clinical characteristics related to depressive switch of bipolar disorder patients after hospital discharge for a manic episode.
Methods: This is a prospective study involving consecutive patients admitted for a manic episode in acute inward in Hospital Clínic de Barcelona. Patients were recruited upon admission to the hospital and followed for a period of six months. Clinical evaluations were conducted during ospital admission and at discharge with Brief Psychiatric Rating Scale, Young Mania Rating Scale, Hamilton Depression Rating Scale and Clinical Global Impression scale for Bipolar Disorder. Patients were contacted for follow-up assessments at 1 month and 6 months after discharge. Presence of a depressive episode was evaluated using the DSM-5 criteria.
Results: A total of 46 patients were recruited, of whom 17 (37%) presented a depressive episode in the following 6 months after discharge. In relation to psychiatric history, manic predominance showed a significant negative association with depressive switch ($p=0.004$), with depressive predominance showing and approached significance for a positive association ($p=0.097$). Also, schizoaffective disorder diagnosis approached significance for a negative association ($p=0.071$). Comorbidity with substance use disorder (except tobacco) showed significant positive association ($p=0.417$). Lithium is the only treatment showing a significant positive association with depressive switch ($p=0.046$).
Conclusions: Lack of significance for clinical variables suggest no clear capacity for predicting follow-up evolution through psychopathological state at discharge. Manic and depressive predominance show, respectively, a negative and positive association with depressive switch, maintaining the global tendency of individual patient's disorder. Interestingly, comorbidity with substance use disorder acted as a protective factor for depressive switching. This finding might be in relation with the fact that, whereas in substance users drugs act as a main factor for their psychopathological state and evolution, with a proneness for stimulants towards manic states, non-users present a higher degree of endogeneity, where depressive states constitute the main tendency.

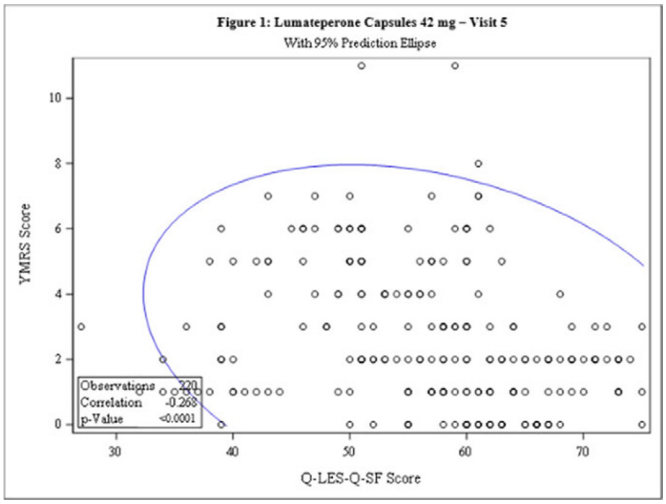
doi: 10.1192/j.eurpsy.2025.1085

Introduction: Lumateperone, an atypical antipsychotic drug approved in 2021 for bipolar depression, has a dual mechanism of action by combination of activity at central serotonin (5-HT2A) and dopamine (D2) receptors. In India, Quetiapine is one of the approved drugs for use in depressive episodes for bipolar disorder.
Objectives: This post-hoc analysis of an Indian Phase 3 study was conducted to evaluate the correlation of quality of life assessed via Quality-of-life enjoyment and satisfaction-short form questionnaire (Q-LES-Q-SF) and severity of hypomania symptoms via Young Mania Rating Scale (YMRS) when treated with Lumateperone 42mg or Quetiapine 300mg.
Methods: The phase-III, randomized, multi-centric, assessor-blind, parallel-group, active-controlled, comparative, non-inferiority study included patients with Bipolar II depression with moderate severity having a Montgomery-Asberg depression rating scale (MADRS) score ≥20 and Clinical global impression–bipolar version–severity (CGI-BP-S) score ≥4. The study was conducted after receiving regulatory and ethics committee approvals. The patients were randomized (1:1) to either receive Lumateperone 42mg [Test] or Quetiapine 300mg [Comparator] for 6 weeks. In this post-hoc analysis, correlation between Q-LES-Q-SF and YMRS were evaluated and for safety outcomes treatment emergent adverse events (TEAEs) were assessed. [Clinical trial registration: CTRI/2023/10/058583]
Results: This post-hoc analysis included 462 patients [231 each in Test and Comparator]. The baseline demographic characteristics were comparable in between treatment arms. The Pearson's correlation coefficient between Q-LES-Q-SF score and YMRS score was statistically significant for both treatment arms at Day 42 [Test: -0.268, p<0.0001; Comparator: -0.281, p<0.0001] and the linear regression between 2 arms was not statistically significant (p=0.8603), indicating weak negative correlation between the 2 scales [Figure 1 and Figure 2]. The incidence of TEAEs were similar in both treatment arms [Test: 34.6%; Comparator: 35.5%] and no serious adverse events were reported.

Image 1:



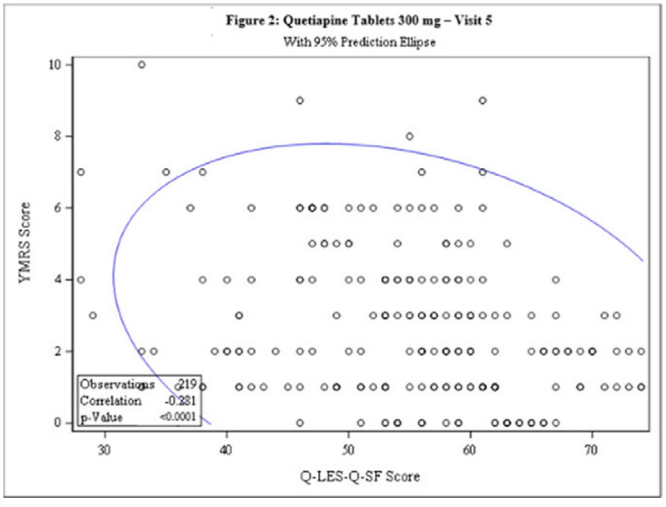


Image 2:

Conclusions: This post-hoc analysis demonstrated that patients with Bipolar II depression when treated with Lumateperone 42mg or Quetiapine 300mg, the improvement in Q-LES-Q-SF score is inversely proportional to YMRS score and both treatments were well tolerated.

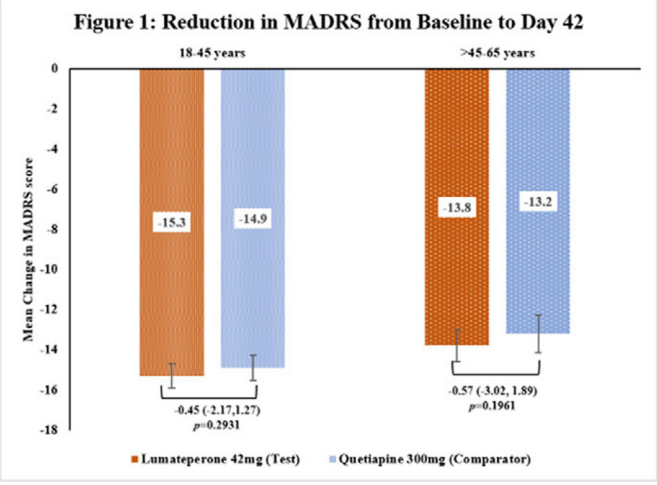
doi: 10.1192/j.eurpsy.2025.1086



Introduction: Lumateperone, an atypical antipsychotic drug, has a dual mechanism of action by combination of activity at central serotonin (5-HT2A) and dopamine (D2) receptors.

Objectives: This subgroup analysis of an Indian Phase 3 study was conducted to evaluate the efficacy and safety of Lumateperone 42mg compared to Quetiapine 300mg in treatment of Bipolar II depression when stratified based on age (18-45, >45-65).

Methods: The phase-III, randomized, multi-centric, assessor-blind, parallel-group, active-controlled, comparative, non-inferiority study included Indian patients with Bipolar II depression with moderate severity having a Montgomery-Asberg depression rating scale (MADRS) score ≥20 and Clinical global impression–bipolar version–severity (CGI-BP-S) score ≥4. The study was conducted after receiving regulatory and ethics committee approvals. The patients were randomized (1:1) to either receive Lumateperone 42mg [Test] or Quetiapine 300mg [Comparator] for 6 weeks. The patients were stratified based on age: Subgroup 1 [S1]: 18-45 years and Subgroup 2 [S2]: >45-65 years. For efficacy outcomes MADRS score, CGI-BP-S (total score, depression subscore and overall bipolar illness subscore), and Quality of life enjoyment and satisfaction-short form questionnaire (Q-LES-Q-SF) score were evaluated and for safety outcomes treatment emergent adverse events (TEAEs) were assessed. [Clinical trial registration: CTRI/2023/10/058583]

Results: This subgroup analysis included 462 patients, out of which 320 in S1[Test=159; Comparator=161] and 142 in S2[Test=72; Comparator=70]. The baseline demographic characteristics were comparable in between treatment arms across subgroups. The primary endpoint of reduction in MADRS score from baseline to Day 42 in Test arm was non-inferior to Comparator arm in both subgroups [Figure 1] as the upper 95% CI was below the predefined margin of 3.0. The reduction of CGI-BP-S (total score, depression subscore and overall bipolar illness subscore) from Day 14 to Day 42 were comparable in both Test and Comparator arms in both subgroups. The improvement in Q-LES-Q-SF score from baseline to Day 42 were comparable in both Test and Comparator arms in both subgroups. The incidence of TEAEs were comparable in both treatment arms [S1: Test=31.4% and Comparator=36.6%; S2: Test=41.7% and Comparator=32.9%] and no serious adverse events were reported.

Image 1:

Conclusions: This subgroup analysis demonstrated that Lumateperone 42mg is non-inferior to Quetiapine 300mg in treatment of Bipolar II depression as assessed via MADRS score from baseline to Day 42, irrespective of age of the patients and both treatments were found to be well tolerated. Hence, Lumateperone can be considered as valuable treatment option in management of Bipolar II depression.

A triptorrelin-induced manic episode: a case report

G. P. Silva[1]*, I. Silva[1], J. Cardão[1], A. Matos[1], B. Martins[1] and C. Agostinho[1]

[1]ULSAALE, Portalegre, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1087

Introduction: Gonadotropin-releasing hormone (GnRH) agonists are the recommended treatment in non-localized prostate cancer. Psychiatric disorders induced by GnRH agonists are rare, but they can include depressive symptoms, irritability, anxiety and auditory hallucinations. Manic episodes are even less frequent.
Objectives: With this case, we aim to remind, that although rare, affective episodes, particularly manic episodes, can occur with the use of GnRH agonists, namely triptorelin.
Methods: Case report.
Results: A 72-year-old man, without relevant psychiatric medical history was admitted to the in-patient unit because of a Manic Episode. It was characterized by hyperfamiliarity, pressured speech, coprolalia, accelerated thinking, flight of ideas and a euphoric/irritable mood. He also had delusional ideas of grandiosity and persecution, centered on his family.
The most common organic causes were ruled out, but it stood out that this patient was under treatment with a long-acting injectable formulation of triptorelin because of a recently diagnosed prostate adenocarcinoma.
Antipsychotics and mood stabilizer drugs were used, but symptoms were only partially remitted. Therefore, we decided to stop all medications, including triptorelin, and a gradual improvement in manic symptoms was observed.
Conclusions: Mood disorders can be an adverse effect of the use of GnRH agonists and, although the expected response to the psychotropic drugs was not observed, symptoms eventually remitted when the effect of Triptorelin wore off, about three months after patient's last dose.
The literature recommends the use of mood stabilizers in the presence of affective symptoms after treatment with GnRH agonists, but some cases may need the GnRH agonists to be discontinued.

doi: 10.1192/j.eurpsy.2025.1088

Introduction: Bipolar disorder (BD) is a severe psychiatric disorder characterized by recurring acute mood episodes of depression or euphoria, alternating with phases of euthymia, with a prevalence in the general population of 2%. Individuals with BD frequently experience disruptions in sleep and circadian rhythms, present during both euthymic and acute mood phases, yet these disturbances are challenging to measure objectively. Tracking these changes can offer insights into the progression of BD and potential risk for mood relapse. Actigraphy, a non-invasive monitoring technique, holds promise for capturing objective, real-world data on sleep and circadian patterns, thereby aiding in the assessment and management of BD.
Objectives: This study aims to assess the feasibility of using actigraphy as a tool for monitoring sleep-wake patterns and physical activity levels in patients with BD over a longitudinal period.
Methods: Within The Bipolar Exposome-Gene Interaction Naturalistic (BEGIN) project we conducted a longitudinal study of individuals diagnosed with BD using wrist-worn actigraphy (Withings Steel HR) to collect data on daily activity and sleep parameters over 12 months. Feasibility was evaluated based on participant adherence to the actigraphy protocol, data quality, technical challenges, and acceptability by patients and clinicians.
Results: Results indicated satisfactory enrolment rate (N=87, 66.4%) in the study and compliance with the use of actigraphy (N= 59, 67.8%). The main reasons for not accepting the study were non-response to contacting efforts (43.2%) and lack of interest (24.3%). No age differences were found between individuals who accepted the study and those who did not. A high retention rate was obtained (N=80, 92%) with the main reason for drop-off being the perception of intense follow-up within the study. Regarding actigraphy, younger individuals were more likely to accept its use ($t = -2.066$, p-value = 0.043) and the main reason for non-adherence was rash development (42.9%). Patient feedback highlighted the ease of use and minimal disruption of daily life.
Conclusions: In conclusion, actigraphy is a feasible and effective tool for continuous monitoring in BD, offering potential for improving the understanding of mood episodes and treatment efficacy in future studies. Further exploration of actigraphy in larger cohorts and its integration with other physiological measures is recommended.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1089

Introduction: Sleep disturbances are common among individuals with bipolar disorder (BD) and may be present even during euthymic phases and significantly impact illness course and quality of life. This preliminary analysis is part of BEGIN (The Bipolar Exposome-Gene Interaction Naturalistic study.
Objectives: Here, we analyze the relationship between subjective sleep disturbances and various lifestyle and environmental factors in BD patients.
Methods: Eighty-seven patients diagnosed with BD (Mean age = 50.7 years, SD = 13.6; 44.7% female; Mean BMI = 26.9, SD = 4.61) all in a three-month euthymic phase, were recruited. At baseline, participants completed lifestyle questionnaires covering diet, light exposure, and time spent indoors, alongside assessments of clinical history and circadian rhythms using the BRIAN scale. Sleep quality was assessed through the Pittsburgh Sleep Quality Index (PSQI, with a cutoff >5 for sleep problems) and the Epworth Sleepiness Scale (ESS, with a cutoff >10 indicating excessive daytime sleepiness). Sociodemographic, clinical, and environmental factors were compared between BD patients with and without sleep disturbances.
Results: Based on ESS scores, patients with excessive daytime sleepiness had significantly higher overall circadian rhythm disruptions, as indicated by the BRIAN total score ($p = 0.049$). A negative correlation emerged between excessive daytime sleepiness and age at first hospitalization ($r = -0.36$, $p = 0.003$). Disrupted eating patterns, reflected in the BRIAN eating subscale, also correlated with excessive daytime sleepiness ($r = 0.27$, $p = 0.027$). Based on PSQI scores tobacco smoking was positively associated with poor sleep quality ($r = 0.42$, $p = 0.013$), while more time spent with artificial light from electronic devices ($r = -0.29$, $p = 0.019$), and less time spent indoors ($r = 0.39$, $p = 0.001$) correlated with worse sleep quality. Patients experiencing poor sleep also showed less consistency in social routines (BRIAN social score, $p = 0.028$).
Conclusions: These preliminary findings suggest that sleep disturbances in BD patients may be intricately linked to lifestyle and environmental factors, such as circadian rhythm disruptions, smoking, and exposure to artificial light. These results highlight the importance of considering environmental and lifestyle modifications to support sleep quality in BD. Future longitudinal analyses will be essential to clarify causal pathways and develop targeted interventions that address circadian and lifestyle factors in managing BD.

Public perception towards marriage involving individuals with bipolar disorder and its relationship with affirming attitudes among general population

Y. Trabelsi[1]*, B. N. Saguem[1] and N. Jaafar[1]

[1]Psychiatry Department, Farhat Hached Hospital, sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1090

Introduction: Public perceptions regarding marriage in individuals with bipolar disorder are often influenced by societal stigma and misconceptions. These views can shape attitudes towards their suitability for long-term relationships. Misunderstandings about mental illness often create barriers to social acceptance.
Objectives: This study aims to explore the general population's perceptions of marriage involving individuals with bipolar disorder and assess how these views relate to broader affirming attitudes towards mental health.
Methods: Across sectional study was conducted via an online formulary shared on social media. It included a detailed description of clinical symptoms and outcomes of bipolar disorder along with 13 questions assessing the perception of the participants about marrying an individual with bipolar disorder. A battery for measurement of affirming attitudes was used, it comprised 3 self-report measures: The Empowerment scale(ES), the Recovery scale(RS) and the self-discrimination scale(SDS).
Results: A total of 304 participants were included, with the majority aged between 20 and 30 years, 71 participant indicated that they were living with someone diagnosed with a psychiatric disorder. Results show that opinions on marriage for individuals with bipolar disorder are mixed. While 50.3% believe such individuals can marry, there is significant doubt about marriage improving symptoms with 63.5% disagreeing that it helps, and 61.8% rejecting the idea of marriage as a cure. Moreover, 53.0% believe that marriage could worsen symptoms. 55.9% would not personally agree to marry someone with this condition. Similarly, 58.6% would not approve of a relative marrying someone with bipolar disorder. However, despite these concerns, 80.6% agree that people with bipolar disorder have the right to make their own decisions concerning marriage.
Additionally, participants who expressed a refusal to marry someone with bipolar disorder ($p<10^{-3}$) had significantly higher RS scores. Moreover, participants who believed that individuals with bipolar disorder are dangerous to their partners exhibited significantly higher ES scores ($p=0.036$). Furthermore, a significant result was observed among participants who disagreed that individuals with bipolar disorder are capable of making decisions regarding marriage, these individuals demonstrated elevated scores on all three scales: RS ($p<10^{-3}$), ES ($p=0.02$), and SDS ($p=0.01$).
Conclusions: This study highlights the ongoing challenge of societal stigma towards individuals with bipolar disorder, particularly regarding marriage. While there are encouraging signs of changing attitudes among certain demographic groups, broader efforts are needed to foster a more inclusive and supportive societal perspective on this topic.

EPV0255

General population's perceptions regarding marriage in patients with Bipolar disorder

Y. Trabelsi[1]*, B. N. Saguem[1] and N. Jaafar[1]

[1]Psychiatry Department, Farhat Hached Hospital, sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1091

Introduction: The general population's views on marrying individuals with bipolar disorder are shaped by a combination of personal experiences, cultural beliefs and media portrayals, and this emphasize the challenges for successful, supportive relationships among them.
Objectives: To explore these perceptions we performed a qualitative analysis of public attitudes toward marriage in individuals with bipolar disorder.
Methods: A cross-sectional study was carried out using a convenience sampling approach among the general population. The survey was distributed through social media platforms and, in addition to collecting socio-demographic and clinical data, it provided a detailed account of the symptoms and outcomes associated with bipolar disorder. It also included open-ended questions aimed to evaluate perceptions of the potential advantages and disadvantages of being in a relationship with someone who has bipolar disorder. The responses were analyzed, and common themes reflecting public opinion were identified.
Results: A total of 304 participants, mostly aged between 20 and 30, were included, with women making up 80.9% of the group. The majority held a university degree. A family history of psychiatric conditions was reported by 35.6% of the participants, and 23.35% mentioned living with someone who has a psychiatric disorder. Additionally, around 87% of the participants acknowledged having consulted a psychiatrist at least once in their lifetime.
Responses regarding potential disbenefits of being married to a patient with bipolar disorder included 9 themes. The most representative ones were 1) the fear of dealing with mood swings and recurrent mood episodes (10.2%); 2) the impossibility of having a stable relationship (7.2%), 3) the risk of physical and/or verbal violence (6.4%); 4) the elevated risk of separation (4.6%); and 5) the risk of suicide (3.9%). Other themes included concerns about 6) transmitting the pathology to their descendants; 7) dealing with a partner who refuses treatments; 8) having an irresponsible companion; and 9) facing financial problems.
About 8.9% of the participants stated that they were willing to get married with a patient with bipolar disorder in order to help him survive his illness; 6.2% of them qualified him as intelligent and affectionate; and 5.2% considered manic episodes as an opportunity to alter routine.
Conclusions: Public perceptions of marriage with individuals with bipolar disorder are shaped by a complex interplay of stigma, fear, and misinformation. While negative stereotypes are prevalent, there is also a recognition that with the right support, successful marriages are possible. Addressing the knowledge gaps and promoting empathy are crucial steps in reducing stigma and supporting individuals with bipolar disorder in their personal and marital lives.

The Effect of Emotion Regulation Strategies on Functioning in Individuals with Bipolar Disorder

R. Ucak[1]*, C. H. Ayhan[1], M. C. Aktas[1] and S. Aktas[2]

[1]Psychiatric Nursing and [2]Psychiatri, Van Yuzuncu Yıl University, Van, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1092

Introduction: Bipolar disorder is a chronic disorder characterized by intense fluctuations in mood, which seriously affects the mental health and quality of life of the individual (APA, 2022). The most prominent features of this disorder include episodes of mania, hypomania and depression. In between these episodes, individuals may generally experience periods of emotional stability; however, the severity and frequency of emotional fluctuations may show individual differences. Bipolar disorder affects not only individuals' mood, but also their cognitive functioning, social relationships, and overall mental health. In this context, the strategies these individuals use to cope with emotional difficulties play an important role in mental health. Especially in manic episodes, individuals often struggle with an uncontrolled increase in excessive positive emotions, while in depressive episodes they have to cope with intense negative emotions (Gruber, 2011). Research shows that individuals with bipolar disorder often resort to dysfunctional emotion regulation strategies, which may have a negative impact on the frequency and severity of episodes. However, studies on the effectiveness of emotion regulation strategies in individuals with bipolar disorder are limited. In particular, more research is needed on how these strategies play a role in different stages of the illness and to what extent the effects of these strategies on individuals' overall functioning differ.
This study aims to examine the effects of emotion regulation strategies used by individuals with bipolar disorder on functioning.
Objectives: The aim of this study is to examine the effect of emotion regulation strategies used by individuals with bipolar disorder on their functioning. In particular, it is aimed to analyze the differences between functional and non-functional strategies on functioning.
Methods: This study was planned according to a descriptive correlational design. Data will be collected from individuals diagnosed with bipolar disorder using the Cognitive Emotion Regulation Scale, Difficulty in Emotion Regulation Scale-Short Form (DERS-16), Young Mania Rating Scale, Brief Psychiatric Functioning Rating Scale and Sociodemographic Data Form. Participants will fill in these scales and the effect of emotion regulation strategies on functioning will be evaluated. The data will be subjected to appropriate methods for statistical analysis.

Results: Data extraction is still on going in detailed style by principal authors. Description of studies and the key findings will be presented.
Conclusions: The results of this study aim to determine the different effects of functional and dysfunctional strategies on functioning in individuals struggling with bipolar disorder and to provide recommendations for interventions that can improve the mental health of these individuals.
Key Words: bipolar disorder, emotion regulation, functioning, coping.

Impact of Apheresis on Lithium Levels in a Patient with Multiple Myeloma and Bipolar Disorder: A case report

D. Üzüm[1]*, M. R. Altunel[1], N. G. Usta Sağlam[1] and S. Turan[1]

[1]Department of Psychiatry, Istanbul University - Cerrahpasa, Cerrahpasa Medical School, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1093

Introduction: Managing lithium levels in patients with coexisting medical conditions can present several challenges. Here, we report a case of a bipolar disorder (BD) patient on lithium therapy who underwent apheresis in the hematology department for autologous stem cell transplantation preparation.
Objectives: Bipolar disorder and multiple myeloma are both challenging conditions to manage individually, but their combination presents unique difficulties. This report details the case of a patient with both conditions, emphasizing the impact of a major medical intervention on psychiatric health.
Methods: Presentation of a patient's case regarding the impact of apheresis on lithium levels.
Results: A 52-year-old woman presented in January 2024 with bilateral hip pain, and MRI revealed lesions on the T12 vertebra, which were identified as multiple myeloma on a PET scan. She underwent neurosurgical intervention for the spinal lesions and was planned for autologous stem cell transplantation by the hematology team, involving apheresis and filgrastim administration. The patient has a 20-year history of BD and and has never been hospitalized in a psychiatric facility. Her condition has remained stable with lithium and quetiapine, especially when lithium levels were maintained between 0.8-0.9 mEq/L. During acute episodes, increasing the quetiapine dosage and adding clonazepam have proven effective. It was noted that her most recent hypomanic episode occured in January 2024, due to the interruption of her medications during her admission to the neurosurgery ward. When the patient was admitted to the hematology ward for apheresis, she was taking 1200 mg/day of lithium and 600 mg/day of quetiapine, with a blood lithium level of 0.56 mmol/L. Since her blood lithium levels were considered low, the dosage was increased to 1500 mg/day. One week later, the patient developed complaints of increased amount of speech, overspending and irritability. She was evaluated in consultation and hypomania was considered as a result of psychiatric examination. Her blood lithium level had decreased to 0.46 mmol/L at that time. Clonazepam 0.5 mg/daily was added to her treatment. The apheresis treatment was completed after 10 days. Four days after the completion of the apheresis therapy, her lithium level increased to 0.81 mmol/L and her hypomanic symptoms have improved.
Conclusions: Although lithium is well-documented to be effectively removed via hemodialysis and peritoneal dialysis, its removal through apheresis is not documented. Managing BD in patients undergoing apheresis presents challenges due to its impact on plasma lithium levels. This case underscores the importance of individualized treatment strategies, including frequent monitoring of serum lithium levels and timely dose adjustments. Clinicians must remain cautious in patients undergoing plasma exchange to maintain mood stability and adjust treatments as necessary.

Disclosure of Interest: None Declared

EPV0258

Enhancing Lithium Monitoring: A Comparative Analysis of Saliva, Erythrocyte, and Plasma Levels in Psychiatric Patients

D. Vlahović[1]*, D. Karlović[1,2], V. Peitl[1,2] and Z. Karlović[3]

[1]Department of Psychiatry, Sestre milosrdnice University Hospital Center; [2]Catholic University of Croatia and [3]Department of Endodontics and Restorative Dentistry, School of Dental Medicine, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1094

Introduction: Lithium is a key treatment for bipolar affective disorder, effectively managing mania, depression, and reducing suicidality. Due to its narrow therapeutic range, regular monitoring of plasma levels is essential to avoid toxicity. However, blood plasma testing can be costly and inconvenient. Non-invasive alternatives, such as saliva testing, have been explored, but with inconsistent results. Previous studies have shown discrepancies in saliva collection and storage, variations in processing methods, and differences in lithium detection techniques. Recent research suggests that erythrocyte lithium levels may better reflect brain concentrations and predict treatment response. This study investigates the correlation between lithium concentrations in different types of biological media, aiming to find a more convenient and effective monitoring method for patients.
Objectives: This study aimed to examine the correlation between lithium concentrations in saliva, plasma, and erythrocytes at multiple daily time points in patients undergoing lithium carbonate treatment.
Methods: A total of 77 patients were recruited from the Clinical Department of Psychiatry, Sestre Milosrdnice University Hospital Center, Zagreb, Croatia, between January and August 2024. Participants included inpatients and day hospital patients diagnosed with bipolar affective disorder, treatment-resistant depressive disorder, or depressive disorder with a high suicide risk. All participants were newly initiated on lithium carbonate therapy, receiving

300 mg at 9:00 and 21:00 for 5 days. Exclusion criteria included conditions affecting salivation, pregnancy, and medications that alter lithium levels. Lithium concentrations in saliva, plasma, and erythrocytes were collected at 9:00, 10:00, 11:00, 12:00, 15:00, and 20:00. Samples were processed and analyzed using a spectrophotometric method.
Results: To assess the correlation between lithium concentrations in saliva, plasma, and erythrocytes, linear regression analysis was conducted. The results indicated a statistically significant correlation between lithium levels in saliva and plasma ($p<0.01$). However, no significant correlations were observed between lithium concentrations in saliva and erythrocytes ($p>0.01$) or between plasma and erythrocytes ($p>0.01$).
Conclusions: Aforementioned finding suggest that saliva could be used for lithium monitoring. Utilizing saliva could significantly enhance treatment options for patients with mood disorders while contributing to treatment efficacy, patient safety, and adherence.

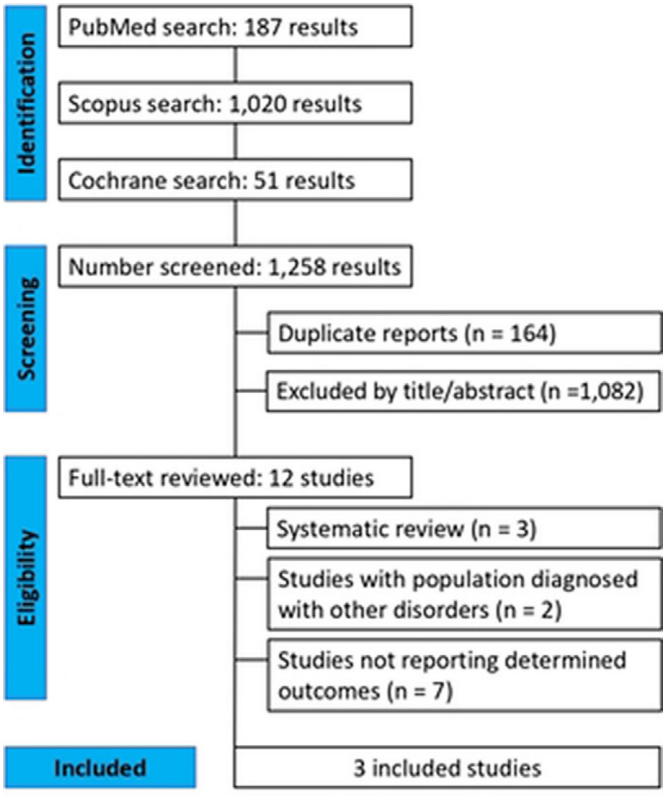
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.437

Introduction: Conduct disorder (CD) is a behavior disorder mostly presented during childhood and adolescence, with a lifetime prevalence between 2 and 10%. Atypical antipsychotics are considered the most effective pharmacotherapy for CD, nonetheless, they are associated with sedation and extrapyramidal side effects. The pediatric use of lithium is well-documented for managing bipolar disorder; however, its efficacy in treating conduct disorders in children remains uncertain.
Objectives: In this study, the authors evaluate the adverse effects of lithium in pediatric patients with conduct disorder.
Methods: We systematically searched PubMed, Embase, and the Cochrane Library for randomized controlled trials and controlled observational studies in pediatric patients with conduct disorder, following the PRISMA protocol. The search strategy included the following keywords: "Pediatric Population", "Conduct disorder", and "Lithium". Review Manager 5.4 and Inverse Variance Random Effects were used for statistical analysis and heterogeneity was examined with the Cochran Q test and I^2 statistics.
Results: From the search of the databases, 1.258 articles were found. After removing duplicates and ineligible studies, 3 articles were included in this study according to the inclusion criteria. We included 161 patients from 3 non-randomized trials. (Figure 1) A total of 136 (84.5%) patients were male. The mean ages between studies ranged from 5.2 to 14.2 years. Only the outcome of adverse effects related to the study population could be found in the 3 studies, and this was used to carry out the single-arm meta-analysis. The pooled proportion of adverse events was 68% (95% CI; 0.30-1.00; I^2 = 98%; $p < 0.01$). (Figure 2) Adverse events included: decreased appetite, stomachache, nausea, vomiting, headache, dizziness, pallor, and fatigue, among others.

Image 1:



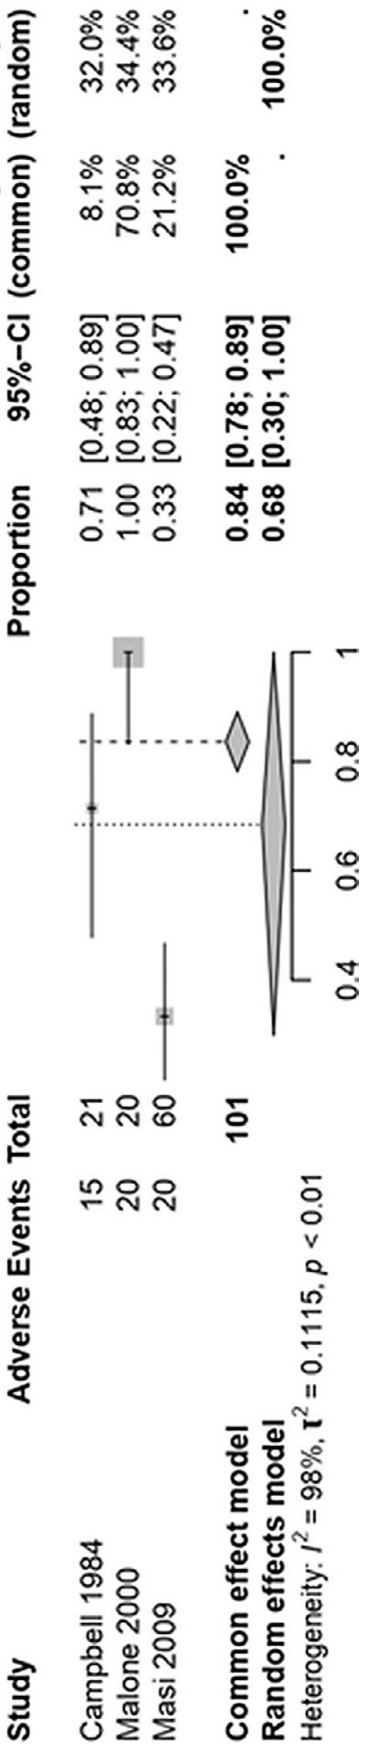


Figure 1. PRISMA flow diagram of study screening and selection

Image 2:

Conclusions: In pediatric patients, lithium appears to be a viable treatment option for conduct disorder. However, some patients may experience adverse events such as decreased appetite, stomach pain, nausea, vomiting, headache, among others. Therefore, more comparative studies are needed to validate the safety and efficacy profile of lithium in this population.

doi: 10.1192/j.eurpsy.2025.644

Introduction: Dialectical Behavior Therapy (DBT) is a comprehensive evidence-based psychotherapy that focuses on teaching skills regarding the acceptance of circumstances and coping with emotional responses.
Objectives: The objective of this study is to perform a systematic review and meta-analysis to investigate the efficacy of DBT in patients diagnosed with Bipolar Disorder (BD) in order to ascertain whether it improves the recurrence of manic and depressive symptoms.
Methods: A systematic search of the PubMed (MEDLINE), Embase, Web of Science, and Cochrane Library databases was conducted to identify studies that had applied DBT to patients with a diagnosis of BD.
Results: A total of 343 patients were included in the study, comprising participants from eight randomized and non-randomized trials. Of whom, 196 patients (57.1%) underwent DBT and pharmacological treatment, while 147 patients (42.9%) were treated with alternative interventions. A total of 12 to 36 sessions of DBT were conducted across all trials, with a follow-up period ranging from three to 15 months. The age range of the participants was 15.8 to 49.3 years. All studies included patients diagnosed with BD type I (n=175), five articles included patients with BD type II (n=100), and two included patients with BD-NOS (Not Otherwise Specified) (n=68). The primary endpoint analyzed was the mean change in the Beck Depression Inventory-II (BDI-II), as reported by three of the included studies. The meta-analysis yielded no statistically significant results, with a mean difference of -4.49 (95% CI: -11.75, 2.76; I^2 = 6%; p = 0.22) (Figure 2). The analysis of the Young Mania Rating Scale (YMRS) revealed a mean of 5.96 in a total of 72 patients (95% CI: 0.29-11.64; I^2 = 97.39%; p < 0.001) (Figure 3).

Image 1:

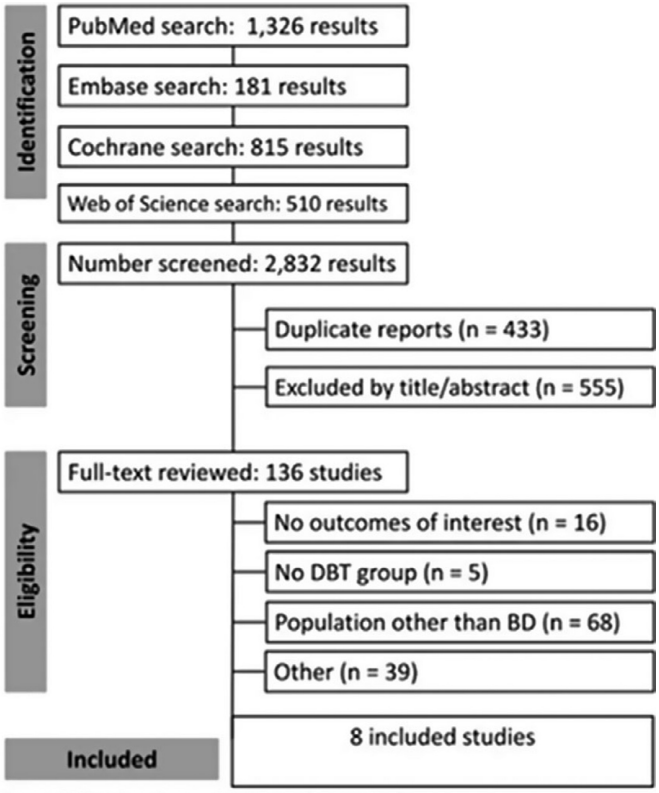

Figure 1. PRISMA flow diagram of study screening and selection

Image 2:

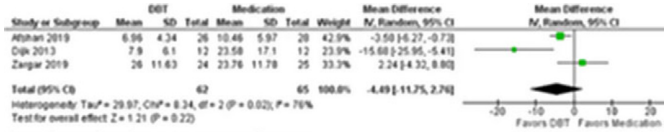

Figure 2. Mean Beck Depression Inventory (BDI-II) score

Image 3:

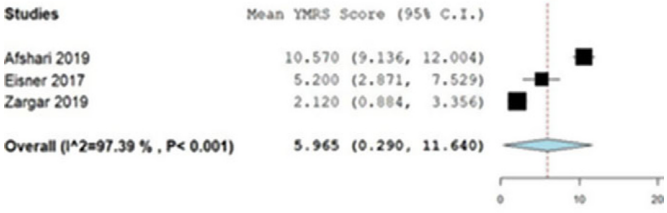

Figure 3. Mean Young Mania Rating Scale (YMRS) score

Conclusions: The DBT was observed to have a beneficial impact on mood episodes and symptomatic manifestations among adolescents and adults diagnosed with BD. Therefore, it may be postulated that the DBT could be employed in conjunction with pharmacological agents to mitigate the severity of symptoms and enhance the overall quality of life in patients with such a diagnosis.

Long-acting Paliperidone in the Management of Severe Behavioral Disturbances Post-Traumatic Brain Injury: A Case Report

A. Y. Al Ghailani[1]*, H. Mirza[2] and S. Al Adawi[2]

[1]Psychiatry, Oman Medical Speciality Board and [2]Behavioural Medicine, Sultan Qaboos University Hospital, Muscat, Oman
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1095

Introduction: Traumatic brain injury (TBI) is a critical public health issue that often results in lasting cognitive and behavioral impairments. These impairments include heightened risks for psychiatric disorders, such as aggression, social withdrawal, and mood instability.
Managing TBI-related behavioral symptoms can be complex, particularly in adolescent patients, where non-adherence to medication presents additional challenges.
Objectives: To evaluate the effectiveness of long-acting injectable paliperidone palmitate in managing severe behavioral disturbances following TBI in an adolescent patient with a history of non-adherence to oral antipsychotic treatments.
Methods: A case study approach was employed to detail the treatment and outcomes of a 16-year-old male who developed persistent aggressive and impulsive behaviors following a severe TBI at age 9.
The patient's treatment history involved multiple oral antipsychotic trials, each limited by adherence issues or side effects, before transitioning to paliperidone palmitate injections.
Behavioral outcomes were monitored, and family-reported assessments of improvement were collected.
Results: Following the initiation of monthly paliperidone palmitate injections at an initial dose of 100 mg, later increased to 150 mg, the patient showed significant reductions in aggression and improved behavioral control.
Family members observed fewer aggressive outbursts and better social interactions.
Mild side effects, including weight gain and an increase in prolactin levels, were reported, but these were generally well tolerated by the patient.
Conclusions: This case demonstrates the potential benefits of long-acting injectable antipsychotics for managing behavioral dysregulation in TBI patients who struggle with medication adherence.
Paliperidone palmitate was effective in stabilizing the patient's behavior, underscoring the need for tailored, multidisciplinary treatment plans that incorporate both pharmacological and psychosocial interventions to optimize long-term recovery in TBI-related neuropsychiatric care.

The Influence of Childhood Adversity on Academic Performance, Cognitive Function, and Life Satisfaction in University Students

K. K. Al Qassabi

Psychiatry, Oman Medical Specialty Board, Muscat, Oman
doi: 10.1192/j.eurpsy.2025.1096

Introduction: Childhood is a pivotal developmental phase, with experiences during this period significantly shaping future outcomes. Adverse Childhood Experiences (ACE), such as abuse, neglect, and household dysfunction, are linked to long-term adverse health outcomes, risky behaviors, and impaired cognitive function. These experiences can also negatively impact academic performance and life satisfaction. Despite the prevalence of (ACE), there is limited research in the Middle East.
Objectives: The study aim to examines the relationship between Adverse Childhood Experiences (ACE), academic performance, cognition, and life satisfaction among Sultan Qaboos University students.
Methods: This cross-sectional study recruited undergraduate students from Sultan Qaboos University using self-administered surveys distributed via social media and college administrations. It assessed ACE scores, academic performance (GPA), cognitive function, and life satisfaction through validated instruments.
Results: The study found that 26.5% of students had high ACE scores, with emotional abuse being the most common. Higher ACE scores were associated with a history of mental illness, urban residence, and lower family financial status. Significant negative correlations were found between ACE scores and life satisfaction, GPA, and cognitive function. Regression analysis revealed that higher ACE scores increased the likelihood of lower GPA and decreased life satisfaction, emphasizing the substantial impact of ACEs on university students' well-being and academic performance.

Table 1: Multinomial Logistic Regression Results of GPA as Dependent Factor.

GPA Category	Predictor	B	Sig. (p-value)	Exp(B)	95% CI for Exp(B)
<2.00	ACE Score	0.317	0.025	1.373	1.041 - 1.811
	Gender	-1.639	0.001	0.194	0.073 - 0.517
	College	-0.229	0.02	0.795	0.656 - 0.964
2.00-2.49	Gender	-1.889	<0.001	0.151	0.066 - 0.345
	Academic Year	0.338	0.012	1.403	1.079 - 1.824
	College	-0.181	0.021	0.835	0.716 - 0.973
2.50-2.99	Academic Year	0.343	0.007	1.409	1.100 - 1.805

Table 2: multiple linear regression analysis SWLS as dependent variable.

Predictor	B	Std. Error	Beta	t	Sig.	95% CI B
Gender	-0.932	0.577	-0.069	-1.614	0.107	-2.066 to 0.203
College	0.358	0.117	0.131	3.066	0.002	0.129 to 0.588
Financial Status	1.14	0.566	0.094	2.015	0.044	0.028 to 2.251
Diagnosed with Mental Illness	-3.355	1.015	-0.144	-3.305	0.001	-5.350 to -1.360
ACE Score	-1.112	0.174	-0.298	-6.41	0.00	-1.453 to -0.771

Conclusions: The Study highlights the need for targeted interventions and support systems to address the diverse needs of students affected by (ACE). By understanding the long-term consequences of (ACE) and the mediating role of sociodemographic factors, educators, policymakers, and mental health professionals can develop strategies to promote resilience and well-being among young adults.

EPV0262

KBG syndrome: a case report of a 12-year-old male child with ADHD

G. Lorenzo Chapatte[1], C. Alario Ruiz[1], L. Rodríguez Andrés[1]*, C. Rodríguez Valbuena[1], M. S. Geijo Uribe[1], M. Ríos Vaquero[1], L. Rojas Vázquez[1], A. Monllor Lazarraga[1], L. Sobrino Conde[2], M. Fernández Lozano[1], N. Navarro Barriga[1], B. Rodríguez Rodríguez[1], M. J. Mateos Sexmero[1], A. Aparicio Parras[2], M. P. Pando Fernández[1], P. Martínez Gimeno[1], M. A. Andreo Vidal[1], M. Calvo Valcárcel[1], M. D. L. Á. Guillén Soto[2], L. del Canto Martínez[1], F. J. González Zapatero[1] and M. E. Espinosa Muth[2]

[1]Psychiatry and [2]Psychology, Hospital Clínico Unversitario de Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1097

Introduction: KBG syndrome is a rare genetic condition (autosomal dominant inheritance - ANKRD11 mutation) with a particular phenotype (short stature, craniofacial dysmorphism and skeletal abnormalities) and neurodevelopmental delay or intellectual disability. Patients with this condition usually have a greater tendency to present symptoms related to impulsivity and distractibility typical of ADHD, as well as behavioral disturbances and aggressiveness.
We present the case of a 12-year-old male child who is being followed up at the Child and Adolescent Mental Health Department for intellectual disability and ADHD combined.
Objectives: To address the importance and multidisciplinary approach of the KBG Syndrome in the pediatric population with a diagnosis of ADHD based on the presentation of the aforementioned clinical case.
Methods: Bibliographic search and description of a clinical case of a patient under follow-up for Child and Adolescent Mental Health at the "Hospital Clínico Universitario de Valladolid".
Results: A 12-year-old boy from Spain was referred to the Child and Adolescent Psychiatry Department for attention and concentration difficulties and impulsivity problems. The parents describe the patient as a restless and nervous child who is sometimes aggressive in moments of important frustration. They point out that he impulsively performs dangerous acts, such as crossing the road without making sure that a car is not coming by, and is easily distracted. The School Center reports that the child is incapable of following the rules and shows great difficulty in learning.
He has a medical history of growth delay with problems of right dorsal scoliosis requiring the use of a night corset, moderate hypoacusis in the right ear, myopia and astigmastism and macrodontia. He also underwent surgery for epigastric hernia.
In addition, he shows a particular phenotype that shares with his mother and for which genetic studies have been performed that determined the ANKRD11 mutation, confirming the diagnosis of KBG syndrome.
Conclusions: KBG syndrome is a rare genetic condition that should be considered in the differential diagnosis of patients with cognitive and behavioral difficulties in combination with a distinctive phenotype.
The importance of the diagnosis of this entity lies in being able to offer a better multidisciplinary medical approach at the organic and mental health level.

It is also important to be able to plan and propose an adapted education at school and to provide tools and management strategies to the family at home for a better prognosis and quality of life of the patient and his environment.

Disclosure of Interest: None Declared

EPV0264

Suicide, suicide ideation and self-harming behaviours in a Day Hospital for children and adolescents with ASD

A. Alvarez[1]*, N. Santamaria[1], V. Bote[1], R. Medina[1], B. Sanchez[1], J. A. Monreal[1] and A. Hervás[1]

[1]Mental Health, University Hospital Mutua Terrassa, Terrassa, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1098

Introduction: The ASD (Autism Spectrum Disorder) Day Therapeutic Unit is a third-level care unit. It consists of 20 beds for the evaluation and treatment of children and adolescents with ASD. In recent years, there has been a significant increase in suicidal thoughts, self-harm and completed suicide in these patients. At the ASD Day Hospital, we offer multidisciplinary and intensive treatment to these patients, but we also want to delve into the causes of this situation: real prevalence, existing psychiatric comorbidities, gender differences, etc. with the aim of being able to improve our clinical and care dedication
Objectives: The objective is to know the clinical and sociodemographic characteristics of patients with thoughts of death, self-harm and completed suicide, in our autism day hospital.
Methods: A review of the clinical history of patients included in the ASD Day Hospital from 2021 to 2023 (both complete) is carried out. The psychiatric comorbidity, age of the patients, gender, multidisciplinary treatment received and average stay are analyzed.
Results: During the years 2021, 2022 and 2023, a total of 255 children (92 women and 163 men) were treated in HD for ASD, with an average age of 11.64 years for women and 11.44 for men. It was found that 40 (15 + 22) of them had suicidal thoughts, where (9 + 16) were women, (6 + 6) men. One patient committed suicide (woman), and 25 presented self-harming behaviors (16 women and 9 men). The most frequently found comorbidities were: anxiety, depression, ADHD and conduct disorders. And the most frequently prescribed drug was fluoxetine, followed by aripiprazole.
Conclusions: Patients with ASD have a high comorbidity with anxiety, depression and behavioural disorders, probably as a consequence of the ongoing socio-family requirements they present. This situation leads to an increase in the prevalence of harmful behaviours and thoughts of death in underage patients, occasionally leading to suicide.
Work on social skills, as well as multidisciplinary intervention, improves the clinical situation of these patients, which should be considered an economic and moral investment for future generations.

EPV0265

An experimental study on the use of BERS-2 test to diagnose behavior and emotion: (a model for teenagers)

K.-U. Mijgee[1] and Y. Amanbyek[1]*

[1]Psychological Service Center, Mongolian National University of Education, Ulaanbaatar, Mongolia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1099

Introduction: This study focuses on studying the most common psychological and physiological phenomena of adolescents, which directly and indirectly affect adolescent behavior and emotions, especially school children, using the BESR-2 test. Youth and peer pressure, crime, family and school stress, drug use, alcohol use, smoking, rape, theft, etc., create anxiety and psychological causes for teenagers in our society. In order to prevent and reduce the negative impact on the behavior and emotional state of the youth, it is imperative to study the current problems and find better solutions. In relation to this social need, the purpose of this study is to conduct a pilot study on how to diagnose the behavior and emotional state of adolescents using the BERS-2 test.
Objectives: When analyzing the relevant theories and principles of the BERS-2 test, the research selects appropriate methods and methodologies (1) review and analyze the theoretical basis of the author's use of the test; (2) examine the internal reliability and convergent validity of the BERS-2; (3) use and examine internal reliability and convergent validity; and finally (4) identify research limitations and future research directions.
Methods: 1,812 students from Ulaanbaatar and the local area, 1,812 teachers, and 1,812 parents, a total of 5,436 participants are participating in the pilot study. In this study, one of the most widely used strengths assessment tools in social services is the Behavioral and Emotional Rating Scale-2 (BERS-2), which includes separate rating scales for youth, parents, and teachers. Although the three assessment forms are similar, a few items have been slightly worded to better reflect the views of Mongolian youth, parents, and teachers. The Interpersonal Strengths subscale (14 items) measures a child's ability to interact with others in social situations. Family involvement (10 items) assesses the child's relationship with the family. The internal self-efficacy subscale (11 items) focuses on how the child perceives his or her own functioning. The school functioning subscale (9 items) assesses the child's performance and abilities in school. The Power Influence subscale (7 items) measures a child's ability to exert and receive influence from others.
Results: The main results of the study are presented as follows.

1. Cronbach's alpha coefficient for test validity was 0.816.
2. Behavioral and emotional indicators of the surveyed teenagers are 34.56% on average.
3. In terms of self-esteem of teenagers, their behavioral and emotional indicators are 47.6% or average; parents - 33.3%; teachers are 29.6%.

Conclusions: it was observed that the superiority of emotions and attitudes is weak for middle class students. In other words, Mongolian children believe that it is necessary to develop emotional and behavioral strengths.

Parents' perception of auditory hypersensitivity in children with Autism Spectrum Disorder

C. J. S. Ribeiro[1], L. D. Bezerra[1] and C. A. D. L. H. Amato[1]*
[1]Universidade Presbiteriana Mackenzie, São Paulo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1100

Introduction: Autism is defined as a broad and complex neurodevelopmental disorder with alterations in behavioral and social communication aspects. Sensory symptoms also occur prevalently in autism spectrum disorder (ASD) and are present early in the etiology, however, little is known about the early developmental patterns of these symptoms (Mccormick *et al.* Autism 2016; 5 572-579). Among these various sensory-perceptual alterations, auditory hypersensitivity is a prevalent sensory alteration in the ASD population (Dunlop *et al.* Front Hum Neurosci 2016; 10 1-12), defined as excessive or abnormal sensitivity and distress to auditory stimuli that are evident in the individual's behavioral reactions (Stefanelli *et al.* CoDAS 2020; 32 1-9). Furthermore, auditory hypersensitivity can trigger atypical reactions that can impact social and academic domains (Danesh *et al. Audiol. Res 2021; 11* 547-556).
Objectives: This research aimed to identify the occurrence and describe the auditory hypersensitivity behaviors presented by children with Autism Spectrum Disorder.
Methods: This is a cross-sectional and descriptive study, composed of parents/guardians of 161 children diagnosed with ASD. The sample consisted of parents of children of both sexes, aged 4 to 12 years. Caregivers answered a sociodemographic form and reported on the presence or absence of auditory hypersensitivity and the behaviors presented by the child. The study was approved by the Ethics and Research Committee under opinion number: 5,862,943.
Results: 161 parents of children with ASD participated, who declared that 108 (67.1%) of the children had auditory hypersensitivity and 53 (32.9%) did not, with 83 (69.2%) of the children being male and 37 (30.8%) female. The most frequently reported behaviors were: difficulty sleeping (79.8%), difficulty concentrating (76.8%), put your hands over ears (74.8%), nervousness (74.6%), fatigue and stress (72%), and irritability (71.8%) in the presence of sound (Table 1).
Tabela 1. Comportamentos de hipersensibilidade auditiva na percepção de pais de crianças com TEA

Image 1:

Conclusions: The results suggest that there is a high prevalence of auditory hypersensitivity in children with autism spectrum disorder and that this symptom can have negative impacts on the individual's quality of life.

EPV0267

Functional language assessment in children with autism spectrum disorder in a Portuguese and English language context

L. D. Bezerra[1], C. J. S. Ribeiro[1] and C. A. D. L. H. Amato[1]*
[1]Universidade Presbiteriana Mackenzie, São Paulo, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1101

Introduction: Autism spectrum disorder (ASD) presents specific characteristics in child development. Behavioral and, mainly, communicative aspects are the most frequent for diagnostic closure (APA Artmed 2014; Asperger Archiv F. Psychiatrie 1944; 117 76-136). The absence, delay or difficulties in establishing expressive language are important social markers in early childhood, being one of the main reasons that lead families to seek therapeutic guidance (Amato USP 2006; Andrade UFPB 2017; Andrade Pró-Fono 2023). One of the aspects related to the communication of children with ASD is the interest in foreign languages, which manifests itself from early childhood (Avelar Universidade Presbiteriana Mackenzie 2018). The use of a foreign language for interpersonal communication presented spontaneously, by children with ASD, is something that needs to be evaluated within the functional aspects of social communication, since the major communicative difficulties faced are related to pragmatic aspects (Andrade Pró-Fono 2023; Balestro *et al.* Rev Soc Bras Fonoaudiol 2012; 17 279-86). The form and means of communication, length of permanence and communicative quality are fundamental elements to be analyzed when comparing expected child development to chronological age. In a research process involving humans, it makes perfect sense to anticipate and understand linguistic, cultural and educational differences, in order to avoid contextual and communicative variables that conflict with the proposed aims.
Objectives: The objective of this study is to evaluate the functional communication of children with ASD in Portuguese and English language contexts.
Methods: 16 children were selected, aged 42 to 72 months, without relatives and/or living with multilingual people. Samples were collected by recording spontaneous communication between patient and therapist in a natural intervention environment. 5-minute clips of greater interaction were made and, from these, the analyzes were carried out. This research has an opinion approved by the Ethics Committee, under number 6,890,786.
Results: Parents' perception of their children's communication difficulties were unanimously reported. Greater communicative ability was demonstrated in the Portuguese language, however, communicative ability and functionality was verified in the English language, without significant statistical differences when comparing the two languages. In the production of grammatical classes, there was greater production in the Portuguese language, with greater lexical production.

Image 1:

Conclusions: The children under observation and evaluation in this study showed satisfactory correlation and performance in the proposed tests. There was communicative performance, with results without significant statistical differences in the Functional Communication Profile in both languages. More studies will be needed to support these results.

Understanding Psychological Bullying in Tunisian Schools: Frequency and Determinants

R. Ayoub[1,2*], N. Maatallah[1], H. Ben Abid[1,2], A. Beji[1] and A. Guedria[1,2]

[1]Child and Adolescent Psychiatry Department, Fattouma Bourguiba university Hospital and [2]University of Monastir, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1102

Introduction: Psychological bullying in schools is a pervasive issue that affects the emotional and psychological well-being of countless children. This phenomenon often manifests as emotional abuse, leading to significant long-term consequences for victims.
Objectives: Determine the prevalence of psychological bullying in schools in the Sousse region and to describe its associated factors
Methods: This is a descriptive and analytical cross sectionnal study that took place in two middle schools and three public high schools in the Sousse region(Tunisia) among adolescents aged between 12 and 18. A pre-established data collection form enabled us to gather socio-demographic characteristics, personal history and bullying behaviours, drawing on questionnaires available in the scientific literature.
Results: Our study included 420 students with an average age of 15.63±1.87 years. The sex ratio was 0.98. More than half the students (58.1%) reported being victims of bullying. The rate of harassment was higher among girls (53.7%), although this difference was not statistically significant (P=0.063). The perpetrator was a friend in 89.8% of cases, and a teacher in 35.2%. The body or physical appearance was the object of harassment in more than half of the cases. We noted that 74.1% of students with a chronic illness reported having been victims of bullying, compared to only 55.5% of students with no medical history. This difference was statistically significant (p = 0.001; OR= 2.94). This phenomenon was also noted in 81.4% of students treated for psychiatric disorders, a rate significantly higher than that of students with no psychiatric history (p<10-3; OR= 3.47).Our results showed that harassment was reported by 78.13% of adolescents living with their fathers, compared to a significantly lower proportion among those living with their mothers (51.16%) and those living with both parents (56.7%) (p = 0.008).
Conclusions: Our study reveals a concerning prevalence of psychological bullying among adolescents, with over half of the participants reporting victimization. These results underscore the urgent need for targeted interventions and support systems to address bullying in schools, particularly for vulnerable populations.

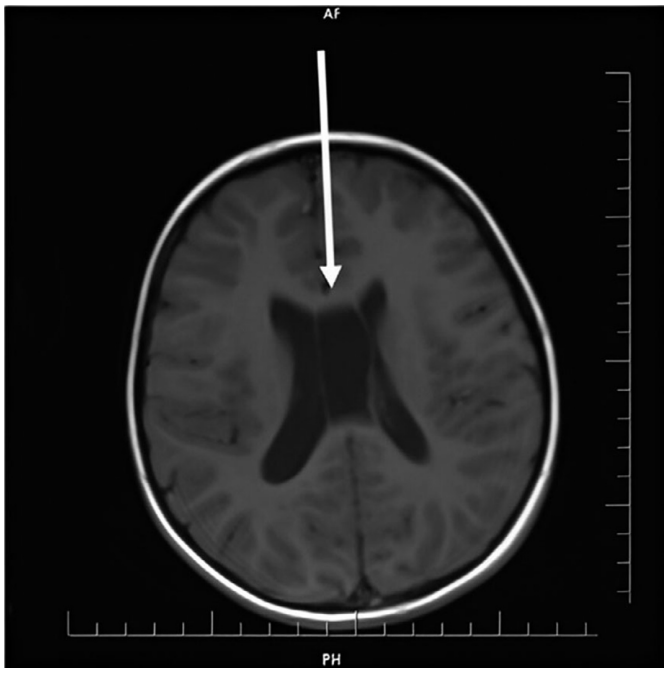
Cavum vergae in a patient with autism spectrum disorder



C. Azizagaoglu[1*], E. Dogan Elmas[1], F. O. Ciftci[1], O. Gulesen[2], F. Mavi[1] and S. Bodur[1]

[1]Child and Adolescent Psychiatry, Gülhane Training and Research Hospital, Ankara and [2]Child and Adolescent Psychiatry, Kirikkale Yuksek Ihtisas Hospital, Kirikkale, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1103

Introduction: A neurodevelopmental disorder known as autism spectrum disorder (ASD) affects approximately 1 in 54 children. It has a complex etiology, but little is known about its neurological and genetic basis. (Loomba *et al.*, 2021 Psychiatry Research:Neuroimaging, *313*, 111301.) The septum pellucidum is a part of the limbic system, which consists of two layers of gray and white matter and forms the medial walls of the lateral ventricles. A cavum septum pellucidum (CSP) is a septum pellucidum that has a division between its two layers. All fetuses have CSP, although around 85% fuse within three to six months after birth. The posterior expansion of the CSP is called the cavum vergae (CV). Up to 30% of neonates have this structure, although less than 1% of people have it in adulthood. (Landin-Romero *et al.*, 2015 Journal of Affective Disorders,186,53-57.)
Objectives: The aim of this study is to understand the relationship between ASD and CV.
Methods: The patient, seven year old, applied to clinic accompanied by his parents due to speech delay in January 2024. He was product of full-term delivery, born by caesarian section secondary to servical stenosis. His mother had servical bleeding in the 6th week of pregnancy which she had taken progesterone for several days.
Results: During our examination, he did not respond to his name every time, maintained eye contact for a short time, did not initiate communication most of the time, did not continue even if he initiated it, showed more interest in objects than people, had echolalia and dysprosody. Based on our evaluation, we diagnosed as ASD and referred for special education. Although most of his tests were normal, CV was reported in brain MRIs (Image1). Retaining the CSP or CV after birth may indicate abnormalities in the development of the brain. Co-occurrence of enlarged CSP and CV persistent into adulthood is less common, but it has also been associated with neurodevelopmental disorders, decreased mental status, psychosis and bipolar disorder. (Landin-Romero *et al.*,2015 Journal of Affective Disorders,186,53-57.) This case, based on the idea that CV is seen more frequently in

psychiatric diseases, supports the idea that neuroimaging findings that have emerged in recent years are changes in the neuroanatomical structure and brain connection of ASD.

Image 1:

Conclusions: Retaining the CSP or CV after birth may indicate abnormalities in the development of the brain. Isolated CV is rather unusual. Co-occurrence of enlarged CSP and CV persistent into adulthood is less common, but it has also been associated with neurodevelopmental disorders, decreased mental status, psychosis and bipolar disorder. (Landin-Romero *et al.,* 2015 Journal of Affective Disorders, 186, 53-57.) This case, based on the idea that CV is seen more frequently in psychiatric diseases, supports the idea that neuroimaging findings that have emerged in recent years are changes in the neuroanatomical structure and brain connection of ASD.

Comparing the risk factors related to intra-familial and extra-familial sexual abuse in cases that underwent medicolegal evaluation and prepared a report

F. Bayraktar[1]* and S. Aras[1]

[1]Child and Adolescent Psychiatry, Dokuz Eylul University Faculty of Medicine, İzmir, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1104

Introduction: Childhood sexual abuse, a serious issue for all societies, is a complex experience that requires many legal and professional initiatives(Odacı et al. Psikiyatride Güncel Yaklaşımlar,2023).It is a widespread, multidimensional problem worldwide, with physical, mental, social, moral, cultural, and legal aspects(İşeri et al. Çocuk ve Ergen Psikiyatrisi Temel Kitabı,2008).
Objectives: This study aimed to evaluate risk factors and medicolegal assessment results in children who were sexually abused.
Methods: The records of children who were victims of sexual abuse retrospectively reviewed at Dokuz Eylül University Faculty of Medicine, Department of Child and Adolescent Psychiatry, between January 2010 and December 2023.Sociodemographic, clinical, psychometric, and medicolegal evaluation data were analyzed.
Results: Of the 537 cases that underwent medicolegal evaluation, 80.3% were male and 19.7% were female.The mean age at the time of sexual abuse incident was significantly higher in females(12.5 ±3.4) than in males(9.8±3.4).Before the incident, 63.0% of cases had at least one psychiatric diagnosis(most commonly Mental Retardation or Developmental Delay(57.5%), MDD(5%), and Conduct Disorder(4.7%)).The period after the incident, 77.1% had at least one psychiatric diagnosis(most commonly PTSD (57.9%) and MDD(49.7%)), most of which occurred after the incident.22.7% of the cases were victims of incest, 77.3% were victims of extra-familial abuse.The most common abuser was the father in incest(7.1%) and a familiar person(neighbor, etc.) in extra-familial abuse(22.4%).51.4% of cases experienced simple sexual abuse, while 48.6% faced sexual penetration.In 42.7% of the cases, sexual abuse was first disclosed to family members. In incest victims, compared to cases of extra-familial sexual abuse; the rates of being female(86.9%-78.3%), having successful-average academic success(55.2%-43.3%), having normal-borderline intelligence (77.7%-67.7%), having an unemployed father(25.5%-16.2%), being subjected to simple sexual abuse(63.1%-48.0%), being subjected to sexual abuse by a single perpetrator(90.2%-81.2%), being subjected to repeated sexual abuse(69.7%-45.8%), living in a broken family (66.7%-38.9%), not having a psychiatric diagnosis before the incident(50.8%-34.2%), and withdrawing the abuse allegation/complaint (18.9%-6%) were statistically significantly higher.The age at the date of the incident was significantly younger(median:11-13), and the time taken to apply to judicial authorities (months) was significantly longer(median:18.5-12).Predictive variables of incest have also been evaluated using logistic regression analysis.
Conclusions: In this study, the findings found in cases that underwent medicolegal evaluation support the literature findings regarding risk factors for sexual abuse and the negative effects of sexual abuse on children and adolescents.

Adolescent motherhood: reflections based on a clinical case

H. Ben Mustapha[1]

[1]Essonne, Barthélemy Durand Public Health Establishment, Île-de-France , France
doi: 10.1192/j.eurpsy.2025.1105

Introduction: Adolescence and motherhood are transitional phases, moving from childhood to adulthood and from womanhood to motherhood. These processes involve significant psychological conflicts, where childhood narcissistic vulnerabilities risk being exposed.

Objectives: The study aims to describe the mother-infant bond and the management of adolescent motherhood. This case informs the psychopathological and therapeutic reflections throughout the study.
Methods: This study examines a clinical vignette of a 16-year-old adolescent followed in the Perinatal Department at Rouen University Hospital, alongside a literature review. Semi-structured interviews were conducted with the adolescent mother and her family from July 2019 to April 2020, covering sociodemographic data, pregnancy experiences and consequences, the adolescent's baby, the baby's father, and the adolescent's family. Written consent was obtained from the mother at the study's outset.
Results: The case involves M.D, a 16-year-old at 16 weeks gestation, is the youngest of two siblings and is in a relationship with a 25-year-old man. Her family history includes maternal depression, and her personal history includes ADHD with irregular follow-up, behavioral hospitalization at age 7, and a pregnancy termination in 2018. She was referred by a midwife due to challenges in envisioning her pregnancy. M.D. lives in a disrupted family dynamic marked by intrafamilial violence, conflicts with her brother, and repeated runaways. She was placed under social services following a report from her mother concerning behavioral issues. Her pregnancy was marked by anxiety over a potential forced termination, conflicts between adolescence and motherhood, and worries about childbirth. Motherhood posed additional challenges, such as infantile regression, irritability, impulsivity, difficulty caring for the baby, emotional immaturity, and ambivalence toward her pregnancy and motherhood. Her interactions and emotional attunement with the baby were inadequate. M.D. received multidisciplinary support (gynecologist, pediatrician, social worker, psychiatrist, child psychiatrist, psychologist, childcare provider) with extensive family and partner involvement. Improvements were noted in mother-infant bonding, reduced impulsivity, and decreased marital conflicts with Methylphenidate.
Conclusions: A collaborative care network is essential to support the bond between the adolescent mother and her child. The father's role can serve as a separating third party, facilitating the child's access to symbolic thinking. This role may also be filled temporarily by professionals who act as substitute third parties, supporting both the mother's and child's development.

Substance Abuse: A growing issue in adolescent population

M. N. Bogdanovic[1]*, S. Brozan[1], A. Kaštelan[1] and D. Petrić[1]
[1]CHC Rijeka, Rijeka, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1106

Introduction: Substance abuse among adolescents has risen significantly in recent years, with serious implications for mental health and development. Factors such as peer pressure, socioeconomic stress, and mental health issues contribute to this trend. Early substance use is linked to long-term risks, including substance use disorders and co-occurring psychiatric conditions. This study examines data from CHC Rijeka, highlighting trends in adolescent substance use over recent years, emphasizing the need for targeted prevention and treatment strategies.
Objectives: This study aims to analyze the number of adolescent patients having issues with drug abuse, who were hospitalized at the Adolescent Psychiatry ward in order to identify trends, assess associated risk factors.
Methods: We compared the numbers of hospitalized patients who were dignosed with substance abuse, as well as the percentages of those patients per year, from 2019 until 2024.
Results: From 2019 to 2024, the number of adolescents hospitalized for substance abuse at the Adolescent Psychiatry ward increased. In 2019, substance abuse was diagnosed in approximately 20% of all adolescent admissions, whereas by 2024, this figure had risen to 28%. This rise in the percentage of substance abuse diagnoses, relative to the total number of admissions, indicates a growing prevalence of substance use disorders among hospitalized adolescents. This trend mirrors broader national patterns of increasing adolescent substance use and underscores the urgent need for targeted prevention and intervention strategies, both in clinical settings and within the community.
Conclusions: The rising percentage of adolescents hospitalized for substance abuse highlights a critical public health issue. To address this, efforts should focus on early intervention, increasing access to mental health and substance use services, and implementing school-based prevention programs. Additionally, enhancing community support networks and reducing the stigma around substance abuse treatment are key to preventing further escalation of this growing trend.

EPV0277

Retarded Catatonia in a 16-Year-Old Male With Schizo-Obsessive Disorder

E. Bolat[1]*, E. Akçay[1] and E. ÇÖP[1]
[1]Child and Adolescent Psychiatry, Ankara Bilkent City Hospital, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1107

Introduction: Catatonia is a complex neuropsychiatric syndrome characterized by a range of motor, cognitive, affective, and autonomic disturbances. It is often associated with psychotic disorders, mood disorders, and pervasive developmental disorders in children. Despite its potential severity, catatonia can be effectively treated with timely intervention, including the use of benzodiazepines and electroconvulsive therapy (ECT). However, treating catatonia in the context of schizo-obsessive disorder presents significant challenges.
Objectives: The case highlights the importance of early diagnosis and intervention in managing catatonia, as well as the need for more ECT sessions in schizo-obsessive catatonia.
Methods: Clinical case report and brief literature review on schizo-obsessive catatonia was done. Informed consent from the patient's legal guardians was obtained.
Results: We present a case report of a 16-year-old male from Ankara, living with his family, who is a middle school graduate but could not start high school due to his disorder. He had been followed in our outpatient clinic with a diagnosis of Obsessive Compulsive Disorder for 4 years. The patient presented to the emergency department with agitation, disrobing, attempting to climb out of a window, and experiencing delusions. He was initially

diagnosed with psychosis and started on risperidone 1 mg and lorazepam 1 mg.
Five days later, during a follow-up, he exhibited non-compliance with commands, mutism, refusal to eat, and urinating in the living room for the past three days. Examination revealed no eye contact, no verbal communication, and a flexed arm posture, leading to a preliminary diagnosis of catatonia and hospital admission. Physical examination, blood tests, brain imaging, and EEG showed no pathological findings. No substances were detected in urine. Despite increasing lorazepam to 6 mg, catatonia symptoms persisted, leading to the initiation of ECT on the fifth day.
After 20 ECT sessions, catatonia symptoms and psychotic content improved, though obsessions persisted. He was diagnosed with schizo-obsessive disorder and treated with fluvoxamine 200 mg/day, olanzapine 10 mg/day, and clonazepam 4 mg/day, with maintenance ECT ongoing.
Conclusions: This case report highlights the complexity of schizo-obsessive catatonia and the necessity for a multifaceted diagnostic and therapeutic approach. The patient's journey from an initial diagnosis of Obsessive Compulsive Disorder to the emergence of psychotic and catatonic symptoms underscores the fluidity of psychiatric diagnoses. The significant improvement following multiple, longer ECT sessions underscores the therapy's potency, particularly in schizo-obsesive catatonia. This case underscores the importance of flexibility in psychiatric treatment, advocating for a tailored approach that evolves with the patient's symptoms.

EPV0278

The importance of screening for trauma symptoms in children and adolescents

T. Bollain Muñoz[1]*, I. Oliveira Amat[1], R. Crespo Rubio[1], J. Gomez Puebla[1], T. Gomez Escribano[1] and J. M. Martinez Avila[1]
[1]Psychiatry, HGUGM, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1108

Introduction: Children and adolescents frequently encounter a range of adverse childhood experiences (ACEs), which encompass various forms of adversity such as abuse, neglect, and household dysfunction. These experiences can have profound and lasting effects on an individual's health and well-being. Alarmingly, nearly three out of four children—approximately 300 million aged 2 to 4 years—are subjected to physical punishment and/or psychological violence by parents and caregivers. Moreover, statistics indicate that one in five women and one in thirteen men were sexually abused during their childhood (ages 0-17). Despite the widespread prevalence of these experiences, trauma in children often goes unrecognized. The nature of trauma can make it challenging for both the child and caregivers to identify and articulate trauma-related symptoms. Children may struggle to understand or express their experiences, and caregivers might misinterpret or overlook these signs, leading to underreporting and a lack of timely intervention.
Objectives: Experiencing adverse events during childhood or adolescence is particularly concerning because it can significantly disrupt normal developmental trajectories, affecting physical, emotional, and cognitive growth. During these formative years, the brain is highly plastic and sensitive to environmental influences, making it especially vulnerable to the effects of trauma and stress. Such exposure can result in long-term consequences, including a heightened risk of developing mental health disorders, behavioral issues, and challenges in academic and social settings.
In this context, early identification of children and adolescents who have faced adverse experiences is crucial. By providing appropriate support and resources early on, it is possible to foster resilience and promote more positive growth despite the challenges posed by early adversity.
Methods: Using tools like the Child PTSD Symptom Scale (CPSS), a widely recognized self-report instrument designed to assess the severity of post-traumatic stress disorder (PTSD) symptoms in children and adolescents aged 8 to 18, can be especially effective for identifying and evaluating the impact of trauma exposure in young individuals and facilitating early intervention.
Results: Research published by the National Institute of Mental Health (NIMH) indicates that early identification through screening can lead to timely interventions, significantly reducing the psychological harm associated with trauma exposure.
Conclusions: Research strongly supports the effectiveness of screening for trauma symptoms in children and adolescents, emphasizing its critical role in early detection, timely intervention, and the prevention of long-term negative outcomes. This proactive approach not only addresses the immediate psychological impact of trauma but also contributes to improved long-term well-being and quality of life for those affected.

EPV0279

A case for personalised medicine in a 17 year old patient with obsessive compulsive disorder

T. Bollain Muñoz[1], I. Oliveira Amat[1], R. Crespo Rubio[1], T. Gomez Escribano[1], J. Gomez Puebla[1]*, J. M. Martinez Avila[1] and J. J. Carballo Belloso[1]
[1]Psychiatry, HGUGM, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1109

Introduction: Pharmacogenomic testing is a cutting-edge precision medicine tool that analyzes genetic variations influencing drug metabolism. By assessing an individual's unique genetic profile, this testing enables the personalization of treatment strategies, improving therapeutic outcomes, and enhancing patient care. Integrating pharmacogenomic testing into clinical practice holds great promise for improving the efficiency and effectiveness of mental health care delivery. In this case, a 17-year-old patient presented with a severe case of obsessive-compulsive disorder showed no response to treatment with sertraline (250mg). Sertraline is metabolized into N-desmethylsertraline through multiple pathways, including CYP3A4, CYP2C19, CYP2B6, and other CYP enzymes, with pharmacokinetic studies identifying CYP2C19 as the primary metabolic pathway.
Objectives: The patient had a poor response to pharmacological treatments previosly used, our aim was to determine the possible involvement of patient specific responses to treatments based on his pharmacogenetic proffile.
Methods: A blood sample was submitted for pharmacogenetic testing. This analysis includes genes involved in the metabolism of sertraline (CYP2C19, CYP3A4, and, to a lesser extent, CYP2B6 and CYP2D6) as well as other pharmacogenes associated with the

metabolism and response to psychiatric medications, including HTR2A, OPRM1, COMT, and DRD2.

Results: Gene | Genotype | Inferred Phenotype

- **CYP2C19** | *1/*1 | Normal Metabolizer
- **CYP2B6** | *1/*1 | Normal Metabolizer
- **CYP2D6** | *3/*4 | Poor Metabolizer
- **CYP3A4** | *1/*1 | Normal Metabolizer
- **OPRM1** | AA | Normal Genotype
- **HTR2A** (rs7997012 A>G) | GG | Normal Genotype
- **HTR2A** (rs6311 G>A) | GA | Heterozygous
- **DRD2A** (rs1799732 G>-) | GG | Normal Genotype
- **DRD2A** (rs1799978 A>G) | TT | Normal Genotype

Conclusions: The patient did not exhibit clinically significant alterations in the metabolism of sertraline (CYP2C19, CYP3A4 and CYP2B6). However, the lack of response to treatment should be further investigated, factors such as potential drug interactions, and other variables including age, renal function, and liver function should be considered. In contrast, the patient has notable alterations in CYP2D6 and HTR2A, which could be important for guiding future treatment decisions. Variants in HTR2A can significantly influence a patient's response to antidepressants, particularly selective serotonin reuptake inhibitors (SSRIs), specific polymorphisms in HTR2A, such as rs7997012 and rs6311 have been associated with differences in treatment outcomes, side effects, and remission rates. Has a CYP2D6 poor metabolizer, this patient may be at risk for higher drug levels and increased side effects when taking medications such as venlafaxine, fluoxetine, paroxetine (SSRIs), haloperidol, and risperidone.

EPV0280

Collaborative interventions with law enforcement in the management of childhood trauma

T. Bollain Muñoz[1]*, I. Oliveira Amat[1], R. Crespo Rubio[1], T. Gomez Escribano[1], J. Gomez Puebla[1] and J. M. Martinez Avila[1]

[1]Psychiatry, HGUGM, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1110

Introduction: Studies indicate that approximately 50% to 70% of children will experience at least one adverse childhood event, such as abuse, neglect, household dysfunction, community violence, or natural disasters.

Yet, accutely traumatized children are rarely seen in outpatient clinics until months or even years later, often presenting with chronic symptoms or maladaptive behaviors. Exposure to adverse childhood experiences (ACEs) has been linked to a wide range of psychiatric disorders, including mood disorders, personality disorders, and substance abuse. Beyond mental health, ACEs have been correlated with higher rates of chronic medical conditions such as heart disease, metabolic disorders, and autoimmune diseases, as well as a reduced life expectancy. Furthermore, children who are abused are more likely to perpetuate abuse in adulthood, leading to a cycle of violence that spans generations. Given its widespread and long-lasting effects, childhood trauma is indeed a public health pandemic.

Objectives: Enhancing our response to and prevention ACEs requires a multisectoral approach.

Methods: One key approach is a collaborative response with law enforcement. Police officers have unique access to children at risk, but they often lack the specialized training to respond effectively. With appropriate training, law enforcement can serve as a critical bridge to mental health assessments for children and their families. The Child Development-Community Policing Program exemplifies such collaboration. This initiative, a partnership between the New Haven Department of Police Services and the Yale University Child Study Center, brings together police officers and mental health professionals for joint training, consultation, and support. This partnership enables them to provide direct, interdisciplinary intervention to children and families who are victims, witnesses, or perpetrators of violent crimes. Law enforcement can refer cases to the Child and Family Traumatic Stress Intervention (CFTSI), designed for the peritraumatic period.

Results: CFTSI focuses on enhancing the caregiver's understanding and response to both their own and their child's traumatic reactions. It also aims to improve the child's comprehension of their emotional responses. The intervention includes establishing strategies to address trauma responses and assessing pre-existing vulnerabilities to determine the need for long-term treatment. Studies have shown that CFTSI is effective in reducing post-traumatic stress symptoms in children and adolescents. A randomized controlled trial (RCT) published in *Child Abuse & Neglect* found that children who received CFTSI had significantly fewer post-traumatic stress symptoms compared to those who received standard care.

Conclusions: Early intervention like this can make a significant difference in the lives of affected children, helping to mitigate the long-term impact of trauma and promote healing and resilience.

Trajectories of adolescents admitted to the emergency department for suicidal behavior between 2019 and 2021: impact of the Covid-19 pandemic, descriptive analysis and predictive model development

A. Bounan[1]*, M. Cayla[1], H. Kerbage[1], N. Franc[1], E. Jeziorski[1] and D. Purper-Ouakil[1]

[1]Université de Montpellier, Montpellier, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1111

Introduction: Adolescent suicidal behaviors have seen a marked increase in incidence, particularly following the onset of the Covid-19 pandemic (Revet *et al.* Eur Child Adolesc Psychiatry 2023; 32 249–256). This surge has presented challenges for emergency and psychiatric services. It highlighted the need for improved understanding of predictive and protective factors linked to recurrent suicide attempts.

Objectives: This study aims to analyze the clinical trajectories of adolescents admitted to emergency departments for suicide attempts between 2019 and 2021 and to identify predictors of recurrence, with a particular focus on conditions that may elevate the risk of repeat attempts (Tomaszek *et al.* Front Psychiatry 2024).

Methods: We conducted a retrospective cohort study at the Montpellier University Hospital, examining pediatric emergency visits related to suicide attempts over three consecutive years (2019–2021). The dataset

included patient demographics, psychiatric diagnoses, treatments prescribed, and hospitalization metrics such as duration and readmission frequency. Statistical analyses employed a multivariate linear regression to identify significant predictors of recurrence.
Results: The incidence of emergency visits for adolescent suicide attempts rose elevenfold from 2019 to 2021, reflecting the global trends in mental health deterioration post-Covid-19 (Lespes-Hislen *et al.* 2023). Recurrence rates were notably higher among patients initially admitted in 2021, with 54% of these adolescents re-presenting for subsequent suicide attempts, indicating a persistent crisis in mental health among this demographic. The selected model identified ADHD diagnosis, the use of mood stabilizers, and prolonged hospitalization as significant predictors of recurrence. In the regression model, each additional day of hospitalization was associated with an estimated increase in recurrence risk of 0.16 additional attempts per 1-day of hospital stay.
Conclusions: This study confirms an increase in suicidal behaviors after the pandemic and highlights the importance of personalized care, especially for adolescents with ADHD. The association between hospitalization duration and recurrence raises questions about the effectiveness of prolonged hospital stays in this population.

EPV0282

Body Esteem among Tunisian adolescents: Prevalence and associated factors

N. E. Ayadi[1], S. Bourgou[1], A. Ben Hamouda[1], F. Charfi[1] and A. Ghenimi[2]*

[1]child and adolescent psychiatry department, University hospital Mongi Slim and [2]child and adolescent psychiatry department, Mongi Slim university Hospital, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1112

Introduction: Body esteem refers to an individual's self-evaluation of their own body or appearance. It plays a critical role in the psychosocial development of adolescents, who become increasingly aware of their bodies and how they are perceived by others.
Objectives: This study aims to examine the specificity of body esteem among Tunisian adolescents and its associated factors.
Methods: This cross-sectional study was conducted via a survey among adolescents attending middle and high schools during the 2023-2024 school year. Participants provided written consent and completed a demographic information sheet, the Body Esteem Scale for Adolescents and Adults (BESAA), and the Adverse Childhood Experiences-International Questionnaire (ACE-IQ).
Results: The study population consisted of 1,005 adolescents, with a sex ratio of 0.73 and a mean age of 14.62 years. We found that 88,1% of adolescents had high body esteem while 11,9% had low body esteem. We found that body esteem is statistically correlated with : low socioeconomic status (p=0,033, OR=0,58 (95%CI [0,35-0,94])), with the history of organix disease (p<0,001, OR=0,415 (95%[0,265-0,650])), with BMI measurements (p<0,001) specifically with obesity (p=0,014 , OR=0,497 (95%CI [0,292-0,846])). The findings suggested that selfie practice was significantly associated with body esteem (p=0,009, OR=1,819 (95% [1,18-2,8])) and that selfie posting on social media was statistically correlated to appearance esteem *with* p-value =0,027.
Additionally, we found that body esteem was directly and significantly associated with all the adverse childhood experiences except for collective violence. Detailed results are shown in the table below:

Adverse childhood experiences		Family relations	Neglect	Family dysfunction	Psychological abuse	Physical abuse	Sexual abuse	Peer violence	Community violence
Body Esteem	*p*	0,018	<0,001	<0,001	0,001	<0,001	0,001	<0,001	0,007
	OR (95% CI)	0,55 (0,34-0,89)	0,33 (0,22-0,5)	0,39 (0,26-0,6)	0,496 (0,32-0,77)	0,429 (0,28-0,64)	0,47 (0,3-0,73)	0,43 (0,27-0,7)	0,53 (0,33-0,84)

Conclusions: By understanding the associated factors of body esteem, this study contributes to a broader comprehension of adolescents' well-being and offers insights for creating a safer and more supportive environment for young people in our country.

Disclosure of Interest: None Declared

EPV0283

Developmental Coordination Disorder and Executive Function in Children with ADHD

L. R. R. Carreiro[1]*, S. M. Blascovi-Assis[1], A. G. Seabra[1], M. C. T. V. Teixeira[1] and M. Á. Muñoz[2]

[1]Universidade Presbiteriana Mackenzie, São Paulo, Brazil and [2]Universidad de Granada, Granada, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1113

Introduction: Developmental Coordination Disorder (DCD) is a motor skills disorder characterized by delayed motor development. It affects approximately 6% of school-aged children, limiting their ability to perform everyday tasks. DCD is often associated with Attention Deficit/Hyperactivity Disorder (ADHD) and executive functions prejudices, making it essential to conduct more detailed investigations.
Objectives: To explore potential correlations and trends between suspected DCD and behaviors related to inattention, hyperactivity, and impulsivity, as well as performance on tasks that involve attention, cognitive flexibility, and working memory.
Methods: The study utilized data from a protocol for ADHD assessment conducted at Mackenzie Center for Research in Childhood and Adolescence in São Paulo, Brazil, with approval from the Ethics Committee. The protocol consists of neuropsychological, behavioral and psychiatric assessments. For this study, the following tests were considered: Rey Complex Figure Test and the Five-Digit Test (FDT) to assess cognitive flexibility and memory, Psychological Battery for Attention (BPA) to assess attention, Total index of the ADHD questionnaire based on DSM-5 criteria (total items of greatest severity), and DCD Questionnaire for DCD assessment. Twelve children aged between 6 and 15 years, who were referred for evaluation due to complaints of inattention and hyperactivity, participated in this study. Pearson correlation analyses were performed between the DCDQ and the other collected data.
Results: The results revealed a significant positive correlation between the DCDQ and the Rey Complex Figure Test (r=0.840, p=0.009), suggesting that better motor performance is associated with improved planning and memory functions. There was also a

marginally significant correlation between the DCDQ and the BPA divided attention test (r=0.646, p=0.083), which engages working memory abilities. A marginally significant negative correlation was found between the DCDQ and the FDT cognitive flexibility test (r=-0.637, p=0.065), indicating that higher DCDQ scores were associated with shorter times to complete the test. A negative correlation was also observed for the most severe items of the ADHD questionnaire related to hyperactivity and impulsivity. However, inattention complaints did not correlate with the DCDQ scores.

Conclusions: Developmental coordination disorders should not be overlooked in studies and assessment protocols for children with suspected ADHD. Further investigations are needed to identify the domains and characteristics most closely associated with DCD. This will provide evidence to support the development of care programs and intervention strategies for these children.

Disclosure of Interest: None Declared

EPV0284

Evaluation of cognitive functions of children aged 8-18 years with acute leukemia 2 years after the end of treatment

S. ÇETİN[1]*, A. AKAY[1] and H. ÖREN[2]

[1]Child and Adolescent Psychiatry Department and [2]Pediatric Hematology Department, Dokuz Eylül University Faculty of Medicine, İZMİR, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1114

Introduction: Children with a history of acute leukemia may experience some deficits in their cognitive functions in the late period (Hewitt *et al.* Childhood Cancer Survivorship 2003).These deficits negatively affect their quality of life by impairing their academic, social and psychological functioning (Jacola *et al.* Lancet Psychiatry 2016; 3-10-965-972).

Objectives: The aim of this study was to compare the cognitive functions of children with a history of leukemia compared to their healthy peers.

Methods: Our study was conducted with 42 cases with a history of leukemia who were followed up in the Pediatric Hematology outpatient clinic of Dokuz Eylül University Faculty of Medicine and 41 healthy controls who were admitted to the Child and Adolescent Psychiatry outpatient clinic of Dokuz Eylül University Faculty of Medicine.After obtaining informed consent from both parents and participants, the Wisconsin Card Sorting Test (WCST), Stroop Test-TBAG form, Trail Making Test (TMT) A and B forms were administered to all participants.The parents of all participants were given a sociodemographic data form and the Childhood Behavior Checklist (CBCL) and asked to complete it. The teachers of all participants were given the Conner's Teacher's Rating Scale-Revised Long form (CTRS-RL) and asked to complete it.

Results: All sub-dimension CBCL scores of the case group were significantly higher than the control group (p<0.05).All sub-dimension CTRS scores of the case group were found to be significantly higher than the control group.The case group performed worse than healthy controls in WCST, Stroop-TBAG and Trail-Making Test. The mean Stroop2-time score was higher in the group that received cranial radiotherapy, whereas the Trail-Making-B-error score was higher in the group that did not.The group receiving the medium-high risk chemotherapy protocol performed worse overall on the Stroop test.Women in the case group performed worse on the WCST than men.Stroop5-error scores were higher in the group with a history of sequelae.It can be said that there is a negative correlation between age at diagnosis, age at the end of treatment and time elapsed after treatment and cognitive test performances.There was a moderate positive correlation between the duration of the treatment and the CBCL-attention problems score (r=0.348, p=0.024) and the CTRS-attention problems score (r=0.432, p=0.04).

Conclusions: In conclusion, it can be said that leukemia treatment may cause deficits in areas such as attention, memory, learning, processing speed, executive function and problem solving in the late period (Montour-Proulx *et al.* J Child Neurol 2005; 20 2 129-133). The difference in the severity of deficits in these areas between individuals can be explained by many biological, social and psychological factors (Duffner *et al.* J Pediatr Hematol Oncol 2014; 36 1 8-15).

EPV0287

Prevalence and correlates of suicide attempts in juvenile bipolar and major depressive disorders

L. Ciampoli[1], R. Abregú Crespo[2], E. Rodriguez Toscano[2], M. Ayora Rodriguez[2], R. Panadero Gómez[2], C. Ordás Díaz[2], A. Sánchez Cámara[2], L. Sevilla Cermeño[2], C. Llorente Sarabia[2] and C. Moreno Ruiz[2]*

[1]Child Neuropsychiatry Unit, IRCCS Institute of Neurological Sciences of Bologna, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy and [2]Department of Child and Adolescent Psychiatry, Institute of Psychiatry and Mental Health, Hospital General Universitario Gregorio Marañón, IiSGM, CIBERSAM, ISCIII, School of Medicine, Universidad Complutense, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1115

Introduction: Major depressive disorders (MDD) and bipolar disorders (BD) are strongly associated with suicide attempts in youth. However, little is known regarding the differences in prevalence and clinical-related features of suicide attempts between these two disorders.

Objectives: The study aimed to examine the prevalence of suicide attempts and related factors in children and adolescents with major mood disorders and compare clinical features between BD and MDD patients who attempted suicide.

Methods: A cross-sectional study was conducted at the Child and Adolescent Psychiatry Department of the Institute of Psychiatry and Mental Health Gregorio Marañón. Patients with diagnosis of major mood disorder were included. All patients were evaluated with K-SADS, CGI (Clinical Global Impression), HDRS (Hamilton Depression Rating scale), YMRS (Young Mania Rating Scale), Conners Rating Scale and CGAS (Children's Global Assessment Scale). Bivariate analysis was conducted to compare patients with and without suicide attempts and BD versus MDD attempters. Subsequently, a multivariate analysis was performed to assess the combined influence of suicide attempts related factors.

Results: The sample included 145 patients (58 males, 87 females) aged 7 to 17 years (mean 15.15), with diagnosis of BD (55.2%) and MDD (44.8%). The prevalence of suicide attempts for MDD and BD were 58.5 % and 28.8 %, respectively (p< 0.001). 56,5 % of BD attempters reported medically serious suicide attempts versus 28.9% of MDD (p=0.03). 61 patients with suicide attempts were compared to 84 patients without suicide attempts. Suicide attempts were associated with female sex (p<0.001), internalizing disorders (p= 0.003), hopelessness (p=0.001), higher punctuation on HDRS score (p=0.03), suicidal ideation (p<0.001) and NSSI (p<0.001). In the multivariate analysis, it was found that female sex (p<0.001), suicidal ideation (p<0.001) and hopelessness (p=0.048) were independently related to suicide attempts. Comparing suicide attempters with BD versus MDD, BD patients showed higher impulsivity (p=0.04) and a more alcohol use proportion (p=0.04) than MDD patients.
Conclusions: Female sex, suicidal ideation and hopelessness are strongly related to suicide attempts in youth with major mood disorder. The findings revealed some differences between BD and MDD for patients with suicide attempts and accentuate the need for early identification of BD and accurate differentiation between BD and MDD in children and adolescents, to treat them adequately and minimize suicidal behaviors.

Disclosure of Interest: None Declared

EPV0288

Relationship Between Chronotype, Sleep Disorders, and Temperament in Adolescents with Attention Deficit Hyperactivity Disorder

I. Cihanyurdu Erdem[1]* and A. T. Bahadır[1]

[1]Child and Adolescent Psychiatry, Marmara University Faculty of Medicine, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1116

Introduction: Studies focusing on the relationship between chronotype, sleep disorders and temperament traits in Attention-Deficit/Hyperactivity Disorder (ADHD) are limited, particularly in the context of adolescents. In adolescents aged 11 to 18 diagnosed with ADHD, we hypothesize that chronotype, sleep problems, and temperament traits may be dynamically interrelated across a broad spectrum. Conducting in-depth studies to examine these relationships could enhance our understanding of ADHD treatment and management strategies, potentially leading to more effective interventions.
Objectives: We aimed to explore the relationship between chronotype characteristics, sleep disturbances, and temperament traits among adolescents diagnosed with ADHD and to compare them with healthy controls.
Methods: Participants included 102 adolescents aged 11 to 18 years with an ADHD diagnosis from the Child and Adolescent Psychiatry outpatient clinic at Marmara University Pendik Training and Research Hospital, along with 101 age-matched controls from a secondary and a high school. Clinical assessments were conducted using the K-SADS-PL. Parents completed the Sleep Disturbance Scale for Children and Children's Chronotype Questionnaire while adolescents completed the Junior Temperament and Character Inventory Revised. These assesments evaluated chronotype characteristics, sleep disturbances, and temperament traits.
Results: Adolescents with ADHD demonstrated significantly higher rates of sleep disturbances and delayed chronotype compared to the controls. Additionally, adolescents with ADHD exhibited significantly higher levels of novelty seeking and harm avoidance scores, while the control group exhibited higher levels of persistence and self-directedness compared to the ADHD group. In the ADHD group, chronotype total score correlated negatively with self-directedness (r=-0.201, p=0.042) and reward dependence (r=-0.199, p=0.045). Novelty seeking was pronounced in those with an evening chronotype and positively correlated with severe sleep disturbances, including difficulties initiating and maintaining sleep (r=0.210, p=0.034). Logistic regression analyses indicated that novelty seeking significantly predicted evening chronotype, while linear regression revealed that both novelty seeking and chronotype scores significantly predicted overall sleep disturbance severity. (R2=0.112, p=0.006).
Conclusions: This study represents one of the initial investigations emphasizing the intricate relationships between chronotype characteristics, sleep disturbances, and temperament traits in adolescents diagnosed with ADHD. More profoundly underscoring these relationships and their clinical significance could be crucial for targeted interventions to improve ADHD management.

Investigation of Factors and Psychological Diagnoses Associated with Cyberbullying/Victimization in Adolescents Applying to Child Psychiatry Clinic

I. D. Çimen[1], A. M. Benk Ayaz[2], M. Dilli Gürkan[3]*, Z. Vatansever Pınar[4], B. Kardaş[1] and Ö. Kardaş[1]

[1]Kocaeli University, Kocaeli; [2]Tokat Dr. Cevdet Aykan Mental Health Hospital, Tokat; [3]Bandırma Research and Training Hospital, Balıkesir and [4]Freelancer, istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1117

Introduction: The emergence of the internet and social media has not only changed the way people communicate, but has also brought with it a new type of bullying: cyberbullying. This type of bullying causes negative effects on the quality of life of individuals, especially adolescents and young adults, and becomes a serious problem for their mental health.
Objectives: The aim of our study was to examine various factors that may be related to cyberbullying in adolescents applying to child psychiatry outpatient clinics and the psychiatric diagnoses of adolescents.
Methods: A total of 174 patients aged 14-18 years who applied to the Department of Child Psychiatry and gave their consent to participate, were included in the study. The Cyberbullying Scale was applied to the youth, and the sociodemographic data form, cyberbullying study questions were applied to their parents.
Results: The average age of the group was found to be 15.60±1.15. 122 (70%) participants were female and 52 (30%) participants were male. Of the 174 adolescents included in the study, 61 (35%) were found to be cybervictims, 29 (17%) were found to be cyberbullies, and 25 (14%) were found to be both victims and bullies. Cyber victimization was found to be significantly related to broken family type, mother's exposure to cyberbullying on the internet, father's internet usage time, and father's exposure to cyberbullying on the internet. Cyberbullying was found to be significantly related to male

gender, father's low level of education, divorce, and mother's and father's internet usage time being between 0-1 hour/day. When the diagnoses of the patients were examined, 39 (22%) adolescents were diagnosed with neurodevelopmental disorders, 37 (21%) adolescents with mood disorders, and 68 (39%) adolescents with anxiety disorders. When the diagnosis groups were examined and the status of being a cyberbully or cybervictim, no significant difference was found in any diagnosis group. No significant relationship was observed between the adolescent's diagnosis of any mental disorder and being a cyberbully or victim.

Conclusions: Cyberbullying is not an issue to be taken lightly, and because it often co-occurs with traditional bullying, prevention and intervention programs need to address both contexts. In our study, it was determined that the majority of cyber victims were also cyberbullies. This situation shows the importance of evaluating bullying situations even though adolescents apply as victims in the clinic interviews. The results suggest that parents do not have enough knowledge about safe internet use and cannot control and guide their children properly. Therefore, during clinical interviews, cyberbullying/victimization issues should be discussed with mothers and fathers and how they can provide information to their children on this issue and safe internet use should be discussed.

Is there a connection between Mental Health issues and poverty? A service evaluation in East Norfolk and Suffolk, UK

D. Collins[1] and J. Beezhold[2]*

[1]CFYP, NHS, Norwich and [2]CYFP, NSFT, Great Yarmouth, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1118

Introduction: It is well established that living, or growing up, in poverty has a negative impact on both physical and mental health. The area our service covers includes Great Yarmouth and Lowestoft, 2 of the most economically impoverished areas of the UK. The vast majority of our patient group will have grown up in relative poverty. While there are associations between poverty and impaired physical health and increased risk of some mental health conditions, the actual causal link is unclear.

Objectives: To explore if there appears to be a link between growing up in poverty and developing a significant mental illness.

Methods: Data anlaysis from Consultant caseload list.

We do know that there are some factors associated with both poverty and increased risk of mental illness and these include;

- Parental drug or alcohol abuse
- Parental mental health problems (if these are not well managed)
- Early/premature death of a parent
- Exposure to domestic violence
- Physical abuse
- Going into the Care System
- Early drug or alcohol use
- Early separation or loss of a parent

Results: Findings

Total number of patients = 122

Number who have a specific factor associated with poverty =56

This equates to 46% of my current caseload.

Gender =35 female (62.5), male 21 (37.5%)

Conclusions: Summary of Findings – "*The poor bear the greatest burden of mental illness" (2)*

This would certainly seem to be the case, from the findings of this service evaluation. Our findings show that a significant percentage of our patient group have mental health issues directly related to poverty.

It is worth noting that the vast majority of my patient case load grew up in poverty, due the demographics of the area we work in (a quick analysis suggests about 97% of my case load are from working class, impoverished backgrounds). We abandoned recording "parental unemployment" in this analysis, because for all but a few, this was the case. Unemployment is an entrenched issue in this area, with the demise of the shipping and offshore industries, currently standing at 5.4% in Yarmouth and 3.5% in Lowestoft (3) (National average 3.8%). For those that are employed, poverty is a significant issue with many in low paid jobs. I have also not included here factors associated with poverty, such as poor diet, smoking, malnutrition, poor dentition, and obesity, but we know these are the case for many patients seen here.

Affective, Behavioural, and Cognitive Disorders (ABCD) of Childhood and Adolescence: Renaming and Regrouping

S. Das[1]*, S. Ghosh[2], S. S. Bhandari[3] and M. N. Tripathi[4]

[1]Psychiatry, Dhubri Medical College & Hospital, Dhubri; [2]Psychiatry, Assam Medical College & Hospital, Dibrugarh; [3]Psychiatry, Sikkim Manipal Institute of Medical Sciences, Sikkim Manipal University, Gangtok and [4]Psychiatry, Tripathi Clinic, Varanasi, India

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1119

Introduction: Psychiatry focuses on disorders of affect, behavior, and cognition (ABC), with half of all psychiatric disorders emerging by age 14 and three-quarters by age 24. Disorders are categorized into four types: Type 1 (affective disorders like depression and anxiety), Type 2 (behavioral disorders like ADHD and ODD), Type 3 (developmental disorders like mental retardation and speech/language issues), and Type 4 (dysfunctional disorders, including psychotic illnesses and mood disorders). These categories—emotional, behavioral, cognitive, and dysfunctional—form the ABCD framework in child psychiatry.

Objectives: The study aimed to categorize childhood and adolescent mental and behavioral disorders into four groups: developmental, disruptive, emotional, and dysfunctional. It also sought to examine intra- and inter-group comorbidities, and analyze the clinical variables of these groups and their comorbidities by age and sex.

Methods: This was an observational cross-sectional study conducted at Gauhati Medical College Hospital (GMCH), Guwahati, Assam, from September 7, 2018, to September 6, 2019. Existing diagnostic systems do not distinguish between child/adolescent and adult mental health, and there is a lack of a unified "common language" for childhood and adolescent mental and behavioral disorders. The study aimed to address this gap, particularly in the

local geo-cultural context, where data for a new classificatory system is scarce. Participants included children and adolescents admitted to the Child Psychiatry Unit or attending the Child Guidance Clinic. Demographic (age, sex) and clinical variables (ICD-10 diagnoses) were studied, with diagnoses categorized into types 1–4.
Results: Total sample size was 137. Adolescents (ten to 18 years of age) were almost double in numbers to that of children (below ten years of age). Boys outnumbered girls. Adolescents were more than children in both among girls and boys (even the single third gender was an adolescent). Most of the children and adolescents were having type 3 disorders, followed by type 1 and type 2 disorders. While majority had type 3 disorders below ten years of age (children), type 1 disorders were highest in the adolescents. Type 1 and type 3 disorders were almost equally distributed among girls, while boys predominantly had type 3 disorders. Within group comorbidity was maximum with type 3 disorders. Across group comorbidity was found mostly in type 2-type 3 disorders.
Conclusions: John Lennon "imagined" of having no countries and no religion too; thus, there will be nothing to kill and die for! Bono of U2 wanted to be there "where the streets have no name"! Likewise, we too dream of a land for child and adolescent psychiatry where if we cannot live without names then let us at least have a few and simple ones: ABCD!

EPV0292

Obsessive-compulsive disorder in a child with poor tolerance to psychotropic drugs, the efficacy of psychotherapy

M. De La Fuente[1]*, L. Cayon[1], M. Ruiz[1], P. Llano[1], M. Polo[1], R. Obeso[1], M. Hoyuelos[1], P. Hernandez[1], C. Sevilla[1], J. Romay[1], I. Ibarra[1], J. Posada[1] and M. Martinez[1]

[1]HUMV, Santander, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1120

Introduction: Obsessive-compulsive disorder (OCD) in children and adolescents presents similarly to that in adults, but with some particularities. In children, the most common obsessions are usually related to fears of contamination, harm to others, or catastrophic situations. The compulsions associated are often: excessive hand washing, repetitive checking, and the need for order. Treatment of OCD is based on both pharmacological measures and psychological therapies. At the pharmacological level, it focuses on the use of selective serotonin reuptake inhibitors (SSRIs). In terms of psychological treatment, cognitive behavioural therapy (CBT) is the psychotherapeutic intervention of first choice for the treatment of OCD, and is considered the most effective intervention, both in monotherapy and in combination with pharmacological treatment. Within CBT, the most effective is Exposure with Response Prevention (ERP).
Objectives: To present the adaptation of the different therapeutic interventions so that they are effective when applied to children, through a clinical case of a 10-year-old child with OCD.
Methods: Our patient first came to the emergency department due to intense anxiety, secondary to obsessive thoughts about suicide and sexual identity. Due to the incoercible anguish caused by these egodystonic thoughts and the secondary low mood, he was admitted to hospital. At the pharmacological level, sertraline was progressively administered up to a dose of 100mg/day and psychoeducation was provided. Despite the initial improvement in anxiety and hospital discharge, after a couple of weeks there was a further worsening, which persisted despite increasing the dose of sertraline. In successive outpatient consultations, psychoeducational intervention and review of confrontation techniques were carried out. The patient began with clinical symptoms typical of hypomanic turn, so SSRIs was lowered back to the initial dose, and aripiprazole 5mg was added. The importance of CBT was emphasised, teaching the parents to practice it daily with their child. In the next visits, psychotherapy work continued in the form of role-play, explaining the difference between distraction and confrontation, lowering the SSRI to 50mg and maintaining aripiprazole. Clinical stabilisation was achieved and has been maintained since.
Results: We see with this case that pharmacological treatment, although necessary to obtain changes at the neuro-biological level, is not sufficient for clinical remission, and that intensive psychotherapy is the cornerstone of the intervention
Conclusions: In conclusion, in the treatment of childhood OCD, the combination of pharmacological and psychological interventions is essential. Although pharmacological treatment is important, it alone does not always guarantee complete remission, highlighting the need for a comprehensive therapeutic approach to achieve sustained results over time.

Scaling A Positive Parenting Intervention from an Institutional Service to the Community Practice: A Qualitative Study of Net PAMA Classroom's Success Factors and Challenges

Q. Dejatiwongse Na Ayudhya[1]*, C. Pornnoppadol[1], S. Chanpen[1] and W. Musikaphan[2]

[1]Psychiatry, Siriraj Hospital, Mahidol University, Bangkok and [2]Institution for Population and Social Research, Mahidol University, Nakhonprathom, Thailand
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1121

Introduction: Mental health issues in children and adolescents are often influenced by ineffective parenting strategies such as poor communication, harsh punishments, lack of positive reinforcement, and imbalance between relationship and regulation. Although effective parenting interventions exist, access is typically limited to institutional services. Net PAMA, an internet-based parent management training program, was created to improve access. However, only city-dwelling, educated parents were able to effectively learn from the platform. A combination of local facilitators and the internet-based program, called 'Net PAMA Classroom', was then proposed as means to reach out to underserved communities.
Objectives: This study examines the success factors and challenges of 'Net PAMA Classroom,' a community-based Parent Management Training intervention conducted by non-professional facilitators, with the use of the internet-based standardized program.
Methods: We interviewed fifteen Net PAMA Classroom facilitators. We then performed data triangulation and thematic analysis using Braun and Clarke's six-step approach.

Results: Three key themes were identified: curriculum, facilitators, and classroom management. Participants valued the practical skills provided through structured lessons. Successful facilitators had backgrounds in child and family work, prior facilitation experience, and supported parents in applying new skills. Support from community leaders significantly impacted the program's initiation, delivery, and sustainability. Recommendations include making the curriculum culturally relevant, flexible, and less internet-dependent. Addressing propriety issues is also crucial for the program's long-term success.
Conclusions: The Net PAMA Classroom's effectiveness relies on a robust curriculum, experienced facilitators, and effective classroom management. Enhancing cultural relevance and flexibility, reducing internet reliance, community support, and resolving propriety concerns are essential for sustainability and scalability.

Descriptive study of the number and duration of physical restraints placed in patientes admitted to an adolescent psychiatric unit from 2020 to 2023

P. Del Sol[1]*, L. Mallol[1], A. Izquierdo[1], R. Fernández[2], M. García Moreno[1], M. Crespo[1] and M. I. Palanca[1]

[1]Hospital Puerta de Hierro, Madrid and [2]Hospital Infanta Cristina, Parla, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1122

Introduction: The management of situations of behavioral dyscontrol is essential in hospitalization units. Strategies such as verbal or pharmacological restraint are the first steps to assist in the emotional regulation of a patient with a potentially escalating state of restlessness. In cases where this fails or is not possible, and there is a risk to the patient or others, physical restraints are a strategy for managing the agitated state. The Adolescent Short Stay Unit at Puerta de Hierro Hospital consists of 11 beds. The age of admission is 12 to 17 years.
Objectives: To present data on the number of physical restraints placed in the Adolescent Brief Hospitalization Unit and the average time of placement from 2020 to 2023. The results from 2024 will be presented in the poster of this abstract.
Methods: Physical restraint data were reviewed through patient records and the physical restraint registry that is part of the unit's protocol.
Results: During **2020**, physical restraints were placed on 8.7% of the patients admitted that year (21 of 240). In that year, a total of 110 physical restraints were placed for a total of 707.73 hours and an average of 7.06 hours. During the year **2021**, 13.3% required physical restraint (30 of 2236). In that year 89 physical restraints were placed for a total of 470.25 hours and an average of 5.35 hours. In **2022**, 6.4% of the patients admitted required physical restraint (15 of 236), 11 of whom were women. In that year a total of 100 physical restraints were placed with a total of 457 hours and an average of 4.57. It should be noted that that year, of the 100 restraints, 52 were on the same patient, with 19 restraints on the second patient requiring the most restraints. In **2023**, 8.2% of patients required mechanical restraint (19 of 229), 14 of whom were women. A total of 169 restraints were placed for a total of 402 hours and an average time of 2.37 hours. This year, 2023, of the 169 restraints, 106 are on the same patient. From January to August **2024** restraints were applied to 10 patient. A total of 58 restraints were placed, with one patient requiring up to 30 restraints.
It should be noted that the patients who require the most physical restraints are patients with a diagnosis of autism spectrum disorder or patients with intellectual disabilities.
Conclusions: A decrease in the average restraint time has been observed(7.06 to 2.37), which we believe is due to greater training on the part of the nursing team. Patients with Autism Spectrum Disorder and patients with Intellectual Disability are those who have received more physical restraint, suggesting that their management requires a structure and intervention different from those offered by the short hospitalization units.

EPV0297

Mental health in children and young people with psoriasis. A comorbidity to consider

M. Del Valle Martín[1]*, D. Velilla Antolin[2] and N. Román Avezuela[3]

[1]Psiquiatría, Hospital Universitario Severo Ochoa, Leganés; [2]Pediatría, Hospital Universitario Rey Juan Carlos, Móstoles and [3]Psiquiatría, Clínica San Miguel, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1123

Introduction: Children and adolescents with chronic cutaneous conditions are at risk of experiencing adverse psychosocial effects such as anxiety, depression, and loneliness. Children with psoriasis had significantly higher rates of any psychiatric disorder, but these are often unrecognised or under-recognised and not referred to mental health services. It is also clear that the well-being of these children's families may also be impacted by their child's condition.
Objectives: The aim of this study was to review current knowledge of the comorbidity of psoriasis and psychiatric disorders in the paediatric population, which are often underdiagnosed and undertreated.
Methods: A narrative literature review was carried out in the PubMed, Cochrane and Embase databases, selecting only the articles published in the last 10 years, using the following keywords: psoriasis, psychiatric disorders, paediatric population.
Results: There is no doubt that psoriasis is one of the most debilitating chronic dermatological conditions affecting children from a quality-of-life perspective. Indeed, numerous studies have demonstrated that its impact is on par with that of other chronic conditions such as diabetes, asthma or epilepsy. Current research generally supports a positive association between paediatric psoriasis and the onset of anxiety and depression. However, it is difficult to establish a causal relationship as there is some evidence that psoriasis and psychiatric illness can exacerbate each other. Children with psoriasis had significantly higher rates of any psychiatric condition, particularly depression and suicidal ideation. Patients with higher disease severity (Psoriasis Area and Severity Index (PASI) and Body Surface Area (BSA) scores) and longer disease duration, are undoubtedly more likely to experience worse anxiety and depression. They may have other psychiatric comorbidities, such as excoriation (skin picking) disorder or obsessive-compulsive disorder (OCD), resulting in body-focused repetitive behaviours that exacerbate psoriatic plaques.
Paediatric patients with psoriasis appear to be more vulnerable to the psychosocial effects of their disease than adults, especially those

diagnosed at a younger age, who had poorer lifetime outcomes due to less robust coping skills compared to other children. Young children may also not be able to understand or express their emotions associated with psoriasis, which is a significant barrier to conducting research. There is little research on supportive treatment, but psychological support (group or individual) during appointments has been reported positively by patients.
Conclusions: It is essential to consider the psychosocial impact of this particular pathology on children and their families, in order to improve their quality of life through a better understanding of their conditions and the implementation of interventions that help to mitigate these effects.

Disclosure of Interest: None Declared

EPV0298

The Impact of Social Media on Adolescent Body Image: A Comprehensive Review

M. Demetriou[1]*, V. Anagnostopoulou[1], V. Markatis[1], M. Peyioti[2] and P. Argitis[1]

[1]Psychiatry Department, General Hospital of Corfu, Corfu and [2]University General Hospital of Alexandroupolis, Alexandroupolis, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1124

Introduction: Social media has become a powerful influence on adolescent body image. Platforms like Instagram and TikTok, which focus on appearance, often promote idealized body standards, leading young users to internalize unrealistic beauty ideals. This has resulted in increasing body dissatisfaction and negative mental health outcomes, as adolescents seek validation through likes and comments.
Objectives: This review examines how social media exposure affects body image and emotional wellbeing in adolescents, particularly whether it contributes to negative outcomes like low self-esteem, body dissatisfaction, and mental health issues.
Methods: A review of international studies published in the last five years was conducted using PubMed and Google Scholar. Search terms included "social media," "body image dissatisfaction," "mental health," and "adolescents." A total of 26 studies that met the criteria were analyzed.
Keywords: social media, body image dissatisfaction, adolescents, mental health, eating disorders, self-esteem, COVID-19
Results: The studies consistently revealed a strong link between frequent social media use and negative body image. Both male and female adolescents reported increased body dissatisfaction, though most studies focused on females. Social media exposure was also linked to higher risks of eating disorders and a drive for thinness. Frequent users of appearance-focused platforms experienced reduced self-esteem and heightened levels of anxiety and depression, with social comparison behavior worsening these effects. Adolescents' body image was further influenced by peer and parental validation, with peer approval playing a critical role in shaping their self-perception. The negative impacts of social media were particularly exacerbated during the COVID-19 lockdown due to increased isolation.
Conclusions: Social media platforms centered on appearance have a significant negative impact on adolescents' body image and mental health. These findings highlight the need for interventions promoting media literacy, critical social media engagement, and support from parents and educators to mitigate these effects.

Should genetic screening be conducted for autism spectrum disorder?A case report of a 20 months old child

E. Dogan Elmas*, C. Azizagaoglu, F. O. Ciftci and S. Bodur

Child and Adolescent Pscyhiatry, Gülhane Training and Research Hospital, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1125

Introduction: Autism spectrum disorder(ASD) is a developmental disorder that includes social communication challenges, restricted interests, repetitive behaviors, and intellectual incapacity. The specific etiology of ASD is unknown. However, it is thought to be a combination of genetic and environmental factors. ASD has been linked to copy number variation (CNV), which alters chromosome structure at the submicroscopic level. 16p11.2 deletion is one of the most commonly documented cytogenetic causes of ASD, with an estimated incidence of 0.5% among ASD patients. (Ju et al. 2021; Frontiers in cellular neuroscience, 15, 718720.)
Objectives: We investigated to explain the hereditary characteristics of a case of ASD that included intellectual disability and dysmorphic facial traits.
Methods: Our patient is 20 months old and applied to our clinic accompanied by his parents due to speech delay and with the story of forgetting a few words he had learned around 1 year old. When we evaluate it from a developmental perspective, he held his head at the 10th month, babbled at the 8th month, sat without support 13 the month, crawled at the 15th month, walked at the 17th month, said his first words at the age of one, but he has regression history around 1 year and 4 months old, and not completed his toilet training yet. At 18 months old, a genetic screening was conducted due to brachycephalic facial structure, prominent forehead ridge and protrusion in the frontal area, mild midface hypoplasia, hypertelorism (interocular distance of 2.9 cm), slightly slanted eye sockets, synophrys, anteverted nostrils, a small nose with a deeply set nasal bridge, mild prognathism, and deeply set, posteriorly rotated ears. The genetic screening revealed a 597.84 kb microdeletion in the short arm of chromosome 16(16p11.2) through CGH array analysis
Results: During our examinations, it was observed that the child is generally passive, does not sufficiently use verbal and non-verbal communication, has inadequate eye contact, and responds inconsistently to their name. Based on the developmental tests and our evaluation, the child was found to be significantly behind in developmental milestones, leading to a consideration of autism and cognitive delay. It was recommended that the child begin special education.
Conclusions: The deletion of 16p11.2 may lead to developmental disorders and poor socio-cognitive performance by disrupting long-range prefrontal synchronization. This is supported by ASD-associated CNV and impaired macroscale connectivity. (Bertero et al. 2018; Brain, 141(7), 2055-2065) Deletions of 16q11.2 are associated with higher rates of psychopathology relative to familial controls, emphasizing the need for early identification,

diagnosis, and intervention (Niarchou et al,2019; Translational psychiatry; 9(1), 8)

Prevalence of PTSD and anxiety among internally displaced Sudanese children in during war in Al Jabalain White Nile state, Sudan, 2024

E. A. BABIKER, E. A. EISA*, M. M. MOHAMED AHMED, S. A. IBRAHIM and A. A. AHMED

Medicine, Alneelain University, KHARTOUM, Sudan
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1126

Introduction: Sudan is currently experiencing the largest child displacement crisis worldwide. Since the conflict erupted in 2023, over 4.6 million children have been internally displaced within Sudan, and nearly one million are seeking refugee in neighboring countries (UNICEF, 2023). The mental health of these children has been overlooked, and there is a noticeable lack of data on their psychological wellbeing.
Objectives: To assess the prevalence of PTSD, anxiety and factors associated with them among internally displaced Sudanese children during war in IDP camps in Al Jabalain district, White Nile state, Sudan, 2024
Methods: A cross-sectional study was conducted among internally displaced Sudanese children in 11 camps in Al Jabablain district. Children were interviewed using a standerdised questionnaire consisting of the PTSD Civilian Checklist Version 5 abracic version and the Hamilton Scale arabic version to assess the prevalence of PTSD and anxiety. Data analysis was conducted using IBM® SPSS, version 26.0.
Results: The sample included 223 children; age median was 12 years (IQR: 9-15). 127 (57%) of them were females, with majority 128 (57.4%) in primary school. Participants who met the criteria for probable PTSD were 23 (14.3%), (median: 32, IQR: 17-28). 150 (67.3%) participants had mild anxiety, with a median score of 11 (IQR: 9-14). Older children had higher levels of PTSD and anxiety. Also, both scales were significantly associated with gender, displacement frequency and separation from close ones (p value <0.05). Females were more likely suffer from anxiety 116/127(91%) in comparison to males 76/96(79%). Yet, 19(59.4%) of children with probable PTSD were males. Children displaced more than four times were more prone to PTSD symptoms and moderate to severe anxiety. Interestingly, recently displaced children were more likely to have higher PTSD scores and lower anxiety scores. Educational level was significantly associated with PTSD, with about one-third of high school students experienced PTSD symptoms. Anxiety scale was significantly associated with direct exposure to violence, as 13.6% of those exposed to violence experienced mild to moderate anxiety.
Conclusions: This study identified significant levels of PTSD and anxiety among internally displaced children in the Al Jableen camps, highlighting the urgent need for mental health interventions, which promotes resilience and coping skills. Factors such as age, gender, frequency of displacement, direct exposure to violence, and educational level significantly impact the development of these mental health conditions.

Which Patients Benefit Most from Intensive Treatment in a Day Hospital for Children and Adolescents?

I. Ezquiaga Bravo[1]*, A. Vilar Garcés[1], C. Pérez Lucero[1], N. Sampayo[1], K. M. Malone[1], I. Tomás[1], C. R. Santana[1], M. Biempica[1], L. M. Martín[1] and S. Batlle Vila[1]

Institut de Salut Mental (ISM), Hospital del Mar, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1127

Introduction: Day hospitals for children and adolescents (DHCA) have experienced a notable increase in demand in the past few years, requiring an exploration of factors that predict treatment outcomes.
Objectives: This study aims to investigate whether all patients derive equal benefit from intensive treatment in a day hospital or if diagnostic orientation and pre-admission severity influence therapeutic efficacy.
Methods: A retrospective pre-post admission study was conducted involving adolescents treated at the DHCA Litoral Mar in Barcelona between January 2022 and December 2023. The analysis focused on the association between clinical and functional improvement, as measured by the CGAS and HoNOSCA scales, and diagnostic orientation and clinical severity, indicated by the history of suicide attempts and prior admissions. Non-parametric tests, specifically Spearman's correlation coefficient and the Kruskal-Wallis test, were used.
Results: The study sample comprised 64 patients, with a mean age of 17.72 years (SD 1.39) and 70.3% female representation. The average length of stay was 130.64 days (SD 43.92). While no statistically significant differences in clinical improvement were observed across diagnoses, patients with psychotic disorders demonstrated the most substantial improvement, followed by those with behavioral disorders, emotional regulation difficulties, and mood disorders. More modest improvements were noted for anxiety disorders and autism spectrum disorders (ASD). A statistically significant positive correlation was identified between the number of previous suicide attempts and improvement on the HoNOSCA scale (p=0.002), with no significant correlation found with previous admissions.
Conclusions: The findings indicate that severe patients benefit most from intensive treatment in day hospitals, while a specific diagnosis is not a clear predictor for outcomes, probably due to the small sample size. These results underscore the importance of considering clinical severity and patient history to optimize treatment effectiveness in intensive care settings.

Importance of revising a psychiatric diagnosis over time in children with neurodevelopmental disorders: a case report of a girl with Asperger's syndrome and intellectual disability

M. Fazlovic[1]* and N. Zigic[2]

[1]Department of Psychiatry, Public Health Institution "Health Center Brčko" Hospital, Brčko and [2]Department of Psychiatry, University Clinical Center, Tuzla, Bosnia and Herzegovina
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1128

Introduction: Autistic spectrum disorders belong to the group of neurodevelopmental disorders, where the manifestations of the disorder differ depending on the severity of the autistic condition. These disorders are often associated with intellectual impairments and structural language disorders. In his patients, Asperger described cases with above-average intelligence as well as cases with low language and intellectual abilities. What they had in common was that they had significant disorders in social and affective communication. The diagnosis of autism spectrum disorders is usually made in childhood, but there are also cases where the diagnosis is made at an older age due to the later manifestation of symptoms.
Objectives: To present a case report of 18 years old girl who was diagnosed with moderate intellectual disability in childhood, while later established with symptoms of Asperger's syndrome and mild intellectual disability.
Methods: Psychiatric interview, medical history, psychological testing
Results: An 18-year-old girl, accompanied by her mother, presented herself to psychiatrist for the first time due to affective disorders that manifested in the form of increased nervousness and outbursts of anger. Early psychomotor development was slow, she started walking at the age of 1.5 years and spoke at the age of two. From early childhood, stereotypies in movements and hypervigilant attention were observed, along with very poor social interactions. Due to difficulties at school, she was categorized at the age of 12 as having moderate intellectual insufficiency and IQ of 35. She underwent long-term speech therapy treatment and finished elementary and high school with the help of teaching assistant. Somewhere in high school, the patient's pronounced talent for drawing was noticed. Observation during the psychiatric examination reveals emotional immaturity, stereotypes and rigidity in social interactions. The patient is referred again for psychological testing, results show IQ of 88 with a lag in emotional development and development of basic social skills. The patient is referred to another psychiatrist for an additional opinion, who agrees with diagnose of Asperger's syndrome. Low dose of lamotrigine was included in therapy, after which affective state stabilized. The patient is referred again for categorization.
Conclusions: This case report that a diagnosis established in childhood period does not have to be definitive and that revision of diagnosis is necessary over time and as necessary, initially due to increase of patient's IQ, as well as due to the later presentation of symptoms characteristic of certain disorder.

"Digital self-harm" as a double-edged sword: a case study

C. García Cerdán[1]*, M. Ligero Argudo[1], I. M. Peso Navarro[1], I. Rodríguez Blanco[1], C. Munaiz Cossio[1], B. Refoyo Matellán[1] and P. Salas Aranda[1]

[1]Psychiatry, University Clinical Hospital of Salamanca, SALAMANCA, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1129

Introduction: Digital self-harm refers to the use of information and communication technologies (ICTs) to post or share self-deprecating or harmful content. This often occurs on forums or social networks, where the use of verbal and non-verbal codes (hashtags, emojis) complicates external monitoring. The rise in ICT usage and self-destructive behaviors online has raised concerns among mental health and education professionals, as these actions are linked to conditions such as depression, anxiety, and traditional physical self-harm in young populations.
Objectives: To explore the phenomenon of digital self-harm and its effects on adolescents.
To examine the role of AI tools in addressing this issue through a clinical case.
Methods: A brief literature review on digital self-harm.
Analysis of a clinical case: A 15-year-old female with a history of multiple hospitalizations due to suicidal risk and self-harming behaviors. Under treatment with Venlafaxine and Aripiprazole, she is diagnosed with "emotion dysregulation disorder of adolescence" and "mixed adaptive disorder." Her social interactions are mostly limited to online networks. She describes her self-harm as "addictive," used not only as an anxiolytic but as a way to achieve "social positioning," posting about it in forums and comparing herself with others. When she reported her self-harm impulse to an AI (artificial intelligence) chatbot for suicide prevention, emergency services were activated, leading to her hospital admission.
Results: International studies indicate that between 6% and 9% of adolescents have engaged in digital self-harm behaviors. In Spain, reports from the ANAR Foundation and UNICEF have shown an increase in this phenomenon since the Covid-19 pandemic. These "online support communities" can foster dynamics of rivalry and become harmful, as they not only share images but also techniques to avoid detection or hospitalization. In the presented case, the patient's initial isolation led her to use ICTs as a way to seek social affirmation and a sense of belonging. Upon encountering specific forums, self-harm, which initially served an anxiolytic function, evolved into a mechanism for achieving social relevance. On the other hand, the AI chatbot for suicide prevention facilitated early intervention in her case.
Conclusions: While the internet can provide social support for isolated adolescents, it also has the potential to normalize and even reinforce self-harming behaviors among vulnerable populations. Therefore, it is crucial to further investigate the psychosocial factors involved in digital self-harm and to develop new tools for mental health professionals. Additionally, AI could serve as an entry point and tool for younger generations, offering potential for both prevention and therapeutic intervention.

Cost-effectiveness study of a home-based mental health hospitalization program for children and adolescents: study protocol

I. Garcia Del Castillo[1], L. Heredia Castro[1], L. Caraballo Romero[1], A. Ortiz Villalobos[1], N. Fernandez Gomez[1], C. Cañadas[2], N. García[3], J. Andreo-Jover[4,5], T. Alonso[4,5], A. Gaona[4,5], A. Moreno Perez[2] and M. F. Bravo Ortiz[1,4,5]*

[1]Psychiatry, La Paz University Hospital, Madrid; [2]Psychiatry, Principe de Asturias University Hospital, Alcala de Henares; [3]Psychiatry, Principe de Asturias University Hospital; [4]Psychiatry, Universidad Autonoma de Madrid and [5]Psychiatry, Hospital La Paz Institute for Health Research , Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1130

Introduction: Psychiatric hospitalization to manage acute symptoms of mental disorders in children and adolescents may be necessary, although there is a growing concern about the clinical and economic effectiveness of psychiatric admission in this population. This suggests the need for the implementation of new intensive family and community care models that would reduce hospitalization.
Home hospitalization provides an opportunity to offer the child or adolescent with intensive treatment within the infrastructure of their home and the supervision of their family or primary caregivers. It therefore requires fewer resources than traditional inpatient treatment while allowing the patient‘s immediate environment to be involved in the treatment, potentially reducing the risk of a failed transition to the home once the patient is discharged.
Objectives: The main objective is to analyze the cost-effectiveness of two Mental Health Home Hospitalization interventions for adolescents as an alternative to traditional hospitalization in two hospitals in Madrid, Spain (La Paz University Hospital and Principe de Asturias University Hospital).
Methods: This is a quasi-experimental pre-post intervention study that examines two models of Mental Health Home Hospitalization as an alternative to full hospitalization. It will analyze various outcome variables, including clinical, functioning, satisfaction, quality of life, and costs /use of clinical resources.
Results: Participants must be adolescents and young adults aged 12 to 18 years (inclusive), who present a psychiatric decompensation requiring an intensity of care similar to that provided in the hospital. Assessments, including CGI, HoNOSCA, C-SSRS, CSQ-8, EQ-5D-Y, will be conducted at the baseline visit, and at the end of the treatment. Resource use and costs will be recorded at the baseline and six months after the treatment.
Conclusions: Home-based mental health hospitalization for adolescents is an emerging area of interest in the treatment of acute symptoms of mental disorders in this population, but there are not standard protocols for such interventions. Several issues remain to be clarified, including the care pathways for adolescents in crisis who require hospital care and whether organizational differences between interventions impact the outcomes.

Evolution and Therapeutic Approaches in Adolescents Hospitalized in a Psychiatric Unit : A 12-Month Study

A. Gharbia, D. Mezri*, S. Boudriga, G. Ouertani, U. Ouali, A. Aissa and R. Jomli

Avicenne, Razi hospital, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1131

Introduction: As mental health challenges among adolescents continue to rise, hospitalized Adolescents in psychiatric units often face complex and evolving challenge.A lot of current research aims to optimize treatment strategies for this vulnerable population.
Objectives: This study aims to explore evolution and therapeutic approaches of adolescents hospitalized for the first time in the psychiatric department.
Methods: It’s a retrospective and descriptive study covering the files of patients who consulted the Avicenna Psychiatry department of Razi hospital aged under 19, during the year 2023.
The collection of anamnestic and clinical data was established using a pre-established form.
Results: Our study included 24 patients aged between 16 and 18 years, with a mean age of 17 years, comprising 13 males and 11 females.
Patient follow-up in our service was regular in 58.33% of cases, while 20.83% of patients were lost to follow-up.
Psychotherapy was recommended in most cases, and medication was prescribed in 100% of cases, with only 58.3% adhering to the treatment. Relapse with rehospitalization was observed in 45.8% of cases, with a range of 1 to 35 readmissions. Parents of these patients were cooperative and receptive to the care in 62.5% of cases, while 12.5% of parents remained rejecting.
Clinical outcomes showed improvement in 33.3% of cases and worsening of symptoms in 45.8% of cases.
Conclusions: Early and individualized therapeutic planning, in collaboration with family and social services can play a crucial role in preventing future hospitalization.

Disclosure of Interest: None Declared

Clinical Aspects of Adolescents Hospitalized in a Psychiatric Unit: A 12-Month Study

A. Gharbia[1], D. Mezri[1], S. Boudriga[1], R. Hosni[1], U. Ouali[1], A. Aissa[1]* and R. Jomli[1]

[1]Avicenne, Razi hospital, Mannouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1132

Introduction: The World Health Organization (WHO) defines adolescence as the developmental stage between childhood and adulthood, spanning ages 10 to 19. This period is characterized by significant physical, cognitive, and psychosocial growth.
Objectives: This study aims to understand the clinical profile of adolescents hospitalized for the first time in the psychiatric department.
Methods:

- It’s a retrospective and descriptive study covering the files of patients who consulted the Avicenna Psychiatry department of Razi hospital aged under 18, during the year 2023.

- The collection of anamnestic and clinical data was established using a pre-established form

Results: Our study included 24 patients aged between 16 and 18 years, with a mean age of 17 years, comprising 13 males and 11 females.

Patients presented voluntarily in 42% of cases, were brought in by law enforcement in 25%, and were referred by a private psychiatrist in 17% of cases. The reasons for consultation were as follows: behavioral disturbances in 63% of cases, a suicide attempt in 21%, and incoherent statements in 8% of cases. 60% of cases used medication ingestion as the method during the suicide attempt. A family history of psychiatric disorders was found in 50% of cases, as well as a family history of suicide attempts in 13% of cases. Additionally, 71% of cases had prior follow-up with a private psychiatrist, 21%of cases had previously attempted suicide, and 33%of cases had personal somatic histories.

The onset of disturbances was progressive in 71% of patients. Upon hospitalization, anxious symptoms were noted in 25% of cases, while depressive symptoms with suicidal ideation were recorded in 29% of patients. hallucinations and delusions were noted in 50% of cases, and behavioral eccentricity was observed in 25% of cases. Instinctual disorders were present in 75% of cases, with sleep disturbances observed in 71%of cases, sexual disorders in 25%of cases, and appetite disorders in 13 %of cases.

Verbal hetero-aggression was identified in 83% of cases, while physical hetero-aggression was noted in 67%of cases. Self-harming behaviors were recorded in 48% of patients.

The diagnoses made according to DSM-5 criteria were distributed as follows: bipolar disorder in 29% of cases, schizophrenia in 17%of cases, and 13%of cases related to a life stage.

Conclusions: Adolescent psychiatric hospitalizations are rising, emphasizing the need to understand clinical characteristics of this population. This study analyzes clinical aspects of adolescents admitted to a psychiatric unit over one year. The findings aim to enhance treatment strategies and patient outcomes.

Treatment of Catatonia Associated with Xp11.22 Duplication Syndrome and Comorbid Autism Spectrum Disorder: A Case Report

C. J. Gideon[1]* and V. Lindegaard[1]

[1]Michigan State University/Pine Rest, Grand Rapids, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1133

Introduction: Xp11.22 duplication syndrome, a rare genetic condition first identified in 2009, has fewer than 100 documented cases in the literature. To date, little is known about the genotype-phenotype relationship in this rare genetic syndrome and there is a paucity of data specifically regarding catatonia in this condition.

Objectives: The primary aim of this case report is to provide a comprehensive description of the clinical presentation, diagnostic approach, and management strategies employed in a case of catatonia occurring in the context of Xp11.22 duplication syndrome and ASD.

Methods: Methods of this case report include assessment of the patient via thorough psychiatric and medical evaluation, as well as additional information obtained through chart review and collateral sources.

Results: Our patient, a 15-year-old Caucasian male, was diagnosed with Xp11.22 duplication syndrome at age 3 due to speech and motor delays. At 14, he experienced sudden behavioral and motor changes, including withdrawal, repetitive speech, slowed gait, and repetitive motor behaviors like “rewind” actions. Over 3 months, symptoms included emotional lability, self-injurious behaviors, and significant disruption to daily functioning. Outpatient management with olanzapine and quetiapine worsened agitation. Referred to a specialist, he was started on lorazepam up to 12 mg daily for suspected catatonia. ECT was considered, but further workup ruled out seizure disorder and autoimmune encephalitis. Pediatric neurology found no alternative etiology and recommended ECT. On admission, BFCRS score was 14, showing catatonic symptoms like automatic obedience, mutism, and immobility. Lorazepam was reduced to 2 mg three times daily, and amantadine 100 mg twice daily was continued. An acute ECT course of 12 bilateral treatments over four weeks reduced catatonic symptoms, improving mutism, motor speed, and daily activities. During a 56-day hospitalization, he received 7 maintenance treatments. Upon discharge, BFCRS decreased to 7, and he continued lorazepam and amantadine.

Conclusions: This case report underscores the complexity of managing catatonia in patients with Xp11.22 duplication syndrome and ASD, highlighting the potential need for multimodal treatment approaches. The significant improvement observed with the addition of ECT to the treatment regimen emphasizes the importance of considering this option in cases of refractory catatonia, even in patients with complex genetic and neurodevelopmental backgrounds. This case raises important questions about the underlying neurobiological mechanisms of catatonia in the context of Xp11.22 duplication syndrome and ASD.

The impact of institutionalization and adoption on ADHD diagnosed children

T. M. Gómez Lezcano[1]*, C. Fernandez Natal[1], P. Campos Abraham[1], M. M. Gonzalvo Navarro[1], M. B. San José[1], M. V. Sánchez[1] and M. García López[1]

[1]Psychiatry Department, Hospital Del Henares, Coslada, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1134

Introduction: Adoption is a process which aspires to protect the children and provide them a secure home. Nevertheless these minors present very often in their new environment a wide range of different difficulties, that enhances them to adapt in their personal and academic spaces. ADHD is one of the most prevalent neurodevelopment diseases among adopted children (Mulas et al., 2016; Doom et al., 2016).

Objectives: The objective of this review is to shed light on the association between ADHD and adoption.

Methods: A literature review has been carried out of scientific studies on the prevalence and risk factors for developing ADHD among adopted children from different countries of origin. Systematic reviews of papers and studies on new developments in the etiology of ADHD were also consulted.

Results: The prevalence of ADHD in adopted children is estimated to be around 25-50% (Mulas et al., 2013; Enriquezet. al., 2017). However, this percentage varies considerably depending on the origin of the children (Eastern Europe (de Maat et al., 2018), versus China (van Ginkel et al. 2016)). However, adopted children are more easily referred to a mental health specialist, as a consequence of the fact that adoptive parents are often particularly focused on the adaptation of these children (Sánchez et al., 2012).
The postnatal environment of adopted and institutionalized childrenchildren is often marked physical, emotional, sexual or other types of abuse (Doom et al., 2016). The quality of these orphanages and foster homes contributes to the lack of stimuli that children should receive in the first 2 to 3 years of life (Mullas et al., 2015). Consequently, this social and emotional deprivation among adopted children has been related to attachment disorders and ADHD (Elovainio et al., 2015).
On the other hand, other pre- and perinatal risk factors that influence the etiology of this disorder are especially prevalent in adopted children: premature birth, low birth weight and exposure to alcohol during pregnancy (Macke et al., 2020).
The role of culture as a possible protective factor is supported by research, with immigrants showing lower rates of ADD than adopted children of the same age range (Tan et al., 2016).
Finally, early foster care in adoptive families and the promotion of family bonding and appropriate parenting strategies can help adopted children improve their regulatory skills and other typical ADHD symptoms (Barca et al.,2017).
Conclusions: The deprivation of affective care and the lacking opportunity to establish a relationship with a main caregiver experienced by institutionalized children can lead to the expression of this disease in genetically predisposed individuals. These fenomenon reveals the importance of connection to family and culture to promote better mental health.

Disclosure of Interest: None Declared

EPV0311

Autism Spectrum Disorder and Comorbid Eating Disorders: Case Presentation of a 14-Year-Old Male with Carotenemia

J. González Benito[1]*, D. Durán López[1] and C. Delgado Torres[1]
[1]Psiquiatría, Servicio Canario de Salud, Santa Cruz de Tenerife, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1135

Introduction: Atypical eating behaviors are more common in children and adolescents with Autism Spectrum Disorder (ASD) compared with neurotypical development. Cognitive inflexibility in ASD can result in rigid food-related rules and preoccupation with eating, similar to Eating Disorders (ED). Several studies have focused on cataloging these atypical eating behaviors, such as Zickgraf H. et al. (2019). [Figure 1].
Objectives: Case presentation attended at the outpatient clinic of the Hospital Universitario Nuestra Señora de Candelaria (Tenerife). Literature review on atypical eating behaviors in ASD patients and their comorbidity with EDs.
Methods: A 14-year-old male, with no prior mental health history, showed normal social and academic adaptation but had a notable deficit in social smiling and persistent food texture rejection. He lives with his mother and has a close relationship with his paternal uncle, a personal trainer and role model.
He was referred to mental health services after multiple episodes of agitation, triggered by disruptions in his eating and exercise routines. Over the past year, he developed an intense focus on physical training practicing calisthenics several times a day, in addition to rejecting high-calorie foods, opting for vegetables (carrots and pumpkins). A conversation with soccer teammates, where comments about his body were made, may have acted as a trigger.
Results: Physical Examination: Yellowish skin pigmentation, particularly on palms and nasolabial folds, not affecting sclera.BMI: 21.7.
Mental Status Examination: Aprosodic speech, limited eye contact. Marked rigidity with daily routines; severe anxiety when disrupted. Irritability related to eating and exercise. Food restriction focused on fruits and vegetables (carrots, pumpkins); interest in "being healthier" (muscle gain, fat loss).No purging or binge eating behaviors.
Psychometric Tests: ASSQ, ASAS, WISC-R suggest Autism Spectrum Disorder, Level 1, with average intellectual functioning.
Differential Diagnosis: Biochemical tests ruled out jaundice, liver disease, hypothyroidism, and diabetes. Diagnosis of carotenemia made by exclusion.
Diagnostic Interviews (EDI-III):Symptoms consistent with Avoidant/Restrictive Food Intake Disorder (ARFID).

Image 1:

Figure 1. Mayes S. D., Zickgraf H. (2019). Atypical eating behaviors in children and adolescents with autism, ADHD, other disorders, and typical development. Research in Autism Spectrum Disorders, 64, 76–83.
*Peculiar patterns of eating like rituals around food or selecting food by particular criteria (brand, color...)

Image 2:

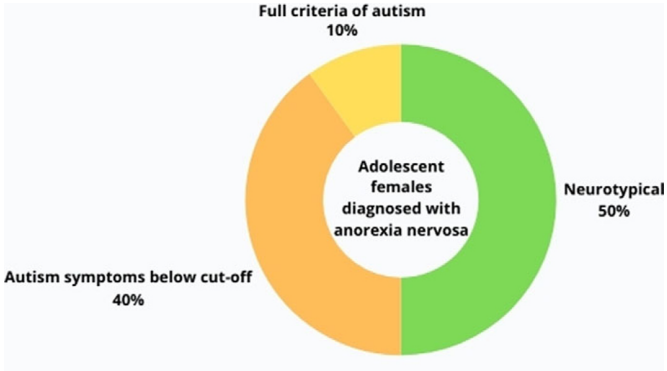

Figure 2. Westwood H., Mandy W., Simic M., Tchanturia K. (2018). Assessing ASD in adolescent females with anorexia nervosa using clinical and developmental measures: A preliminary investigation. Journal of Abnormal Child Psychology, 46(1), 183-192.

Image 3:

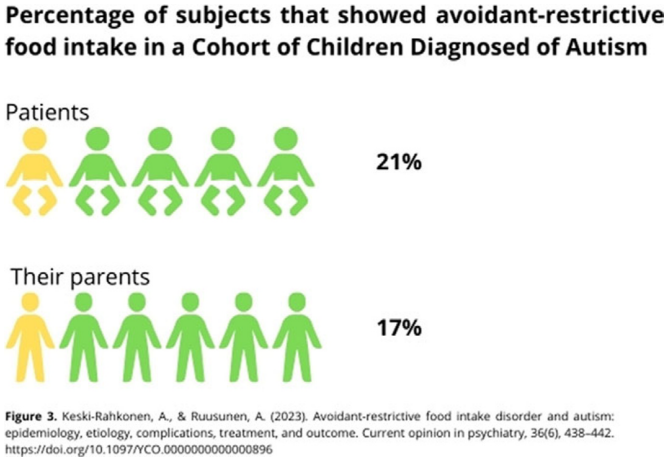

Figure 3. Keski-Rahkonen, A., & Ruusunen, A. (2023). Avoidant-restrictive food intake disorder and autism: epidemiology, etiology, complications, treatment, and outcome. Current opinion in psychiatry, 36(6), 438–442. https://doi.org/10.1097/YCO.0000000000000896

Conclusions: The relationship between ASDs and EDs is common. Brede et al. (2020) proposed that certain autism traits, such as sensory sensitivities, social difficulties, identity issues, and the need for control, may contribute to restrictive eating behaviors. Westwood et al. (2018) [Figure 2] found a high prevalence of autism symptoms in adolescents with severe anorexia nervosa. Additionally, studies like Keski-Rahkonen et al. (2023) [Figure 3] report a significant prevalence of Avoidant/Restrictive Food Intake Disorder (ARFID) in individuals with ASD and their relatives. Further research is crucial to improve treatment approaches for these comorbid conditions.

Disclosure of Interest: None Declared

EPV0312

Characterizing the 16p12.2 Microdeletion and Its Association with Psychotic Disorders: A Genetic and Clinical Perspective

R. González Núñez[1]*, L. Mallol Castaño[1], R. Albillos Pérez[1], A. Castelao Escobar[1], C. Alguacil Núñez[1] and P. Sanz Sánchez[1]

[1]Hospital Universitario Puerta de Hierro, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1136

Introduction: This report presents a case involving a patient diagnosed with a 16p12.2 microdeletion and associated psychotic symptoms.
Objectives: Throughout the course of this case, we will develop a deeper understanding of the symptoms associated with this chromosomal anomaly.
Methods: The case is described below: A 15-year-old woman was admitted to the psychiatric unit at Puerta de Hierro Hospital due to behavioral disturbances. The patient was born with plagiocephaly, experienced learning difficulties, and has a documented history of a 16p12.2 microdeletion, epilepsy, and obesity. Her first contact with mental health services occurred in 2017 due to disruptive behaviors, and she began treatment with risperidone. Her condition worsened in 2020, leading to three hospital admissions and treatment changes, including aripiprazole, clozapine, and paliperidone, under the diagnosis of an unspecified psychotic disorder related to the 16p12.2 microdeletion. Currently, she is on sertraline (200 mg), paliperidone (12 mg), and valproic acid (600 mg).
The patient lives with her parents and twin sister, who has the 16p12.2 microdeletion and schizophrenia. Recently, she has shown increased irritability, heteroaggressiveness, insomnia, and difficulties with emotional regulation. The diagnosis is behavioral disturbances in the context of the 16p12.2 microdeletion.
Results: Upon admission, the valproic acid dosage was increased to 900 mg, and olanzapine 2.5 mg was introduced. This was accompanied by therapy and a structured environment. The result was progressively more syntonic behavior and an improved capacity for self-regulation.
Conclusions: Most genomic disorders result from non-allelic homologous recombination (NAHR) between segmental duplications. The clinical presentation of the 16p12.2 microdeletion is highly heterogeneous and includes developmental and growth delays, craniofacial anomalies, epilepsy, sleep disorders, learning difficulties, hypotonia, cardiac malformations, and psychiatric and behavioral disturbances. Diagnosis is established through chromosomal microarray analysis or other genomic tests. Treatment is directed at addressing the specific problems identified.

ADHD symptoms among school-age children in Monastir (Tunisia): A cross-sectional study

A. Guedria[1]*, N. Maatallah[1], R. Ayoub[1], A. Beji[1], T. Brahim[1] and H. Ben Abid[1]

[1]Child and adolescent Psychiatry, Fattouma Bourguiba university Hospital- University of Monastir, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1137

Introduction: Attention deficit disorder with or without hyperactivity (ADHD) is a neurodevelopmental disorder. It represents the most common psychiatric disorder in pediatric population. Children with ADHD can experience academic and social difficulties, as well as psychological complications.
Objectives: The objective was to determine the prevalence rate and the clinical profile of children with ADHD symptoms in the governorate of Monastir (Tunisia) and to study the comorbid symptoms.
Methods: We carried out a cross-sectional study, applying the Strengths and Difficulties Questionnaire (SDQ) scale and the short versions of Conners 3 to parents and teachers of 435 school children in a sample of 18 public and private schools randomly selected from 6 delegations in the governorate of Monastir.
Results: The prevalence of ADHD symptoms was 12% of which 51.9% were boys and 48.1% were girls. The average age was 9.8 [9.2;10.4] years.
We found a predominance of the inattentive form with a frequency of 57.7% compared to the impulsive-hyperactive and combined forms which have a frequency of 17.3% and 25% respectively.
In 40% of the ADHD group, an emotional disorder was found, and in 54% of cases there were behavioral disorders, with a statistically significant difference. Relationship problems rise to 74%, but with no statistically significant difference.

Conclusions: The prevalence of ADHD symptoms in the governorate of Monastir is similar to the rate found in other parts of the world. Identifying predisposing factors helps early intervention, which in turn reduces the psychosocial impact of this disorder.

Cyberbullying in the Digital Age: Prevalence and Associated Factors

A. Guedria[1,2*], N. Maatallah[1], R. Ayoub[1,2], A. Riahi[1] and K. Faidi[1]

[1]Child and Adolescent Psychiatry Departement , Fattouma Bourguiba Hospital and [2]University of Monastir, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1138

Introduction: Cyberbullying has emerged as a significant concern in today's digital age, particularly among adolescents. As technology becomes increasingly integrated into daily life, the prevalence of online harassment has risen, impacting the mental health and well-being of students.
Objectives: This study aims to explore the prevalence of cyberbullying among Tunisian schoolchildren and to identify the associated factors that contribute to its occurrence.
Methods: This is a cross-sectional descriptive and correlational study among students from two public middle schools in the Sousse governorate (Tunisia) for the year 2020/2021 using an information sheet concerning: Socio-demographic data, schooling, peer relationships, child's use of the Internet and also the 'Cyberbullying Screening Test' which is a self-administered questionnaire designed to assess cyber-bullying behaviour among young people aged 12 to 18.
Results: We included 238 middle-school students.63.6% of the population were girls, with a sex ratio of 0.57. The majority of participants (83.1%) was between 13 and 15 years old. More than half of middle school students (51.3%) reported having been cyberbullied at least once and 30.2% having been sexually harassed at least once by cell phone or on the Internet. We identified a significant association between cyberstalking and the mother's level of education (P=0.041). There was a statistically significant relationship between cyberbullying and the student's place of residence (P=0.023). School repetition among students was also associated with cyberbullying with a strong significance (P=0.002). A notable relationship was found between cyberstalking and the frequency of digital technology use on weeends (P=0.055).
Conclusions: The findings of this study reveal a significant prevalence of cyberbullying among Tunisian middle school students, with notable associations linked to many environmental and individual factors. These results emphasize the urgent need for comprehensive strategies to combat cyberbullying and support affected students in educational environments.

COVID-19 Vaccination Among Students in Tunisia: Perceptions and Attitudes

A. Guedria[1,2*], Y. Akkari[1], R. Ayoub[1,2], S. Nabli[1] and H. Ben Abid[1,2]

[1]Child and Adolescent Psychiatry Departement , Fattouma Bourguiba Hospital and [2]University of Monastir, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1139

Introduction: COVID-19 has had a major impact on public health globally, prompting mass vaccination campaigns to curb virus transmission and severe disease outcomes. Vaccination uptake among young adults, including university students, plays a crucial role in achieving herd immunity. However, perceptions about vaccine safety, effectiveness, and necessity influence vaccination rates and acceptance.
Objectives: Assessing the prevalence of COVID-19 vaccination among students at the Higher Institute of Technological Studies in Ksar Hlel, Tunisia, and exploring their perceptions regarding vaccination, including willingness to receive future doses and attitudes toward vaccine mandates.
Methods: This is a cross-sectional descriptive study conducted from the 6th to the 15th December 2021, involving a sample of students from the Higher Institute of Technological Studies (ISET) in Ksar Helal, Tunisia , using a pre-established questionnaire. Data entry and statistical analysis were performed using SPSS software, version 22.
Results: Our sample consists of 315 students, of whom 43.5% were aged between 18 and 20, and 42.9% were in their first year. The sex ratio was 0.53. Ninety-nine students (31.4%) had contracted COVID-19, with 76 rapid or PCR tests (24.1%) conducted. COVID-19 had affected 190 of the students' family members (60.3%). COVID-19 vaccination coverage among the students was 76.8% (242 students). Among the vaccinated, 135 students (55.8%) received one dose, and 107 (44.2%) received two doses. Regarding the reasons for vaccination, 183 students (75.6%) accepted the vaccine to prevent transmitting COVID-19 to their family or friends, 179 students (74%) to protect themselves from the virus, and 152 (62.8%) to help end the COVID-19 pandemic. Adverse effects from vaccination were reported by 86% of students (208) including headaches (97.9%), arm pain (68.4%), and fever (58.3%). In our sample, 202 students (64.1%) were convinced of the benefits of vaccination, while 176 (55.9%) opposed mandatory vaccination, and 228 (72.4%) were against receiving a third dose. Among the unvaccinated students, 11 (15.1%) expressed confidence in the vaccination and indicated willingness to get vaccinated in the future.
Conclusions: The study reveals a high prevalence of COVID-19 vaccination among students, with a majority expressing confidence in the vaccine's benefits. However, there is notable resistance to mandatory vaccination and additional doses, indicating mixed perceptions and lingering concerns.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1140

Introduction: Children with Attention Deficit Hyperactivity Disorder (ADHD) often experience comorbid anxiety. While their anxiety is typically assessed through both children's and parents' reports, discrepancies between these reports are common and poorly understood. Children with ADHD also present sensory-motor dysfunctions, of which explicit expressions may mask children's emotional state.
Objectives: Here, we test whether parents of children with sensory-motor dysfunctions may underestimate their children's anxiety levels.
Methods: Participants were 85 children: ADHD-only (n=28), ADHD+DCD (n=38), and typically developing (TD; n=19). Hyperactivity/Impulsivity was assessed by DSM-V. Anxiety was assessed by children and parents using the Screen for Child Anxiety-Related Disorders questionnaire (SCARED-C/P). Sensory-motor functions were evaluated using the Movement Assessment Battery for Children (MABC-2), balance subtest of the Bruininks Osteresky Test of Motor Proficiency (BOT-2), and vestibular tests of Dynamic Visual Acuity (DVAt) and standing posturography.
Results: Anxiety ratings were higher by children with ADHD than TD children (t-tests, $0.001<p<0.05$). Anxiety ratings were higher by children than their parents (t-tests, $0.001<p<0.05$), and the correlation between child and parent anxiety ratings was lower in ADHD dyads ($0.22<r<0.33$, $p<0.05$) compared to TD dyads ($0.60<r<0.70$, $p<0.01$). Panic anxiety ratings by children correlated positively with vestibular dysfunction ($r=0.22$, $p<0.05$), indicating that anxiety ratings increase with vestibular dysfunction. Anxiety ratings by parents correlated negatively with motor dysfunctions on the vestibular, postural stability, balance, and motor function tests ($-0.36<r<-0.22$, $p<0.05$), indicating that anxiety ratings decrease with motor deficiency. Finally, the ADHD cohort was assigned to an "agreement" cluster (55%) with comparable child-parent anxiety ratings and to a "disagreement" cluster (45%) with anxiety ratings lower by parents than children. Children in the "disagreement" vs. "agreement" cluster demonstrated higher hyperactivity/impulsivity scores by DSM-V ($p<0.05$) and lower motor performance by MABC-2 ($p<0.05$).
Conclusions: Findings suggest that parents of children with ADHD underestimate their child's anxiety, mainly when children's sensory-motor symptoms are prominent. We summarize these results under the term "blinding effect," which implies that parents' primary concern is the child's sensory-motor dysfunction, thus neglecting the expressions of anxiety. This "blinding effect" should be studied in the context of additional neurodevelopmental disorders sharing sensory-motor dysfunctions, and clinicians should be aware of the potential child-parent bias in reporting anxiety.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1141

Introduction: Screening children for the potential development of psychosis is challenging, resulting in a suboptimal healthcare transition from pediatrics to psychiatry.
Objectives: In this prospective study, we aimed to evaluate the predictive ability of the Child Psychosis-Risk Screening System (CPSS) for schizophrenia spectrum disorder (SSD) by observing the outcomes of pediatric and psychiatric outpatients.
Methods: A total of 478 outpatients aged 6–18 years visiting the pediatric and psychiatric departments of university and community hospitals were enrolled in this study. Assessments included the Child Behavior Checklist (CBCL) and clinical data (sex, age, birth month, chief complaint, diagnosis, abuse, bullying, and withdrawal). The CPSS calculated the risk of developing SSD using eight CBCL subscale scores. The presence of SSD was confirmed after one year. Receiver operating characteristic (ROC) curve analysis was used to evaluate the accuracy of the CPSS in predicting SSD onset. Light-gradient boosting machine (LightGBM) learning algorithm was used to calculate the importance of each clinical data point for SSD onset prediction.
Results: ROC analysis demonstrated that CPSS showed adequate predictive power for determining SSD onset (area under the curve = 0.902, 95% confidence interval: 0.866–0.939). LightGBM revealed that the importance of the CPSS risk% in predicting SSD onset exceeded other variables, including the CBCL Thought Problems subscale.
Conclusions: The CPSS demonstrated adequate predictive power for SSD development and may serve as an objective adjunctive diagnostic method to screen children at risk for SSD who require early psychiatric referral. As a simple screening system utilizing common clinical practice CBCL data, we advocate CPSS implementation in pediatric-to-psychiatric healthcare.

Strategies for coping with stress in early adolescents and their association with sociodemographic risk factors

J. Hamidovic[1]*, L. Dostovic Hamidovic[2], A. Brigic[1] and M. Mesanovic[1]

[1]Department of Psychiatry and [2]Department of Pediatrics, University Clinical Center Tuzla, Tuzla, Bosnia and Herzegovina
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1142

Introduction: The concept of dealing with stress refers to different forms of behavior that an individual uses in response to stressful situations, with the aim of reducing the effects of those stressful events or situations. Ways of coping are important as a prerequisite for positive growth and development and can be a significant factor in the etiology of psychological and somatic problems. Coping strategies include all those behaviors that are used to overcome difficulties in stressful situations. They refer to emotional, cognitive and behavioral responses to stressful situations that vary with time and characteristics of a specific stressful situation. In adolescence, the child encounters various forms of life situations and stresses, without yet having developed a wide range of coping strategies on which to rely. Children's growth and development and the influence of sociodemographic factors represent certain risks that can directly or indirectly affect stress coping strategies.
Objectives: The aim is to determine ways of coping with stress in early adolescents and their connection with sociodemographic risk factors.
Methods: We analyzed a group of 240 early adolescents (11-15 years) from Tuzla Canton, Bosnia and Herzegovina, in the general population. The sample was chosen because the early adolescent period is vulnerable in children's growing up and psychological development. The Kidcope coping scale for children and adolescents was used to assess the way of coping. The data were processed using the method of descriptive statistics. Pearson's correlation test was used to assess the association between sociodemographic risk factors and coping methods.
Results: On the coping scale, early adolescents showed a statistically significantly higher level of self-blame and blaming others. On the questionnaire of psychosomatic symptoms (PS), the obtained results show that living in a rural area leads to frequent blaming of others as a way of coping ($p<0.05$), as well as a significantly higher level of prayer ($p<0.05$). Higher economic status and higher monthly income are significantly positively associated with resignation ($p<0.01$). Higher educational status of the mother and better living conditions are also positively related to resignation as a way of coping with stress ($p<0.05$). Disturbed family relationships are associated with a higher frequency of distraction ($p<0.05$).
Conclusions: Early adolescents show significant levels of various stress coping strategies. There is a significant correlation between sociodemographic risk factors (place of residence, economic status of the family, disturbed family relations) and psychosomatic symptoms in early adolescents.

Examining Alterations in Electroencephalograms in a Sample of Egyptian Children Suffering with ADHD

M. M. Hamouda[1]

[1]psychiatry, Al-Azhar faculty of medicine, Cairo, Egypt
doi: 10.1192/j.eurpsy.2025.1143

Introduction: A frequent developmental problem known as attention deficit hyperactivity disorder causes inattention, which may or may not be accompanied by hyperactivity.
Having trouble focusing, engaging in excessive activity, and acting in ways that are inappropriate for one's age are all signs of ADHD. In the United States, research on the use of EEG to diagnose ADHD is still underway. The FDA has authorized the use of EEG to assess the illness's morbidity alone.According to a different study, the EEG theta/beta ratio cannot definitively distinguish between people who have ADHD and those who do not.
Objectives: the purpose of this study was to determine whether children with ADHD had altered EEGs.
Methods: study was carried out from January to June 2024 on sixty non-epileptic children with ADHD (8–18 years old) at Al Hussian university hospital, Egypt.
This study was authorized by the Al-Azhar Faculty of Medicine's Ethical Committee. Following an explanation of the purpose of the study and the acquisition of verbal agreement, all children underwent semi-structured clinical interviews and were excluded from any other neuropsychiatric or medical disorders. All study children have been diagnosed with ADHD according to the DSM IV criteria SCID, Conner's scale for ADHD was applied for all the study's children. EEG was obtained for all the children in the study. SPSS version 20.0 was employed. Numbers and percentages were used to characterize the qualitative data, and the significance of the outcomes was assessed at the 5% level.
Results: The research involved 60 children with ADHD diagnoses, of whom 70% were younger than 8 years old, 71.7% of whom were male, 28.3% of whom were female, and 53.3% of whom were in rural settings.Based on study statistics, the mixed form of ADHD was the preponderance kind, with 56.7% of participants having ADHD. Oppositional defiant disorder (ODD) was a co-morbid disorder. the study indicates a strong statistical correlation (P value<0.001) between the combined type of ADHD and the individuals' educational attainment.Accompanied conditions and male ADHD children were shown to have a high statistical significance ($P<0.005$) , as was age less than 8 years old ($P=0.026$)
Only 10% of the non-epileptic ADHD children in the study had aberrant EEG readings, and there was no statistical correlation between them. there is a significant correlation ($P<0.007$) between co-morbid conditions and ADHD children, irrespective of their kind.

Behavioral stabilization through low-dose Clozapine in a youth justice center.

C. Hidalgo Vazquez[1]*, Á. Armendáriz Lacasa[2] and N. Del Prado Sánchez[2]

[1]Consorci Sanitari de Terrassa and [2]Psychiatry, Parc Sanitari Sant Joan de Déu, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1144

Introduction: Behavioral dysregulation and aggression pose substantial challenges in treating adolescents within youth justice systems, particularly in cases with complex psychiatric histories and diagnostic ambiguity. Autism spectrum disorder (ASD) is often underdiagnosed due to its different presentations, particularly in females. Many girls with ASD show strong desire for social interaction, but due to difficulties in navigating social relationships, they frequently experience frustration, resulting in explosive and auto and heteroaggressive behaviors. For those ASD patients with comorbid conduct disturbances, standard antipsychotic treatments can be insufficient, being necessary to try alternative pharmacological approaches.
Objectives: To explore the therapeutic impact of low-dose clozapine on severe conduct dysregulation and auto/heteroaggression in this minor with ASD, and to assess clozapine's effectiveness in reducing anxiety and improving adaptability within a structured therapeutic environment.
Methods: We present a 17-year-old female patient with a history of severe behavioral disruptions with aggressiveness, initially diagnosed with various psychiatric conditions and treated with high-dose antipsychotics without clinical improvement. The case follows her through two separate admissions to a youth justice center's therapeutic unit, where a retrospective review of her history and a longitudinal study of her diagnosis were made. After conducting a review of clozapine's effects on reducing aggression, low doses of clozapine are finally tried, with the goal of stabilizing behavioral disturbances and reducing the patient's associated distress.
Results: When low-dose clozapine (up to 150 mg/day) was introduced, improvements in conduct regulation and emotional distress were documented. A treatment interruption occurred between admissions due to a lapse in its administration, followed by relapse in behavioral symptoms. Upon re-initiation of clozapine in the second admission, the patient's symptoms stabilized again, with substantial behavioral improvement and reduced anxiety, enhancing the patient's ability to function within the structured environment of the therapeutic unit. The patient achieved sustained clinical stability for over two months, a period marked by the absence of pharmacological rescue interventions or containment measures.
Conclusions: Low-dose clozapine may be a viable option for managing severe behavioral disturbances in adolescents with ASD within youth justice settings, especially when other treatments prove ineffective. This case underlines the potential of clozapine not only to mitigate aggression but also to facilitate better adaptive functioning and reduce anxiety, contributing to a more stable therapeutic experience. Further investigation into clozapine's role in treating conduct dysregulation in ASD is warranted.

Investigating Sequence Variations in CNTNAP2 and SETBP1 Genes in Language Disorders

B. Turan[1], E. Göktaş[1], N. Uzun[2], A. T. Hıra Selen[2]*, A. G. Zamani[1] and M. S. Yıldırım[1]

[1]Medical Genetics and [2]Child and Adolescent Psychiatry, Necmettin Erbakan University, Konya, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1145

Introduction: Language Disorder, a prevalent developmental disorder, impedes children's communication skills, with genetic and environmental factors playing pivotal roles in its pathomechanism.
Objectives: This study aims to investigate the involvement of sequence variations in *SETBP1* and *CNTNAP2* genes, along with environmental variables, in Language Disorder's etiology.
Methods: Between September 2022 and March 2023, thirty children aged 2-7 diagnosed with language disorders according to DSM-5 criteria, and evaluated using the Ankara Developmental Screening Inventory, were studied to identify genetic and environmental factors contributing to etiology.Thirty healthy children with similar age were included as a control group. DNA samples isolated from peripheral blood of both groups were analyzed for *SETBP1* and *CNTNAP2* genes using next-generation sequencing (custom design panel). The frequencies and clinical significance of the identified variants was evaluated, and variant verification and segregation analyses were performed by Sanger sequencing. The obtained data were compared using appropriate statistical methods.

Results: Language Disorder showed a male-dominant distribution. The *SETBP1* rs11082414-CC genotype frequency was significantly higher in patients (p=0.024), and two rare variants (CNTNAP2: c.973C>G:p.P325A; *CNTNAP2:* c.2236G>A:p.D746N) were exclusive to cases. In silico analyses yielded conflicting results for rare variants, inherited paternally from unaffected parents. Among non-genetic factors, patients had higher birth weights (p=0.043) and shorter lactation durations (p=0.044).
Conclusions: Homozygosity for *SETBP1* rs11082414 polymorphic variant increases Language Disorder susceptibility. This study underscores the genetic dimension of Language Disorder, urging physicians' awareness and early intervention strategies to mitigate its impact.

Classifying Suicide Attempts from Suicidal Ideation among Adolescents using Machine Learning

J. Hong[1]* and C.-M. Yang[2]
[1]Psychiatry, Iksan hospital and [2]Psychiatry, Wonkwang University , Iksan, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1146

Introduction: Suicide is a leading cause of death among adolescents and its prevalence among young people has steadily increased in recent years.
Objectives: This study aimed to identify patterns of risk factors that differentiate adolescents who experienced suicidal thoughts from those who attempted suicide using six different machine learning (ML) algorithms for Korean adolescents using data from online surveys.
Methods: Data were extracted from the 2011−2018 Korea Youth Risk Behavior Survey (KYRBS), conducted annually since 2005 by the Korean Ministry of Education, Ministry of Health and Welfare, and Korean Disease Control and Prevention Agency. The pipeline was solely generated from classic ML (CML) methods, namely logistic regression (LR), random forest (RF), artificial neural networks (ANN), support vector machines (SVM), and extreme gradient boosting (XGB).
Results: Among the 69,840 adolescents included in the analysis, 13,288 cases (19.0%) were identified as having made a suicide attempt. Prediction models using seven relevant features calculated by Boruta algorithm was developed and five features (drug experience, current smoking, grade, current alcohol drinking and sadness or hopelessness) were identified as the most important predictors. The performance of the six ML models on the balanced testing dataset was good, with area under the receiver operating characteristic curve (AUROC) and area under the precision−recall curve (AUPRC) ranging from 0.66 to 0.73.

The Relationship Between Prenatal Heart to Heart Synchrony and Postnatal Mother-Infant Attachment and Behavior

D. Ilki[1]*, L. Babayev[1], E. Sever[1], B. Ö. Konakçı[2], E. M. Karahan[2], B. Semiz[3], C. Ünal[4], M. Turğal[4] and T. Mutluer[2]

[1]School of Medicine, Koç University; [2]Child and Adolescent Psychiatry Department, Koç University Hospital; [3]Electrical and Electronics Engineering Department, Koç University and [4]Obstetrics and Gynecology Department, Koç University Hospital, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1147

Introduction: Synchronization refers to the coordinated physiological, biological, and behavioral changes during interpersonal interactions.
Objectives: The project aims to assess correlations between preterm physiological synchrony and post-birth behavioral synchrony between mothers, fathers, and their anxiety, depression levels, and attachment styles. Since the development of early synchronization remains unclear, the project investigates its initiation between mother and fetus, with a focus on including fathers in early attachment and synchrony research. It is hypothesized that synchrony plays a key role in predicting a child's attachment style.
Methods: BIOPAC Student Lab MP36 measures ECG data from parents, while cardiotocography records the fetus's heartbeat. Women in their 24-36th weeks of their first pregnancy without any chronic illnesses and their partners are being included in the study. Surveys for the participants cover sociodemographic scales, Beck Anxiety (BAI) and Depression Inventories (BDI) and The Relationship Scales Questionnaire. The recordings last fifteen minutes, with the first and last five minutes taking place in a non-stimulatory environment. During the middle five minutes, the fetus's heartbeat is projected for the parents. ECG data are analyzed in Matlab for synchrony. At 3 months, parent-infant interactions will be videotaped and analyzed via Ruth Feldman's *Coding Interactive Manual* for behavioral synchrony. Triads who show higher levels of physiological synchrony during pregnancy will be expected to show corresponding levels of behavioral synchrony at three months old.
Results: The ECG and survey data of 16 participants have been collected. BAI results have shown the mean anxiety results of the mothers and the fathers to be 14.6 (mild anxiety), 4.9 (minimal anxiety), respectively, whereas BDI yielded mean depression results of 7.3, 6.3, both minimal depression for mothers and fathers. Out of 8 mothers, 4 showed secure and 4 showed dismissive attachment. 2 of the mothers with dismissive attachment showed moderate and severe levels of anxiety as expected whereas the other 2 mothers showed mild anxiety. The mothers with dismissive attachment showed higher anxiety levels and are expected to show lower physiological synchrony levels with their partners and babies. Among fathers, the most prevalent attachment style was secure, observed in 3 (37.5%), with the second being Dismissive attachment identified in 3 fathers (37.5%). One father exhibited a preoccupied/dismissive style, (12.5%)while one father showed a mixed secure/dismissive pattern(12.5%).
Conclusions: The ECG data of the 16 participants are currently being evaluated for physiological synchrony between the triad and recruitments are still ongoing. After the infants are 3 months old, behavioral and physiological synchrony within the triads will be evaluated and analyzed for further relationships.

Parents' burden of adolescents with autism spectrum disorder and coping mechanisms: which association?

R. Jbir[1,1]*, F. Cherif[1], R. Masmoudi[1], N. Bouattour[1], J. Boudabous[2], M. Chaabene[2], I. Feki[1], F. Guermazi[1] and J. Masmoudi[1]

[1]psychiatry 'A' department and [2]Child psychiatry department, Hedi Chaker university hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1148

Introduction: Adolescence in young people with autism spectrum disorder (ASD) is a special time of life, for them facing physical and mental changes, and for their parents who must cope with the new challenges associated with their child's development. Research has shown that the severity, violence and behavioral disorders help to explain the major difficulties encountered by these families.
To cope with these difficulties, parents often use a variety of coping strategies. These coping strategies encompass all an individual's cognitive and behavioral efforts, which are constantly evolving, to manage a situation perceived as stressful.
Objectives: Our study aimed to assess the coping strategies adopted by parents of adolescents with ASD, their level of burden and to determine the relationship between these two variables
Methods: We conducted a descriptive and analytical cross sectional study among parents of adolescents with ASD followed at the "Erraihan" therapeutic farm in Sfax during the period of May 2024.
The hetero-questionnaire used a pre-established form for collecting data relating to parents and adolescents and two psychometric scales:

- The BRIEF-COPE scale: to assess coping mechanisms in parents, of which there are four: problem-focused mechanisms, avoidance-focused mechanisms, social support-focused mechanisms and emotion-focused mechanisms.
- The zarit Burden Inventory (ZBI): used to assess the level of burden.

Results: Forty-three parents were enrolled. Their mean age was 50.6 ±7.93 years (min=36; max=81). The average age of the adolescents was 17.79 years, with extremes of 13 and 20 years.
Emotional focus (mean score=2.54) was the coping mechanism most used by parents, followed by problem focus (mean score=2.50) and social support (mean score=2.45).
Avoidance was the least-used coping mechanism (mean score=1.63).
Assessment of parental burden showed that the mean Zarit score was 24.6±20.14, with extremes of 0 and 48. Twenty-seven parents (62.80%) felt a burden of severe intensity.
In our study, only the humor-based emotion-focused coping strategy was more important in parents with absent to moderate levels of burden (1.98 versus 1.41; p=0.02). For the other coping strategies, there was no significant association with level of burden. Social support scores between parents with absent to moderate and severe levels of burden were close.
Conclusions: Our results show that parents feel the heavy burden of caring for their sick adolescent. Indeed, ASD generates a great deal of stigmatization in the parent, who avoids discussing the illness with those around him, for fear of suffering further stigmatization. This vicious may explain the absence of a link between the level of burden and coping strategies centred on social support.
Thus, the question of the role of family support and associations for autistic families, proves crucial.

The parent-adolescent dyad in autism spectrum disorder: which level of burden?

R. Jbir[1,1]*, F. Cherif[1], R. Masmoudi[1], M. Chaabene[2], J. Boudabous[2], I. Feki[1], F. Guermazi[1] and J. Masmoudi[1]

[1]psychiatry 'A' department and [2]Child psychiatry department, Hedi Chaker university hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1149

Introduction: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder that begins in early childhood. For the young people with ASD Adolescence is a particular time of life, in which they are facing physical and mental changes and for their parents who have to cope with the challenges associated with their child's development. The effect of these different stressors on caregivers represents the burden.
Objectives: The aim of our study was to assess the level of burden experienced by parents of adolescents with ASD and to investigate the factors associated with it.
Methods: Our study was cross-sectional, descriptive and analytical conducted in the form of a survey during the month of May 2024. It concerned the parents of adolescents with ASD followed at the "Erraihan" therapeutic farm in Sfax. All data relating to adolescents and parents were processed solely by the interviewer.
The form included a section for collecting data relating to the adolescent and the parent, and one to measure caregiver burden via the Zarit Burden Interview (ZBI).
Results: Our population was comprised of 43 parents with a sex-ratio equal to The mean age of parents was 50.6 ±7.93 years, with extremes of 36 and 81 years.
As for the adolescents, the mean age was 17.79 ±2.29 years (min=13; max=20).
Psychometric assessment of parental burden showed that the mean Zarit score was 24.6±20.14, with extremes of 0 and 48. The results showed that 62.80% of parents felt a burden of severe intensity.
The level of parental burden increased with the presence of at least one history of somatic illness (p=0.03).
Similarly, severe burden was significantly associated with the presence of more than two children in the family (p=0.02) and the presence of sibling rivalry (p=0.04).
With regard to adolescent characteristics, the level of severe burden was significantly associated with male gender (p=0.03) and rank as the eldest sibling (p=0.01).
The presence of severe burden in the parents was significantly associated with the presence of self-aggressive behavior in the adolescent (p=0.02).
With regard to therapeutic characteristics, the use of risperidone and sodium valproate was significantly associated with an absent to moderate level of burden(p= 0.01 for both cases).
Similarly, the adolescent's previous integration into school was significantly associated with an absent to moderate level of burden (p=0.01).
Conclusions: The results suggest that parents of adolescents with autism need more support to cope with the burden generated by the adolescent's behavior. It is therefore necessary to adjust the support provided to parents in order to optimize the quality of care provided for their adolescents.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1150

Introduction: Autism spectrum disorder (ASD) is a neurodevelopmental disorder that appears in early childhood. The diagnosis is based on a clinical dyad: impaired social communication and restricted and repetitive behavior. From the age of 13, children with ASD are integrated into the "Erraihan" therapeutic farm.
Objectives: The aim of our study is to describe the clinical profile of adolescents with ASD followed at the "Erraihan" therapeutic farm.
Methods: This is a descriptive and analytical cross-sectional study of 43 parents of adolescents with ASD treated at the therapeutic farm.
The "Erraihan" therapeutic farm is a center that takes in adolescents aged over 13 with ASD.
A questionnaire using a pre-established form was administered to the parents by the same doctor to collect data relating to the adolescent.
Results: Forty-three adolescents followed for autism spectrum disorder were included in our study. Their mean age was 17.79 ±2.29 years (min=13; max=20) with a male predominance 79.1% (n=34). Adolescents with autism were older in 48.8% of cases. They suffered from a chronic illness in 44.2% (n=19) of cases. The most frequently reported somatic antecedent was epilepsy (n=17).
Psychiatric comorbidity was found in 55.8% of adolescents. It was mainly mental retardation (n=22). Adolescent age at first consultation ranged from 1 to 4 years, with an average of 1 year 6 months. Age at diagnosis ranged from 3 to 6 years, with an average of 3 years 3 months.
Time to diagnosis ranged from 0 to 24 months, with an average of 5 months. Twenty-three adolescents (53.5%) communicated with poor speech intelligibility.
Behavioral problems were present in 72.1% of adolescents. Medication was prescribed in 62.8% of cases. The most commonly prescribed drug was risperidone (44.2%).
Sphincter autonomy was acquired in 69.8% of adolescents. Thirty-four adolescents (79.1%) had received speech therapy in childhood. Almost half (44.2%) had entered kindergarten at an early age, and only 14% had started school and then withdrawn.
Conclusions: This study sheds light on the clinical profile of adolescents with autism spectrum disorders at the "Erraihan" therapeutic farm. The results underline the importance of early and appropriate care. Although the majority of adolescents have acquired certain skills, such as sphincter autonomy and access to speech therapy, challenges remain, particularly in terms of communication and behavior. This information underlines the need for ongoing follow-up and personalized approaches to improve the quality of life of these young people within their therapeutic environment.

Idiopathic Central Precocious Puberty and Attention Deficit Hyperactivity Disorder: A Clinical Case Study

G. Juárez[1]

[1]Psiquiatria, Hospital Universitario La Paz, Madrid, Spain
doi: 10.1192/j.eurpsy.2025.1151

Introduction: Precocious puberty is defined as the appearance of secondary sexual characteristics before the age of 8 in girls and 9 in boys. It can be classified into central precocious puberty (dependent on the hypothalamic-pituitary-gonadal axis) and peripheral precocious puberty. Attention Deficit Hyperactivity Disorder (ADHD) occasionally co-occurs with precocious puberty, complicating its management. This case focuses on a 9-year-old girl diagnosed with idiopathic central precocious puberty, treated with both GnRH analogues and stimulant medication, showing significant improvement in symptoms.
Objectives: The primary objective is to explore the relationship between these two conditions through the presented clinical case. Additionally, the study aims to evaluate the impact of hormone-suppressing medications and ADHD treatment on the patient's social and academic functioning.
Methods: A 9-year-old girl with precocious puberty and ADHD symptoms, diagnosed through hormonal tests and ADHD scales administered to parents and teachers, as well as clinical assessments of emotional status. A multidisciplinary approach is essential for managing complex cases involving idiopathic central precocious puberty and ADHD. Follow-up was conducted every 3 months to assess pubertal status, ADHD symptoms, and psychosocial adjustment.
Results: GnRH analogue therapy successfully arrested pubertal progression, with bone age stabilization and normalized growth velocity.ADHD symptoms improved significantly with extended-released methylphenidate, leading to better attention, reduced hyperactivity, and improved classroom behavior.The patient demonstrated enhanced self-esteem, better peer relationships, and a positive psychosocial outlook.
Conclusions: The relationship between ADHD and precocious puberty may be due to a combination of hormonal, neurobiological, and psychosocial factors. Although the precise connection has not been fully determined, there appears to be an interaction between the neuroendocrine system and brain pathways that regulate behavior and development.

Adolescents hospitalized in adult psychiatric departments: socio-demographic features and clinical profile

A. Karmous[1]*, H. Ghabi[2], M. Karoui[2], H. Nefzi[2], R. Kammoun[2] and F. Ellouze[2]

[1]emergency and outpatient department and [2]Department G, Razi hospital, Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1152

Introduction: Adolescence is a critical period of physical, cognitive and emotional development. Mental health among adolescents is a major public health issue. The number of teenagers requiring psychiatric care is constantly increasing and several studies have found high prevalences of psychiatric disorders in this group.
Objectives: The aim of the study was to describe sociodemographic and clinical characteristics of adolescents hospitalized in an adult psychiatric department.
Methods: We carried out a retrospective descriptive study. It included adolescent patients, aged between 16 and 19 years, who were admitted to the department G of Razi Hospital (Tunisia), between May 2019 and May 2024 (the minimum age for hospitalization in adult psychiatric wards was 16). Data were collected from patients' files.
Results: Thirty-five adolescents were included. The mean age was 17.8 ± 0.8 years. A male predominance was noted with 65.7% of patients. We found that 57.1% of teenagers were using at least one psychoactive substance. Tobacco was the most used substance (54.3%), followed by cannabis (42.9%) and alcohol (40%). The most common motive for hospitalization was behavioral disturbances with 79.1% of patients. The most common psychiatric disorders were schizophrenia (32.6%) and schizophreniform disorder (18.6%). Antipsychotics were the most prescribed medication (58.13%) followed by benzodiazepines (30%).
Conclusions: Knowing the profile of adolescents hospitalized in psychiatry, their sociodemographic and clinical characteristics would enable us to better the care we offer to them.

Assessment of Eating Disorders and Self-Esteem in Adolescents

Z. Nesrine*, D. Ben touhemie, J. Boudabous, I. Hadjkacem, K. chiha, H. Ayédi, K. khemekhem and Y. Moalla

pédopsychitrie, Hedi chaker hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1153

Introduction: Self-esteem is a significant indicator of health and well-being, as well as an explanatory variable for various aspects of human behavior. The relationship between self-perception, self-esteem, overall mental well-being, and eating disorders (ED) is considered particularly important, especially during adolescence.
Objectives: to evaluate the relationsheep between eating disorders (ED) and self-esteem among adolescents and identify associated factors.
Methods: This was a cross-sectional, descriptive, and analytical study conducted between June 2024 and September 2024 among adolescents resident in Sfax. Data were collected through an online Google Forms questionnaire exploring sociodemographic and relational data. We used the "Eating Attitudes Test 40 (EAT-40)" to detect the presence of ED, with a score of ≥ 30 indicating the presence of an eating disorder. Self-esteem was assessed using the Rosenberg Self-Esteem Scale: A score below 25 indicates very low self-esteem. A score between 25 and 30 indicates low self-esteem. A score between 31 and 33 indicates average self-esteem. A score between 34 and 39 indicates high self-esteem. score above 39 indicates very high self-esteem.
Results: We collected data from 120 adolescents, with an average age of 16 years and a predominance of females (71.7%). The majority of participants (79.3%) lived in urban areas, 69.2% had a medium socioeconomic status, and 80.8% were enrolled in secondary schools, 33.3% of adolescent have reported relational difficulties with peers,41,5% of Adolescents were living in particular family situations(death of one parent, parental separation, relational difficulties with parents). In our study, 30% of adolescents had personal psychiatric histories. The prevalence of eating disorders estimated at 47.5%. Among participants, 43.3% had very low self-esteem, 55.8% had low self-esteem, and 0.8% had average self-esteem. Our study objectified a signifiant correlation between eating disorders and low self-esteem (p=0.005).
Conclusions: The results of the study show a high prevalence of eating disorders among adolescents, associated with several factors, notably low self-esteem. This underscores the need to develop prevention strategies focused on improving self-esteem during adolescence. Developing effective interventions in this regard could be beneficial for addressing the behaviors and attitudes observed in eating disorders.

Assessment of Eating Disorders in Adolescents: Tunisian cross-sectional study

Z. Nesrine[1]*, D. Ben touhemie[1], I. Hadjkacem[1], J. Boudabous[1], K. chiha[1], H. Ayédi[1], K. khemekhem[1] and Y. Moalla[1]

[1]pédopsychiatrie, Hedi Chaker hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1154

Introduction: Adolescence, around the time of puberty, is the life stage most prone to the emergence of eating disorders, with bodily and psychological transformations at the center of the issue. The body serves as a key medium for expressing distress in adolescents.
Objectives: To estimate the prevalence of eating disorders (ED) among adolescents and to determine associated factors to ED
Methods: This is a cross-sectional, descriptive, and analytical study conducted between June 2024 and September 2024 among adolescents resident at Sfax, Tunisia. Data were collected via an online Google Forms questionnaire exploring sociodemographic and relational data. We used the "Eating Attitudes Test 40 (EAT-40)" to detect the presence of ED, with a score of ≥ 30 indicating the presence of an eating disorder.
Results: We collected data from 120 adolescents, with an average age of 16 years and a predominance of females (69.2%). The majority of participants (84.6%) lived in urban areas, 80.8% were enrolled in secondary schools, and 33.3% of adolescent have reported relational difficulties with peers. 41,5% of Adolescents were living in particular family situations(death of one parent, parental separation, relational difficulties with parents).
In our study, 30% of adolescents have a psychiatric disorder. The average total score on the EAT-40 scale was 35.03, the prevalence of eating disorders was estimated at 47.5%. The factors correlated with ED included: female gender (p=0.012), relational difficulties with peers (p=0.002), the death of one parent (p=0.024), and personal psychiatric history (p=0.00).
Conclusions: This study reveals a significant prevalence of eating disorders among adolescents in Sfax, Tunisia. Gaining a deeper

understanding of this condition and its underlying factors could greatly improve the care and support provided to these young individuals.Bas du formulaire

Electroencephalogram (EEG) Based Prediction of Attention Deficit Hyperactivity Disorder (ADHD) Using Machine Learning

J. Kim[1]* and S. Yang[1]

[1]Psychiatry, Daegu Catholic University School of Medicine, Daegu, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1155

Introduction: Attention Deficit Hyperactivity Disorder (ADHD) is a complex neurodevelopmental disorder that presents challenges in achieving accurate and timely diagnosis.
Objectives: This study investigates the effectiveness of using electroencephalogram (EEG) data combined with machine learning techniques to enhance the prediction accuracy for ADHD diagnosis.
Methods: A total of 168 subjects were evaluated using the Kiddie Schedule for Affective Disorders and Schizophrenia Present and Lifetime Version Korean Version (K-SADS-PL-K), categorizing them into two groups: ADHD (n=107) and Neurotypical (NT, n=61). We analyzed quantitative EEG (qEEG) data across 19 channels, focusing on frequency ranges including delta (1–4 Hz), theta (4–8 Hz), alpha (8–12 Hz), beta (12–25 Hz), high beta (25–30 Hz), and gamma (30–80 Hz). To classify ADHD versus NT groups, the Extreme Gradient Boosting (XGBoost) classifier was utilized, with Leave-One-Subject-Out (LOSO) cross-validation employed to assess model performance.
Results: To address the issue of limited data, we segmented each subject's EEG data into 30-second intervals, resulting in 2434 segments for the ADHD group and 1060 segments for the NT group (figure 1). These segments were used to train the machine learning model. The XGBoost algorithm, combined with the LOSO cross-validation strategy, achieved a test accuracy of 90.81% and an F1 score of 0.9347, demonstrating robust performance in distinguishing between ADHD and NT subjects (figure 2). Feature importance analysis using SHAP values highlighted that EEG features from specific frequency bands, particularly the middle beta/theta ratio and relative gamma of O1 electrode sites, played a crucial role in the classification (figure 3).

Image 1:

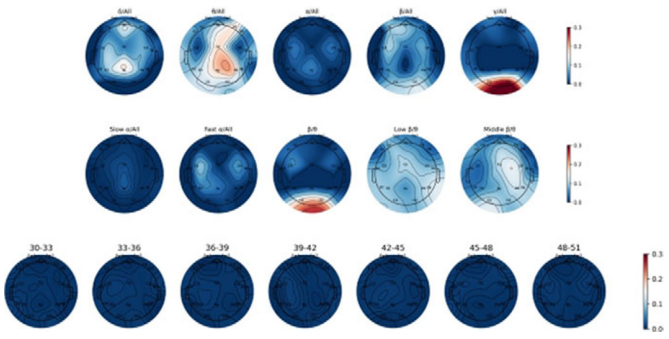

Image 2:

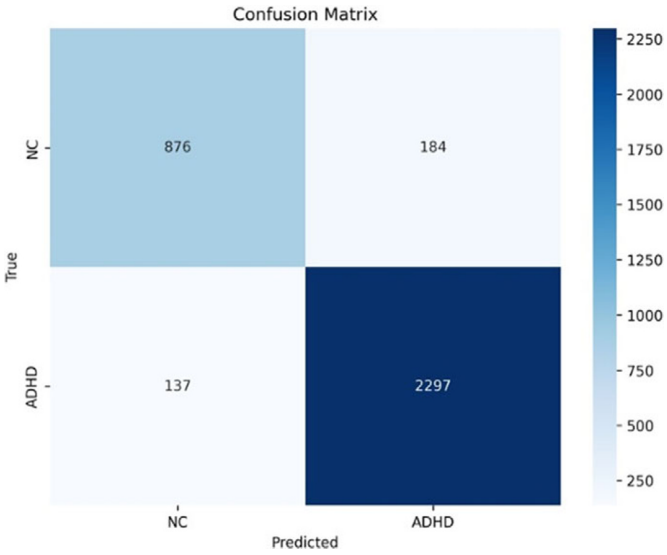

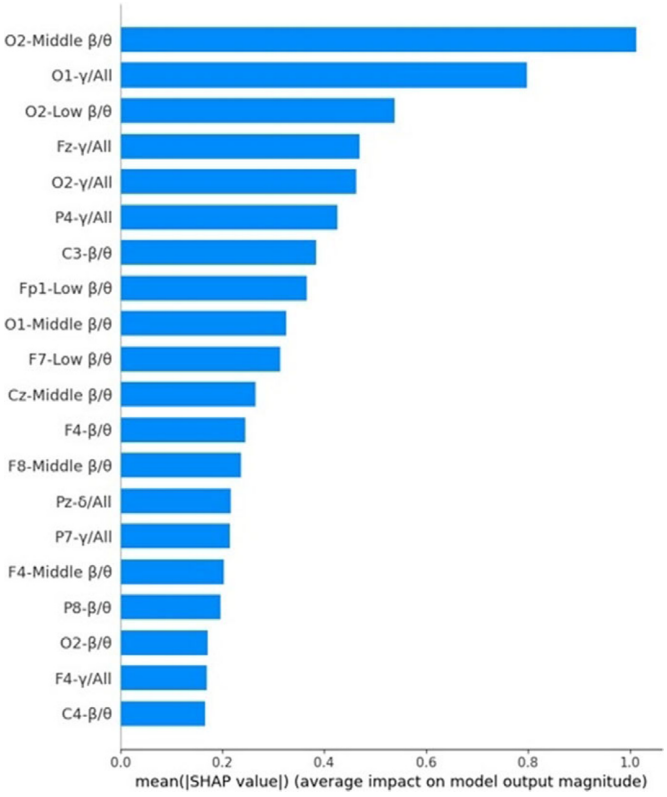

Image 3:

Conclusions: Our findings suggest that EEG-based machine learning models hold significant potential as non-invasive tools for assisting in the diagnosis of ADHD. Further research with larger datasets and additional validation is necessary to confirm these results and explore their clinical applicability.

The relationship of nomophobia and social media addiction with psychiatric symptoms, self esteem, and perceived parental attitudes in adolescents

S. Kultaş[1]*, F. Coşkun[1] and Ö. F. Akça[1]

[1]CHILD AND ADOLESCENT PSYCHIATRY, NECMETTIN ERBAKAN UNIVERSITY, KONYA, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1156

Introduction: The growing prevalence and impact of digital device usage in everyday life have brought technological addiction to the forefront.Nomophobia and social media addiction are also increasingly significant types of technological addiction among adolescents.
Objectives: The objective of our study is to identify nomophobia and social media addiction in a community sample of adolescents and to examine their associations with psychiatric symptoms, self-esteem and perceived parental attitudes.
Methods: 500 adolescents between the ages of 13-18 were included in our study.The entire sample completed a sociodemographic data form, Nomophobia Questionnaire, Social Media Addiction Scale for Adolescents Short Form, Children's Anxiety and Depression Scale Child Form,Conners-Wells Adolescent Self-Report Scale Short Form, Rosenberg Self-Esteem Scale and Parentıng Style Scale.
Results: %56.6 of the sample had moderate or higher severity nomophobia and %31.4 had social media addiction.In both boys and girls, nomophobia and social media addiction were found to be positively correlated with attention deficit and ADHD index. In addition, in boys, nomophobia and social media addiction were found to be positively correlated with behavioral problems and hyperactivity. In girls, only social media addiction and behavioral problems were positively correlated. In both girls and boys, nomophobia and social media addiction were found to be positively correlated with RCADS subscales and self-esteem scale. In both girls and boys,nomophobia and social media addiction were found to be negatively correlated with acceptance-involvoment and psychological autonomy. In addition, a positive correlation was found between nomophobia and strictness-supervision subscale in girls. As a result of regression analysis: total anxiety was found to predict nomophobia in both girls and boys, total anxiety and obsessive-compulsive disorder were found to predict social media addiction in boys, ADHD index and major depression were found to predict social media addiction in girls. In the path analysis, it was found that behavioral problems and parental attention interacted with each other and predicted social media addiction; social media addiction predicted internalizing disorders both directly and indirectly through self-esteem.
Conclusions: The results of our study explain the relationship between nomophobia and social media addiction and psychiatric symptoms, self-esteem, and perceived parental attitudes. Considering that early detection and intervention of psychiatric disorders reduces the risk of addiction, our study is an important step towards raising awareness about technological addictions.

Comparison of Neuropsychological Characteristics in Children and Adolescents with Autism Spectrum Disorder and Tic Disorder

S. Lee[1]*, S. Y. Lee[1] and B.-N. Kim[1]

[1]Seoul National University Hospital, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1157

Introduction: Individuals with autism spectrum disorder (ASD) show notable intellectual impairment compared to other neurodevelopmental disorders, as seen in intelligence and neuropsychological tests, including attention assessments. Given the strong link between intellectual and neuropsychological performance, it is essential to determine if low neuropsychological scores stem from general intellectual limitations or specific domain vulnerabilities.
Objectives: To assess specific neuropsychological vulnerabilities in ASD, we will administer intelligence and neuropsychological tests to both ASD and Tic disorder groups, examining group differences after controlling for FIQ. Within the ASD group, we will further analyze performance variations by symptom severity and explore links between test results and specific ASD symptoms.
Methods: We recruited children aged 5-16 with no comorbidities into Tic (n=75) and ASD (n=97) groups, administering the Wechsler Intelligence Scale and neuropsychological tests (ATA, CCTT, WCST, Stroop). Using SPSS 29, we performed an ANCOVA with FIQ as a covariate to examine group differences. In the ASD group, ADOS-2 scores further distinguished autism spectrum and autism groups, and correlations were analyzed between neuropsychological scores and ADOS-2 Social, RRB, and Total scores.
Results: The ASD group had a significantly lower FIQ than the Tic group ($t(66) = 2.54$, $p = .013$) and showed poorer WCST performance with fewer correct responses and more errors, even after controlling for FIQ. In the ATA, the ASD group's response time was significantly faster, with higher false alarms, indicating hasty judgments. The Stroop color-word task showed poorer ASD performance, while the CCTT interA_rate was higher in the Tic group. No significant differences were found between the autism spectrum and autism groups on neuropsychological tests, except intelligence. ATA scores correlated significantly with ADOS-2 social, RBB, and total scores, whereas WCST scores correlated only with RBB.
Conclusions: This study's WCST, ATA, and Stroop test results indicate that the ASD group has deficits in cognitive flexibility and inhibitory control, independent of FIQ. The absence of significant differences between autism and spectrum groups suggests these traits are inherent to the autism spectrum, regardless of symptom severity. Unexpectedly, the CCTT interA_rate was high, likely due to a floor effect given the ASD group's longer CCTT 1 completion time. ATA scores correlated with overall autism symptoms, while WCST scores correlated only with RBB, linking social interaction difficulties to attentional control and repetitive behaviors to cognitive rigidity and insistence on sameness.

Latent profiles of Intelligence Quotient and Autism symptom severity in children with ASD

Y. K. Lim[1]*, E. J. Chung[1] and B. N. Kim[1]

[1]Department of Child and Adolescent Psychiatry, Seoul National University Hospital, Seoul, Korea, Republic Of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1158

Introduction: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by difficulties in social communication and interaction, as well as restrictive and repetitive stereotyped behaviors, with considerable variation in cognitive and adaptive functioning. Accordingly, behavioral symptoms observed in daily life are likely to vary across individuals.
Objectives: The present study aimed to explore the heterogeneity in intellectual abilities and behavioral issues among individuals with ASD using Latent Profile Analysis (LPA). This study was conducted between 2020 and 2021, with approval from the Institutional Review Board (IRB) of SNUH.
Methods: A cross-sectional analysis was conducted on 66 children (ages 6-18) diagnosed with ASD. The following psychometric instruments were used: Autism Diagnostic Observation Schedule-2 (ADOS-2), Wechsler Intelligence Scale for Children-Fourth Edition (WISC-IV), Child Behavior Checklist 6-18 (CBCL 6-18), Social Responsiveness Scale (SRS).
Results: As the 3-profile solution returned a significant BLRT value and model entropy was estimated to be 0.93, the LPA of the WISC-IV indices and ADOS-2 comparison scores revealed three profiles that were clinically meaningful and balanced in group sizes: Profile 1 ("Higher ASD score with intellectual disability"; ADOS = 6.25, VCI = 55.16, PRI = 52.34, WMI = 53.47, PSI = 50.31), Profile 2 ("Higher ASD score with borderline intelligence"; ADOS = 5.76, VCI = 78.59, PRI = 80.65, WMI = 80.82, PSI = 67.12), and Profile 3 ("Lower ASD score with above-average intelligence"; ADOS = 4.41, VCI = 105.53, PRI = 108.41, WMI = 106.35, PSI = 89.41). On the SRS subscales, Profile 3 showed significantly lower scores in Social Cognition, Social Communication, and Social Motivation compared to Profile 1 ($F(2, 63) = 10.45$, $p < .001$; $F(2, 63) = 5.24$, $p < .01$; $F(2, 63) = 8.75$, $p < .001$). Additionally, on the CBCL syndrome subscales, Profile 3 showed significantly lower problem behaviors in Withdrawal/Depression, Social Immaturity, and Attention Problems ($F(2, 63) = 4.57$, $p < .05$; $F(2, 63) = 5.07$, $p < .01$; $F(2, 63) = 4.19$, $p < .01$).
Conclusions: In the present study, Latent Profile Analysis (LPA) using IQ and ADOS scores identified three distinct profiles within children with ASD. The findings suggest that while high-functioning ASD has traditionally been defined by an IQ threshold of 70–75, further distinction between borderline and above-average intelligence ASD groups may be warranted. Furthermore, targeted interventions addressing negative emotions, such as depression, may be indicated for the ASD group with intellectual disability.

EPV0358

Body dysmorphic disorder in adolescents: nosology, evolution and treatment. A case report

L. Mallol[1]*, P. Del Sol[1] and L. García-Murillo[1]

[1]Hospital Puerta de Hierro, Majadahonda, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1159

Introduction: Body dysmorphic disorder is a diagnostic entity within the somatoform disorders of the obsessive-compulsive spectrum according to the DSM-V. Its prevalence is between 0.7% and 2.5%, being more frequent in men and usually beginning in adolescence or early adulthood. Its central symptom is cognitive distortions regarding appearance, with concern about imaginary physical defects, slight or even invisible to others and in some cases close to a delusional condition.
Objectives: To delve deeper into the clinical aspects and nosological conditions through the description of a clinical case.
Methods: This is a 16-year-old patient who was admitted three times to the Acute Psychiatric Unit of the Puerta de Hierro Hospital due to behavioral disorders in the context of dysmorphophobia with intense concern about the shape of his nose. The patient gradually abandoned his daily routines, stopped attending classes at school and isolated himself from his social circle.
He is the youngest of two sisters. He lives with his parents and sister. He had good academic results until the time of diagnosis.
The patient's concern about his nose began at about age 15, coinciding with the diagnosis of leukemia of his mother, who was undergoing chemotherapy treatment. The patient reports that the symptoms have increased until causing significant functional limitation.
He says that his nose is very large and he doesn't allow anyone to see it. He leaves the house wearing a mask, performs rituals of checking it for hours in front of the mirror and has even manipulated his nose with objects to try to deform it. He appears to have a delusional component with significant emotional and behavioural repercussions.
Results: Several pharmacological treatments were started, including SSRIs (sertraline) and various antipsychotics (risperidone, pimozide and olanzapine), with little response in all cases. Psychotherapeutic treatment was carried out in a day hospital for adolescents, but this was also unsuccessful. Finally, he was involuntarily transferred to a Medium Stay Unit given the significant impact of the symptoms on his life, showing progressive improvement after several months of treatment.
Conclusions: The nosology of TDC has evolved: the DSM IV specified a delusional variant within the psychotic spectrum and a non-delusional one within the somatoform spectrum. The DSM V integrates it within the obsessive-compulsive spectrum. In order

to assess a correct treatment, a continuum could be established between TDC and eating disorders. Both present similar symptoms: dissatisfaction and distortion with body image, need for continuous checking and concern about imperfections in perceived appearance. Given the chronicity of TDC and the tendency to abandon treatment in the first months, long-term follow-up by a multidisciplinary team is necessary, as well as psychoeducation and the establishment of a solid therapeutic alliance.

Sensory integration in a department of child and adolescent psychiatry

M. L. Maria Del Carmen

Psychiatry, Hospital General Universitario Gregorio Marañon, Madrid, Spain
doi: 10.1192/j.eurpsy.2025.1160

Introduction: The area of Sensory Integration has its origin in the 1960s, developed by the neuroscientist and occupational therapist Jean Ayres. Although the first studies focused on the relationship between learning problems and atypical sensory processing, today there are new applications in clinical practice. Sensory integration is defined as the neurological process responsible for organizing the sensations that one receives from one's own body and from the environment, in order to respond and function adequately in relation to environmental demands.
Objectives: This work has several objectives. On the one hand, review the concept of sensory integration, the definition and theoretical basis as well as the scientific evidence of this theory. On the other hand, review the use of sensory integration in psychiatric practice from the 1960s to the present day. Also, explain the experience of a child and adolescent psychiatry unit with the use of sensory integration as part of the treatment. Finally, new challenges, approaches and needs of psychiatry services will be considered for the implementation or improvement of this new work tool in a multidisciplinary team.
Methods: A bibliographic search has been carried out in the main sources of medical information such as pubmed, uptodate as well as in national and international journals. Likewise, the knowledge and clinical experience of the team has been reviewed.
Results: In our clinical experience, the child and adolescent psychiatry device for intensive outpatient treatment where patients between 12 and 17 years of age with severe mental disorders attend, initially passed the sensory profile by occupational therapy to patients who presented behavioral or emotional symptoms. not consistent with the psychopathological examination. In view of the results and magnificent progress, this intervention began to be carried out systematically to the boys who joined the device. We present the case of a 15-year-old patient who attended the device due to emotional dysregulation and suicidal risk. During evolution, possible difficulties were seen in sensory integration that made it difficult for the patient to improve with psychiatric or psychological therapy alone. The patient was evaluated and treated by the team's occupational therapist, specifically trained in sensory integration. It was evaluated with the sensory profile, with the results having a sensory sensitivity profile and auditory and tactile avoidance. The specific measures that were carried out were: sensory diet and environmental modifications.
Conclusions: Sensory integration is a therapy with sufficient clinical evidence to implement it in child and adolescent psychiatry services. Therapy should be performed by suitably trained and validated occupational therapists. This therapy must be included in a multidisciplinary approach to the patient and specific modifications that can be developed at home and at school are provided.

"Antidepressants and movement disorders: a case of an adolescent with major depressive disorder"

M. Ríos Vaquero[1], M. Esperesate Pajares[1], O. Martin Santiago[1]*, G. Lorenzo Chapatte[1], L. Rojas Vázquez[1], A. Monllor Lazarraga[1], L. Sobrino Conde[1], B. Rodriguez Rodriguez[1], N. Navarro Barriga[1], M. Fernández Lozano[1], M. J. Mateos Sexmero[1], P. Pando Fernández[1], M. Calvo Valcarcel[1], M. Andreo Vidal[1], P. Martínez Gimeno[1], L. Del Canto Martinez[1], F. J. González Zapatero[1], M. D. L. Á. Guillén Soto[1] and A. Aparicio Parras[1]

[1]Psychiatry, Hospital Clínico Universitario de Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1161

Introduction: Drug-induced movement disorders are a rare side effect of which some cases have been reported and published. It may be due to antidepressants, antipsychotics or other drugs. In these cases it is important to realize differential diagnosis, identify the medication that may have caused it and implement appropriate management to solve it.
Objectives: To present the case of a 16-year-old adolescent diagnosed with major depressive disorder with movement disorders after treatment with escitalopram.
Methods: A literature review was conducted on movement disorders and treatment with antidepressants in child-adolescent population.
Results: Our case is about a 16-year-old adolescent who is living with his family and he is studying at the high school. The patient has no personal psychiatric history and in his family only his father has an adaptive disorder treatment. The first time he comes to consultation, he said that in the last few weeks he has anxiety attacks in different environments and an increase in basal anxiety. He has been in a low mood for about two years with apathy, which has increased in recent weeks. He is diagnosed of major depressive disorder and we decided to continue with escitalopram 10 mg and chlorazepate dipotassium prescribed a week ago by his family doctor. After one month, he goes to the second consultation with difficulty in walking, stiffness and instability that is related to the introduction of treatment. In addition, he comments on mild improvement of anxiety and mood. Due to the timing of the onset of movement disorder and the onset of escitalopram, it is decided to suspend it. Chlorazepam dipotassium is maintained and short-term for evaluation of evolution. In the following consultation, no movement disorder symptoms are seen and the onset of another antidepressant with a different course of action is assessed.
Conclusions: Drug-induced movement disorders as in the case described are a rare side effect of which some cases have been reported and published. Different studies reveal the different behavior of antidepressants in the adult and child-adolescent population. In a meta-analysis on antidepressants and depression in the child-and-youth population (1), the results indicated that

sertraline, escitalopram, duloxetine and fluoxetine could be considered as the first option although cases with associated extrapyramidal symptoms (EPS) were reported. According to a study on the association of antipsychotics, antidepressants with movement disorders in children and adolescents (2), the risk-benefit profile of antipsychotic use should be considered as an adjuvant to reduce EPS. In addition, in a post-marketing study (3), a potentially harmful association was found between movement disorders and the use of antidepressants mirtazapine, vortioxetine, fluvoxamine, citalopram, paroxetine, duloxetine, escitalopram, fluoxetine, sertraline, venlafaxine, among others.

Beyond Diagnosis: The Multifaceted Relationship Between Gender Dysphoria and Pervasive Developmental Disorders

M.-M. Mihai[1]*, M. Moise[2] and T. Costea[3]

[1]Darent Valley Hospital, Dartford and Gravesham NHS Trust, Dartford, United Kingdom; [2]University of Medicine and Pharmacy Carol Davila and [3]Professor Doctor Alexandru Obregia Clinical Hospital of Psychiatry, Bucharest, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1162

Introduction: This case series examines five adolescents with both gender dysphoria and pervasive developmental conditions, highlighting the social, familial, and psychological challenges involved. The cases reveal how these conditions intersect, shaping identity, social interactions, and family dynamics. Findings suggest a trend toward isolation and virtual spaces for acceptance, with limited family support often exacerbating isolation. Integrated therapeutic approaches addressing both gender dysphoria and developmental conditions are recommended to improve mental health and self-acceptance.
Objectives: To explore the diversity of gender dysphoria manifestations within pervasive developmental disorders.
Methods: We analysed five cases of adolescents from Professor Doctor Alexandru Obregia Clinical Hospital of Psychiatry in Bucharest, each diagnosed with both gender dysphoria and a pervasive developmental disorder. Each case highlights unique psychological and social factors influencing the adolescents' identities and interactions. Patients were monitored over an average period of one year to observe developments and responses to therapeutic interventions.
Results: The cases illustrate diverse expressions of gender dysphoria among adolescents with pervasive developmental disorders:
Case 1: 12-year-old with Asperger's syndrome and gender dysphoria, with interests and social withdrawal shaped by online interactions, further isolating her.
Case 2: 15-year-old with severe depression and Asperger's syndrome, marked by social withdrawal, a strong attachment to solitary pursuits, and an identity struggle.
Case 3: 16-year-old with significant gender dysphoria and past suicide attempts, feeling alienated with a strong focus on transitioning.
Case 4: 17-year-old facing gender dysphoria complicated by family resistance, social anxiety, and unresolved grief, destabilizing family acceptance.
Case 5: 15-year-old with major depression, social anxiety, and emergent gender dysphoria, poor medication response, and preference for solitude, indicating an uncertain prognosis.
Conclusions: This study explores whether pervasive developmental disorders and gender dysphoria coexist by chance, influence each other, or share a common cause. It examines whether atypical gender identity might lie dormant and what may trigger its expression. These cases highlight the complexity of treating gender dysphoria in adolescents with developmental disorders, suggesting that tailored support and therapy can improve psychosocial outcomes and self-acceptance.

Whispers of hunger: a journey through anorexia nervosa

A. Monllor[1]*, M. Rios[2], G. Lorenzo Chapatte[1], L. Rojas Vazquez[1], G. Guerra Valera[2], P. Marques Cabezas[1], M. Queipo de Llano de la Viuda[1], M. Andreo Vidal[1], M. Calvo Valcarcel[1], M. P. Pando Fernandez[1], P. Martinez Gimeno[1], B. Rodriguez Rodriguez[1], N. Navarro Barriga[1], M. Fernandez Lozano[1] and M. J. Mateos Sexmero[1]

[1]Hospital Clínico de Valladolid and [2]Hospital Clínico Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1163

Introduction: A 13 years old girl, who has always been an A* student, was brought to our Emergency Room, referred by her Psiquiatrist, to be hospitalized in our Unit.
During the first interview in the ER, the patient reported that she refused to eat food that had empty calories, which were essentially everything except water, and even water at times was an issue. She had a IMC of 16,57 kg/m2.
Objectives: The objetive of this case is to try and explain how serious of a disorder anorexia nervosa can be, at times severe enough to distort completely the patients reality.
Methods: The following patient will be presented, doing a thorough systematic bibliography review.
Results: The patient remains admitted to our unit. After more than one month and a half, since first being admitted, the patient has both verbalized wanting to end her life before gaining weight, as well as improved her disorder awareness.
At first, she was bluntly negative to eat any food, to a point to such extent, that feeding via nasogastric tube was necessary.
After daily interviews, along with many consultations, both with clinical psychology and psychiatry, using both cognitive behavioral psychotherapy and psychotrpic drugs; we achieved a slight improvement by eating half plates of both first and second plate, as well as dessert of a 1300-1500kcal diet.
Nonetheless, the patient still manifest up to this day, her willingness of not to eat and to end her life if its necessary to avoid eating.
Conclusions: Given the severity of the eating disorder suffered by the patient, social work was notified of the refferral to a long-term center specialized in eating disorders. The patient verbalized not wanting to got there, but recognized her disorder was getting more severe and the need for a long-term Unit.

Oxidative Stress and Cortical Thickness in the Psychosis Spectrum: Investigating Glutathione Metabolism and Antioxidant Defenses in Youth

R. Moreno-Comellas[1]*, M. Ortuño[2], I. Martínez[2], F. Fesce[2], E. de la Serna[3], J. Castro-Fornieles[2,4], I. Baeza[2,4] and G. Sugranyes[2,5]

[1]Psychiatry, Benito Menni CASM; [2]Department of Child and Adolescent Psychiatry and Psychology; [3]Psychiatry, Institute of Neuroscience, University of Barcelona, Barcelona; [4]CIBERSAM, Madrid, Spain and [5]Psychiatry, CIBERSAM, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1164

Introduction: Oxidative stress, particularly through disruptions in glutathione metabolism and Total Antioxidant Capacity (TAC), has been implicated in cortical thinning and other brain structural changes seen in psychosis. These changes may be more pronounced in the early psychosis spectrum, but this relationship remains underexplored.
Objectives: This study investigated the relationships between key oxidative stress markers—reduced glutathione (GSH), oxidized glutathione (GSSG), the GSH/GSSG ratio, and TAC—and cortical thickness in the cingulate, insula, and fronto-temporal brain regions.
Methods: A total of 57 youths on the early psychosis spectrum and 44 healthy controls participated, with a mean age of 15.51 years. There were no significant differences in age or sex between the groups. Cortical thickness was measured using MRI, and blood samples were analyzed for oxidative stress markers. Partial correlations were performed, controlling for total intracranial volume, age, and sex, to examine the relationships between oxidative stress markers and cortical thickness. A permutation analysis was then conducted to assess group differences in these associations.
Results: In healthy individuals, a higher GSH/GSSG ratio was significantly associated with increased cortical thickness in the right insula ($r = 0.50$, $p < 0.05$). Conversely, in the early psychosis spectrum group, there was a consistent trend of negative correlations between TAC and cortical thickness, particularly in the left frontal cortex. Permutation analysis revealed significant group differences in the association between GSH and cortical thickness in both the left insula and left temporal regions ($p < 0.05$). Additionally, TAC showed significant differences in its relationship with cortical thickness in the left and right frontal regions ($p = 0.01$ and $p < 0.05$), indicating asymmetrical oxidative stress involvement across hemispheres in the early psychosis spectrum group compared to healthy controls.
Conclusions: These findings suggest that oxidative stress markers, particularly related to glutathione metabolism and TAC, are linked to regional cortical thickness variations. The results highlight distinct oxidative stress effects in the early psychosis spectrum compared to healthy individuals, emphasizing the potential role of oxidative stress markers as early indicators of neuroanatomical changes in psychosis.

A Multilevel Investigation of Conduct Problems in Adolescents: Insights from Neural, Cognitive, and Environmental Perspectives

C. Mou[1]*, Y. Shi[2], P. Liu[3] and Y. Wang[3]

[1]School of Psychology, University of Nottingham, Nottingham, United Kingdom; [2]Department of Psychology, National University of Singapore, Singapore, Singapore and [3]State Key Laboratory of Cognitive Neuroscience and Learning, Beijing Normal University, Beijing, China
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1165

Introduction: Conduct problems (CP) in adolescents are associated not only with long-term personality and social development challenges, but also impose significant burdens on families, schools, and communities.
Objectives: While numerous risk factors for CP have been identified in prior research, a comprehensive understanding of the underlying deficit mechanisms remains incomplete.
Methods: Utilizing data from the Adolescent Brain Cognitive Development (ABCD) study (N = 11,875), the largest longitudinal investigation of brain development and child health in the United States, we conducted a systematic analysis of the neural, cognitive, and environmental features linked to CP. The findings were further tested for generalizability across diverse cross-cultural datasets.
Results: Our results propose a novel framework that accounts for cognitive deficits associated with CP, while also highlighting the interactions between biological and environmental factors in the development and potential remission of CP in adolescents.
Conclusions: These insights provide valuable directions for future research and intervention strategies targeting adolescent conduct problems.

EPV0367

Focusing on ADHD: Analyzing Five-Year Search Trends

C. Noureddine[1], A. Sterchele[1] and K. Petersen[1]*

[1]Psychiatry, Icahn School of Medicine at Mount Sinai, New York, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1166

Introduction: An estimated 10% of children in the United States carry a diagnosis of ADHD (Li *et al.* JAMA Netw Open 2023; 6). Parents, caregivers, and children themselves utilize search engines to better understand their diagnosis and treatment options as well as discover other resources such as finding providers or support groups. Furthermore, evaluating search trends may elucidate individual and societal barriers towards accessing treatment. (Zhao *et al.* Adm Policy Ment Health 2022; ***49*** 357–373)

Objectives: This study examines Google search trends for the term "ADHD" from 2019 to 2023 to shed light on public interest and awareness patterns.
Methods: A Google Trends search was performed for the term "ADHD" in the global search database from 2019 to 2023. Weekly absolute search volumes were exported for each year. A one-way ANOVA calculation including Tukey HSD was conducted using Social Science Statistics' calculator, which was cross referenced with AAT Bioquest's calculator.
Results: The ANOVA analysis revealed significant differences in the number of searches across the five different years. The f-ratio value is 689.19733. The p-value is < .00001. Post hoc comparisons using the Tukey HSD test indicated that search results differed significantly from among all years except between the years 2019 and 2020. The average number of searches steadily increased from M2019 = 278201.4839, SD2019=38184.594 and M2023 = 642020.8824, SD2023 =33099.9021. There is a relatively steady level of interest in the search term throughout the year with slight fluctuations. Seasonal trends were examined, showing an increased number of searches in February, October, and June, and decreased searches in December.
Conclusions: Both the overall and temporal trends described in this study have important clinical ramifications. The general increase in search trend frequency suggests increased awareness not due to a significant change in prevalence. The seasonal trends noted above suggest that the increased search frequency is related to school-related activities, particularly year-end exams in June, while the decrease in December may reflect the shift in focus from academics during the holiday break. This study highlights the importance of having evidence-based resources be accessible and understandable to the general public

Language of Anxiety on Social Media: Distinguishing "Anxious" from "Nervous" in Youth Conversations

C. Noureddine[1], A. Sterchele[1], C. Pham[1]* and C. Wang[1]
[1]Psychiatry, Icahn School of Medicine at Mount Sinai, New York, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1167

Introduction: Social media has evolved into a primary arena for mental health discussions, with particular relevance to youth who engage extensively in online spaces. This study seeks to investigate how distinct language choices—specifically the terms "anxious" and "nervous"—influence the tone, themes, and context of discussions around anxiety.
Objectives: By examining the frequency and context of these terms in social media posts, this study aims to shed light on how language affects the portrayal of anxiety and, potentially, the associated experiences. We hypothesize that understanding these differences can provide valuable insights into public perceptions especially with younger audiences.
Methods: We conducted a targeted search of X (formerly Twitter), focusing on posts that included either the term "anxious" or "nervous," filtered for English-language content to ensure relevance to a broader audience. The top 100 tweets containing each term were then subjected to a sentiment analysis to assess the emotional tone of the content. Additionally, a word cloud generator was used to identify the most frequently associated terms, with connecting words excluded to maintain clarity in theme identification.
Results: Posts containing the term "anxious" often reflected intense personal distress, introspection, and struggles with internal emotions. The most commonly associated terms included "feel" (mentioned 19 times), "god" (16), "like" (15), "can" (14), "don't" (14), and "stressed" (8), each of which underscored the personal and often existential nature of these expressions. The frequent presence of terms such as "always," "day," "got," "walk," "hate," and "sad" further emphasized the internalized and enduring aspects of anxiety, suggesting more persistent or generalized anxiety concerns. On the other hand, posts containing the term "nervous" were more likely to relate to situational anxiety, external circumstances, or performance-based fears. The most frequently appearing words alongside "nervous" included "system" (15 mentions), "can" (13), "just" (9), "like" (8), and "people" (7), indicating that these posts often referenced responses to specific events or temporary stressors. Notably, terms like "first," "lot," "making," "now," and "video" suggest that individuals using "nervous" may be describing anxiety linked to immediate, often identifiable stressors, as opposed to the more generalized or chronic anxiety depicted in "anxious" posts.
Conclusions: This study underscores the significance of linguistic nuances in mental health conversations on social media and highlights how the choice of words—such as "anxious" versus "nervous"—can shift both the perceived and intended meaning of these discussions. By understanding these subtle differences, mental health professionals, educators, and content creators can develop resources and messaging that are more attuned to the experiences and language of youth.

EPV0369

Emotional dysregulation in a sample of adolescent inpatients: clinical and psychopathological characterization

G. L. Nuzzo[1]*, G. Longo[1], A. Cicolini[1], L. Orsolini[1] and U. Volpe[1]
[1]Unit of Clinical Psychiatry, Department of Clinical Neurosciences/DIMSC, Polytechnic University of Marche, Ancona, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1168

Introduction: Emotional dysregulation is an unhealthy emotional response to stimuli and a common reason for adolescent hospitalization. Linked to disorders like depression, borderline personality disorder, childhood trauma, and eating disorders, understanding its underlying causes may improve outcomes and prevent relapse.
Objectives: The aim of this study is to characterize emotional dysregulation among adolescent impatient.
Methods: Our study involves inpatients (16-24 years) hospitalized at our Transitional Psychiatric ward in Ancona (Università Politecnica delle Marche, Italy). The used rating scale were: Temperament Evaluation in Memphis, Pisa and San Diego (TEMPS-M), Difficulties in Emotion Regulation Scale (DERS), Barratt Impulsiveness Scale-11 (BIS-11), Toronto Alexithymia Scale-20 (TAS-20), Aggression Questionnaire (AQ). Descriptive analysis, simple and multivariate linear regression analysis were conducted.
Results: 97 adolescent patients were admitted from February 2022 to March 2023. The mean age of the sample is 17.3±1.9. The mean score to the BPRS is 43.9±10.3. The 70.7% (n=70) of the sample are

females and the 79.8% (n=79) lives with their parents. Disruptive, impulse-control, and conduct disorders are the prevalent disorders in the sample (32.3%, n=32). The 21.1% (n=21) was diagnosed with depression, the 13.2% (n=13) with bipolar disorder and the 9.1% (n=9) with psychosis. According to the DERS, patients with emotional dysregulation are the 82,2% (n=37) of the sample. The 25.3% (n=24) of the sample could be classified as alexithymic. The most represented temperaments in the sample are the dysthymic 24.4% (n=11) and cyclothymic 22.2% (n=10). The mean score of the DERS is 122.33±29.5, the mean score of the TAS-20 is 58.9±166 and the mean score of the AQ is 78.7±30.1, the mean score of the BIS-11 is 65.2±19.1. A simple linear regression between DERS and AQ (R=0.536, R^2=0.287, F(1)=15.284, p<0.001), TAS-20 (R=0.502, R^2=0.252, F(1)=12.819, p=0.001) and BIS-11 (R=0.534, R^2=0.285, F(1)=15.128, p<0.001) was observed. A multivariate linear regression was observed between the DERS (R=0.917, R^2=0.842, F(1) =25.708, p<0.001) and the subscale about physical aggressivity of the AQ (β=2.065, p=0.008), the dysthymic subscale of the TEMPS (β=1.87, p<0.001), the hostility subscale of the AQ (β=-3.321, p<0.001), the subscale about difficulty identifying feelings of the TAS-20 (β=1.598, p=0.001), the total score of the AQ (β=0.5, p=0.006) and the subscale about cognitive impulsivity of the BIS-11 (β=1.024, p=0.047).

Conclusions: The results suggest a link between emotional dysregulation, impulsivity, aggression, and alexithymia. Notably, emotional dysregulation appears in those with a dysthymic temperament, marked by high aggression, difficulty identifying feelings, cognitive impulsivity and low hostility. Further research is needed to explore these findings and develop treatment strategies.

Pharmacogenetics and its impact on pharmacological management of severe attention deficit hyperactivity disorder

M. Okružnik Želalić[1]*, I. Stefanović[1], I. Žunić Išasegi[1], L. Šimičević[2], L. Ganoci[2], M. Živković[3,4] and I. Begovac[1,3]

[1]Department of Child and Adolescent Psychiatry; [2]Department of Laboratory Diagnostics, University Hospital Center Zagreb; [3]School of Medicine, University of Zagreb and [4]Department of Psychiatry, University Hospital Center Zagreb, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1169

Introduction: Attention Deficit Hyperactivity Disorder (ADHD) varies in presentation and associated comorbidity conditions. Diagnosis and treatment is often challenging, highlighting the need for individualized approaches in managing ADHD. Optimal therapy includes a combination of different methods such as psychological interventions and pharmacotherapy. Pharmacogenetics allows for a more personalized and effective treatment plan, which can reduce empirical prescribing of medication, meaning less side effects, faster treatment response and achieving remission. Altogether, this leads to improved compliance and outcomes.

Objectives: In our opinion this is an interesting case study which explores the challenging presentation, medical management, and treatment of a patient with ADHD and its comorbidity.

Methods: We present a male subject, age 14, who met DSM- V criteria for ADHD at the age of 8. The treatment effects of conventional approaches with psychosocial interventions and individual psychotherapy as well as child and parental psychoeducation had not proven sufficient, so pharmacotherapy was added to the treatment strategy. He was initially introduced to methylphenidate therapy and developed side effects in the form of depressive symptoms and motor tics. Regression of side effects occurred when the drug was discontinued. Impulsive and aggressive behaviors became severe so antipsychotics were prescribed, which resulted in improvement of behaviour. Attention and concentration disturbances remained, however. During this period, the subject experienced a growth spurt, gained in body weight and his laboratory findings showed high liver enzymes. We conducted a multidisciplinary approach that included a complete examination by a geneticist, an endocrinologist, and a cardiologist. EEG and psychological testing were performed. Due to a lack of progress in socio-emotional functioning, genotyping analyses of CYP2D6, CYP1A2, CYP2C9, CYP2C19, CYP3A4, CYP3A5, ABCB1, ABCG2, 5-HTTLPR, DAT1 VNTR was performed.

Results: The pharmacogenetic findings suggested a higher activity of the CYP2D6 enzyme than normal. Significantly reduced and weak transport function of protein ABCB1 was observed. Atomoxetine is not a substrate for ABCB1, so the introduction of atomoxetine is planned after the stabilization of liver enzymes.

Conclusions: Various treatment strategies can help ameliorate ADHD symptoms. Finding an effective medication and dosage for a given child with ADHD can be a complex process. Although pharmacogenetic testing is not a standard procedure in child and adolescent psychiatry, it can have an impact on the management of treatment-resistant symptoms and medication-related side effects. The potential for pharmacogenetics to enhance treatment precision remains a promising area for future research in psychiatry.

Beyond the Rainbow: Suicide, Suicidal Gestures and Self Harm Disparities Among Gender Minorites

J. Parkerson, C. Noureddine* and A. Sterchele

Psychiatry, Icahn School of Medicine at Mount Sinai, New York, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1170

Introduction: Transgender and Gender Non-Conforming (TGNC) individuals are at increased risk of diagnosis with mental disorders, including suicidality and suicidal gestures (Anderson & Ford. Nursing Inquiry 2022; 29). Patients' psychological distress may be secondary to gender dysphoria; however, the evidence may be unclear.

Objectives: The goal of this review was to compile current evidence to assess a relationship between gender dysphoria and suicidal ideation, suicidal attempt, and self-harming behavior.

Methods: A literature review on PubMed databases was conducted using the search terms "transgender," "gender non-conforming "suicidality," "self-harm," "suicidal gestures," "child," "adolescent," and "youth" in various permutations to assess recent evidence on suicidality and suicidal gestures among TGNC children and adolescents. We also reviewed relationships between gender-dysphoria, social support as a protective factor, and suicidality and/or suicidal gestures among TGNC youths.

Results: A study conducted across 19 states in the United States and large urban school districts found that within the last year, 43.9% of transgender students reported they have seriously considered attempting suicide compared to 20.3% in cis-females and 11.0% cis-males, 39.3% of transgender students reported having a suicide plan compared to <16.0% of cisgender students, and 16.5% of transgender students reported having a suicide attempt requiring medical treatment compared to <2.5% of cisgender students (Garthe et al. Transgend Health 2022; 7 416-422). Another study conducted across three different US cities found higher levels of suicidal ideation and behavior among TGNC youths, compared to their cisgender counterparts (Johns et al. MMWR 2019; 68, 67–71) . Also, chosen name use was associated with less suicidal ideation, behavior, and depressive symptoms (Russel et al, J Adolesc Health 2018; 63 503–505). Additionally, a surveillance analysis concluded that TGNC youths reported experiencing higher levels of emotional distress, bullying victimization, risk behaviors (substance use and sexual behavior), and lower levels of protective factors such as internal assets, family connectedness, and feeling safe in their community (Eisenberg et al. J Adolesc Health 2017;61 521–526)
Conclusions: Further research needs to be conducted regarding the relationship between gender dysphoria and suicidality, and the presence of suicidal gestures. However, the current data suggests decreased depressive symptoms, as well as suicidal ideation and behavior associated with increased chosen name usage.

Attention deficit hyperactivity disorder in prematurely born children: role of neuroinflammation caused by human cytomegalovirus infection

B. Pavković[1]*, J. Skoric[2], M. Zaric[1], J. Lakic[1], M. Bozinovic Stanojevic[3] and I. Paripovic[4]

[1]Department of Mental Health; [2]Department of Pediatrics, Health Center "Dr Simo Milosevic", Belgrade; [3]Specialist Practice for Child Psychiatry "Psiho Centar MM", Nis and [4]Insitute of Neonatology, Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1171

Introduction: Numerous studies have revealed the association between deficit hyperactivity disorder (ADHD) and brain inflammation due to immune system response to congenital or perinatal human cytomegalovirus (CMV) infection.
Objectives: The aim of study was to examine the impact of neuroinflammation caused by CMV infection on the development of ADHD in prematurely born children.
Methods: The medical records of 126 prematurely born children aged 7-11 were retrospectively analyzed. Participants were divided into two groups, the observed population of 56 children with ADHD and the control group without ADHD. Three parameters were observed, C-reactive protein (CRP) as an indicator of inflammation, IgM antibodies to CMV for etiological diagnosis of CMV infection and cranial ultrasound findings for the confirmation of structural changes in the brain.
Results: Statistical analysis of our data showed the association between the onset of ADHD and the presence of congenital/perinatal CMV infection in prematurely born children ($p<0.01$). Nevertheless, these two variables had a very low positive correlation (phi coefficient 0.07173). The results did not show the association between elevated levels of CRP and presence of ADHD in prematurely born children ($p>0.01$), which confirmed that not every inflammation, regardless of the cause, was associated with ADHD. The analysis also confirmed the positive correlation between the variables listed in pairs: elevated levels of CRP and positive IgM on CMV, elevated levels of CRP and altered ultrasound neuroimaging findings, as well as positive IgM on CMV and altered ultrasound neuroimaging findings. All of these correlations speak in favor of the CMV caused neuroinflammation as etiopathogenetic basis in ADHD.
Conclusions: In our sample CMV-induced neuroinflammation was associated with the development of ADHD in prematurely born children.

EPV0381

Understanding the Overlap: Exploring the Complex Comorbidity of ASD and ADHD

A. Rodríguez-Quiroga[1]*, A. Álvarez Astorga[1], A. M. Matas Ochoa[1] and J. Quintero[1]

[1]Psychiatry, Hospital Universitario Infanta Leonor, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1172

Introduction: Autism Spectrum Disorder (ASD) and Attention-Deficit/Hyperactivity Disorder (ADHD) are neurodevelopmental conditions that often co-occur, leading to complex clinical presentations. While ASD is characterized by deficits in social communication and restricted, repetitive behaviors, ADHD is marked by inattention, hyperactivity, and impulsivity. The comorbidity between these conditions is increasingly recognized, yet their combined impact on diagnosis, treatment, and patient outcomes remains underexplored.
Objectives: This study aims to investigate the prevalence and nature of the comorbidity between ASD and ADHD. We also seek to identify the shared and distinct cognitive, behavioral, and developmental features, and assess the implications of this overlap for clinical practice, especially in diagnosis and treatment planning.
Methods: A systematic literature review was conducted, examining peer-reviewed studies published in the last 10 years. Key databases such as PubMed, PsycINFO, and Scopus were searched for studies involving ASD and ADHD comorbidity in children and adolescents. Data on prevalence rates, diagnostic criteria, symptom overlap, and treatment approaches were extracted and analyzed.
Results: The findings confirm a high prevalence of comorbidity between ASD and ADHD, with estimates ranging from 30% to 50% in pediatric populations. Shared symptoms, particularly inattention and executive dysfunction, often complicate differential diagnosis. Children with both ASD and ADHD tend to exhibit more severe social and cognitive impairments, and have a higher risk for anxiety, mood disorders, and academic challenges. The results suggest that overlapping symptoms may delay or complicate accurate diagnosis, affecting treatment efficacy.
Conclusions: The comorbidity of ASD and ADHD presents unique challenges for clinicians and families. Early identification of both conditions is crucial for tailored interventions. A multidisciplinary approach, combining behavioral, cognitive, and pharmacological treatments, appears to be the most effective. Further research is needed to develop clearer diagnostic criteria and targeted

therapeutic strategies to address the specific needs of individuals with this comorbid profile.

Sail training as a blue intervention. Strenghtening hardiness and resilience of adolescents

M. W. Romaniuk[1]* and M. Gawrych[1]

[1]The Maria Grzegorzewska University, Warsaw, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1173

Introduction: Nature based interventions are becoming more popular in mental health prevention and treatment. Blue therapies are rarely known because of limited access and high costs. The poster presents the results of research on the level of the hardiness and resilience of high sea cruises participants. The study involved 123 people, including 65 girls and 58 boys, and 55 young adults, including 15 women and 39 men.
Objectives: The aim of the study was to assess the impact of blue intervention on the level of the hardiness and resilience of high sea cruises participants.
Methods: Pre-posttest study with questionnaires issued on the first and last day of each cruise. Dispositional Resilience Scale (Bartone et. al., 1989) was used to measure mental hardiness, commitment, openness to challenges and a sense of control of participants. EEA Resilience Scale (Maltby et. al., 2015) was used to measure ecological and engineering resilience and adaptive capacity of partifcipants.
Results: The results show a statistically significant increase in hardiness level. There was also a significant increase in commitment, openness to challenges and a sense of control of participants, which are measured by subscales of the DRS. Significant increase of ecological resilience and adaptive capacity has been noted.
Conclusions: Hardiness and resilience are key protective factors for mental health. Blue interventions can be effetcive ways of mental wellbeing improvement.

Anxiety and Depressive Symptoms in Parents of Extremely Preterm Newborns and Their Association with Parent-child Bond

A. Romero Teruel[1]*, M. J. Molina-Aguilera[2], J. Merchán-Naranjo[2], E. Rodriguez-Toscano[2], B. Almansa[3], S. Zeballos-Serrato[4], D. Blanco-Bravo[4], A. Garcia-Blanco[3] and L. Pina-Camacho[2]

[1]Department of Psychiatry, Hospital Dr. Rodríguez Lafora; [2]Department of Child and Adolescent Psychiatry, Institute of Psychiatry and Mental Health, Hospital General Universitario Gregorio Marañon, CIBERSAM, IiSGM, School of Medicine, Universidad Complutense, Madrid; [3]Neonatal Research Group, Health Research Institute La Fe, University and Polytechnic Hospital La Fe, Valencia and [4]Neonatology Service, Hospital General Universitario Gregorio Marañon, IiSGM, School of Medicine, Universidad Complutense, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1174

Introduction: Extreme preterm birth (<28 weeks) is a significant risk factor for adverse neurodevelopmental outcomes in infants but also for heightened psychological stress in parents, both of these impacting on parent-child bonding style. Abnormal parent-child bonding may impact, in turn, on child's emotional development. Longer stays at NICUs, with their stressful environment and caregiving demands, alongside psychosocial factors and perinatal complications can exacerbate parental emotional stress.
Objectives: (i) To compare, around birthtime, levels of anxiety and depressive symptoms in parents of extremely preterm newborns (EPTN) compared to parents of born-at-term healthy control (HC) newborns; (ii) to assess, in parents of EPTN, longitudinal changes in levels of anxiety and depressive symptoms from birth up to 40 postmenstrual weeks (40PMW), and their association with demographic, clinical and environmental risk factors; (iii) to assess, in parents of EPTN, the impact of NICU-related stress and psychosocial / family context on levels of symptoms; and (iv) to examine, in parents of EPTN, the association between levels of anxiety and depressive symptoms and parent-child bonding quality around hospital discharge.
Methods: Observational, longitudinal, prospective, 24-month follow-up study. We recruited a cohort of n=150 EPTN and n=50 HC (the PeriStress-PremTEA cohort) in two tertiary hospitals in Spain. Of those, parents of n=70 EPTN and n=42 HC successfully completed, around birthtime (and at 40 PMW in EPTN) the STAI state & trait, BDI, PBQ, MSPSS and PPS at NICU questionnaires. We also gathered demographic, clinical and obstetric data from all patient & HC families. We compared, in EPTN vs HC, parental symptom levels around birth. Using logistic regression, we assessed, in EPTN, the association between demographic/perinatal variables, parental symptom levels around birth time and parent-child bonding quality at discharge.
Results: Both fathers and mothers of EPTN showed higher anxiety and depressive symptom levels than those of HC (all p<.01). In EPTN, parental symptom levels around birth time were highly correlated with PSS NICU scores (p<.01). Levels of anxiety and depressive symptoms in mothers of EPTN predicted parent-child bonding quality at discharge, above and beyond other potential risk factors, as did level of depressive symptoms in fathers of EPTN (p<.01).
Conclusions: Our findings support the need to establish screening and longitudinal monitoring programs of psychopathology in parents of EPTN, both for mothers and fathers of these children, and even more so in higher-risk subgroups, such as those with higher perception of NICU-related stress.

EPV0386

Auditory hallucinations in a young person with Jacobsen Syndrome and Partial Trisomy 10q Syndrome

J. Sánchez-Cerezo[1]* and P. Del Sol Calderon[1]

[1]Division of Child and Adolescent Psychiatry, Department of Psychiatry, Hospital Universitario Puerta de Hierro, Majadahonda, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1175

Introduction: Jacobsen syndrome (JS) is a rare genetic disorder caused by a partial deletion of the long arm of chromosome

11 (11q23.3qter), affecting approximately 1 in 100,000 births. It is associated with physical and developmental abnormalities, including pre- and postnatal growth retardation, facial dysmorphism, and multiple congenital malformations. Intellectual disability and psychomotor retardation are also common, with 97% of individuals presenting with varying degrees of cognitive impairment. Autism spectrum disorder (ASD), attention deficit hyperactivity disorder (ADHD), and, in rare cases, severe psychiatric disorders like schizophrenia or bipolar disorder, may complicate the clinical picture. JS management is complex, often requiring multidisciplinary care. Partial trisomy 10q is a rare chromosomal disorder, with around 40 reported cases worldwide. It is characterized by distinctive facial features, minor physical anomalies, and possible cardiac or renal malformations, with severity depending on the duplicated region.
Objectives: The aim of this case report is to present a 13-year-old female with Jacobsen syndrome and Partial Trisomy 10q Syndrome who was diagnosed with ASD and intellectual disability (ID) who later developed psychotic symptoms.
Methods: The patient, a 13-year-old girl, was diagnosed with Jacobsen syndrome and Partial Trisomy 10q Syndrome following a neurological evaluation conducted at two months of age. Medical records were reviewed from her initial assessments to recent follow-ups.
Results: The patient has ASD and ID, with poor verbal communication, repetitive behaviours, and social isolation. A notable regression in both language and behaviour was observed after the age of 10, coinciding with her school integration. Neuroimaging showed ventriculomegaly and loss of white matter, but no active demyelination or epileptic features were found. Due to impaired attention, we suspected ADHD, and started her on methylphenidate, later changing it to atomoxetine with poor response. Due to patient's very limited speech, mental state examination was difficult. We observed that she was anxious, had hearing phenomena, and was talking in jargon, so we suspected psychotic symptoms in the form of auditory hallucinations. Treatment with Aripiprazole was initiated at doses of up to 7 mg daily, with a good response. Aripiprazole also helped to reduce social withdrawal and improve attention. Currently, the patient is maintained on a stable dose of Aripiprazole, alongside behavioural therapies and educational support.
Conclusions: This case highlights the complexity of managing young people with neuropsychiatric symptoms in patients with genetic syndromes, especially when poor language and speech skills are associated. Future research is needed to better understand the neuropsychiatric implications of JS Partial Trisomy 10q Syndrome and optimize treatment strategies for these patients.

EPV0387

Physical Activity intervention effect on wellbeing and overall functioning in an CAMHS low secure service

C. Schneider[1,2*] and E. Stephen[1]
[1]RCPsych and [2]BAP, london, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1176

Introduction: Potters Bar Clinic, CAMHS LSU, Elysium Healthcare, collaborates with external physical exercise therapy provider *Psychesoma.* Psychesoma operates within two CAMHS Low Secure wards. Psychesoma works with patients who have mental health problems, ASD, and learning disabilities. Psychesoma offer person-centred group and individual sessions aiming to improve young peoples' mood state, wellbeing, and health through Physical exercise therapy.
Objectives: We study the influence of physical exercise intervention in positive well-being, psychological distress, and fatigue measures in young people receiving mental health treatment under section 3 of the MHA in a LSU environment.
Methods: The *Subjective Exercise Experience Scale (SEES; McAuley & Courneya, 1994)* is a measure of global psychological responses to exercise stimuli and is a standardised measures used in previous similar research. The SEES assesses three general categories of subjective responses to exercise stimuli: positive well-being, psychological distress, and fatigue. Each sub-scale includes 4 emotion statements, with 12 statements in total. Young people are required to rate the degree to which they feel each emotion in the present moment on a Likert-type scale (1; 'Not at all' – 7; 'Very much so').
Results: This measure is completed pre- and post- Psychesoma sessions. The data was collected by Psychesoma trainers between December 2022 and November 2023. The measure was completed 63 times in total by 11 young people. On the positive wellbeing sub-scale, the cohort had a mean pre-session score of 11.63, and a mean post-session score of 17.23, representing a 5.31 point increase in positive wellbeing. On the psychological distress sub-scale, the cohort had a mean pre-session score of 9.18 and a mean post-session score of 7.06, representing a 2.21 point decrease in psychological distress. On the fatigue sub-scale, the cohort had a mean pre-session score of 14.73 and a mean post-session score of 10.69, representing a 3.68 point decrease in fatigue
Conclusions: Data indicated that young people experience an increase in positive wellbeing and a decrease in psychological distress and fatigue immediately following Psychesoma sessions. Further research in place to explore the long term duration of these effects.

Social determinants of youth with mild intellectual disability in outpatient care for mental health problems: a case-control study

M. Storm[1*], E. J. Giltay[1], R. R. Vermeiren[1], W. M. van Eldik[1], E. C. Palstra[2], E. D. van Duin[2] and D. van den Berg[2]
[1]LUMC, Leiden and [2]AMC, Amsterdam, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1177

Introduction: Children with mild intellectual disability (MID) face specific challenges threatening their development, particular their mental health. They face a heightened risk of psychopathology (Buckley et al. ANZJP 2020; 54 970–984). This heightened susceptibility is theorized to be shaped by a complex interplay of diverse socio-demographic factors experienced by these children, collectively known as social determinants of mental health (SDOMH), include ethnicity, socioeconomic status, household conditions, family dynamics, and neighborhood deprivation (Allen et al. IJP 2014; 26 392–407).
Objectives: This study examined the collective and unique role of diverse social determinants of mental health (SDOMH) associated with mental health problems (MHP) for children with MID, compared to peers with and without MHP.

Methods: Combining microdata from Statistics Netherlands, municipality data from The Hague and mental health care records, this population-based case-control study included four groups aged 0-17 years (M_{age} = 10.6, 35.6% female). Two groups of children receiving outpatient mental health care for MHP with MID (n=505) and without MID (n=2,767), each with a matched control group from the general population (n=2,525 and n=13,835, respectively), were studied. Through multivariate logistic regression analyses, both MHP groups were compared to their control group and each other to examine the likelihood of a particular SDOMH associated with receiving mental health care for MHP in children with and without MID.
Results: Children with MID receiving mental health care showed significant differences in multiple domains compared to their control group and to children receiving mental health care without MID. In the multivariate model, they were less likely to have European-born mothers, more likely to have parents with moderate or low education levels, and tended to live in smaller, single-parent, lower-income households. Similar, though less deviant, patterns were observed for children without MID receiving mental health care compared to the general population, except for parental education. Additionally, children without MID were more likely than their controls to reside in densely populated areas with lower neighborhood education levels.
Conclusions: Our study highlights that diverse SDOMH are associated with the likelihood of receiving care for MHP in children. Moreover, children with MID face disproportionate disadvantages, particularly regarding low parental education and household income. Thus, interventions should not only target the child but also their family and environmental context.

"Evaluating the Implementation and Best Practices of Foster Care in Greece: Insights from Law 4538/2018 and the Anynet System"

I. Farmakopoulou[1], V. Baltsioti[1] and M. Theodoratou[2,3]*
[1]Sciences of Education and Social Work, University of Patras; [2]Social Sciences, Hellenic Open University, Patras, Greece and [3]Psychology, Neapolis University Pafos, Pafos, Cyprus
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1178

Introduction: The institution of child fostering aims to protect minors who lack a secure family environment. In Greece, the implementation of Law 4538/2018 and the Anynet electronic system sought to de-institutionalize minors. This paper, based on a doctoral thesis, investigates the law's impact and identifies best practices in child fostering.
Objectives: This study aims to evaluate the implementation of Law 4538/2018 in Greece and the Anynet electronic system, focusing on their impact on de-institutionalizing minors. Additionally, it seeks to identify best practices in the foster care system and their application in child protection settings.
Methods: A mixed-method approach was used. The first part involved a quantitative study targeting Directors of Child Protection Frameworks across Greece and foster parents. The second part employed a qualitative case study method, using semi-structured interviews with social workers from four selected Child Protection Frameworks recognized as examples of best practices
Results: The research revealed that, despite the introduction of Law 4538/2018, foster care in Greece remains underutilized, especially for adolescents. Long-term fostering is the most common form, with most children aged four to six. Contact with biological parents is limited, often leading to adoption. Social workers lack sufficient training and familiarity with Anynet, impacting foster placements. However, child protection frameworks that applied specialized strategies for difficult cases saw fewer placement failures. A Unified Foster Care Protocol could standardize and improve foster care practices nationwide.
Conclusions: Though Law 4538/2018 and Anynet are steps forward, Greece's foster care system is still underdeveloped, with minimal increases in placements. Targeted case management and better social worker training are essential for success. Implementing a Unified Foster Care Protocol could enhance consistency and improve outcomes for fostered children.

Reflective Functioning, Emotion Regulation and Physiological Reactivity in Children with and without Behavioral Disorders: a Multimethod Approach

M. Tironi[1]*, A. Schiavoni[1], F. Rospo[1], F. Bizzi[1] and S. Charpentier Mora[1]
[1]University of Genoa, Genoa, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1179

Introduction: Mentalizing (operationalized as reflective functioning; RF), emotion regulation (ER), and reactivity (operationalized as physiological reactivity; PR) are highly relevant protective factors during development. However, limited research has examined these constructs during middle-childhood using a multimethod approach.
Objectives: The first aim compared differences in these constructs between children with behavioral disorders and a non-clinical group, measuring PR during a dyadic stress task involving conflict with the mother. The second aim explored the relationship between RF and both ER and PR considering the moderating role of externalizing symptomatology.
Methods: The study involved 50 children with behavioral disorders (*Mage* = 11.3, *SD* = 1.76; 58% male) and 89 non-clinical children (*Mage* = 10.6, *SD* = 1.64; 48% male). The *Child Reflective Functioning Scale* applied to the Child Attachment Interview was used to assess RF, the *How I Feel* to assess self-reported ER over the past three months, and the *Positive and Negative Affect Scale for Children* to assess self-reported ER before and after the dyadic stress task. Shimmer 3 GSR+ device has been applied to measure physiological indexes of heart rate variability (HRV) and galvanic skin response (GSR) to assess PR during the dyadic stress task. Mothers completed the *Child Behavior Checklist* to assess child's externalizing symptomatology.
Results: Children with behavioral disorders showed lower levels of both global and others-oriented RF and reported higher levels of negative emotions in the previous three months, compared to their non-clinical peers. Both global and others-oriented RF were negatively correlated with reported negative emotions. In contrast, the non-clinical group exhibited higher levels of positive emotions in the previous three months and greater PR during the

dyadic stress task. Additionally, externalizing symptomatology moderated the association between others-oriented RF with 1) physiological reactivity (i.e., GSR), only at lower levels of externalizing symptoms; 2) emotion regulation (i.e., emotional control subscale of the *How I Feel*), only at higher levels of externalizing symptomatology.

Conclusions: These findings reinforce prior research suggesting that children with behavioral disorders exhibit lower levels of RF, especially towards others, and negative emotions which may be risk factors for the development of behavioral disorders. Using a multi-method approach allowed to both evaluate ER and PR, highlighting the differences between the subjective perception of emotions and their physiological response. Lastly, the lower PR during the dyadic stress task in the clinical group could be a consequence of greater habituation to conflict, a hypothesis that could be explored in future research.

How to Tackle ADHD Medication Shortage and Changes in Shared Care Protocol (SCP) in Child and Adolescent Mental Health Services (CAMHS)

S. M. Toparlak[1]*, E. Fergusson[1], M. Costa[1], C. Kowalski[1], R. Chapman[1], F. Whitaker[1] and R. Hogan[1]

[1]Oxford Health NHS Foundation Trust, Oxford, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1180

Introduction: Our team faced two challenges in prescribing for patients with ADHD. On 27 September 2023, a shortage of methylphenidate prolonged-release capsules and tablets, lisdexamfetamine capsules, and guanfacine prolonged-release tablets was announced in the UK.

SCP is an agreement between secondary care, patient and GPs, which asks GPs to continue prescribing ADHD medication when young person is stable on a dose, this also applies to when the doses are changed. However, many GP practices in Oxfordshire declared a position statement that they would decline prescribing ADHD medication to adult or child patients on a "shared care" basis due to funding issues to support specialist reviews. These challenges led us to adapt our practices and create a protocol.

Objectives: To make all staff members aware of recent updates on ADHD medication stock availability at local depots to ensure continuity of care and minimise distress.

To help reduce the number of declined shared care requests by GPs in 6–17-year-olds.

To identify the patients of GP practices that do not prescribe ADHD medication to adults so that a planned discontinuation of treatment can take place prior to discharge from CAMHS services.

Methods: Young people's and their carers' feedback regarding the medication shortage were carefully recorded.

Concerns were raised and discussed in multi-disciplinary meetings via MS Teams and in person.

Team members shared information with each other with a view to creating a protocol to minimise the risk to patients' safety and distress in families.

Results: Regular updates on ADHD medication availability, along with equivalent conversions of long-acting medications were sent to all staff members via email by the Trust.

Our service developed a "protocol for CAMHS ADHD when the children and young people's (CYP) shared care protocol is declined and how to handle discharges at age 18."

We agreed to make young people and carers aware of the current situation for prescribing ADHD medication in adults within Oxfordshire to explore the need for continuing medication in reviews.

ADHD medications were planned to be discontinued prior to discharge, if patients are 17, on ADHD medication, whose GP practice declines SCP. and do not meet threshold for community adult mental health team referral.

We agreed to consider prescribing for a brief time beyond age 18 on a case-by-case basis if patients are preparing for, or are currently taking, A-level (or other) exams or whereby discontinuing medication poses significant risk.

Conclusions: Patients and staff members were greatly affected by the ADHD supply issues as well as current changes in SCP. However, team members took necessary steps to address the current issues proactively.

We plan to develop guidelines about stopping stimulants under supervision prior to discharge from CAMH services.

Maternal perinatal depressive disorders and the risk of attention deficit and hyperactivity disorder in offspring: A retrospective cohort study using linked data

B. S. Tusa[1,2]*, R. Alati[1,3], K. Betts[1], G. Ayano[1] and B. Dachew[1,4]

[1]School of Population Health, Curtin University, Perth, Australia; [2]Department of Epidemiology and Biostatistics, College of Health and Medical Sciences, Haramaya University, Haramaya, Ethiopia; [3]Institute for Social Science Research, The University of Queensland, Brisbane and [4]enAble Institute, Curtin University, Perth, Australia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1181

Introduction: Maternal perinatal depression may increase the risk of neurodevelopmental disorders such as attention deficit hyperactivity disorder (ADHD), in children, either directly or through indirect pathways involving adverse birth outcomes.

Objectives: This study assesses the risk of ADHD in offspring born to mothers with perinatal depressive disorders, examining both the direct and indirect pathways through adverse birth outcomes such as low birth weight, low APGAR scores, and preterm birth.

Methods: The study employed a retrospective cohort design, utilising administrative-linked health data from New South Wales. Maternal perinatal depressive disorders and offspring ADHD were identified using the International Classification of Diseases (ICD-10) codes. A generalised linear model with a binomial distribution and a log link function was applied to estimate the direct association. Additionally, a mediation analysis examined the mediational effect of low birth weight, low APGAR scores, and preterm birth on the association between maternal antenatal depressive disorder and ADHD.

Results: After adjusting for potential confounders, offspring of mothers with antenatal, postnatal, and perinatal depressive disorders are respectively 2.10 times (RR = 2.10, 95% CI = 1.75–2.53), 1.81 times (RR = 1.81, 95% CI = 1.41–2.31), and 2.16 times (RR =

2.16, 95% CI = 1.84–2.54) more likely to have ADHD compared to their counterparts. The impact of maternal antenatal depressive disorder on offspring ADHD was mediated by preterm birth, but not by low birth weight or low APGAR scores. The proportion of the total effect mediated by preterm birth was only 0.73%, indicating this mediation effect was very minimal, about 45 times smaller than the direct effect.
Conclusions: Our study revealed that maternal perinatal depressive disorders are associated with an increased risk of offspring ADHD, with very minimal or no mediating effects from adverse birth outcomes. Therefore, implementing early intervention strategies aimed at improving maternal mental health is crucial to reducing the risk of ADHD in children.

Urban mental health of children and youth: how cities affect our brains

J. Vecerina[1]* and Z. Kušević[2]

[1]Diagnosis and treatment, Zagreb child and youth protection center and [2]Clinic for child and adolescent psychiatry, University hospital center Zagreb, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1182

Introduction: This literature review will present the results obtained by searching available databases on the connection of everyday life in urban environments with the occurrence of symptoms of anxiety and depression, the use of addictive substances, schizophrenia as well as the occurrence of suicide in children, adolescents, and young adults. The results will be compared to the occurrence in suburban and rural areas.
Objectives: The work aimed to clarify the hitherto known risk and protective factors associated with everyday life in the urban environment and to show how its adaptation has the potential to promote and protect the mental health of children and adolescents.
Methods: Search of available databases: Medline, Scopus, PubMed.
Keywords: Urban mental health; Adolescent mental health; Environment and health; Urban design for mental health;
Results: The results of the presented studies indicate an ambivalent influence of the urban environment on the mental health of young people: on the one hand, better education and employment opportunities, easier choice of social circles, accessibility to health care services (especially if all of the mentioned services are accessible to young people independently through active mobility) contributes to the improved feeling of mental well-being. On the other hand, fewer green spaces, oversaturation with sound and visual stimuli, as well as involuntary interactions with other citizens can endanger mental health.
The collected data indicates a greater number of young people and adults with depression, anxiety symptoms, and psychotic symptoms in cities, while the frequency of attempted and committed suicides is more common in rural areas.
Many different interventions in the urban environment can improve the day-to-day experience and cumulative effect of city streets on our mental health. Such interventions in the built environment include increasing the amount of space dedicated to young people (especially young women) at the same time with the placement of green areas, decreasing automobile dependency, and improving active mobility infrastructure and public transport safety and efficiency.

Protective and risk factors of urban environments

Education accessibility	Lack of green spaces
Employment accessibility	Air pollution
Healthcare services accessibility	Involuntary interpersonal interactions
Improved mobility and autonomy	Overwhelm with visual and hearing stimuli
More autonomy in choosing social circles	Alienation

Image 3:

SLIKA 3-4: Životna prevalencija, prevalencija u posljednjih godinu dana i prevalencija u posljednjih mjesec dana uzimanja sedativa ili trankvilizatora, na razini cijelog uzorka, po stupnju urbaniziranosti (%)
Prevalence of sedatives and tranquilizers usage in Croatian population dependent on urbanization degree

Conclusions: Urbanization is related to the mental health of citizens, especially young people, and it is important to follow the guidelines when designing the public space of urban areas, which relate to the presence of green spaces, opportunities for active

movement, and the existence of places that enable and encourage socialization, all with the perception security.
The results known so far should be kept in mind during further research into the etiology and epidemiology of mental health in young people, starting with epigenetics and ending with healthcare planning.

EPV0397

Trends in Depressive Disorders Among Patients at the Child and Adolescent Psychiatric Unit at Siriraj Hospital Over a 9-Year Period

N. Virikulcharoen[1]* and W. Atsariyasing[1]

[1]Department of Psychiatry, Mahidol University, Bangkok, Thailand
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1183

Introduction: Depression is a significant global health issue among children and adolescents. It has been identified as a leading cause of disability among this population worldwide.
Objectives: This study compares the characteristics and related factors of depressive disorders among child and adolescent patients in Thailand between 2014 and 2022, with the aim of enhancing treatment and screening strategies.
Methods: We included child and adolescent patients diagnosed with depressive disorders at Siriraj Hospital, comprising 93 patients in 2014 and 172 patients in 2022. Data on demographics, personal and social history, diagnoses, comorbidities, and treatment outcomes were collected from medical records. Results were analyzed using relative risk, 95% confidence intervals, and p-values through modified Poisson regression.
Results: The proportion of female patients significantly increased from 49.5% in 2014 to 73.7% in 2022 (p<0.001). The prevalence of domestic violence rose from 7.5% in 2014 to 20.3% in 2022 (p=0.006). Suicidal ideation increased from 16.1% to 51.2% (p<0.001), and self-harming behaviors rose from 22.7% to 57.6% (p<0.001). Referrals to psychologists doubled from 22.6% in 2014 to 43.9% in 2022 (p<0.001), while hospitalization rates within the first year of treatment also increased from 6.5% in 2014 to 15.2% in 2022 (p=0.037). No significant differences were observed in age, family structure, parenting style, disease-triggering factors, psychotic symptoms, comorbidities, medication use, or remission rates between the two years. Our regression analysis indicated that authoritative parenting significantly influenced remission rates, with patients under authoritative parenting being 1.98 times more likely to achieve remission compared to those under other parenting styles (p=0.042).
Conclusions: There is a rising trend in the prevalence of depressive disorders among female child and adolescent patients, accompanied by more severe symptoms such as increased suicidal ideation and self-harming behaviors. Hospitalization rates within the first year of treatment have also increased. Despite these trends, remission rates have remained unchanged. The study highlights the potential role of authoritative parenting in improving remission rates. These findings underscore the need for enhanced screening protocols, updated treatment guidelines, and targeted parental counseling to improve depression management in the future.

The Association between Impulsivity and Anxiety in Adolescents with Insomnia: The Moderating Role of Evening Chronotype

Y. L. Wong[1]*, H. F. Sit[1], F. T. W. Cheung[1] and S. X. Li[1,2]

[1]Department of Psychology and [2]The State Key Laboratory of Brain and Cognitive Sciences, The University of Hong Kong, Hong Kong, Hong Kong
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1184

Introduction: Adolescence is a unique stage of cognitive, psychosocial and physical growth and development. This period is often associated with increased evening tendency, as well as increased risks for mental health and sleep problems. Insomnia is amongst the most common sleep problem in youths and is commonly associated with impulsivity and anxiety symptoms. Previous research suggested the comorbidity of insomnia and eveningness as a significant risk factor for anxiety symptoms in adolescents. Meanwhile, there has been some evidence suggesting that insomnia and eveningness are respectively associated with impulsivity. Nonetheless, the relationships among eveningness, impulsivity and anxiety in the context of insomnia remained unclear.
Objectives: To investigate how circadian preference moderates the association between impulsivity and anxiety symptoms in adolescents with insomnia.
Methods: Adolescents aged 12-20 years old diagnosed of DSM-V insomnia disorder were recruited. They completed self-reported questionnaires, including the Morningness-Eveningness Questionnaire (MEQ) for assessing circadian preferences, Insomnia severity indexes (ISI) for assessing insomnia symptoms, the General Anxiety Disorder (GAD) scale to measure anxiety symptoms, and the Barret Impulsiveness Scale (BIS) for assessing impulsivity. Participants completed an objective cognitive task (the Balloon Analog Risk Task, BART) to measure risk-taking behavior. Their sleep was objectively assessed by 7-day actigraphy.
Results: Eighty-eight participants were recruited into this study (age:18.20 ± 1.61 years). Among them, 44% of the participants were identified as eveningness type (MEQ < 42). There were no significant differences in anxiety symptoms and impulsivity based on both self-reported and behavioral task between circadian preferences (*all* $p > .05$). Circadian preferences was found to significantly moderate the association between self-reported impulsivity and anxiety symptoms after controlling age and sex factor ($p = .009$) but not the association between risk-taking behavior and anxiety symptoms ($p > .05$). Specifically, higher self-reported impulsivity was associated with more severe anxiety symptoms in adolescents with insomnia and eveningness ($p = .006$). No significant association was found between self-reported impulsivity and anxiety symptoms in non-eveningness group ($p > .05$).
Conclusions: The findings suggested the role of circadian preference in moderating the association between impulsivity and anxiety symptoms in adolescents with insomnia. Further research may explore different aspects of impulsivity and examine the causation between eveningness, insomnia, impulsivity and anxiety among adolescents in a longitudinal design.

Longitudinal study of mental abilities in teaching primary school students with intellectual disabilities

Y. Sidneva[1,2*], A. Zakrepina[1,3], T. Butusova[3] and L. Pronina[3]

[1]rehabilitation, Clinical and Research Institute of Emergency Pediatric Surgery and Traumatology (CIEPST); [2]neuropsychiatry, National Medical Research Center of Neurosurgery named after N.N. Burdenko and [3]defectology, Federal State Budgetary Scientific Institution Institute of Correctional Pedagogics /FGBNU ICP, Moscow, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1185

Introduction: The results of achievements in mastering the program material of students of a special school by the end of the fourth year of study are characterized by a large variability in training, which allows us to assert the need to develop and apply special teaching techniques and methods, harmonize the academic workload

Objectives: to study the mental capabilities and identify learning difficulties of fourth-grade students with mental disabilities in elementary school by the end of study

Methods: Two samples of fourth-graders (132 students) were identified: Group 1 - 100 students with mild mental retardation, Group 2 - 32 students with severe intellectual disabilities. Methods: observation, pedagogical experiment, cluster analysis

Results: Clustering criteria: volume and level of assimilation of program material in academic subjects; achievement of subject and personal results.

In group 1 (75%), 3 clusters were identified by academic performance in the main academic subjects, which are uniform in terms of the variability of dynamics, which indicates the homogeneity of the group of students; however, the groups differ in the level of achievement of subject and personal results (sufficient, average, minimal).

In group 2 (25%), 3 clusters were also identified, which are variable, but do not duplicate each other, and have an individual spread of indicators in the dynamics of subject and personal results within each cluster, which indicates the heterogeneity of the group of students in each cluster

Conclusions: three levels of dynamics in the education of students with varying degrees of mental retardation were identified. The range in the variations of the results of the 2nd group of students with severe intellectual disabilities indicates the need for individualization of education, selection of partial programs taking into account the special educational needs of each student, and the development of special personalized approaches to education. Apparently, it is also necessary to select the optimal amount of academic workload and the level of complexity of the material studied, compliance with health-saving technologies in accordance with the individual psychological characteristics of the student

Disclosure of Interest: None Declared

EPV0402

Anxiety disorders and self-esteem levels of primary school children

F. Erotokritou[1], I. Koutelekos[2], A. Soldatou[3] and A. Zartaloudi[2*]

[1]MSc in General Pediatrics and Pediatric Subspecialties - Clinical Practice and Research, University of Athens; [2]University of West Attica and [3]University of Athens, Athens , Greece

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1186

Introduction: There is no doubt that childhood is a crucial period in a person's development. Anxiety disorders in modern times are at the forefront, with a huge number of children and adolescents suffering from them. An important asset, a protective shield against anxiety disorders that promotes mental well-being is self-esteem.

Objectives: The present study aims to investigate the level of self-esteem and the differentiation of various anxiety disorders, as well as the assessment of the severity of anxiety symptoms exhibited by children aged 9-12 years, who were attending the 4th, 5th, and 6th grades of public primary schools in the Larnaca district of Cyprus. Additional objectives are to investigate possible associations between these variables and the socio-demographic characteristics of the students in combination with their teacher-reported school performance.

Methods: To 249 students were administered (a) a Sociodemographic Characteristics Questionnaire, (b) the Rosenberg Self-Esteem Scale, (c) the Spence Children's Anxiety Scale (SCAS), and their teachers were given a questionnaire to assess the academic performance of each student individually.

Results: The protective role of self-esteem in the development of anxiety disorders ($p<0.001$) and feelings of loneliness and the positive effect on school performance was confirmed by the study. Besides, high levels of self-esteem were associated with reduced feelings of loneliness (p 0.001), increased school performance (p 0.020) and greater satisfaction with teacher help (p 0.001). Additionally girls had more frequent anxiety disorder behaviours compared to boys (p 0.028), especially panic disorders, agoraphobia (p 0.020), specific phobias (p 0.012) and separation anxiety (p 0.005). Interestingly, the study found that stronger feelings of loneliness at school were associated with increased occurrence of anxiety disorders ($p<0.001$). It was also found that older students were less likely to develop anxiety disorder behaviours (p 0.002), while children with more siblings in a family showed worse ratings of student performance at school (p 0.001). Finally, it appears that school performance was associated with less social phobias (p 0.048) and that those children who received parallel support had lower performance than those who did not ($p<0.001$).

Conclusions: Promoting increased levels of self-esteem, especially in children, is very important as it can help safeguard mental health. Anxiety disorders are a crucial problem in modern times, so their continuous study and treatment are essential. Holding informational and awareness-raising conferences for teachers, parents, and generally all professionals who come into frequent contact with children at this sensitive age is necessary and indisputable.

Investigation of Sociodemographic Characteristics and Psychosocial Risk Factors in Adolescents Diagnosed with Major Depressive Disorder and Their Effects on Suicide Probability

M. Dilli Gürkan[1]* and S. G. Sismanlar[2]

[1]Child and Adolescent Psychiatry, Bandırma Education and Research Hospital, Balıkesir and [2]Child and Adolescent Psychiatry, Kocaeli University, Kocaeli, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.445

Introduction: Those with a history of depression during adolescence are at increased risk of suicidal ideation, attempts, and suicide completion in adulthood. Therefore, in order to reach adolescents at risk of suicide attempt or death due to suicide, it is important to determine the risk factors for MDD and predictors of suicidal ideation in adolescents diagnosed with major depressive disorder (MDD) in clinical samples.
Objectives: This study aimed to compare adolescents diagnosed with major depressive disorder with healthy adolescents in terms of sociodemographic characteristics and psychosocial risk factors and to determine the important predictors of suicidal ideation based on sociodemographic variables.
Methods: The study group included 53 adolescents aged between 15 and 18 years who were newly diagnosed with major depressive disorder (MDD) 53 adolescents matched in terms of age and gender, who did not have a mental disorder diagnosis.Schedule for Affective Disorders and Schizophrenia for School-Age Children (6-18 Years) - Present and Lifetime Version - DSM-5 was applied to the adolescents by the clinician, and the Sociodemographic Data Form was filled in with the information obtained from both adolescents and parents. Adolescents were asked to fill out the Suicide Probability Scale.
Results: In our study, adolescents diagnosed with major depressive disorder (MDD) were found to have higher rates of smoking, alcohol use, broken family structure, and school absenteeism compared to the control group; while the family's monthly income, the child's academic success, the rate of attending daycare during childhood, and their participation in social activities were found to be lower. Alcohol use and family relationship were found to be factors that increase the likelihood of suicide in adolescents diagnosed with depression. In the study, adolescents diagnosed with depression were found to have a higher rate of physical abuse, self-harm behavior, and a history of suicide attempts, domestic physical violence, and a history of suicide attempts among friends compared to the control group. Domestic physical violence was found to be factors that increase the likelihood of suicide in adolescents diagnosed with depression.
Conclusions: In our study, we tried to define the sociodemographic differences and possible risk factors of depression in adolescents diagnosed with depression who applied to a university hospital clinic compared to healthy adolescents.Conducting large-sample community-based studies to understand the risk factors for depression and suicidal thoughts, which are common in children and adolescents, is very important in terms of community mental health and preventive mental health.

Prevalence and Comorbidities of Tourette Syndrome in Children and Adolescents: Insights from the National Survey of Children's Health (NSCH)

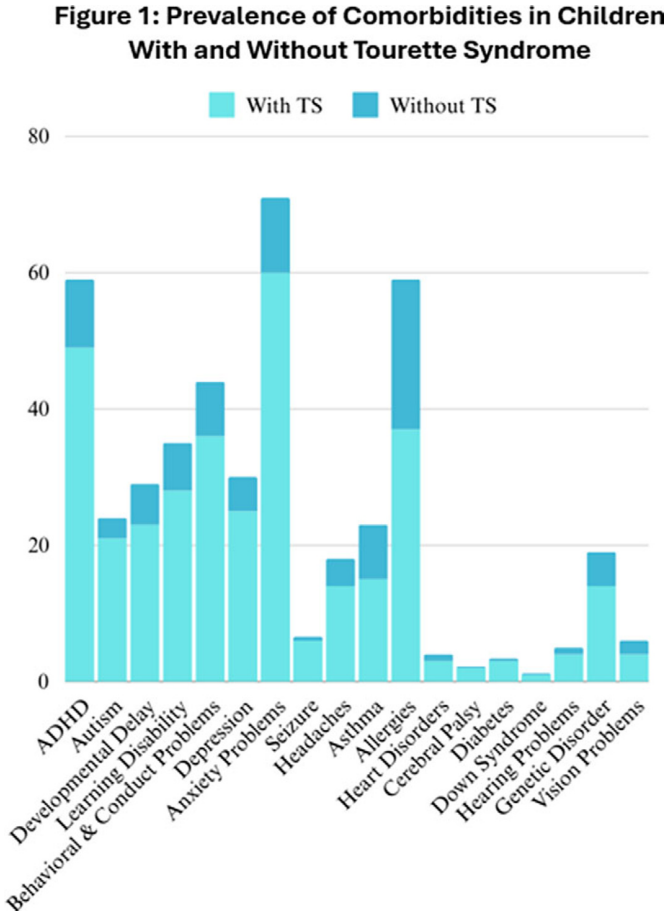
M. Saeidi[1]*, O. Alzein[1], K. Jafari[1], M. Salehi[2], S. Jaka[3] and S. Gunturu[1,4]

[1]Department of Psychiatry, Bronx Care Health System, New York; [2]Department of Psychiatry, University of Minnesota School of Medicine, Minneapolis; [3]Department of Psychiatry and behavioral Sciences, Nassau University of Medical Center and [4]Department of Psychiatry, Icahn School of Medicine at Mount Sinai, New York, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.450

Introduction: Tourette Syndrome (TS) is a neurodevelopmental disorder involving multiple motor and vocal tics, typically beginning in childhood with symptoms peaking around age 10-12. Though the exact cause remains unknown, genetic and environmental factors are believed to contribute to its development. Children with TS often face significant social, emotional, and academic challenges, further complicated by comorbidities which can lower their quality of life and place stress on family dynamics.Using data from the 2021 National Survey of Children's Health(NSCH), this study provides updated insights into the prevalence and comorbidities of TS.
Objectives: Assess TS prevalence in children aged 3-17 using 2021 data
Identify common TS comorbidities and evaluate TS's demographic distribution
Methods: This cross-sectional study utilized 2021 NSCH data collected via parent-proxy responses in English and Spanish through mail and web-based surveys in the United States. Statistical analyses, including t-tests, Chi-Square tests, and multivariate regression, were performed to explore associations between TS, socio-demographic factors, and comorbidities. Results were reported using adjusted odds ratios and confidence intervals, with analyses conducted in Stata 18.0.
Results: This study included 79,236 participants, of which 208 (0.26%) had TS.The TS group had a mean age of 12.7 years, with most cases found in adolescents aged 11-17.Males made up 74% of TS cases. While TS was slightly more common in White participants (72%), no significant racial differences were found. Higher-income households had lower odds of TS.Comorbidities were more common in individuals with TS:
Neurodevelopmental and Behavioral Disorders: ADHD (49% in TS vs. 10.2% in non-TS), Autism (21% vs. 3.2%), Learning disabilities (28% vs. 7.5%), Developmental delay (23% vs. 6%), Behavioral problems (36%)
Psychiatric Disorders: Anxiety (60% in TS vs. 11.3%), Depression (25% vs. 5%), Seizures (6%), Headaches (14.4%).
Immune Conditions: Asthma (15.5% in TS vs. 8%), Allergies (37%).
Physical Health: Hearing problems (3.8%), Vision problems (4.3%). *Fig. 1*
Children with TS born prematurely or with low birth weight had higher rates of comorbidities. Asthma was more common in the TS with a history of prematurity (37.1%) and TS with a history of low birth weight(30.7%) compared to the overall TS population (15.5%). Autism was also more prevalent in these groups, suggesting

increased risks of comorbidities due to premature birth and low birth weight. *Fig.2*

Image 1:



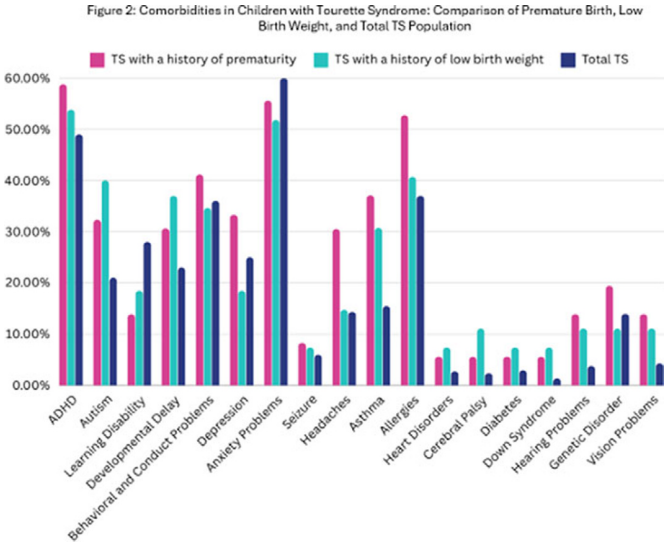


Image 2:

Conclusions: The study highlights significant socio-demographic disparities and the increased burden of comorbid conditions in children with TS. These findings emphasize the need for early diagnosis and comprehensive management strategies to address the complex challenges of TS, particularly the high prevalence of neurodevelopmental, psychiatric, and physical health comorbidities.

"Unspecified Dissociative Disorder: A Case Report"

F. J. Gonzalez Zapatero[1], L. Del Canto Martinez[1], M. B. Arribas Simon[1]*, P. Martinez Gimeno[1], B. Rodriguez Rodriguez[1], M. A. Andreo Vidal[1], M. Rios Vaquero[1], A. Monllor Lazarraga[1], M. P. Pando Fernandez[1], M. Calvo Valcarcel[1], N. Navarro Barriga[1], M. Fernandez Lozano[1], M. J. Mateos Sexmero[1] and L. ROJAS VAZQUEZ[1]

[1]Hospital Clinico Universitario de Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1187

Introduction: Psychosis is a complex mental disorder characterized by a profound impairment in reasoning, emotional regulation, memory, and daily functioning. It is often accompanied by symptoms such as delusions and hallucinations, which can significantly disrupt an individual's ability to engage in everyday activities. This case study focuses on a 37-year-old Senegalese woman who presented with disorganized behavior and incoherent speech, illustrating the challenges in diagnosing and treating unspecified psychosis.
Objectives: The primary aim of this study is to analyze the clinical presentation, differential diagnosis, and treatment outcomes of a patient diagnosed with unspecified psychosis. Additionally, it seeks to highlight the importance of cultural considerations and language barriers in psychiatric assessment.
Methods: The patient arrived at the emergency department in a distressed state, accompanied by a friend due to her inability to communicate in Spanish. Clinical assessment revealed disorganized speech, severe anxiety, and potential auditory hallucinations. The clinical interview indicated that the patient had exhibited increasingly erratic behavior over several weeks, including withdrawing from work and engaging in bizarre actions such as throwing objects and speaking to herself. Comprehensive laboratory tests, including routine blood work and urine analysis, were conducted to exclude other psychiatric and medical conditions.
Results: The laboratory results were largely normal, with the exception of a positive serology for hepatitis B. A thorough differential diagnosis ruled out other psychiatric disorders, including schizophrenia, substance-induced psychosis, and major depressive episodes. After establishing the diagnosis of unspecified psychosis, the treatment regimen was initiated with Amisulpride (100 mg) and Lorazepam (1 mg). Following treatment, the patient demonstrated a significant reduction in delusional thoughts and an improvement in her overall psychiatric condition.
Conclusions: The findings support the effectiveness of atypical antipsychotic medication in treating unspecified psychosis,

particularly in alleviating delusional ideas and associated psychiatric symptoms. Furthermore, this case underscores the critical role of family support and the necessity for ongoing monitoring and follow-up in the management of psychotic disorders. It emphasizes the need for culturally sensitive approaches to psychiatric care, especially in cases involving language barriers.
This case illustrates the complexities involved in diagnosing and treating unspecified psychosis, particularly in patients from diverse cultural backgrounds. Early intervention and a combination of pharmacological and psychosocial support are essential for improving patient outcomes. Continued research and awareness are necessary to enhance the understanding and management of psychotic disorders in various populations.

doi: 10.1192/j.eurpsy.2025.1188

Introduction: Speech patterns offer valuable insights into cognitive and emotional states, particularly in mental health conditions such as Major Depressive Disorder (MDD). Traditional assessments often fail to capture its full severity, prompting the need for objective, non-invasive tools.
Objectives: The objective of this study is to explore the potential of automatic speech analysis as a new method for distinguishing between varying severities of Major Depressive Disorder (MDD), and to assess how childhood trauma may further influence speech characteristics in individuals with depression.
Methods: Participants were recruited from the psychiatric clinic at the University Hospital in Nice, France. The cohort consisted of 27 patients diagnosed with MDD, divided into mild-to-moderate and severe depression groups based on Beck Depression Inventory (BDI) and Montgomery–Åsberg Depression Rating Scale (MADRS) scores. Speech recordings from semi-structured (V0) and free (V1) clinical interviews were analyzed using automatic speech recognition and feature extraction. Linguistic, prosodic, and spectral features were examined. Additionally, childhood trauma was assessed using the Childhood Trauma Questionnaire (CTQ), and associations with speech characteristics were explored.
Results: In the severe depression group, longer pause durations and lower word frequency were observed in V0 interviews. Word frequency and proper noun usage were significantly different between groups, but the small differences in means made interpretation difficult. Free speech analysis (V1) showed that more severe depression correlated with fewer repetitions and reduced semantic richness. In BDI-based analysis, severe depression was associated with lower F2 frequency and bandwidth, alongside lower Harmonics-to-Noise Ratio (HNR), which persisted in both V0 and V1. Prosodic parameters revealed less speech duration and articulatory effort in severe cases. Analysis of childhood trauma showed that traumatic load correlated with longer speaking time and greater discourse complexity, in contrast to depression severity, which was associated with shorter speech and fewer repetitions.
Conclusions: Speech parameters, particularly pause duration and word frequency, demonstrate potential for distinguishing depression severity. Childhood trauma influences linguistic complexity, suggesting different underlying mechanisms between trauma and depression. Further studies are needed to validate these findings and explore the clinical applicability of speech analysis in psychiatric assessments.

EPV0407

Assessing the Mental Health Effects of Climate Change: A Narrative Review

H. J. Gomes[1*], M. Pires[2], C. Freitas[3], M. Albuquerque[3] and R. M. Freitas[3]

[1]Department of Psychiatry and Mental Health, Nordeste Local Health Unit, Bragança; [2]Department of Psychiatry and Mental Health, Guarda Local Health Unit, Guarda and [3]Integrated Responsability Center - Mental Health, Hospital Pedro Hispano, Matosinhos Local Health Unit, Matosinhos, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1189

Introduction: Climate change refers to any change in climate over time, whether due to natural variability or human activity. It is estimated that between 2030 and 2050, climate change will cause an additional 250,000 deaths annually. Therefore, climate change has emerged as one of the most pressing global challenges of the 21st century, with far-reaching environmental, social, and economic consequences. Beyond its direct physical impacts, growing evidence links climate change to adverse mental health outcomes.
Objectives: This review aims to synthesize current research on the impact of climate change on mental health, identifying key mental health disorders associated with climate-related stressors and highlighting vulnerable populations.
Methods: We performed a narrative literature review by searching PubMed, Google Scholar, and ScienceDirect articles published in English in the last ten years.
Results: Climate change significantly affects mental health, with literature suggesting that for every one-degree Celsius increase in temperature, the incidence of mental health problems rises by approximately 0.9%. Extreme weather events like hurricanes, floods, and wildfires linked to climate change can negatively impact mental health, particularly by contributing to higher rates of depression and post-traumatic stress disorder. Additionally, more gradual shifts in climatic conditions, such as rising temperatures and declining air quality, have also been found to harm mental well-being, contributing to "eco-anxiety" and feelings of helplessness. Vulnerable populations, such as children, the elderly, the mentally

ill, and marginalized communities, are at greater risk because of their limited coping resources and increased exposure to the impacts of climate change.
Conclusions: The effects of climate change can be direct or indirect, short-term or long-term, with a growing body of evidence showing its contribution to a wide range of psychological disorders. Policy-makers and mental health professionals must consider mental health in climate adaptation strategies and create support systems for affected populations. The European Psychiatric Association (EPA) has recently published a position paper urging the inclusion of mental health considerations in climate strategies. Nevertheless, more research is needed to document the extent of these impacts and the best options for mitigating and treating them.

Do pollutants and meteorological factors trigger more psychiatry admissions?

E. López Bardón[1]*, M. Menéndez Muñoz[1] and A. Serrano García[1]
[1]Servicio de Psiquiatría , Complejo Asistencial Universitario de León, León, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1190

Introduction: The high prevalence of mental health disorders makes investigating their etiology a fundamental activity. Factors influencing their physiology include genetic predisposition, substance use, environmental factors, etc. Among these, weather and atmospheric pollutants are two of the least studied. The biologically active agents in the atmosphere interact with living beings, disrupting their homeostasis and leading to alterations in both physical and mental health. This interaction was already noted in the Corpus Hippocraticum in the 4th century BC.
Objectives: The objective is to analyze the impact of various environmental factors and atmospheric pollutants on daily emergency hospital admissions for mental disorders in the healthcare area of the province of León from 2011 to 2022.
Methods: An observational, retrospective, ecological, longitudinal, and time series study is conducted. Admission data is sourced from the coding office at the Complejo Asistencial Universitario de León, meteorological data from the Agencia Estatal de Meteorología, and pollutant data from the Junta de Castilla y León. A combined database in Excel is created for statistical analysis, both descriptive and analytical (Poisson regression), using the SPSS statistical package.
Results: It was observed that hospital admissions for mental disorders are significantly related to sunlight hours, ozone, precipitation, average wind speed, CO, NO2, maximum atmospheric pressure, NO, and PM10.
Conclusions: The findings of this study show that meteorological factors and atmospheric pollutants are related to hospital admissions for mental disorders. Applying this information in psychiatric emergencies could improve forecasting and resource management during periods of higher demand.

Co-existence of Autism Spectrum Disorder (ASD) traits in an Irish sample of adults diagnosed with ADHD. Longitudinal outcomes.

D. Adamis[1,2,3,4]*, N. Langan[2], B. Gavin[5] and F. McNicholas[5]
[1]Psychiatry, University College Dublin, Dublin; [2]Sligo Mental health Services, Sligo; [3]University of Galway, Galway; [4]University of Limerick, Limerick and [5]University College Dublin, Dublin, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1191

Introduction: Autism Spectrum Disorder (ASD) and ADHD are both neurodevelopmental disorders which share genetic heritability and often coexist in adults diagnosed with ADHD and vice versa. Despite the overlap between the two disorders there are enough phenomenological differences to indicate that these conditions are sufficiently distinct
Objectives: To estimate the coexistence of ASD traits in an adult sample diagnosed with ADHD; to compare those screening positive for possible ASD to those scoring negative, in terms of functionality, quality life and clinical outcomes; to explore the effects of ADHD medication in three main outcomes (clinical, quality of life, and functionality) in those with only ADHD and in those with a coexistence of ASD and ADHD.
Methods: Prospective longitudinal study of an adult sample diagnosed with ADHD. Data collected on age, gender, medications and on scales: Autism Spectrum Quotient (AQ-10); Adult ADHD Clinical Outcome Scale (ACOS); Adult ADHD Quality of Life Questionnaire (AAQoL); Weiss Functional Impairment Rating Scale (WFIRS).
Results: Sample of 165 participants was recruited. The AQ-10 showed that n=74 (44.8%) of the participants had traits of ASD. Longitudinal analyses demonstrated that people with ADHD and ASD traits have worse clinical outcomes, quality of life, social skills and family functioning compared to those with ADHD only. The effects of ADHD medications (stimulants, atomoxetine) were significant in the three examined outcomes across the time but no significant effects of medications to those with ASD traits was found.
Conclusions: Hight coexistence of ADHD and ASD traits. Perhaps lesser if clinical diagnosis for ASD was performed. Medications for ADHD did not improve those with ADHD and ASD traits. Service implications (for local services): neurodevelopmental clinics is necessity now and not only special for ADHD, where adults with ADHD and ASD can be diagnosed and treated accordingly.

A possible explanation for resistance in schizophrenia

S. Laabidi[1], O. laabidi[1], A. touiti[1], A. Aissa[2]* and N. bram[1]
[1]forensic psychiatry and [2]psychiatry A, Razi hospital, manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1192

Introduction: Arachnoid cysts are intra-arachnoid space-occupying brain lesions, typically of a benign, congenital nature. Such cysts are quite rare, accounting for only 1% of all lesions in the intracranial space. In most cases, they are diagnosed accidentally by neuroimaging.Treatment-resistant schizophrenia (TRS) has a high burden both for patients and healthcare services. There is a need to identify treatment resistance earlier in the course of the illness, in order that effective treatment can be offered promptly. Recently, the co-occurrence of arachnoid cysts and schizophrenia has captured the popular attention about possible relevancy.
Objectives: Through a case report and a review of the literature, we hypothesize that arachnoid cyst is the cause of resistance in a patient with treatment-resistant schizophrenia.
Methods: Starting from a case report, we conducted a literature review on "PubMed", using key words "arachnoid cyst,arachnoid cyst and psychosis", "arachnoid cyst and treatment-resistant schizophrenia",
Results: We present a 47-year-old who is single and unemployed. His past psychiatric history revealed a diagnosis of schizophrenia, having been admitted several times in different inpatient psychiatric wards. In the psychiatric examination, the presence of auditory hallucinations, dissociated thinking, and predominantly negative symptoms was observed. His symptoms showed only minimal responsiveness.He was diagnosed with TRS owing to the inadequate response to two sequential antipsychotic trials (with adequate dose, duration, and adherence).Our evaluation of TRS began with a thorough review of the patient's psychiatric and treatment history. All nonpsychiatric causes, including untreated medical problems, that may contribute to ongoing psychotic symptoms have been ruled out. Physical examination and blood tests were unrevealing.Electroencephalography showed no signs of seizure activity. Following the evaluation process, a head CT scan showed a left paramedian cystic lesion at the level of the pineal gland. A cerebral MRI was performed in order to get a more detailed image. It confirmed the nature of the lesion and revealed the existence of an arachnoid cyst about 2.5 cm × 3.5 cm × 2.0 cm in size, centered on the quadrigeminal cistern with triventricular dilatation. This neurological tumor didn't require neurosurgery.
Conclusions: Our case emphasises the importance of considering an organic cause like any space-occupying lesion in the brain (an arachnoid cyst in our case) for the induction of psychopathological symptoms, even those of treatment-resistant schizophrenia, which represents a major clinical challenge. This also underlines the interest of neuroimaging in the initial workup and supports the hypothesis of psychosis as a global network.

EPV0414

Obstructive hydrocephalus caused by colloid cyst and treatment –resistant schizophrenia

S. Laabidi[1], O. laabidi[1], A. touiti[1], A. Aissa[2*] and N. bram[1]

[1]forensic psychiatry and [2]psychiatry A, Razi hospital, manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1193

Introduction: Treatment-resistant schizophrenia can be of primay or secondary etiology. Systematic and thorough differential diagnostics is essential to exclude organic causes for treatment-resistant schizophrenia .Colloid cysts are congenital benign tumor accounting for 15-20 % of intraventricular mass but only about 1% of intracranial ones.They frequently cause psychiatric disturbances. The pathology behind these psychiatric symptoms remains unclear.
Objectives: Through a case report and a review of the literature, we hypothesize that a colloid cyst in the third brain ventricle is the cause of resistance in a patient with treatment-resistant schizophrenia.
Methods: Starting from a case report, we conducted a literature review on "PubMed", using key words "colloid cyst and psychosis", "colloid cyst and treatment-resistant schizophrenia",
Results: We present a 48-year-old male who has a family history of malignant neoplasm.There was no history of physical illness. His past psychiatric history revealed a diagnosis of schizophrenia, having been admitted several times in different inpatient psychiatric wards.In the psychiatric examination, the presence of auditory hallucinations, dissociated thinking, and predominantly negative symptoms was observed.Recently, he has been diagnosed with treatment-resistant schizophrenia owing to the inadequate response to two sequential antipsychotic trials (with adequate dose, duration, and adherence). After a 2-month hospitalization, the severity of the psychotic symptoms had decreased but did not show remission. With no prodromes or triggering factors, our patient presented a drop attack without loss of consciousness and with instantaneous recovery to baseline status. He did not have any of the same experience previously.The physical and neurological examination did not reveal any positive findings. All biochemistry parameters were reported as normal range. Following the evaluation process, an urgent head CT scan showed a colloidal cyst at the anterior end of the third ventricle with dilatation of the lateral ventricles. A cerebral MRI was performed in order to get a more detailed image; it confirmed the diagnosis of a third ventricle colloid cyst immediately adjacent to the foramen of Monro with obstructive hydrocephalus. The patient was referred to the neurosurgical department for further evaluation. This neurological tumor didn't require neurosurgery.
Conclusions: Our case implies the importance of neuroimaging in patients with treatment-resistant schizophrenia to rule out any underlying organic cause.It also emphasises the importance of considering an organic cause like any space occupying lesion in the brain (colloid cyst in the third brain ventricle in our case) for induction of psychopathological symptoms, even those of treatment-resistant schizophrenia.

Post-Traumatic Diabetes: Focus on Psychiatric Trauma

C. Bey[1*], T. Ach[1,2] and A. Ben Abdelkarim[1,2]

[1]University of Sousse, Faculty of Medicine of Sousse, 4000 and [2]Endocrinology department, Farhat Hached University Hospital of Sousse , Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1194

Introduction: Physical and/or psychological trauma may contribute to the onset of type 1 diabetes. Forensic medicine experts recognize post-traumatic diabetes in rare cases that meet specific criteria, including the severity of the trauma, its occurrence within a short timeframe before diabetes onset, and the absence of prior diabetes indicators.

Objectives: This study aims to describe the clinical and biological characteristics of post-traumatic diabetes, with particular emphasis on the psychiatric aspects.
Methods: This retrospective, cross-sectional study analyzed cases of patients hospitalized for acute diabetes following physical or psychological trauma. The diagnosis of post-traumatic diabetes was based on the criteria of French forensic experts: acute autoimmune diabetes, trauma occurring within six months before diagnosis, and no signs suggesting pre-existing diabetes. Autoimmune involvement was confirmed by the presence of anti-pancreatic antibodies, specifically anti-glutamic acid decarboxylase (GAD) and/or anti-tyrosine phosphatase IA2.
Results: The study included 10 patients (8 men and 2 women) aged between 17 and 47 years (mean age 29.5±11 years). Family history of autoimmune disease was present in 40% of cases, and type 2 diabetes in 60%. The average body mass index was 24±6 kg/m², with obesity in 30% of cases. The mean blood glucose at admission was 14.54±3.48 mmol/L, and the average HbA1C was 6.51±0.56%. Anti-GAD antibodies were present in all patients, while anti-IA2 antibodies were detected in 20%. Clinically, 60% of patients presented with ketosis, and 40% with ketoacidosis. Psychiatric trauma, including grief in 3 patients and divorce in 2 patients, was the triggering factor in 50% of cases. All patients required insulin therapy upon admission, with obese patients receiving additional metformin.
Conclusions: This study supports the hypothesis of post-traumatic diabetes, particularly in cases of severe psychiatric trauma. Although scientific literature remains inconclusive, the role of stress in the onset of diabetes warrants further investigation due to the heterogeneity of findings regarding stress episodes preceding diabetes development.

Stunned Into Silence: Classical Catatonia secondary to Viral Myocarditis, a Case Report

F. R. Bhatti[1] and S. Liaqat[2]*

[1]Psychiatry, Pakistan Institute of Medical Sciences, Islamabad, Pakistan and [2]Psychiatry, RUSH University Medical Center, Chicago, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1195

Introduction: Catatonia due to myocarditis is rare and poses a significant diagnostic challenge. We present a case of classical catatonia secondary to viral myocarditis.
Objectives: We want to highlight the clinical issues in diagnosing catatonia due to specific medical conditions, especially in a resource-limited setting like Pakistan.
Methods: The case is discussed, followed by suggestions and a literature review.
Results: A 22-year-old male with no known medical and psychiatric comorbidities presented to the emergency department in April 2023 with avolition, alogia and fever for 2 weeks. Patient was admitted to Neurology for workup; CSF analysis, CSF autoimmune screen, CSF culture, CSF HSV PCR, blood culture, urine culture, serum ceruloplasmin, MRI Brain were all unremarkable. He was treated with broad-spectrum antibiotics, following which his fever remitted. On initial psychiatric exam, patient scored 13 on Bush Francis Catatonia Rating Scale for mutism, staring, posturing/catalepsy, stupor, grimacing, mitgehen, gegenhalten and rigidity. Initial work up included normal CBC, CMP, TSH, HIV/Syphilis, Urine toxicology, ESR and a CRP of 43 mg/L. He underwent echocardiography which revealed a severely reduced Ejection Fraction of 30% and dilated cardiomyopathy, consistent with viral myocarditis; which was considered in remission and thus managed conservatively by Cardiology. The patient then received IV infusion of Diazepam 10mg BID which adequately treated his catatonia over 3 days and he was discharged with instructions for close follow-up. On followup visits, the patient continued to display remission of catatonic symptoms, but exhibited new symptoms of acute psychosis including 2nd person auditory hallucinations and delusions of reference and persecution. These were treated with Olanzapine 5mg PO resulting in complete remission over 4 weeks. The patient continued to have residual symptoms of social withdrawal, decreased motivation and poor concentration on his most recent presentation. Patient was also noted to have an exaggerated startle reflex which was not associated with any other neurologically relevant symptoms. It prompted a workup to rule out seizure disorder, the results for which are pending at time of this submission.
Conclusions: This case underscores the clinical complexity and diagnostic challenge of catatonia linked to medical conditions. It also depicts the evolving presentation over time. It is important to note that the patient did not receive IV Lorazepam due to its unavailability in Pakistan. Electroconvulsive therapy should have been considered for his catatonic symptoms but was delayed due to his pending diagnosis. Limited findings from literature review related to catatonia associated with viral myocarditis demonstrate the need for further research to bridge the gaps in evaluation and management.

Psychiatrists' practices on monitoring cardio-metabolic adverse effects: a narrative review

D. Dos Santos[1]*, A. C. Silva[1], F. Miranda[1] and M. Araújo[1]

[1]Department of Psychiatry and Mental Health, Hospital Garcia de Orta, Almada, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1196

Introduction: Several medications in use in the psychiatry field, particularly in severe mental illness (SMI), are associated with weight gain and other cardio-metabolic side effects and are usually prescribed long-term. Extensive research has been conducted on the contribution of these effects to poorer physical health and a 10- to 20-year mortality gap in patients with SMI. Many factors have been reported, such as patients' lifestyle behaviours, lower search for medical care, delayed diagnosis and treatment, diagnostic overshadowing by mental illness, and stigma towards this population. In this context, psychiatrists may have a role in monitoring medication's side effects their role is still to be defined.
Objectives: To access usual practices and barriers on cardio-metabolic monitoring of patients by psychiatrists.
Methods: We conducted a narrative review on general psychiatrists' practices of cardio-metabolic monitoring. A search was conducted in Pubmed and PsycNet using the keywords "practice",

"assessment", "weight gain", "metabolic", and "psychiatrist". Further papers were included after references and citations review of relevant articles. Papers focused exclusively on guidelines or on border programs (such as first psychotic episode protocols) were excluded.
Results: Most of the research dedicated to reporting psychiatrists' practices regarding monitoring of cardio-metabolic side effects focused on patients treated with long-term antipsychotics. Despite knowledge and concern about these side effects being transversally reported, it doesn't always translate into clinical practice, and practices are widely diverse. Many factors were appointed as explanations; the most commonly reported were training limitations, poorer physical examination skills, underestimation of side effects, overshadowing of co-occurring physical disease by mental symptoms, lack of scientific consensus amongst different specialties resulting in contradictory guidelines, fragmentation of care across different healthcare providers and specialties, and the still undetermined role of psychiatrists in diagnosing and treating cardio-metabolic complications.
Conclusions: Despite knowledge and awareness of cardio-metabolic side effects are almost transversal in psychiatrists' practice and translated into the selection of treatments, management of these complications still needs to be put into action. Some strategies may be introduced, such as improving medical training and including this training in residency programs, developing consensual and multidisciplinary guidelines for the assessment and treatment of these side effects, defining the responsibility and improving the coordination of different health care providers in a community setting.

Comorbidity factors between Obsessional-Compulsive Disorder (OCD) and Schizophrenia: Through Case Report and Literature Review

A. Daoud[1], N. Halouani[1], S. Elloumi[1]*, C. Walha[1], S. Ellouze[1], M. Turki[1] and J. Aloulou[1]

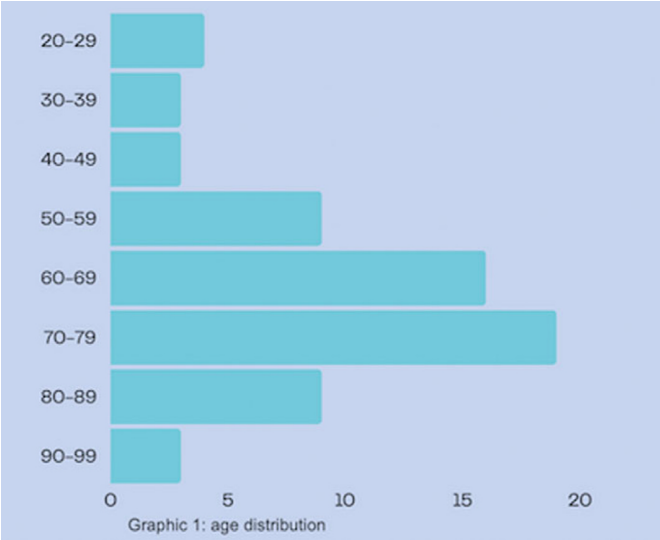
[1]Psychiatry B, Hospital University Hedi Chaker , Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1197

Introduction: Obsessional-Compulsive Disorder (OCD) can involve poor insight, which may complicate the differential diagnosis of schizophrenia. Otherwise, few cases may associate both diagnosis highlighting the need for a clearer understanding of the factors of their coexistence.
Objectives: Understand the factors that contribute to the comorbidity between OCD and schizophrenia.
Methods: Our study employed a case report approach that describes a patient admitted in our psychiatric unit. Data were collected through clinical interviews, personal and family medical history. We also conducted a literature research focusing on articles published between 2000 and 2023 in PubMed using the keywords « OCD », « schizophrenia » and « comorbidity ».
Results: The case concerns Mr. N, a 43-year-old man with no significant medical or psychiatric history and no reported substance use behaviors, who was admitted to our psychiatric unit. He was diagnosed with both OCD and schizophrenia. The therapeutic evaluation revealed that Mr. N was initially prescribed anxiolytics, with a second-generation antipsychotic subsequently added. Some researches suggests that second-generation antipsychotics may induce obsessive-compulsive symptoms which could explain the coexistence of the two diagnosis in Mr N. Additionally, other studies have indicated that genetic factors can predispose individuals to both conditions whereas our patient does not have any notable family history of psychiatric disorders. Finally, literature says that neurobiological factors particularly shared dopaminergic and serotonergic pathways may provide an explanation for the comorbidity of OCD and Schizophrenia.
Conclusions: The comorbidity of OCD and schizophrenia may be explained by several factors, making diagnosis and treatment challenging.

Disclosure of Interest: None Declared

EPV0426

Adjustment Disorder in Mental Health Unit of Matosinhos Hospital: a retrospective observational study of 420 patients.



B. Fernández[1]*, R. Freitas[2], T. Valadas[2] and D. Areias[3]

[1]Psychiatry, ULSNE, Bragança; [2]Psychiatry, ULSM and [3]Psychiatry, Hospital Magalhaes Lemos, Matosinhos, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1198

Introduction: Adjustment Disorder (AD), introduced in DSM-III-R, is an emotional or behavioral reaction to a psychosocial stressor that causes significant distress and impairment. Symptoms include excessive worry, sadness, anxiety, and sleep disturbances. U.S. prevalence ranges from 11.5% to 21.5%, higher in those with suicide attempts and twice as common in women. Diagnostic criteria include symptom onset within 1-3 months, significant distress or impairment, and resolution within 6 months after the stressor or its consequences. Subgroups are based on predominant symptoms of anxiety, depression, or behavior (DSM-5).
Objectives: Analysis of Adjustment Disorder cases in patients admitted to medical-surgical Units in 2023 at Hospital de Matosinhos.
Methods: Review of Clinical Records of all internal consultation requests made to the Liaison Psychiatry Team during 2023 at Matosinhos Hospital. Demographic data, psychiatric history, medical-surgical history, multidisciplinary intervention, and post-discharge guidance were obtained.
Results: Out of the 420 patients observed in internal consultation in 2023, 67 were diagnosed with AD, representing 15.9%.
53% were men and 47% women.
The age distribution is represented in figure 1. Most of patients have an age gap between 50-70 years old. 58% is married, 9% single, 9% divorced and 22% widower.
79.1% of the patients live with their family and 20.9% lives alone.
All comorbidities found in patints with adjustment disorder is represented in figure 2. We can see that metabolic diseases and cardiovascular events are the most common comorbidities associated with AD.
Only 32% had seen a psyhiatrist before, while 68% had never contacted with a psychiatrist.
75% of the requests were made by internal medicine and general surgery.

According with the results of figure 3 we can tell that most of the patients started a new medication and just a few had psychological support.

Image 1:

Graphic 1: age distribution

Image 2:

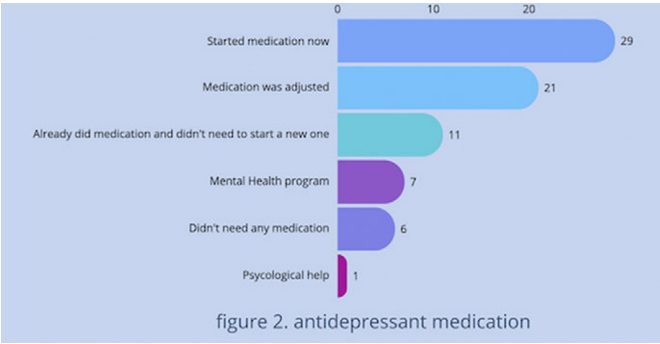


figure 2. antidepressant medication

Image 3:

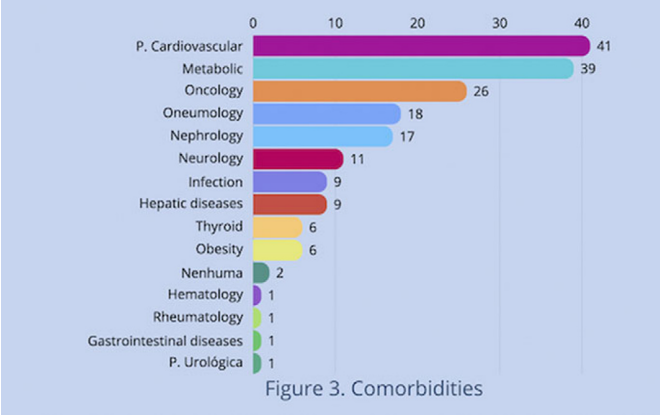

Figure 3. Comorbidities

Conclusions: The diagnosis is subject to a degree of subjectivity and requires clinical judgment. There is a lack of clearly defined diagnostic criteria. It depends on a stressor and a reaction to the stressor that is considered excessive relative to what would be expected in the patient's cultural and social context.

Treatment is underinvestigated. The basic pharmacological management consists of symptomatic treatment of insomnia, anxiety and panic attacks. The use of benzodiazepines to relieve these is common. In this study it is clear the need of giving medication to treat the symptoms even though we know that most of them would stop naturally. However, there is a lack of brief psycological interventions even though they are recommended.

It is now a critical time for advancing our knowledge of the disorder and further studies should be done.

Influence of polygenic risk for schizophrenia and cannabis use on cognition

A. Flores[1,2]*, G. Cano[2,3], I. Zorrilla[1,2], S. Amoretti[4], E. Vieta[4], L. Pina-Camacho[5], A. M. Sánchez-Torres[6], D. Bergé[7], S. Mas[8] and A. González-Pinto[1,2,3]

[1]Hospital Santiago Apóstol; [2]BIOARABA; [3]CIBERSAM, Vitoria-Gasteiz; [4]Hospital Clínic, Barcelona; [5]Hospital Gregorio Marañón, Madrid; [6]Complejo Hospitalario Navarra, Pamplona; [7]Hospital del Mar and [8]CIBERSAM, Barcelona, Spain

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1199

Introduction: There is increasing scientific evidence linking the influence of cannabis on the onset of a first psychotic episode (FEP). However, this association may not always be one-way when studying the relationship between cannabis use and cognition.

The role of polygenic risk score for Schizophrenia (PRS-SZ) and lifetime cannabis initiation (PRSCI) and cannabis use disorder (PRSCUD) use remains unresolved. For this reason, a study was carried out to clarify how these factors are related to each other.

Objectives: To study the interaction between genetic risk and environmental factors

To analyze the relationship between polygenic risk scores and clinical features

To determine the impact of cannabis use on cognitive performance

Methods: A neuropsychological study was carried out on a sample of 138 cannabis users, divided into cases and controls according to the existence of a FEP. This assessment included domains of processing speed, verbal memory, attention, working memory, executive function, social cognition, and determination of premorbid IQ, using validated tests.

Three GWAS summary statistics were used to calculate individual PRS conferring risk for SZ, CI and CUD. PRS were constructed using PRS-CS.

The results obtained were then statistically correlated with the polygenic risk score for schizophrenia, cannabis use disorder, and lifetime cannabis use, respectively.

Results: The patient group presented worse processing speed as the risk for schizophrenia increased. In the case of PRS-CU, an opposite effect was evident. For verbal memory, a higher PRS-CUD was associated with poorer performance. Cannabis consumers with

lifetime risk presented better executive function than consumers with lower genetic risk.
Conclusions: The relationship between PRS for Schizophrenia and cannabis use remains uncertain. However, different clinical profiles can be determined thanks to the cognitive assessment.

Complex post-traumatic stress disorder and dissociation: Co-occurrence and relationships with depressive symptoms and functional impairments

H. W. Fung[1]*, A. K. C. Chau[2], C. H. O. Huang[3], C. T. Y. Cheung[4] and S. K. K. Lam[5]

[1]School of Nursing, The Hong Kong Polytechnic University, Kowloon; [2]Department of Psychiatry; [3]Department of Social Work and Social Administration, The University of Hong Kong, Pokfulam; [4]Department of Social Work, Hong Kong Baptist University, Kowloon and [5]The Nethersole School of Nursing, The Chinese University of Hong Kong, Shatin, Hong Kong
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1200

Introduction: Although complex post-traumatic stress disorder (CPTSD) is closely associated with dissociative symptoms, and although dissociation is often conceptualized as a response to trauma, less is known about the co-occurrence of dissociation and (C)PTSD.
Objectives: This study examined the co-occurrence of CPTSD and dissociation and their relationship with depressive symptoms and functional impairments.
Methods: We analyzed baseline data from a clinical trial that evaluated a web-based trauma program. This study included 220 treatment seekers from Hong Kong (Mage = 35.3; SD = 7.9; 82.3% female). Participants completed measures of CPTSD, dissociation, depression and functional impairment, which were assessed with the International Trauma Questionnaire (ITQ), the Dissociative Experiences Scale-Taxon (DES-T), the Patient Health Questionnaire-9, and the Work and Social Adjustment Scale, respectively.
Results: In this sample, 34.1% screened positive for CPTSD only, 10.0% for dissociative symptoms only (DES-T ≥ 25), and 25.0% for both conditions. For participants with CPTSD (n = 130), 42.3% had dissociative symptoms. For participants with dissociative symptoms (n = 77), 7.8% had PTSD, and 71.4% had CPTSD. Hierarchical multiple regression analyses showed that, after controlling for age, gender, education level, and trauma exposure, PTSD ($\beta = .127$, $p = .033$), disturbances in self-organization (DSO) ($\beta = .524$, $p < .001$), and dissociative ($\beta = .169$, $p = .002$) symptoms were all associated with depressive symptoms. Yet, only DSO symptoms were associated with functional impairments ($\beta = .519$, $p < .001$).
Conclusions: This study provides updated data regarding the co-occurrence of CPTSD/PTSD and dissociation. About half of people with CPTSD have considerable dissociative symptoms, while most dissociative individuals may be suffering from CPTSD/PTSD. Moreover, this study found that, among different trauma-related symptoms, DSO symptoms are the strongest predictor of depressive symptoms and functional impairments, highlighting the importance of providing skills training for trauma survivors to address these difficulties in clinical settings.

Muting the self": emotional dysregulation & appeareance and performance-enhancing drugs (APEDs); a clinical report

G. García Cepero[1]*, M. E. Román Mazuecos[1], M. A. Morillas Romerosa[2], M. Velasco Santos[1], I. D. De Juan[1], P. Vázquez Giraldo[1] and H. Rincón Reques[1]

[1]Servicio de Psiquiatría, Hospital Universitario La Paz and [2]Centro de Salud Mental de Tetuán, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1201

Introduction: Appearance and performance-enhancing drugs (APEDs) are a group of loosely-related substances that are used to improve characteristics perceived as desirable, such as external appearance, mental efficiency and sexual prowess. Besides the increasingly popular anabolic-androgenic steroids (AAS), there is an ever-growing array of anorectics, anabolism-enhancers, sedatives and nootropics available to the public.
Objectives: This case report aims to explore the connection between emotional dysregulation, self-actualization and side-effects that arise in users of these drugs.
Methods: We present the case of a 34-year-old male diagnosed with posttraumatic stress disorder and comorbid use of both anabolic-androgenic steroids (including testosterone, nandrolone and trenbolone) and chemsex-related substances (such as mephedrone, GHB and sildenafil). He reported frequent mood swings, constant feelings of loneliness and despair and occasional suicidal ideation; and attributed his pattern of substance abuse to a desire to escape from his "ordinary" self. After being admitted at a local emergency room during a suicidal crisis, he was referred to a mental health outpatient service and informed about the area's addiction treatment resources. During the first outpatient interventions he related his symptoms (tachycardia, excessive sweating, restlessness, bursts of rage and paranoid reactions) to his pattern of APED consumption. He is currently undergoing both individual and group therapy in an MBT-based intervention; reports several months substance-free and has been started on a course of antidepressants (vortioxetine, up to 20 mg per day) and sedatives (zolpidem, 10 mg a day) to help him cope with his distress.
Results: Several authors have explored the relationship between personality and APED use. While some have found a correlation between the "dark triad traits" (mostly machiavellianism) and AAS consumption, others have noted the role these substances play in building up both identity and self-worth. According to Macho et al. (Front Psychol 2021; 12:648467) APEDs provide access to an "actualized" and "extraordinary" self that enables amateur athletes to escape both everyday life and previous trauma. This way out might be dangerous for the user's health, but proves to be an enticing road, particularly to young males such as the one we present in this case.
Conclusions: APEDs are an increasingly popular group of substances, and they are going unnoticed in some clinical settings. Unlike other drugs, its use is not only recreational but directed to a specific goal; a quest for extraordinariness (in appearance, performance or prowess) that is deeply embedded in our culture. Having both a broad spectrum of physical side effects and a myriad of

psychiatric implications, it is vital for mental health professionals to be familiar with this reality when assessing patients, particularly young men.

Assessment of Functionality, Global Clinical Impression, and Addiction Severity in Patients with Dual Diagnosis Treated with Long-Acting Injectable Antipsychotics in a Specialized Center in Bogotá-Colombia

J. Gonzalez Giraldo[1]* and A. Cruz[1]

[1]Campo Victoria, Grupo Cisne , Bogota, Colombia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1202

Introduction: Dual diagnosis, involving both a mental disorder and an addiction disorder, significantly impacts patients' functionality and quality of life. In Colombia, from 2009 to 2017, an average of 20,590 individuals with dual diagnosis were treated annually, representing 7.2 Disability-Adjusted Life Years (DALYs) (Ministerio de Salud, Boletín de Salud Mental No. 7, 2018). This study investigates effective therapeutic strategies for this complex condition by examining six patients with schizophrenia or other psychotic disorders and comorbid addiction who were treated with depot antipsychotics. We assessed their personal and social functioning, symptom severity using various surveys.
Objectives: Describe outcomes of long-acting injectable antipsychotics in patients with dual diagnosis beyond the clinic
To promote research involving a larger number of subjects with dual diagnosis and co-occurring mental disorders, like schizophrenia
Continue the pursuit of tools aimed at improving the quality of life in patients with dual diagnosis.
Methods: This case series involved six patients, all men, aged 20-40 years, all of them using depot antipsychotics (paliperidone quarterly = 2, paliperidone monthly = 3, and risperidone biweekly = 1), followed over 12 months in an addiction program with quarterly evaluations (T0=initial contact, T1=three months, T2=six months, T3=nine months, T4=twelve months) from July 2022 to August 2024 on an outpatient basis. All participants had an addictive disorder and schizophrenic and schizoaffective disorder diagnosed. We administered four periodic surveys (ASSIST, CGI-I, PSP) to evaluate personal and social functioning and symptom severity. Results were collected in a database through in-person visits or telephone contact, with surveys conducted by a multidisciplinary team including psychology, social work, occupational therapy, and psychiatry.
Results: the ASSIST scores improved from [T0=1.333 (44.43%) to T4=2 (44.67%)], CGI-I scores decreased from [T0=4.33 (61.9%) to T4=3 (42.8%)], and the PSP scale showed improvement from [T0=1.666 (55.53%) to T4=2.166 (72.20%)]. These results reflect enhanced cognitive and social functions, particularly in social functioning. Similar results were observed in patients with schizophrenia in a study by Shi et al. (Neuropsychiatr Dis Treat. 2016;12:2095-2104), supporting the potential benefits of depot antipsychotics for dual diagnosis patients.
Conclusions: Depot antipsychotics can be a valuable tool for managing dual diagnosis, enhancing treatment adherence, general functionality and reducing symptom severity. However, this observational study did not account for substance types or socioeconomic factors.

EPV0431

Schizophrenia and pain: a prospective clinical study from 2002-2022 on 753 men with schizophrenia and sensitivity to pain compatible with the cause, reduction or lack of sensitivity

E. Guertzenstein

Dep. Neurologia - Divisão de Neurocirurgia, Faculdade de Medicina da Universidade de S. Paulo, S. Paulo, Brazil
doi: 10.1192/j.eurpsy.2025.1203

Introduction: Schizophrenia is a complex neuropsychiatric disorder, which affects 1% of people in the world. It presents marked heterogeneity in terms of clinical presentation, course and prognosis, although patient with schizophrenia may have diseases of other physical causes, in which pain has a protective role for the individual and diagnostic importance. Studies on pain in schizophrenia are rare and predominantly experimental. The cause of decreased sensitivity or lack of sensitivity to pain in patients with schizophrenia is unknown. Among the hypothesis are lesions in the thalamus and psychotic symptoms that would decrease the patient's concentration or divert his attention from the pain.
Objectives: The aim of this research was to study the presence/absence and intensity of pain compatible with the cause in 753 men that we have been treating for schizophrenia for 20 years.
Methods: We asked all our patients with schizophrenia at their first consultation in 2002 whether they would be willing to be clinically investigated for the presence/absence and intensity of pain compatible with any cause.
We divided our patients into 3 groups:
Group 1: 51 patients aged 17 – 25 years
First episode currently symptomatic-negative symptoms.
Group 2: 325 patients aged 27-31 years
Multiple episodes currently symptomatic, 25 negative symptoms, 300 positive symptoms.
Group 3: 377 patients aged 40-45 years
Continuous currently – 7 negative symptoms, 370 positive symptoms.
These patients were examined every 3 months by clinicians and dentists for 20 years.
Treatment
Patients with:

- Positive symptoms (delusional beliefs, hallucinatory perception, and disorganization of thinking and behavior) associated with excessive dopamine release, who respond adequately to (FL-APM) First Line dopamine antagonist medication.
- Positive symptoms which does not respond adequately to FL-APM, who respond adequately to chlozapine.
- Refractory schizophrenia treated with electroconvulsive therapy.

Results: 100 patients quit of the survey
653 had (at least once in these 20 years) headache, toothache or earache.
51 did not complain of pain with trigeminal neuralgia.
30 patients did not complain of pain when they had herpes zoster.

Patients with negative schizophrenic symptoms and resistance to treatments showed an absence of pain (pertinent to their physical illness)
Conclusions: The causes of reduced or absent pain sensation in patients with schizophrenia are unknown. Proposed explanations include thalamic damage and psychotic symptoms that render the patient unable to perceive pain. Our patients did not have thalamic damage but had severe negative psychotic symptoms and resistance to treatments.

Depression and suicidal risk in autism spectrum disorder: efficacy of intranasal esketamine. Clinical experience from a public mental health service in Italy

A. Guffanti[1], F. Mazzoni[1,2], A. Silva[2], F. Calorio[2], P. Politi[1,2], N. Brondino[1,2] and M. Olivola[3]*

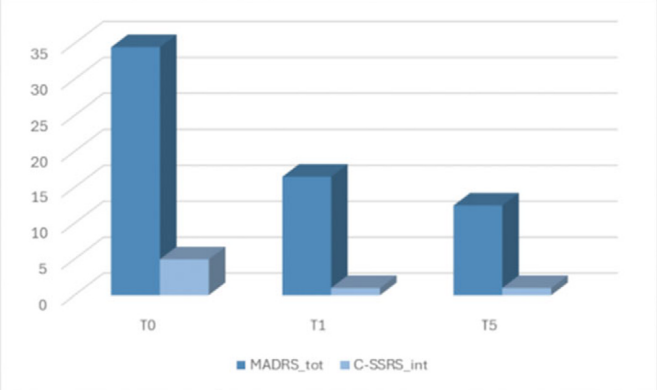
[1]Dipartimento di Scienze del Sistema Nervoso e del Comportamento, Università degli Studi di Pavia; [2]Dipartimento di Salute Mentale e Dipendenze, ASST di Pavia, Pavia and [3]Dipartimento di Salute Mentale, ASST Fatebenefratelli-Sacco, Milano, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1204

Introduction: Depressive disorders and anxiety disorders are typical comorbidities in autism spectrum disorder (ASD), with a reported prevalence of 20% and 9%, respectively (Lai, 2019). Autistic subjects are more at risk for suicidal thoughts and behaviors compared to typically developing peers; moreover, depressive symptoms are often resistant to both pharmacological and psychotherapeutic treatments. In 2019 intranasal esketamine was approved in Italy for treatment-resistent depression (TRD). We observed two young outpatients affected by autism (diagnosis made by "Lab-Aut", a specialized mental health service in Pavia) treated with esketamine in our ambulatory for TRD. Clinical information and personal details were summarized in **Image 1**.
Objectives: To evaluate the clinical response to intranasal esketamine in subjects with major depression in ASD and to compare the outcome with neurotypical patients.
Methods: Autism diagnosis wase made according to ADOS-2 and ADI-R scores, confirmed by a clinical judgment of senior psychiatrist. Our follow-up protocol during esketamine treatment consists in the following scales: MADRS, C-SSRS, DES-II, Psychace Scale, Reading the Mind in the Eyes Test, HAM-A, HAM-D, BDI, PANSS. Psychometric evaluation was performed at T0 (before esketamine), T1 (one week of pharmacotherapy), T2 (one month), T3 (2 months) T4 (3 months) and T5 (6 months). We collected results from neurotypical patients (n=12) and autistic patients (n=2) between 2022 and 2024.
Results: Both in autistic patients and in neurotypical ones we noticed a premature decrease in depressive symptoms and a reduction of suicidal thoughts. This improvement was testified by a reduction from T0 to T1 in MADRS total score and in C-SSRS sub-score focused on intensity of suicidal ideation. The reduction was maintained during the observation period **(Image 2)**. Due to the small sample size of autistic patients, we couldn't reach the statistical significance threshold for this population. Considering the entire sample (n=14) we obtained significant results (T0-T1: MADRS decrease p=0,00006, C-SSRS decrease p=0,00009. T0-T5 MADRS and C-SSRS variations p<0,00001). Comparing our subsamples, it's possible to notice a similar trend in follow-up between autistic and neurotypical patients. **(Image 3)**.

Image 1:

	Patient 1 (G.B.)	Patient 2 (E.S.)
Gender and age	Female, 25 y	Male, 20 y
Job	Student	Student
Intellectual disability	No	No
Hospitalizations	2021, suicidal ideation	2023, sucide attempt 2024, depressive episode
Familiar anamnesis	Depression	Depression, eating disorders
Suicidal attempts	No	1 (2023, setting fire)
Self-harming	Yes	No
Drug abuse	No	No
Pharmacotherapy	Sertraline 200 mg/day, Aripiprazole 15 mg/day	Venlafaxine 300 mg/day Aripiprazole 10 mg/day Propranolol 40 mg/day
Esketamine posology	84 mg	84 mg
Esketamine duration	6 months	7 months (ongoing)
Hospitalizations during Esk	0	0
Suicidal attempts during Esk	No	No
Self-harming during Esk	No	No
Medical comorbidities	No	Hypertension, obesity

Image 2:



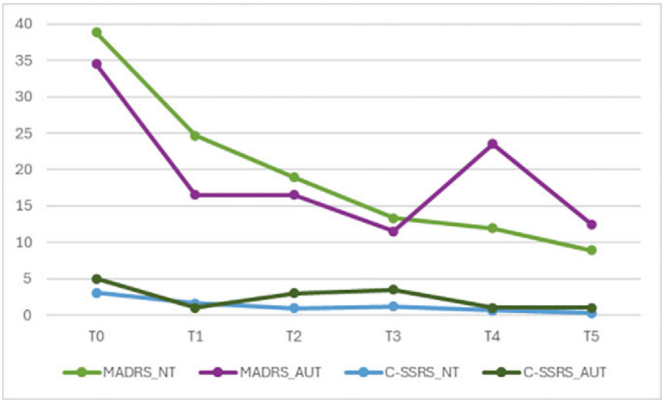


Image 3:

Conclusions: Our preliminary data coming from clinical experience suggest the efficacy of intranasal esketamine in depressive episodes occurring in autistic patients. A larger sample size of autistic patients will be necessary to set a comparative study and to give significance to these results. Esketamine could represent an important therapeutic option in depressed patients with ASD comorbidity.

Handling of diet-related risks in psychosomatic rehabilitation clinics

R. Hiltensperger*, J. Neher, L. Böhm and A. S. Mueller-Stierlin

Institute for Epidemiology and Medical Biometry, University of Ulm, Ulm, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1205

Introduction: People with mental health conditions frequently encounter diet-related challenges that contribute to the onset of physical comorbidities, further diminishing their quality of life and life expectancy. To date, diet-related problems often are not adequately addressed in mental health care for reasons like overshadowing.
Objectives: Psychosomatic rehabilitation clinics are a potential setting for tackling these problems as the admission takes place beyond acute crisis and as multi-professional teams, including dietitians, are available. However, little is known so far about the extent to which this potential is being exploited.
Methods: In summer 2024, we conducted 22 qualitative interviews with physicians, dietitians and other staff members at six psychosomatic rehabilitation clinics in Germany to explore the current state of action in handling diet-related risks in psychosomatic rehabilitation clinics.
Results: Interviewees elaborated on their eexperiences with the prescription and utilization of diet-related interventions in psychosomatic rehabilitation and their subjective assessments of the potential added value of screening tools in care planning. Preliminary analyses indicate that diet-related problems have not yet been systematically captured in the rehabilitation process. Due to a lack of time, a comprehensive nutrition-related assessment is hardly possible and therefore the diet-related activities tend to be one-size-fits-all services.
Conclusions: The findings of the qualitative study endorse the implementation of a multi-faceted screening tool, such as the NutriMental screener. By this way, diet-related problems of service users might be recognized at the beginning of inpatient rehabilitation and being addressed appropriately during the inpatient stay by selecting suitable rehabilitation measures, especially dietary interventions.

Cerevicalgia and Depression: Comorbidity and Pathopysiology

D. Labunskiy[1], N. Kurgaev[1]*, D. Baranov[1], S. Kiryukhina[1] and D. Kuzmin[2]

[1]Ogarev Mordovia State University, Saransk and [2]Vidnoe Hospital, Vidnoe, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1206

Introduction: The widespread prevalence of neck pain does not mean that one should stoically endure suffering. There is some truth in the fact that many people have such problems, but it is not true that one should not go to the doctor for such trivial reasons. Therefore, if pain in neck occurs, you should go to a neurologist immediately. This is especially true in cases where episodes of pain are repeated, they are persistent or intensify.
Objectives: There are many causes of neck pain:
Fractures, dislocations, injuries to the vertebrae, joints, muscles and ligaments in the neck.
Infections that cause inflammation of bone and cartilage tissue, muscles, cervical lymph nodes and nerves (osteomyelitis, abscess, shingles).
Radiating pain in diseases of the heart, lungs, stomach, esophagus, and other organs. Rheumatological diseases (arthritis, myalgia, fibromyalgia).
Methods: Statistical analysis was performed.
Results: Neuroendocrine pathologies, non-specific factors (herniated and displaced intervertebral discs, problems with intervertebral joints, narrowing of the spinal canal, arthrosis, muscle spasms, osteochondrosis, problems caused by insufficient muscle activity), Intracranial diseases (benign or malignant neoplasms of the brain, stroke, abscess), and also psychosomatics.
Conclusions: There are several reasons that cause depression due to depletion of cartilage tissue. First of all, we are talking about the disruption of cerebral circulation associated with disorders in the cervical spine. Lack of blood flow, and therefore oxygen, leads to starvation of various parts of the brain responsible for certain important functions of the body. This is how nervous system disorders begin to develop: depression, aggression, panic attacks and insomnia.

EPV0438

Complex Care: Schizophrenia Meets Rheumatoid Arthritis

O. Laabidi[1]*, S. Laabidi[1], A. Touiti[1] and N. Bram[1]

[1]Forensic psychiatry department, razi hospital, la manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1207

Introduction: The management of coexisting schizophrenia and rheumatoid arthritis (RA) is complex due to the lack of clear guidelines. While immunosuppressants are the cornerstone of RA therapy and clozapine is the gold standard for treatment-resistant schizophrenia, their shared adverse effects make combined treatment challenging, requiring alternative therapeutic options.
Objectives: present the therapeutic complexity of managing treatment-resistant schizophrenia alongside RA.
Methods: We report a case of drug-induced toxidermia in a patient being treated for RA with some therapeutic particularities.
Results: Mr. W, a 66-year-old man, has been under treatment since 2007 for schizophrenia. Somatically, he has rheumatoid arthritis (RA) that has been progressing since 2016, for which he is treated with Methotrexate.
The diagnosis of treatment-resistant schizophrenia was made. Given this resistance, the introduction of Clozapine was proposed. However, the issue of an interaction between Methotrexate and Clozapine, contraindicated according to pharmacologists' report, required therapeutic reevaluation.
Clinical and biological evaluation showed remission of RA with an EVA score of 0, NAD of 0, NAG of 0, a DAS28 score of 1.13, and an VS of 5 mm. The choice then fell on Sulfasalazine to replace Methotrexate, with a progressive introduction of the drug, starting at 500 mg and increasing by 500 mg every 7 days up to a dose of 2000 mg/day, accompanied by weekly control tests.
Twelve days after the introduction of Sulfasalazine, at a dose of 1000 mg/day, the patient presented with a diffuse rash associated with erythroderma, facial and eyelid edema, an infiltrated, pruritic maculo-erythematous rash, confluent in places but sparing the palms and soles. Given the characteristics of the dermatological lesions and their timing, drug-induced toxidermia caused by Sulfasalazine was strongly suspected. Consequently, Sulfasalazine was discontinued, as well as the antipsychotic, and the patient was treated with topical skin treatments and two boluses of intravenous corticosteroids.
The initial biological workup was normal. However, seven days after stopping Salazopyrin, the patient became febrile with a temperature of 40°C, accompanied by erythematous pharyngitis, an elevated CRP of 45, monocytosis, and the presence of activated lymphocytes on the blood smear. Pharmacovigilance opinion: a DRESS syndrome was suspected, with a Regi score of 2. Two weeks later, the clinical course was favorable, with the complete disappearance of dermatological lesions and normalization of biological parameters.
Conclusions: Managing treatment-resistant schizophrenia alongside rheumatoid arthritis poses a therapeutic challenge due to drug interactions. The case of Sulfasalazine-induced toxidermia highlights this complexity. Close monitoring and tailored treatment alternatives are crucial to minimize risks while ensuring efficacy.

The longitudinal impact of health behaviours on mental health, diabetes distress, and quality of life in people with type 1, type 2, and gestational diabetes: A scoping review

A. M. McInerney[1,2]*, C. Flynn[1], K. Fardfini-Ruginets[3], S. Liu[4], C. Koretsidou[1], R. J. Burns[3] and S. S. Deschênes[1]

[1]Psychology, University College Dublin, Dublin, Ireland; [2]Pobulation-Based Medicine, Eberhard Karls Universität Tübingen, Tübingen, Germany; [3]Psychology, Carleton University, Ottawa, Canada and [4]Department of Medical Epidemiology and Biostatistics, Karolinska Institute, Solna, Sweden
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1208

Introduction: There can be a considerable mental health burden to living with diabetes. Health behaviours are modifiable factors that influence mental health in the general population. However, despite the centrality of health behaviours to diabetes management, there are significant gaps in our understanding of their longitudinal impact on mental health in people with diabetes.
Objectives: This scoping review aimed to synthesise the longitudinal evidence from observational and intervention research on the impact of health behaviours on mental health and related psychological factors in people with type 1, type 2, and gestational diabetes.
Methods: PubMed, PsychINFO, Embase, CINAHL, and PsycArticles were searched for intervention and observational studies examining the effect of health-promoting, health-risk, or diabetes-specific health behaviours on aspects of mental health, diabetes distress, and quality of life, in people with all types of diabetes. Abstracts, titles, and full texts were screened by two independent reviewers.
Results: In total, 100 relevant studies were identified, including 29 observational studies and 71 intervention studies. Studies had a mean follow-up time of 12.9 ± 17.8 months. The health behaviours investigated in the included studies were adherence, alcohol, carbohydrate-counting, diet, diet and exercise combined, exercise, fasting, medical visits, sleep, self-monitoring blood glucose, smoking, and weight. The review identified knowledge gaps surrounding diabetes-specific behaviours, behaviour interactions/clusters, sleep, sedentary behaviour, screen-time, gestational diabetes, mood and ecologically valid and objective measurements. Exercise was the most freqently investigated health behaviour and also the most likely to be found to have a mental health promoting impact.
Conclusions: Findings suggest that health-promoting behaviours influence mental health in people with diabetes. There is less conclusive evidence regarding the impact of health-risk or diabetes-specific health behaviours. In particular, a broad range of physical activities may improve mental health and wellbeing in people with diabetes.

Disclosure of Interest: None Declared

Dual Challenges: Managing Schizophrenia Relapse in a Patient with Sickle Cell Anemia

S. Ben Aissa[1]*, C. Najar[1], K. Razki[1], M. Cheour[1] and F. Fekih-Romdhane[1,2]

[1]Razi Hospital, LaManouba and [2]Faculty Of Medicine of Tunis, Tunis El Manar University, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1209

Introduction: Sickle cell anemia (SCA) is a genetic disorder resulting in chronic hemolysis and vaso-occlusive crises, which can lead to severe systemic complications. Schizophrenia is a major psychiatric disorder characterized by persistent psychotic symptoms, including delusions and hallucinations. The intersection of these two conditions presents unique clinical challenges, as the management of SCA may complicate the treatment of schizophrenia and vice versa. Despite the prevalence of such comorbid cases, there is a significant gap in research addressing the complexities of managing these conditions concurrently.
Objectives: This case report aims to describe a rare and complex case of schizophrenia in a patient with sickle cell anemia, including the clinical presentation, diagnosis, and management. Additionally, it seeks to highlight the challenges of managing these co-occurring conditions and to promote further research into integrated treatment strategies for such comorbidities.
Methods: We present a 32-year-old male with a history of sickle cell anemia and schizophrenia who was admitted to the psychiatric department at Razi Hospital, LaManouba. The patient was admitted following a suicide attempt driven by acute psychotic symptoms, including delusions and auditory hallucinations commanding self-harm. Upon admission, he was started on a regimen of benzodiazepines to manage severe anxiety and antipsychotic medication to address the hallucinations and delusions. The initial physical examination revealed no significant abnormalities. On the third day of hospitalization, the patient began exhibiting respiratory symptoms, including chest pain and difficulty breathing, which prompted further diagnostic evaluation.
Results: On the third day of hospitalization, the patient developed respiratory symptoms including chest pain, fever, and dyspnea. Evaluation, including lab tests and imaging, revealed acute chest syndrome. Given the risk of benzodiazepines worsening respiratory issues, their use was discontinued, and Haloperidol was introduced at 5 mg to manage psychotic symptoms, with close monitoring for suicidal ideation. The hematology and pneumology departments initiated a treatment protocol involving oxygen therapy, intravenous hydration, paracetamol for pain management, and antibiotics (ceftriaxone and clarithromycin). Within a week, both psychiatric and respiratory symptoms significantly improved, leading to a reduction in supplemental oxygen and discharge with a comprehensive follow-up plan.
Conclusions: This case underscores the complexity of managing co-occurring schizophrenia and sickle cell anemia, highlighting the need for a multidisciplinary approach. Integrated treatment strategies are crucial for effectively addressing both psychiatric and medical complications in such comorbid conditions

Systemic Inflammation from Periodontal Disease and its Neuropsychiatric Implications

D. Patel[1,1]*, D. Nolasco[2] and B. Carr[2]

[1]Medicine, Nova Southeastern University, Davie and [2]Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1210

Introduction: Chronic oral health issues, particularly periodontal disease, are significant contributors to systemic inflammation. Emerging evidence indicates that this inflammation can influence neurophysiological processes and contribute to psychiatric disorders, including depression and anxiety. Recent literature review has revealed that periodontal disease and depression share common biomarkers, such as lipopolysaccharide (LPS), C-reactive protein (CRP), interleukin-6 (IL-6), and cortisol.
Objectives: To elucidate the connection between poor oral health and psychiatric disorders through the lens of systemic inflammation and its neurophysiological impacts.
Methods: A comprehensive literature review was conducted using PubMed, PsycINFO, and Google Scholar, focusing on studies from the past decade that examine the relationship between periodontal disease, systemic inflammation, and psychiatric disorders. Key findings regarding the involvement of pro-inflammatory cytokines and their neurophysiological effects were synthesized.
Results: The review highlighted that periodontal disease leads to elevated levels of pro-inflammatory cytokines. Such cytokines as CRP, IL-6, and tumor necrosis factor-alpha (TNF-α) can cross the blood-brain barrier, contributing to neuroinflammation and dysregulation of neurotransmitter systems. One significant effect is on serotonin metabolism, which is critical in the pathophysiology of depression. Pro-inflammatory cytokines can lead to reduced serotonin availability by upregulating genetic expression of serotonin transporters and increased serotonin metabolism. Given the interplay between inflammatory cytokines and neurotransmitter metabolism, the studies indicate that individuals with periodontal disease are more likely to exhibit depressive and anxiety symptoms, with neuroinflammation serving as a mediating factor.
Table 1: Impact of Pro-inflammatory Cytokines on Neurophysiological Processes

Cytokine	Effect on Neurophysiology
CRP	Contributes to neuroinflammation and affects processing skills, motor function, and working memory.
IL-6	Promotes neuroinflammatory responses via impacting neurotransmitter regulation and gut-microbiota-brain axis
TNF-α	Crosses BBB, leading to neuroinflammation and activates hypothalamus-pituitary axis leading to serotonin and tryptophan dysregulation.

Conclusions: Systemic inflammation resulting from poor oral health significantly impacts neurophysiological processes associated with psychiatric disorders. These findings underscore the need for integrated healthcare approaches that consider both oral and mental health to mitigate the adverse effects of neuroinflammation on psychiatric well-being.

From NMDA Receptor Antagonism to Cerebrovascular Effects: The Dual Facets of Nitrous Oxide in Bipolar Depression

C. Pinheiro Ramos[1]*, A. F. Reis[1], C. Batista[1], M. J. Freire[1] and S. Mendes[1]

[1]Setúbal Hospital Center, Setúbal, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1211

Introduction: Nitrous oxide (N2O) was first discovered in 1772 by Joseph Priestley. Since its anesthetic properties were realized in 1844, it has been used in the medical and dental fields. Nitrous oxide is also known as "laughing gas" or "nos".
Recent literature suggests that studying N2O is important, not only for understanding the pathophysiology of bipolar depression but also for exploring its potential as a treatment.
N2O is often used recreationally for its euphoric, anxiolytic, and dissociative effects.
Objectives: To better understand the role of nitrous oxide, as well as its clinical implications.
Methods: A search was conducted in various databases, including PubMed.
Results: N2O has two potential ways to help with bipolar depression. Firstly, it can block NMDA receptors which can be beneficial for mood stabilization. Secondly, it can widen blood vessels in the frontal brain regions which can improve blood flow and oxygenation.
Clinical studies have suggested the effectiveness of NMDA receptor antagonists in the treatment of depression. Among these studies, the use of ketamine has been a significant breakthrough in the treatment of depression.
Despite its medical uses, N2O has also gained popularity on a recreational level due to its relaxing, euphoric effects and its ability to provoke hallucinations. Unfortunately, recreational use of N2O can lead to various neuropsychiatric symptoms, such as emotional symptoms (mania, depression, anxiety), personality changes, aggressive behaviour, and psychotic symptoms.
Conclusions: Further research is needed to determine if N2O is beneficial in treating bipolar depression or if its use could lead to brain dysfunction (if taken recreationally).

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1212
Introduction: Cluster headache (CH) and bipolar disorder (BD) are cyclic disorders with shared clinical aspects, e.g. disturbed sleep patterns, response to lithium and a tendency to use illicit drugs.
Objectives: We investigated comorbidity of BD in patients with CH, prevalence of BD amongst CH family members, circadian aspects and use of illicit drugs.
Methods: Patients from the Leiden University Cluster headache neuro-Analysis program (LUCA) were screened cross-sectionally for BD online, using the Mood Disturbance Questionnaire (MDQ-NL) and Altman Self Rating Scale (ASRM-NL) and, if indicated, further evaluated with the Mini international neuropsychiatric interview (MINI). Circadian aspects were analyzed using the Circadian Type Inventory (CTI) and the Munich Chronotype Questionnaire (MCTQ).
Results: The life-time prevalence of BD in patients suffering from CH was 6.5%. Patients with comorbid BD (CH+BD) were more likely to have family members with BD (standardized OR= 1.50, 95% CI=1.15;1.95, p=0.003) and were more likely to suffer from chronic CH (OR=3.05 95% CI=1.18;7.87, p=0.02) after adjustment for age and sex. They also more often used illicit drugs, compared to patients with only CH. Circadian type and chronotype did not differ between the two groups after adjustment for confounders.
Conclusions: There is a high prevalence of BD in CH patients. CH +BD patients are more likely to have a positive family history for BD. CH+BD patients are more likely to suffer from chronic CH and more often use illicit drugs. In clinical practice it is important to screen for BD when treating patients with CH.

Predisposing Factors for the Development of Insomnia in Patients With ADHD

G. Rossi[1]*, I. De Martino[1], G. Longo[1], M. Servasi[1], L. Orsolini[1] and U. Volpe[1]

[1]Unit of Clinical Psychiatry, Department of Clinical Neurosciences/ DIMSC, Polytechnic University of Marche, Ancona, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1213

Introduction: Attention-Deficit/Hyperactivity Disorder (ADHD) often coexists with insomnia. Challenges of ADHD, like racing thoughts and restlessness, can exacerbate sleep issues. Addressing both conditions concurrently is crucial for comprehensive treatment and improved quality of life.
Objectives: The aim is to identify factors promoting insomnia in patients with ADHD.
Methods: The study is conducted on patients >18 years referred to the adult ADHD outpatient service of the Psychiatric Clinic of Ancona (Università Politecnica delle Marche, Italy). The Diagnostic Interview for ADHD in adults (DIVA 5.0) was used for diagnosis. Administered rating scales included Temperament Evaluation in Memphis, Pisa and San Diego (TEMPS-M), Coping Orientation to the Problems Experiences-new Italian version (COPE-NVI), Temperament and Character Inventory-Revised (TCI-R) and Insomnia Severity Index (ISI).
Results: 76% (n=170) of all screened patients were diagnosed with ADHD in adulthood. In our sample of ADHD subjects, those who have bipolar disorder in comorbidity tend to suffer more frequently from insomnia (χ^2=4.290; p=0.038). A multivariate linear regression was observed between the ISI (R^2=0.237; F(3,56)=13.150;

p<0.001) and TEMPS-M cyclothymic temperament subscale (B=0.206; p=0.027), TCI-R responsibility subscale (B=-0.255; p=0.005), and TCI-R self-transcendence subscale (B=0.101; p=0.06). A logistic regression analysis was performed to ascertain the effects of all TCI-R, COPE-NVI, TEMPS-M subscales, on the likelihood of developing insomnia. The logistic regression model was statistically significant, ▫ ▫ 2(1)=4.539, p=0.033. The model explained 62.3% (Nagelkerke R2) of the variance in patients with ADHD and insomnia and correctly classified 76.7% of cases. Insomnia was significantly predicted by TEMPS-M irritable temperament subscale (exp(B)=1.272; p=0.003), TCI-R disorderliness subscale (exp(B)=0.628, p=0.004), TCI-R purposeful subscale (exp (B)=0.781, p=0.003), TCI-R social acceptance subscale (exp(B) =1.232, p=0.052), TCI-R compassion subscale (exp(B)=0.795, p=0.001) and TCI-R transpersonal identification subscale (exp(B) =1.268, p=0.002).

Conclusions: Findings suggest a link between ADHD patients with comorbid bipolar disorder and a higher incidence of insomnia. Personality traits such as cyclothymic temperament, low sense of responsibility, and high self-transcendence are significantly associated with insomnia in ADHD. The logistic regression model accurately predicted and identified key predictors for insomnia in ADHD patients, highlighting the substantial role of irritable temperament, rigidity in being orderly, low determination, high friendliness, low compassion, and high transpersonal identification. Understanding these associations is pivotal in developing targeted interventions and support strategies for individuals with ADHD prone to insomnia, emphasizing the intricate role of temperament and personality traits in sleep disturbances.

Unveiling the Hidden Burden: Psychiatric Comorbidities in Dialysis Patients

M. Sant'ovaia[1]*, J. M. de Castro[1], C. Martins[1], S. Martins[1], A. C. Ramos[1] and T. M. Afonso[1]

[1]Psychiatry, ULS Amadora Sintra, Lisboa, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1214

Introduction: Patients with End-Stage Renal Disease (ESRD) undergoing hemodialysis (HD) are particularly susceptible to psychological disorders, such as anxiety and depression, which can significantly affect their quality of life and clinical outcomes. However, in spite of its prevalence, psychiatric comorbidity in this population remains under-recognized, contributing to worse health outcomes and increased mortality.

Objectives: The primary aim of this study is to explore the prevalence of psychiatric comorbidities, particularly depression and anxiety, among HD and PD patients. Insights into the different psychological effects of different dialysis treatments are offered, emphasizing the importance of integrated mental and physical healthcare in improving patient outcomes.

Methods: A narrative review was carried out using PubMed and Google Scholar to identify relevant articles with the keywords "dialysis," "psychiatry," and "comorbidities."

Results: The review underscores the important burden of psychiatric disorders among dialysis patients. Studies suggest that depression may affect up to 50% of these individuals. Both HD and PD patients exhibit varying degrees of psychological distress, exacerbated by factors such as the invasiveness of dialysis, comorbid medical conditions (e.g., diabetes), and socioeconomic challenges. The evidence suggests that HD patients may experience an even more heightened psychiatric burden due to the more invasive nature of HD compared to PD, which imposes greater restrictions on daily activities. Psychiatric disorders in these patients are often underdiagnosed, leading to treatment non-compliance, increased hospital admissions, and elevated mortality rates. The findings stress the necessity of regular mental health screenings and the integration of psychiatric care into routine dialysis practice.

Conclusions: Psychiatric comorbidities are prevalent among dialysis patients, with HD patients exhibiting a greater psychological burden. This review highlights the urgent need for routine mental health screening and intervention within the dialysis care framework. The integration of mental health support into dialysis treatment protocols could lead to improved patient outcomes, fewer hospitalizations, and better treatment adherence. Future research should focus on developing customized mental health interventions that address the specific challenges faced by dialysis patients, thereby enhancing their quality of life and clinical outcomes.

Disclosure of Interest: None Declared

EPV0451

A Case Report on The Course and Outcome of A Patient Diagnosed with Trichotillomania and Major Depressive Disorder

Z. C. G. Tan[1]* and I. C. S. Tan[1]

[1]Department of Psychiatry and Behavioral Medicine, University of the Philiippines Philippine General Hospital, Manila, Philippines
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1215

Introduction: Trichotillomania (TTM) and Major Depressive Disorder (MDD) are two psychiatric conditions that frequently co-occur, presenting a significant challenge for treatment due to their complex interplay. TTM involves repetitive hair-pulling, leading to noticeable hair loss and distress, while MDD is characterized by persistent low mood and loss of interest or pleasure leading to dysfunctionality.

Objectives: This case report aims to discuss a case of a 21-year-old female with major depressive disorder and trichotillomania, management challenges, and the importance of a comprehensive, multifaceted therapeutic approach to address both disorders effectively.

Methods: A 21-year-old female college student and youth church leader presented with chronic hair-pulling and depressive symptoms. She had low self-esteem and a strong need for validation. Despite her responsibilities, she struggled with emotional distress exacerbated by family dynamics and her church role. Her symptoms were linked to self-esteem threats and feelings of inadequacy. She was diagnosed with Trichotillomania, Scalp, and Major Depressive Disorder.

Initial pharmacologic management was Fluoxetine 20mg/day up titrated to 40mg/day with no improvement hence shifted to Escitalopram 20mg/day and N-acetylcysteine 1200mg/day with noted significant improvement in symptoms. Non-pharmacologic strategies included supportive-expressive psychodynamic psychotherapy, cognitive-behavioral techniques, and family therapy. Psychoeducation,

suicide safety planning, and an interprofessional approach with dermatology co-management were also integral.
Results: Over the course of 15 therapy sessions, the patient demonstrated significant improvement in both her depressive symptoms and hair-pulling behavior. Her active engagement in therapy, combined with pharmacological support, facilitated better emotional regulation and a more cohesive sense of self. Her adherence to the treatment plan, along with the collaborative efforts of the interprofessional team, contributed to her positive outcomes.
Conclusions: This case highlights the significance of addressing both TTM and its comorbid conditions for effective treatment outcomes. The interplay between TTM and MDD underscores the need for comprehensive treatment plans incorporating pharmacological and psychotherapeutic approaches. Future practice should consider the benefits of an interprofessional approach for managing complex cases like this.

The Incidence of Depression among female patients with Schizophrenia Hospitalized in the Clinical Hospital of Psychiatry, Chișinău, R. of Moldova

V. Țapeș[1]*, I. Cosciug[1], I. Deliv[1] and L. Sanduleac[1]

[1]Mental Health, Clinical Psychology and Psychotherapy Department, University of Medicine and Pharmacy "Nicolae Testemitanu", Chisinau, Moldova, Republic of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1216

Introduction: In schizophrenia, depressive and negative symptoms often overlap, complicating the diagnosis. Symptoms such as lack of energy, anhedonia and association make the distinction difficult. A subjective state of sadness may indicate depression, while affective flattening is characteristic of schizophrenia. Other symptoms relevant to diagnosing depression include hopelessness, negative self-assessment, guilt, anxiety, and self-destructive thoughts.
Objectives: This study, conducted over 6 months, aims to establish both the rate and the total number of patients with schizophrenia, suffering from depression to provide a better understanding of the clinical particularities of this type of comorbidity.
Methods: The research provided for a cross-sectional study to assess the incidence of depression among patients with schizophrenia hospitalized in the Clinical Psychiatric Hospital of Chisinau during the reference period. The Calgary depression scale for schizophrenia (CDSS) has been used as an evaluation tool to highlight the presence of depressive symptoms, while PANSS (negative symptoms) has been used, to measure their severity in schizophrenia. The data collection process involved structured questionnaires, semi-structured interviews with patients and clinical history analysis to obtain additional information.
Results: The study included 155 women diagnosed with schizophrenia, aged between 18 and 55. Of these, 28.39% had more than two admissions during the year. Most of the patients included in the study (73.55%) suffered from F20.0, the rates of other forms of schizophrenia being: F20.1 (1.29%); F20.2 (14.84%); F20.3 (9.68%) and F20.9 (0.65%). According to the questionnaire applied to patients with different types of schizophrenia, it was observed that, 40.65% achieved a total score of more than 6 points on the CDSS scale (clinically significant depression) and 34.92% required repeated hospitalisation in the same year. Of those repeatedly admitted, 74.6% suffered from F20.0; 14.29% (F20.2) and 11.11% (F20.3), which probably could be a confirmation of the increased severity of the patient's condition in case of comorbidity – schizophrenia-depression.
Conclusions: It can be assumed that the comorbidity of schizophrenia-depression negatively influences the social recovery process, but also the quality of life of patients; increases the risk of relapse. Patients with depression often experience higher rates of hospitalization because depressive symptoms can lead to emotional instability, cognitive impairments, undermining interpersonal relationships, social networking and reintegration . It is essential that mental health professionals identify and treat depression in patients with schizophrenia in order to increase their quality of life.

Better understand the semiology of the dysgraphia in DCD children by highlighting a motor control disorder

L. Vaivre-Douret[1,2,3,4,5]* and C. Lopez[3]

[1]Department of Medicine Paris Descartes, University of Paris Cité, Faculty of Health; [2]Chair of Neurodevelopmental Clinical Phenotyping, Institut Universitaire de France (IUF); [3]Faculty of Medicine, University of Paris-Saclay, UVSQ, Villejuif, Research team "Neurodevelopment and learning disabilities", Necker-Enfants Malades hospital, INSERM Unit 1018-CESP; [4]University hospital, AP-HP. Centre, Necker Enfants Malades and [5]Department of Endocrinology, Necker-Enfants Malades hospital, IMAGINE Institute, Paris , France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1217

Introduction: Handwriting is mainly a motor process involving an efficient level of motor organization lead-ing to fine coordination of movements, thus, children with developmental coordination disorder (DCD) are particularly affected with handwriting disorders.
Objectives: We aimed to investigate handwriting disorders in DCD children in order to better understand the semiology of dysgraphia.
Methods: Data from 65 children aged 5 to 15 years (mean age 8.9 years, SD = 2.5) with DCD were collected on DSM-V criteria. They had no other medical or psychiatric condition and born full-term. They were assessed with handwriting testing and standardized assessments of neuropsychological, neurovisual, MRI and neuropsychomotor functions (NP-MOT neurodevelopmental battery), including muscular tone examination. Particular attention was paid to minor neurological dysfunctions (MND) which can be detected with the NP-MOT battery, such as a mild phasic stretch reflex (PSR).
Results: Findings showed a high rate of visual perceptual motor, visuo-spatial, and visuo-constructional impairments (> 82%), visual pursuit disorders (93%) and 89% of handwriting disorders (HD, n=58). Among these HD, there are 83% of poor handwriting (PH) and 17% of dysgraphia (DysG). Moreover, we found in HD, 36% of PSR (with 29% in PH vs 70% in DysG) correlated to imbalance of axial tone (hyper-extension) associated with increase of neuropsychomotor disorders such as dissonance between spontaneous gestural, usual and psychosocial lateralities ($P = 0.03$), impairments of coordination between upper and lower limbs ($P = 0.001$), impairments of manual dexterity ($P < 0.001$), impairments of dynamic balance ($P = 0.002$), and dysdiadochokinesis ($P < 0.001$).

Comparing PH and DysG groups, dysgraphia is associated to PSR (P = 0.04). 38% of abnormal MRI scans were heterogeneous and non-specific to the level of handwriting disorder and to PSR.
Conclusions: Dysgraphia appears to be a singular disorder as a comorbidity of DCD, which is significantly associated with a high incidence of motor impairments, suggesting a disturbance of the motor pathway (mild distal spasticity of the pyramidal corticospinal tract dysfunction). The presence of MND such as PSR highlights a mild impairment of the motor voluntary movement from the premotor cortex. PH appears primarily due to an immaturity of handwriting gesture consecutive to disorders of coordination programming in DCD.
Dysgraphia should be assessed not only with a simple handwriting test (legibility and speed) but completed with a developmental standardized physical neuropsychomotor examination assessing the presence of MND because to know the nature of the disorder is useful in clinical decision-making processes for handwriting remediation.

Utilizing Artificial Intelligence to Predict Psychiatric Disorders in Patients with Inflammatory Bowel Disease (IBD): Insights Based on a Systematic Review

A. A. Pillai[1], A. S. Nagendrapandian[2], J. Parmar[3], R. Walwaikar[1], A. A. Kumar[4], A. Agrawal[5] and F. Sheikh[6]*

[1]SSPM Medical College and Lifetime Hospital , Sindhudurg, India; [2]West Windsor Plainsboro High School South, New Jersy, United States; [3]Government Medical College , Amritsar; [4]GMERS Medical College, Vadnagar, India; [5]Humanitas University, Milan, Italy and [6]Greater manchester mental health trust, Manchester, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1218

Introduction: The scientific literature recognizes the Gut-brain axis (GBA) as a crucial connection between gastrointestinal health and mental well-being. Patients with inflammatory bowel disease (IBD) are at a disproportionately higher risk of developing psychiatric disorders due to factors including gut dysbiosis and chronic inflammatory changes. Recent developments in artificial intelligence (AI) and machine learning, provide novel opportunities to predict the comorbid psychiatric outcomes in patients with IBD by analyzing complex datasets including but not limited to the gut microbiome and neuroimaging data.
Objectives: This systematic review discusses the current evidence for AI-driven models to aid in the prediction of psychiatric disorders in IBD patients, with a focus on their performance and potential challenges around their clinical implementation.
Methods: A systematic search on PubMed, EMBASE, Scopus, and Cochrane databases, identified 28 studies utilizing AI-based models to examine gut microbiota and neuroimaging data in patients with IBD. Data extraction illuminated the following artifacts: classification thresholds (i.e. predictive), relevant supervised learning or deep learning modeling (e.g. random forest classifiers, convolutional neural networks, and unsupervised models like attention-based learning), sensitivity, specificity, accuracy, and both accuracy measures and AUC-ROC curve values.
Results: A pooled analysis of the included studies demonstrated an estimated sensitivity of 81% (95% CI: 77-85%) and specificity of 78% (95% CI: 73-82%) to predict psychiatric disorders in patients with IBD with the highest predictive accuracy elicited by studies based on microbiome and neuroimaging data. Yun et al. (2024), for instance, demonstrated a predictive accuracy of 86% using microbiome profiles and structural brain imaging data while Fil et al. (2024) elucidated the positive correlation between gut dysbiosis and psychiatric symptoms based on microbial signature models. Additionally, the variability noted in the predictive performance of the models was found to be based on the patient population, quality of data, and machine learning strategy.
Conclusions: AI models present promising evidence in predicting psychiatric disorders in IBD patients by leveraging microbiome and neuroimaging datasets. Overall, the meta-analysis reports strong predictive strength with high sensitivity and specificity. Future work in this field should focus on the validation of these prediction models in various clinical populations, improving their generalizability and standardization to enable widespread use and integration in the field of personalized psychiatry, especially in patients with IBD.

EPV0455

Psychiatric Conditions Following Surgical Interventions: A Case Series

Y. M. Akkaya[1]*, K. Şahin Akkaya[1] and H. Kaya[1]

[1]Psychiatry, Erenkoy Mental and Nervous Diseases Training and Research Hospital, Istanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1219

Introduction: The surgical treatment process involves not only physical recovery but also the management of psychiatric and psychosocial issues. Psychiatric disorders can negatively affect postoperative recovery, complicate adherence to treatment and decrease the quality of life (Begum *et al.* World J Surg 2022; 46(6) 1408-1419).
Objectives: This case series highlights less commonly encountered psychiatric conditions that arise after surgery and emphasizes the importance of considering how these conditions interact with pre-existing diseases during postoperative follow-up.
Methods: This case series examines three distinct cases of psychiatric disorders following surgical interventions:
Delusional disorder after hypophysectomy
Somatization disorder after cystoscopy
Psychotic depression following colostomy creation
Informed consent was obtained from all patients.
Results: Case 1
A 62-year-old male patient diagnosed with hypophyseal macroadenoma underwent transsphenoidal hypophysectomy. Two months after surgery, he developed paranoid delusions, believing his wife was having an affair. Initially treated with aripiprazole 15 mg/day, the patient did not improve. His treatment was switched to risperidone 2 mg/day, resulting in resolution of his symptoms.

Case 2
A 58-year-old male with benign prostatic hyperplasia (BPH) developed persistent groin pain after cystoscopy. Despite urological treatment, the pain did not subside, and he was referred to algology for gabapentin, which was ineffective. Referred to psychiatry, he reported pain radiating to his back and arms, worsened by stress, and trouble sleeping due to his pain. Diagnosed with somatization disorder, he was treated with olanzapine 2.5 mg/day and cognitive interventions, which led to decreased pain.
Case 3
A 72-year-old male patient with rectal cancer, following abdominoperineal resection and colostomy creation, began consuming other people's medications. He exhibited disorganized behavior and suicidal ideation, and was diagnosed with psychotic depression. Treated with olanzapine 5 mg/day and venlafaxine 75 mg/day, his disorganized behavior resolved during follow-up, and olanzapine was discontinued. He remains in remission on venlafaxine 75 mg/day.
Conclusions: This case series illustrates the diversity of psychiatric conditions that can arise after surgical interventions and emphasizes the importance of postoperative psychiatric monitoring. Although there is a lack of sufficient studies on this topic, a postoperative follow-up study conducted with a group of 200 patients found that the risk of developing anxiety after surgery was 31%, and the risk of developing depression was 56% (Basak *et al.* Int J Surg 2015; 23 18-22). Psychiatric symptoms can complicate physical recovery, affect adherence to treatment, and reduce quality of life. A multidisciplinary approach is essential to support both physical and psychological recovery, ultimately improving the overall health status of patients.

Evaluating the Psychometric Properties of Arabic Version of the Patient Health Questionnaire-9 (PHQ-9) among Omani Patients with End Stage Renal Disease on Dialysis

O. S. Alkalbani[1]*, M. al alawi[2] and S. al farsi[1]
[1]psychiatry, omsb and [2]psychiatry, squh, muscat, Oman
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1220

Introduction: Depression significantly affects patients with chronic kidney disease (CKD), with prevalence rates reaching up to 39% among those on hemodialysis, and is often overlooked in screening. This study aims to assess the PHQ-9's effectiveness in Omani dialysis patients, potentially improving early detection and mental health care integration.
Objectives: The objectives of this study are as follows: 1) To assess the sensitivity, specificity, positive predictive value and negative predictive value of the PHQ-9 in detecting depression among Omani renal dialysis patients at Al Seeb and Bausher dialysis units from October 2023 to January 2024. 2) To evaluate the psychometric properties of the PHQ-9, including the optimal cut-off score, internal consistency, and criterion validity, in Omani renal dialysis patients by January 2024
Methods: This cross-sectional study was conducted from October 1, 2023, to January 31, 2024, at two renal dialysis centers in Muscat, focusing on adults aged 18 and older who had undergone dialysis for at least three months. Data collection included a sociodemographic questionnaire, the Patient Health Questionnaire (PHQ-9) for depression symptoms, and the Structured Clinical Interview for DSM-5 (SCID-5) for psychiatric evaluation, with all ethical standards adhered to and Institutional Review Board approval obtained. Data analysis utilized MedCalc® software, with statistical significance set at $p < 0.05$, and the diagnostic accuracy of the PHQ-9 evaluated through ROC curve analysis.
Results: The study included 209 patients with Chronic Kidney Disease (CKD), averaging 48.43 years, with demographics summarized in **Table 1**. The Patient Health Questionnaire-9 (PHQ-9) effectively screened for Major Depressive Disorder (MDD), achieving an AUC of 0.87, as illustrated in **Figure 1**, with an optimal cutoff score of 9, sensitivity of nearly 78%, and specificity of about 85%. Additional metrics are detailed in **Table 2**, confirming the PHQ-9's overall accuracy of 83.25% in identifying depression, highlighting the importance of clinical evaluation for diagnosis.

Image 1:

Table 1: Distribution of Patient Characteristics

Table 2: Diagnostic Accuracy of PHQ-9

PHQ9	Sensitivity % (95% C.I.)	Specificity % (95% C.I.)	Area Under Curve (AUC) % (95%	Positive Likelyhood Ratio % (95% C.I.)	Negative Likelyhood ratio % (95% C.I.)	Positive Predictive value % (95% C.I.)	Negative predictive value % (95% C.I.)	Accuracy % (95% C.I.)
PHQ - ≥ 9	78.43 (64.68 – 8.71)	84.81 (78.25 – 90.02)	0.816 (0.76 – 0.87)	5.16 (3.48 – 7.67)	0.25 (0.15 – 0.43)	62.50 (52.88 – 71.23)	92.41 (87.79 – 95.38)	83.25 (77.49 – 88.05)

Conclusions: This study provides strong evidence for the validity and reliability of the PHQ-9 as a depression screening tool for Omani dialysis patients, emphasizing the need for culturally sensitive approaches in screening. It suggests adjusting cutoff scores to enhance diagnostic accuracy, with significant implications for clinical practice in Oman and similar regions. Healthcare professionals are urged to consider cultural factors when implementing screening protocols to improve patient care. Future research should broaden the validation of the PHQ-9 across other regions in Oman and the Middle East, examining how linguistic and educational differences may affect its effectiveness.

Catatonia as a debut of systemic lupus erythematosus: a case-report on a diagnostic challenge

H. Andreu[1]*, B. Serra-Sarró[1], L. Bueno[1], Ò. de Juan[1], I. Ochandiano[1], L. Olivier[1], H. Álvarez[1], A. Herrero[1], C. Mantellini[1], M. Vicente[1], M. Sagué-Vilavella[1,2], L. Ilzarbe[2,3], L. Pintor[1,4], M. Garriga[1,5], V. Llorca-Bofí[1,5] and M. Bioque[1,5]

[1]Psychiatry and Psychology Department; [2]Bipolar and Depressive Disorders Unit; [3]Servei de Psiquiatria i Psicologia; [4]Consultation Liaison Psychiatry Unit and [5]Schizophrenia Unit, Hospital Clínic de Barcelona, Barcelona, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1221

Introduction: Systemic lupus erythematosus (SLE) is an autoimmune disorder characterized by a wide range of symptoms, including neurological and psychiatric symptomatology. Between 37 and 95% of SLE patients present psychiatric symptoms, which can appear at any point in the disease and may present in various forms, ranging from more common conditions like depression and anxiety to rarer manifestations such as psychosis and catatonia (Carrión-Barberà *et al.* Autoimmunity Reviews 2021;20:102780).
Objectives: To describe the case of a patient who presented a SLE debut with catatonic symptoms and to review neuropsychiatric and specifically catatonic symptoms in SLE patients.
Methods: We present the case of a 32-year-old woman with no previous psychiatric history who was brought to our psychiatry emergency department (PED) for difficulties in language emission, only being able to babble for the last days. Approximately two weeks ago she had started to present anxiety, insomnia and catastrophic thoughts, so she consulted a psychiatrist who recommended starting escitalopram up to 15mg/d. In the next days she started to present difficulties of speech which worsened. Upon arrival, several diagnostic tests were performed including blood tests, CT scan, lumbar punction and electroencephalogram, showing no abnormalities. However, since the symptoms did not improve she was hospitalized for diagnostic affiliation.
Results: During her hospitalization, more diagnostic tests were performed, including brain MRI and more exhaustive blood tests with autoimmunity profile, although the results were not available until several days later. Although the diagnosis was not yet clear and there were doubts among psychosis, neurologic functional disorder and organic mental disorder, several drugs were started including corticotherapy and olanzapine 15mg/d, venlafaxine up to 150mg/d and clonazepam 2.5mg/d with partial improvement of the symptoms, still showing motor retardation, blocking, perplexed gaze and mutism. In parallel, blood tests results emerged, showing high titre ANA antibodies, positive anti-double-stranded DNA and anti-Sm antibodies and decreased complement C3 component. With these findings, the diagnosis orientation was systemic lupus erythematosus (SLE).
Conclusions: Catatonia is a rare psychomotor syndrome that can be associated with SLE. Given its rarity, there still no standardized treatment for it in SLE patients, although some options have been proposed including, as in any other SLE manifestations, flare immunosuppressive at high doses and in these patients, the usual psychiatric management (Boeke *et al.* Psychosomatics 2018;59:523-530; Sundaram *et al.* Rheumatology Journal 2021;42:1461-1476) Clinicians should keep this in mind to correctly diagnose and treat these patients, since early identification of this syndrome and prompt treatment leads to a more favorable outcome.

Mental or Metabolic?: Misdiagnosis of Wilson Disease as Primary Psychiatric Disorder in Multiple Members of a Pakistani Family

F. R. Bhatti[1] and S. Liaqat[2]*

[1]Psychiatry, Pakistan Institute of Medical Sciences, Islamabad, Pakistan and [2]Psychiatry, RUSH University Medical Center, Chicago, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1222

Introduction: Wilson disease is an autosomal recessive disorder that leads to defective copper metabolism. It manifests as neurologic, hepatic and psychiatric symptoms (Benhamla et al. Encephale 2007; 33(6):924–32). Through a case series of three family members, we emphasize the varied presentation of Wilson disease, and the need for investigation of metabolic causes of such symptoms especially in families with a history of consanguinity.
Objectives: We aim to underscore the importance of considering metabolic causes of psychiatric symptoms, particularly when these symptoms cluster within families.
Methods: The cases are presented followed by an exploration of social context, gaps in existing literature, and suggestions for clinical practise.
Results: Case 1: A 32-year-old male previously having received diagnoses of Treatment-Resistant Schizophrenia and Obsessive Compulsive Disorder over a period of 13 years presented with cognitive decline, delusions of persecution and reference, 2nd and 3rd person auditory hallucinations, preoccupation with cleaning and a significant decline in the ability to perform activities of daily living. Despite extensive psychiatric treatment, his symptoms worsened, raising suspicion for an underlying medical condition.
Case 2: A 16-year-old male, once a bright student, presented with progressive cognitive decline, poor working memory, social withdrawal, needing assistance with ADLs and sialorrhea for 2 years. These symptoms were initially misattributed to psychological stress and academic pressure, but the lack of response to treatment and worsening neurological signs of poor coordination raised suspicion for an organic cause. His eye exam was positive for Kayser Fleischer ring and his serum ceruloplasmin was below threshold level. This prompted a similar workup for his elder brother which was positive for Wilson disease.
Case 3: The mother of the aforementioned two patients, after witnessing her younger son's decline, developed major depressive disorder with psychosis. Her symptoms started follwoing the stress of her children's health problems and their lack of response to treatment.
Upon genetic counselling, the siblings of the first two patients revealed that they were both respectively engaged to be married to their first cousins and that their mother was adamant about these matches due to family traditions.
Conclusions: These cases underscore the need for a heightened suspicion of Wilson disease and other metabolic disorders in patients who belong to regions with high rates of consanguinity and have clustering of psychiatric disorders in their family. Further studies are needed to determine the true prevalence of Wilson disease in Pakistan which may be relatively high due to the common practise of cousin marriages (Zimbrean et al.Gen Hosp Psychiatry.2014;36(1):53–62).

Does Psychological Resilience Affect Sexual Satisfaction in Women with Polycystic Ovary Syndrome? A Cross-Sectional Observational Study

A. Bicer[1]*, A. C. Kahve[2], D. G. Mert[1], B. Elmas[3] and E. Göka[1]

[1]Psychiatry, Health Sciences University Ankara City Hospital; [2]Psychiatry, Gazi University and [3]Obstetrics and Gynecology, Health Sciences University Ankara City Hospital, Ankara, Türkiye

doi: 10.1192/j.eurpsy.2025.1223

Introduction: Polycystic Ovary Syndrome (PCOS) is a common endocrine disorder in women of reproductive age, characterized by hyperandrogenism, oligomenorrhea/amenorrhea, and polycystic ovary morphology. PCOS can negatively impact sexuality due to physical issues like hyperandrogenism, metabolic syndrome, and infertility, as well as the psychological burden of the disease and associated mental health issues. Psychological resilience, defined as the ability to cope with stress and recover, is known to aid in managing physical illnesses and improve treatment outcomes. Although psychological resilience and sexuality are individually studied in relation to physical and psychological problems, research on their relationship, especially in PCOS, is limited.
Objectives: This study aimed to explore the relationship between psychological resilience and sexual satisfaction in women with PCOS, comparing it with a healthy control group, and to identify factors affecting sexual satisfaction in PCOS patients.
Methods: 70 women aged 18-40 with a PCOS diagnosis and 69 healthy controls matched for age and education participated in this study. Participants underwent a psychiatric interview according to the SCID-5 and completed the Sociodemographic Data Form, Psychological Resilience Scale for Adults (RSA), Hospital Anxiety and Depression Scale (HADS), Golombok Rust Inventory of Sexual Satisfaction (GRISS), and Arizona Sexual Experiences Scale (ASEX). Blood tests requested by the gynecologist were also documented for the PCOS group.
Results: Women with PCOS exhibited lower psychological resilience than healthy controls, particularly in self perception area as shown in **Table 1**. They also reported lower sexual satisfaction with partners. No significant difference was found in masturbation frequency between the groups, nor was masturbation related to sexual satisfaction in either group. However, increased psychological resilience was associated with higher sexual satisfaction in both groups, with future perception area on the RSA significantly impacting sexual satisfaction. Examination of the relationship between RSA scores and GRISS and ASEX scores in women with PCOS is presented in **Table 2** and **Table 3**.

r:Spearman's rho correlation coefficient; n: number of people; PCOS: Polycystic ovary syndrome; RSA: Resilience Scale for Adults

Conclusions: Psychological resilience, especially the future perception area, may play an influential role in sexual satisfaction. In light of these findings, it can be suggested that the treatment of PCOS should involve a multidisciplinary approach that includes mental health professionals. It is important to evaluate the sexual life of these women during follow-ups, provide psychoeducation, and adopt a hopeful approach. Considering factors that influence psychological resilience, interventions aimed at reducing risk factors and increasing protective factors could be anticipated to be important tools in preventing and treating sexual problems.

The interplay among mental and physical health in patients with psoriasis: results from an observational study

S. Cipolla[1]*, P. Catapano[1], A. Cirino[1], D. D'Amico[1], A. Volpicelli[1], V. De Santis[1], M. Luciano[1], F. Perris[1] and F. Catapano[1]

[1]Department of Psychiatry, University of Campania "L. Vanvitelli", Naples, Italy

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1224

Introduction: Psoriasis is a chronic skin condition affecting 2-3% of the global population and is often associated with various comorbidities, including psychiatric disorders. The psychological burden of psoriasis is substantial and multifaceted. Patients frequently experience stigma, social isolation, and reduced self-esteem due to the visible and often disfiguring nature of the disease. These psychosocial stressors can precipitate or exacerbate psychiatric conditions such as anxiety and depression.

Objectives: This study aims to identify the factors influencing psychopathological symptoms in patients with psoriasis, with a specific focus on the mediation role of physical and mental health on psychopathological distress in patient with psoriasis.

Methods: This observational study included 112 patients diagnosed with psoriasis. Dermatological and psychiatric evaluations were performed using Psodisk, the Hamilton Anxiety Rating Scale (HAM-A), the Hamilton Depression Rating Scale (HAM-D), the Symptom Checklist-90-Revised (SCL-90-R), and the 36-Item Short Form Health Survey (SF-36). Descriptive statistics, correlation analysis, mediation models were used for data analysis. To develop the mediation models, Psodisk subscales were used as independent variables, and the Global Severity Index (GSI) of SCL-90-R as the outcome variable; both physical (PCS) and mental (MCS) components of the SF-36 were used as mediators.

Results: The sample consisted predominantly of middle-aged males (mean age 48.91 years). Females ($p < 0.001$), patients with arthritis ($p < 0.05$), and those leading a sedentary lifestyle ($p < 0.05$) exhibited higher scores for anxiety and depression. Psodisk subscales showed a significant correlation with psychiatric symptoms and QoL measures ($p < 0.001$). The mediation analysis revealed that the mental component of quality of life (MCS) had a statistically significant mediating effect in all models, being the only mediator for the effect of health, pain, and sleep domains of the Psodisk on GSI ($p < 0.001$; $R^2 = 0,2$). Furthermore, when total Psodisk score was used as independent variable, MCS mediating effect on GSI was also significant ($p < 0,001$; $R^2 = 0,32$) with a non-significant role of PCS.

Conclusions: This study highlights the complex relationship between psoriasis, psychiatric comorbidities, and QoL. Mediation

analysis shows that mental component of quality of life can play a more significant mediating role than physical alterations in determining psychiatric symptoms in patients with psoriasis. All psoriasis patients, regardless of physical changes, should be considered at risk for developing psychiatric symptoms, and direct collaboration between general practitioners, dermatologists, and psychiatrists may be able to identify the most vulnerable patients and limit the onset of severe mental disorders.

Functional Neurological Disorder with functional ptosis: Clinical challenges and opportunities for learning. (Case study)

S. Crowley[1]*, O. O'Toole[2], E. O'Neill[3], J. Malaka[3] and E. Kelleher[4,5]

[1]South Lee Mental Health Services, Cork University Hospital; [2]Department of Neurology, Cork University Hospital, Wilton; [3]Department Of Psychiatry; [4]Department Of Consult Liaison Psychiatry, South Lee Mental Health Services, Cork University Hospital and [5]Department Of Psychiatry, University College Cork, Cork, Ireland

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1225

Introduction: Functional Neurological Disorder (FND) is a well-recognised disorder that is seen by both neurology and psychiatry services. It is an unconscious disorder that may involve motor or sensory neurological symptoms, classically ascribed to underlying psychological distress, the aetiology of which can sometimes be difficult to ascertain.

Objectives: This case presented highlights several key features of FND.

Presentations can involve pain and may evolve to involve multiple locations that may not follow a neuroanatomical distribution.

There may be initial reluctance of the patient or family to accept the diagnosis.

These can be difficult cases but there is potential for improvement with multidisciplinary support.

Inclusion of the patients' perspective of going through the diagnostic process, in this case, gives a unique perspective of being a patient with this disorder,

Methods: .

Results: A young female presented to the emergency department with acute onset severe right facial pain, subjective facial swelling, minor ptosis of the right eyelid and headache. Symptoms evolved over the next week to include speech disturbance, right shoulder pain, and reduced sensation in her right arm. After initial extensive negative work, it was felt that the patient most likely had a functional neurological disorder and underwent multidisciplinary treatment. The patient represented four months later after a minor fall at work with re-emergence of the right arm and facial pain associated with speech disturbance. Relapsed functional neurological disorder (FND) was diagnosed. A multidisciplinary team (MDT) approach with neurology, liaison psychiatry, speech and language therapy (SALT), physiotherapy and psychotherapy was instituted resulting in the resolution of symptoms. FND is a common disorder in which clinicians receive limited training. This case highlights a complex presentation of FND including "pseudoptosis", a rarely seen functional symptom, and how MDT input led to symptomatic improvement. Relapse of FND is not uncommon, sometimes after minor physical or psychological stress or trauma. There is hope to improve symptoms when this happens. Our review also includes the patient's perspective of going through the FND diagnosis.

Conclusions: Functional Neurological Disorders are common and greater training in and understanding of these disorders is important.

Symptoms that are rarely functional such as ptosis, do not exclude FND.

FND can be a difficult diagnosis for patients and families to accept, but accepting the diagnosis is key to appropriate treatment and recovery

An MDT approach incorporating neurology, psychiatry, physiotherapy, psychology, speech and language therapy and occupational therapy provides the best opportunity for recovery.

Early diagnosis and multi-disciplinary treatment can aid recovery, reduce the development of further disability and reduce healthcare utilisation and costs.

EPV0465

Defining Brain Fog - A Transdiagnostic Narrative Review

P. Denno[1]* and A. Hampshire[2]

[1]Imperial College London and [2]Kings College London, London, United Kingdom

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1226

Introduction: The term brain fog is increasingly used by patients and researchers, but is poorly-defined. Understanding the symptom is important, as it is highly-prevalent, and linked to poor quality of life, and social and occupational disability. Furthermore, it is reported in a broad and seemingly unrelated set of conditions including COVID, menopause, hypothyroidism, traumatic brain injury (TBI), chronic fatigue syndrome (CFS/ME), fibromyalgia, and systemic lupus erythematosus (SLE). Transdiagnostic similarities may indicate common mechanisms or therapeutic targets, and opportunities for translation of research findings.

Objectives: We aimed to review research characterising brain fog across diagnoses and summarise findings on phenomenology, definitions, objective cognitive measures, and neurobiological correlates. We aimed to highlight transdiagnostic commonalities and differences, and make recommendations on terminology and future research.

Methods: We conducted a narrative review of biomedical research into brain fog. We chose a non-systematic approach due to the fragmentary nature of the literature and our exploratory aims.

Results: Brain fog is associated with cognitive symptoms - predominately difficulties with attention, memory, and language, contributing to a subjective "fog" or lack of "mental clarity". It overlaps with fatigue, and psychiatric symptoms, including anxiety, depression, and dissociation. It is chronic but often transient or variable. There are many transdiagnostic similarities, but research conducting direct comparisons is lacking. We argue that transdiagnostic commonalities in brain fog must arise at one of 3 levels - ambiguous language, common cognitive mechanisms, or common neurobiology. Neurobiological correlates appear heterogenous. Objective cognitive findings are mixed, between mild deficits in attention

and memory and no deficits. Evidence for correlation between subjective and objective symtpoms is mixed. Many studies find objective deficits are mediated by associated symptoms such as fatigue, depression, or anxiety.
Conclusions: We suggest researchers avoid the term brain fog in favour of clearly-defined terms where possible. While brain fog appears to refer to a broad range of phenomena, it captures a characteristic assocation of fatigue, cognitive and affective symptoms, and mild objective deficits across diagnoses. Brain fog appears to overlap substantially with mental fatigue. Further research is needed, including direct transdiagnostic comparisons. Measures should include high-precision cognitive batteries, as well as measures of affect (e.g., GAD / PHQ9), fatigue (e.g., FAS), and metacognition, to enable the role of non-cognitive factors to be assessed and compared across conditions.

EPV0466

Frustration reactions as a factor of adherence to treatment in patients with cardiovascular diseases

E. V. Deshchenko[1]* and E. I. Pervichko[1]

[1]Lomonosov Moscow State University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1227

Introduction: Adherence to treatment plays a key role in the effectiveness of therapy of the cardiovascular diseases. Patient's personality becomes an inevitable determinant of health behaviour influencing the way the patient reacts to the illness itself. The painful sensations, the need to adapt to the disease may be the cause of frustration in patients (Heszen-Klemens. Soc Sci Med 1987, 24 (5) 409-416). Hence, it is necessary to assess how the frustration reactions are connected with the adherence to treatment.
Objectives: The aim of the research was to study the relationship between the frustration reactions and the adherence to treatment in patients with cardiovascular diseases.
Methods: The Picture Frustration Test (Rosenzweig. Journal of Personality 1945, 14 3-23) was used to assess frustration reactions of the patients. The Questionnaire for Comprehensive Assessment of Treatment Adherence was used to provide a complex evaluation of the adherence to treatment (Nikolayev, Skirdenko. Clinical Pharmacology and Therapy 2018, 1 74-78). The study was conducted from January 2024 to April 2024. The sample consisted of 42 male patients hospitalised with multiple cardiac pathology, whose average age was 49.40±7.71.
Results: The average adherence to treatment of the patients with cardiovascular diseases in our sample was 61.17±18.53%, with twelve (30%) participants being defined as low-adherent and nine (22.5%) as high-adherent. What concerns direction of frustration reactions, low-adherent patients were more likely to exhibit extrapunitive reactions (H=7,760, p=0,021), whereas high-adherent patients demonstrated intropunitive reactions more often (H=6,062, p=0,048). More interestingly, there were significant differences in types of frustration reactions, with need-persistent reactions being more characteristic for the high adherent-patients (H=6,551, p=0,038). Intropunitive and need-persistent frustration reactions were associated positively with the adherence to treatment (r=0.428, p=0.013; r=0.459, p=0.007). Extrapunitive reactions were found to be negatively associated with the adherence (r=-0.409, p=0.004).
Conclusions: Our study was the first to consider the connection between the frustration reactions of the patients with cardiovascular diseases and their adherence to treatment. The results indicate that the way in which patients typically react to the frustration is connected with the way in which they handle limitations and requirements of the treatment process. When the patient is more likely to react to frustration in problem-solving manner, the chances are that their health behaviour will also lead to a sufficient adherence to treatment.

EPV0467

Maturity of defense mechanisms as a predictor of adherence to treatment in patients with cardiovascular diseases

E. V. Deshchenko[1]*, E. I. Pervichko[1] and E. V. Akatova[2]

[1]Lomonosov Moscow State University and [2]Russian University of Medicine of the Ministry of Health of Russia, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1228

Introduction: Promoting adherence to treatment is essential for increasing the effectiveness of therapy of the cardiovascular diseases. The role of defense mechanisms and frustration reactions of the cardiac patients in their adherence to treatment was not studied previously.
Objectives: The aim of the research was to study the relationship between defense maturity and adherence to treatment in patients with cardiovascular diseases.
Methods: To measure the adherence to treatment the Questionnaire for Comprehensive Assessment of Treatment Adherence was used (Nikolayev *et al*. Clinical Pharmacology and Therapy 2018, 1 74-78). Defense mechanisms were assessed using the Defense Mechanisms Rating Scales (DMRS-SR-30; Di Giuseppe *et al*. Front. Psychiatry 2020, 11:870). The Picture Frustration Test was used to assess patients' frustration reaction types (Rosenzweig. Journal of Personality 1945, 14 3-23). Structural equation modeling (path analysis method) was used for data analysis. The study was conducted from December 2022 to April 2023. The sample consisted of 42 male patients hospitalised with multiple cardiac pathology, whose average age was 49.40±7.7.
Results: The majority of the patients in our sample demonstrated middle level of the adherence to treatment, with mean score being 61.17±18.53%. Twelve (30%) participants were defined as low-adherent and nine (22.5%) were defined as high-adherent. Assessment of frustration reactions showed that the adherence to treatment is positively connected with intropunitive and need-persistent reactions (r=0.428, p=0.013; r=0.459, p=0.007) and negatively connected with extrapunitive reactions (r=-0.409, p=0.004). What concerns defense mechanisms, the maturity of defenses appeared to be positively connected with the adherence to treatment (r=0,388, p=0,021). Using path analysis, we found only one theoretical model to be representative of the empiric data. The model constructed reveals indirect effect of the defense maturity on the adherence to treatment, mediated by the type of frustration reaction. The paths are positive, significant and equal

0.242 (χ2=1.871, p=0.171, CFI=0.947, RMSEA=0.176). Patients that use more mature defenses are more likely to give need-persistent reactions to frustration, hence, they have better adherence to treatment.
Conclusions: Thus, the results of our study demonstrate that defense maturity can be used as a predictor of the adherence to treatment in patients with cardiovascular diseases due to its role in determining the type of frustration reactions. More mature defenses allow patients to be more flexible in their reaction to the illness and its limitations that leads to higher adherence to treatment.

EPV0468

Psychological factors of adherence to treatment in patients with cardiovascular diseases

E. V. Deshchenko[1]*, E. I. Pervichko[1], E. V. Akatova[2] and O. P. Nikolin[2]

[1]Lomonosov Moscow State University and [2]Russian University of Medicine of the Ministry of Health of Russia, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1229

Introduction: Cardiovascular diseases are one of the leading causes of death worldwide. Adherence to treatment is considered to be a key determinant of the effectiveness of therapy. Patient's personality and other psychological characteristics play a regulating role in health behaviour but there is still no consistent evidence on their connection to the adherence to treatment.
Objectives: The study aimed to determine the role of psychological factors regarding the adherence to treatment in patients with cardiovascular diseases.
Methods: Adherence was measured using the Questionnaire for Comprehensive Assessment of Treatment Adherence (Nikolayev *et al.* Clinical Pharmacology and Therapy 2018, 1 74-78). To provide a complex assessment of psychological factors we used the Short Health Anxiety Inventory (Salkovskis *et al.* Psychological Medicine 2002, 32 843-853; Pervichko, Shishkova. National Psychological Journal 2022, 2), the HEXACO Personality Inventory (Ashton, Lee. Personality and Social Psychology Review 2007, 11 150-166; Egorova *et al.* Issues of Psychology 2019, 5 33-49), the Defense Mechanisms Rating Scales (DMRS-SR-30; Di Giuseppe *et al.* Front. Psychiatry 2020, 11:870), and the Picture Frustration Test (Rosenzweig. Journal of Personality 1945, 14 3-23). The study was conducted from January 2024 to April 2024. The sample consisted of 42 male patients hospitalised with multiple cardiac pathology, whose average age was 49.40±7.71.
Results: Patients with cardiovascular diseases mostly demonstrated middle level of the adherence to treatment (61.17±18.53%), twelve (30%) participants were defined as low-adherent, nine (22.5%) were high-adherent. The component of health anxiety known as vigilance to bodily sensations was found to be positively associated with the adherence to treatment (r=0.316, p=0.047). Conscientiousness was the only personality trait to demonstrate significant positive associations with the adherence (r=0.378, p=0.023). More interestingly, adherence to treatment appears to be positively associated with need-persistent and intropunitive frustration reactions (r=0.428, p=0.013; r=0.459, p=0.007) and negatively associated with extrapunitive frustration reactions (r=-0.409, p=0.004). Assessment of defense mechanisms reveals positive associations between overall defense maturity and adherence to treatment (r=0.388, p=0.021), indicating that low-adherent patients are more inclined to use less mature defenses.
Conclusions: Thus, adherence to treatment in patients with cardiovascular diseases is associated with greater vigilance to bodily sensations, conscientiousness, defense maturity, use of need-persistent and intropunitive frustration reactions and lesser use of extrapunitive frustration reactions.

EPV0469

A Diagnostic Challenge: Korsakoff Syndrome Misdiagnosed as Hepatic Encephalopathy

D. Erbil[1]*, O. Akay[1] and B. Koparal[1]

[1]Psychiatry, Gazi University Faculty of Medicine, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1230

Introduction: The abrupt occurrence of neuropsychiatric symptoms in patients with alcohol-related cirrhosis requires detailed evaluation not only for hepatic encephalopathy but also for other etiologies like Wernicke-Korsakoff Syndrome. In this case, we present a patient with alcohol-related cirrhosis who was initially admitted to gastroenterology unit with a preliminary diagnosis of hepatic encephalopathy but was ultimately diagnosed with Korsakoff Syndrome.
Objectives: This case highlights the critical need for comprehensive neuropsychiatric assessment in patients with alcohol-related cirrhosis and offers a review of the current literature on the definition and clinical presentation of confabulation.
Methods: Description of a clinical case and literature review
Results: 45-year-old male with a history of alcohol-related cirrhosis was admitted to gastroenterology unit with symptoms suggestive of hepatic encephalopathy. On hospital day two, he was consulted to consultation-liaison psychiatry unit with the complaints of sleep disturbances and meaningless talking. In his story; over the past 3 months, he was talking about unrealistic events, having anger outbursts and disrupted sleep cycle, although his total sleep duration remained normal. Aside from grandiosity, mild irritability and disruptions in thought content, there were no signs of manic episode, such as euphoria, distractibility or reduced sleep. In mental state examination, he was alert, oriented in time, place and person, displaying normal psychomotor activity, speech, and impulsivity with euthymic mood. Neurological examination revealed no signs of Wernicke encephalopathy, such as nystagmus, ataxia or confusion. Subsequent psychiatric evaluations revealed fluctuations in narrative, lack of insight, mild memory impairment, and grandiose thought content suggestive of momentary confabulation, all indicative of Korsakoff Syndrome. He was transferred to the psychiatry inpatient unit and treatment with amisulpride at 200 mg daily and thiamin at 300 mg per day were initiated. Following treatment, there was a gradual improvement in aggression; however, no significant enhancement in confabulations or memory function was observed.
Conclusions: To our knowledge, this is the first case report of Korsakoff Syndrome presenting with a preliminary diagnosis of hepatic encephalopathy. The neuropsychiatric components of hepatic encephalopathy can manifest with a variety of symptoms,

posing a challenge in differentiation from psychiatric disorders, such as mania or Korsakoff Syndrome. This report highlights the importance of a collaborative evaluation for patients presenting with neuropsychiatric symptoms and a history of alcohol-related cirrhosis.

Descriptive Study on Attentional and Executive Functioning Following CAR-T Cell Therapy in Paediatric Patients with Acute Lymphoblastic Leukaemia

C. Campoy-Lacasa[1], V. Galán-Gómez[2], B. González-Martínez[2], A. Pérez-Martínez[2,3,4] and E. Fernández-Jiménez[1,5,6]*

[1]Department of Psychiatry, Clinical Psychology and Mental Health; [2]Department of Pediatric Hemato-Oncology, La Paz University Hospital; [3]Department of Pediatrics, Universidad Autónoma de Madrid; [4]CIBERER-ISCIII. IdiPAZ-CNIO Pediatric Onco-Hematology Clinical Research Unit, Spanish National Cancer Research Center (CNIO); [5]Hospital La Paz Institute for Health Research (IdiPAZ), Madrid and [6]Faculty of Social Sciences and Communication, Universidad Europea de Madrid, Villaviciosa de Odón, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1231

Introduction: Chimeric antigen receptor–engineered T-cell (CAR-T) therapy is a newly approved treatment that has shown high remission rates among patients with acute lymphoblastic leukaemia. However, its neuropsychological impact remains largely unknown. To our knowledge, this is the first study to examine the neurocognitive effects of CAR-T therapy in children.
Objectives: To analyse attentional and executive functioning outcomes in paediatric patients with acute lymphoblastic leukaemia after CAR-T therapy.
Methods: This study was conducted at the Child Neuropsychology Unit of La Paz University Hospital in Madrid, Spain. Thirteen paediatric patients aged 7–16 years (mean age = 12 years and 1 month; 75% male) were assessed. Neurocognitive assessments were performed at an average of 1 year and 4 months after CAR-T therapy (ranging from 3 months to 3 years and 4 months). Neurocognitive measures included the Symbol Digit Modalities Test (SDMT), the Omission score from the Continuous Performance Test Third Edition (CPT 3), the Test of Nonverbal Intelligence Fourth Edition (TONI-4), and the Verbal Fluency Test (FAS). Descriptive analyses were conducted, including median, minimum and maximum scores for age- and sex-adjusted z-scores, with significant impairment defined as $z < -1.5$.
Results: Findings revealed that 58.3% of the children scored significantly below norms on non-verbal abstract reasoning (TONI-4: Median = -1.53; Min = -3.27; Max = 1.27), 53.9% displayed significant sustained attentional deficits (Omission CPT 3: Median = -3.1; Min = -4.0; Max = 0.70), and 41.7% showed relevant impairments in both processing speed (SDMT: Median = -1.5; Min = -5.7; Max = 1.9) and phonological verbal fluency (FAS: Median = -0.7; Min = -2.9; Max = 1.5).
Conclusions: Paediatric acute lymphoblastic leukaemia survivors treated with CAR-T therapy show deficits in processing speed, sustained attention, abstract reasoning, and phonological verbal fluency. These findings underscore the need for both short- and long-term neuropsychological monitoring, and tailored interventions targeting attentional and executive functioning deficits in this population. Future studies should replicate these analyses by using larger sample sizes.

Delirious mania in a 19 year-old Ukrainian refugee

N. Goh[1]*, I. Onwuemelie[2] and S. Patel[3,4]

[1]Rehabilitation Psychiatry, National Forensic Mental Health Service; [2]Perinatal Psychiatry, Galway-Roscommon Mental Health Service; [3]Liaison Psychiatry, University Hospital Galway and [4]Liaison Psychiatry, University Hospital Portiuncula, Galway, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1232

Introduction: We present a case study of a 19-year old Ukrainian refugee presenting with delirious mania, with no personal or family psychiatric history. Delirious mania is a complex and severe neuropsychiatric condition that remains under-recognised in diagnostic manuals. Delirious mania describes a neuropsychiatric state where a patient is exhibits signs and symptoms of mania, delirium and often catatonia. Most of the patients described in past case reports are older in age than our patient and have a personal or family history of a mood disorder.
Objectives: Our objectives were to investigate the signs and symptoms of delirious mania in this this 19 year-old patient. We sought to compare his presentation to the existing diagnoses in the Diagnostic and Statistical Manual of Mental Disorders Fifth Edition and International Classification of Diseases 11th Revision. These include delirium, mania and catatonia. In addition, we aimed to study existing literature on delirious mania as well as cross-cultural factors in formulation of this complex case.
Methods: We assessed this patient daily as part of the Liaison Psychiatry team and compared his presentation to existing diagnostic criteria of delirium, mania and catatonia. We performed a literature review of delirious mania to identify suggested diagnostic criteria, management strategies and cultural considerations.
Results: Our patient presented to the Emergency Department with a four-day history of bizarre behaviour and poor sleep. He had no past psychiatric history. He was admitted to the general medical ward for a medical work-up, which ultimately yielded no organic pathology. During this time, our patient fulfilled separate diagnostic criteria for delirium, manic episode and catatonia. We found that there was no overarching diagnosis within international diagnostic manuals that encompassed this patient's presentation. However, delirious mania has been described in the literature since 1849. There are various suggested diagnostic criteria for delirious mania suggested in the literature, such as those by Bond (1980) and Fink (1999). This patient was successfully treated with intramuscular lorazepam. In our discussion, we considered various unique factors in the formulation. These included the cultural considerations given that the patient had recently entered the country as a Ukrainian refugee, difficulties in assessment and treatment due to language and cultural barriers and the limitations of psychiatric treatment on a general medical ward.

Conclusions: Delirious mania continues to be unrepresented in diagnostic manuals, which in turn leads to confusion over diagnosis and treatment. Given the complexity of this neuropsychiatric condition, early recognition is key in providing effective treatment before progression into a malignant state. This would be aided by having delirious mania recognised in international classifications.

EPV0476

A Service Audit of Psychiatric Presentations of Displaced Ukrainians in the Emergency Department or as a ward consult in University Hospital Galway from March 2022 to December 2023

N. Goh[1]*, I. Onwuemelie[2] and S. Patel[3,4]

[1]Rehabilitation Psychiatry, National Forensic Mental Health Service; [2]Perinatal Psychiatry, Galway-Roscommon Mental Health Service; [3]Liaison Psychiatry, University Hospital Galway and [4]Liaison Psychiatry, University Hospital Portiuncula, Galway, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1233

Introduction: We are seeing an increasingly diverse population in the Emergency Department. There have been increasing numbers of displaced Ukrainians attending the Emergency Department and referred from the general medical/surgical wards for psychiatric assessment since the Russian invasion of Ukraine in 2022.
Objectives: The objective of this retrospective audit was to examine the demographic and clinical characteristics of displaced Ukrainians presenting to the University Hospital Galway with psychiatric presentations. Our aim was to review the impact of psychiatric presentations of displaced Ukrainians on the Liaison Psychiatry/on-call Psychiatry service
Methods: We utilised the Liaison Psychiatry patient database to extract data on status as a displaced Ukrainian, presenting complaint, working diagnosis, use of interpreter, location of review, outcome of review and other demographic data. This was a retrospective audit using anonymised data.
Results: We found that a total of twenty-eight patient presentations were seen by Liaison Psychiatry or by the on-call Psychiatry doctor from March 2022 to December 2023 (inclusive). Twenty-three patient presentations (82.1%) were seen in the Emergency Department. Nineteen patient presentations (67.9%) required the services of an interpreter. 16 patient presentations (57.1%) were in relation to low mood with or without suicidal ideation. 16 patient presentations (57.1%) resulted in a referral to a Community Mental Health Team.
Conclusions: There is a significant number of Ukrainian refugees attending the Emergency Department for psychiatric reasons. The vast majority of these patients do not speak English and require an interpreter. Being able to communicate effectively is crucial in taking a psychiatric history and further improvements should be made to improve the experience that this population of patients have in the Emergency Department. This audit can be used to inform service development in the Liaison Psychiatry department to better serve the needs of displaced Ukrainians, such as through the introduction of translated patient information documents.

EPV0477

Post-Stroke Psychosis Following Basilar Artery Occlusion: A Case Report

H. J. Gomes[1]*, M. Pires[2] and J. R. Gomes[1]

[1]Unidade Local de Saúde do Nordeste, Bragança and [2]Unidade Local de Saúde da Guarda, Guarda, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1234

Introduction: Approximately 16 million individuals experience a first-time stroke annually, with vertebrobasilar (VB) strokes accounting for 20% of all strokes and transient ischemic attacks. Neuropsychiatric symptoms affect at least 30% of stroke survivors and are associated with low quality of life, an increase in the burden of caregiving, and impaired functional status. These complications can range from mood disorders to psychosis. Psychosis is a relatively rare complication after stroke but is among the most serious of the poststroke syndromes. However, there are no specific guidelines for its treatment.
Objectives: To describe a case of psychosis following a vertebrobasilar stroke and review the relevant literature on the topic.
Methods: We report a case of post-stroke psychosis in a man with no prior psychiatric history and conduct a non-systematic review of the literature.
Results: A 46-year-old man with a history of dyslipidemia and testicular cancer 13 years prior and no previous psychiatric history was admitted to the Stroke Unit under the care of Internal Medicine and Neurology due to a vertebrobasilar stroke. Liaison Psychiatry was called to assess the patient on the 27th day of hospitalization due to visual hallucinations. On examination, the patient presented with a suspicious facial expression, persecutory and infidelity delusions, and both visual and auditory hallucinations. No other psychopathological changes were observed. The case was discussed with the Neurology team, and the patient underwent laboratory tests, a new head computed tomography, and an electroencephalogram, none of which showed recent significant abnormalities. The patient was started on olanzapine 5 mg daily. The patient was reassessed after one week and continued to have the described psychotic symptoms, leading to an increase in the olanzapine dose to 10 mg. After two weeks of treatment, there was a noticeable reduction in the psychotic symptoms.
Conclusions: Psychosis is a possible complication of stroke and is associated with impairment and increased mortality. According to the literature, strokes in the vertebrobasilar territory can cause hallucinations. Guidelines for managing post-stroke psychosis are currently lacking, and to assure evidence-based care, further research is needed. This case underscores the importance of early detection and intervention, emphasizing the need for a multidisciplinary approach to managing post-stroke psychosis.

EPV0478

Gardner-Diamond Syndrome: A Comprehensive Review of Pathophysiology, Diagnosis, and Treatment

H. J. Gomes[1]*, R. A. Moreira[1], J. P. Correia[1] and J. R. Gomes[1]

[1]Departamento de Psiquiatria e Saúde Mental, Unidade Local de Saúde do Nordeste, Bragança, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1235

Introduction: Gardner-Diamond Syndrome (GDS), also known as psychogenic purpura, is an uncommon psychosomatic disorder characterized by painful, ecchymotic, purpuric lesions that typically appear after a period of stress, surgical operations or hard physical work, predominantly affecting women. The pathophysiology of GDS is still poorly understood, and diagnosis is often challenging due to its overlap with other hematological, dermatological, or psychosomatic disorders. Appropriate diagnosis is essential for symptom management and patient risk reduction.
Objectives: This review aims to synthesize the current knowledge on GDS, encompassing its etiology, clinical presentation, diagnostic criteria, and treatment approaches while identifying areas for future research.
Methods: We performed a narrative literature review by searching PubMed, Google Scholar, and ScienceDirect articles written in English. Relevant studies, case reports, and reviews published from 1955 to 2023 were included.
Results: Gardner-Diamond Syndrome predominantly affects middle-aged women, but the literature has also published reports concerning men and children. It is often associated with psychological stress, anxiety, or depression. Many authors suggest the presence of histrionic personality traits and a tendency toward somatic reactions in affected individuals. In 1955, Frank Gardner and Louis Diamond identified and described Gardner-Diamond Syndrome after observing four women who experienced recurrent bruising, accompanied by localized pain, erythema, and swelling, following minimal or no trauma. The spontaneous bruising observed in GDS lacks a hematological cause, with most studies suggesting a psychosomatic origin. The diagnosis is made with a detailed medical and psychiatric history, physical examination, laboratory examination, and exclusion of other possible causes. Psychological therapies, such as cognitive-behavioral therapy, alongside pharmacological treatments, have shown variable success in symptom management. However, most patients experience long-term cycles of remission and relapse, and a standardized treatment protocol has yet to be established.
Conclusions: Gardner-Diamond Syndrome represents a complex interaction of psychological and somatic factors, highlighting the importance of a multidisciplinary approach to both diagnosis and treatment. Diagnostic challenges persist due to the absence of definitive biomarkers and reliance on exclusionary criteria. Also, GDS lacks treatment options. While psychological interventions play a central role in management, further research is needed to clarify the underlying pathophysiology and improve therapeutic outcomes. Most patients benefit from a combination of cognitive behavioral therapy and antidepressant treatment. Increasing clinician awareness may help reduce diagnostic delays and improve the quality of life for patients.

EPV0479

Late onset mixed delirium after reconstructive breast operation revealed pituitary macroadenoma: a rare case report

I. GRAMMATIKOPOULOS[1]*, A. TARAR[1], M. IJAZ[1], M. McDONALD[1], B. O'LEARY[1] and J. CHANDRAKANTH[1]

[1]DEPARTMENT OF PSYCHIATRY, UNIVERSITY HOSPITAL WATERFORD, WATERFORD, Ireland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1236

Introduction: Delirium has been considered a reflection of diffuse cerebral metabolic insufficiency, and the pathophysiology of underlying delirium is quite diverse.
Objectives: We present a rare case of mixed delirium with shifting activity level between the hyperactive and hypoactive delirium types as the only manifestation in a 42-year-old woman presented with psychotic symptoms without any prior psychiatric history, one month after a reconstructive breast cancer operation.
Methods: To provide an overview, describe the clinical features and differential diagnosis, as psychiatric conditions are among the most difficult to differentiate from delirium, and finally review the clinical management.
Results: Presentation of a 42-year-old female with a history of right breast cancer with triple negative B5b invasive carcinoma, twice operated after local recurrence (first operation 4 years ago), and a second reconstructive operation one month ago, with no past psychiatric history, who presented with symptoms of mixed delirium. During the clinical and laboratorial investigation, exams revealed hyperprolactinemia. The patient showed no other clinical signs or symptoms compatible with adrenal insufficiency and displayed normal ACTH and serum cortisol concentrations. Brain magnetic resonance imaging revealed pituitary macroadenoma without any brain metastasis. The patient was treated with antipsychotics and not corticosteroids, resulting in rapid remission of the psychotic symptoms.
Conclusions: Clouded sensorium and behavioral dysregulation in delirium can be easily mistaken as thought and behavioral disorganization in acute psychotic episodes, and detailed evaluation of precipitating factors is required to differentiate delirium.

Screening for neurodevelopmental disorders in preterm Infants

N. Zaidi[1]*, D. Ben touhemie[1], K. khemekhem[1], K. chiha[1], J. Boudabous[1], I. Hadjkacem[1], A. Gargouri[2], H. Ayédi[1], N. Ben hmida[2] and Y. Moalla[1]

[1]pédosychiatrie and [2]néonatologie, Hédi Chaker university hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1237

Introduction: Early detection of neurodevelopmental disorders (NDD) allows for timely intervention and tailored support to address behavioral and learning issues and reduce the impact of

severe disabilities. Certain populations of newborns, particularly premature infants, are at higher risk for developing such disorders; identifying them enables the establishment of preventive monitoring and screening.
Objectives: to evaluate the frequency of neurodevelopmental disorders (NDD) in preterm children seen at the outpatient Neonatology department
Methods: Our study was a descriptive cross-sectional study conducted on 193 premature infants hospitalized in the Neonatology service. All children underwent at least two psychiatric assessments evaluating child development, early interactions, and behavioral problems. These assessments were conducted at the Neonatology outpatient department by a child psychiatrist in the presence of at least one parent, from 2016 to June 2024. Sociodemographic and clinical data were collected from their medical records.
Results: In our sample, the average age of infants was 2 years, with a range from 10 months to 3 years. The sex ratio was 1:1. According to the psychiatric interview and clinical examination, we found that 74.1% of children exhibited psychomotor developmental delays, 15% of them have global developmental delays, 11.4% of children have language delays, and 6.7% of them have been diagnosed with autism spectrum disorder, according to DSM-5 criteria. Among the assessed children, 6.7% showed behavioral issues, and 2.5% presented with reactive attachment disorders. Among the examined children, 24.4% were referred for regular follow-up at the outpatient child psychiatry clinic.
Conclusions: Our study indicates that preterm infants are at a high risk of developing neurodevelopmental disorders due to the immaturity and vulnerability of their brains during critical developmental periods. These findings underscore the importance of Child Psychiatry examination for this population.

EPV0484

A Case of Iatrogenic Panhypopituitarism: Exploring Psychological Symptoms and Psychiatric Interventions

L. Kozina[1]*, L. Murn[2] and J. Sušac[1]

[1]University Psychiatric Hospital Vrapče and [2]Psychiatry Department, Clinical Hospital Dubrava, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1238

Introduction: Panhypopituitarism is a rare and life-threatening endocrine condition characterized by the loss of pituitary hormone function. Literature mentions the very rare occurrence of iatrogenic panhypopituitarism caused by neurosurgical operations, radiotherapy, and pharmacotherapy – long-term use of corticosteroids can suppress the HPA axis, leading to secondary cortisol insufficiency, which, in very rare cases, progresses to global panhypopituitarism. Psychological symptoms are often present but are unfortunately rarely recognized.
Objectives: A case of a patient with psychological symptoms due to panhypopituitarism is presented.
Methods: A case report is presented with a literature review.
Results: A 37-year-old patient, has experienced fatigue, tremors, loss of sexual desire, blood pressure and glucose fluctuations, and impaired temperature and pain sensation. Endocrinological testing revealed insufficiency of all pituitary hormones. Multiple MRI scans of the brain showed a normal appearance of the pituitary gland. It was discovered that he had a severe car accident with a head injury 10 years ago. Since then, he has been taking high doses of corticosteroids on his initiative due to severe spinal pain. It is believed that the condition developed iatrogenically due to corticosteroid medication. His psychological condition significantly worsened after one of the adrenal crises. He describes an experience of "encountering death" during one of the adrenal crises. Furthermore, he describes that after this adrenal crisis, his corticosteroid dosage was significantly increased, resulting in feelings of excessive energy, worse anxiety, insomnia, and irritability. Because of this, he began self-reducing the corticosteroid dose, leading to a "vicious cycle" where he fears another crisis. In complex patients like this one, it is crucial to develop a comprehensive treatment plan and ensure good collaboration with somatic physicians. This patient presents with depressive and anxiety symptoms within the context of an adjustment disorder. Additionally, corticosteroid therapy contributes to emotional instability, and the patient also exhibits symptoms of PTSD due to a near-death experience. Also, the patient's complex psychodynamic profile presents significant challenges to treatment. The therapeutic goals for this patient are: mood stabilization and anxiety reduction, sleep regulation, and breaking the "vicious cycle". CBT is the treatment of choice for addressing the patient's anxiety, fear of adrenal crisis, and self-reduction of corticosteroid doses. The patient's complex psychodynamics and high cognitive functioning make him an excellent candidate for long-term psychodynamic psychotherapy.
Conclusions: The psychiatrist plays a crucial role in treating such complex patients, and close collaboration with somatic physicians, along with an adequate and thorough therapeutic treatment plan, is necessary.

Disclosure of Interest: None Declared

Depression and compliance in hemodialysis patients: pilot study

S. Mizera[1], A. Osuch[2], A. Bąk[2], T. Cyganek[2], M. Zatorski[3], D. Gojowy[4], M. Adamczak[4], K. Krysta[5]* and A. Więcek[4]

[1]Doctoral School; [2]Medical Students' Association, Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia; [3]SWPS University of Social Sciences and Humanities; [4]Department of Nephrology, Transplantation and Internal Medicine and [5]Department of Rehabilitation Psychiatry, Medical University of Silesia, Katowice, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1239

Introduction: Lack of compliance is well-known limiting factor in achievement of the therapeutic targets in medical care. The frequency of noncompliance as well as the factors contributing to this condition are currently not well understood. In hemodialyzed patients lack of precise adherence to medical recommendations is particularly important for long time survival. Depression occurrence may have an adverse impact on the medical compliance of these patients.
Objectives: The aim of this study was to analyze prevalence of depression symptoms and its impact on compliance to medical recommendations in patients on chronic hemodialysis.
Methods: Forty (M=26;F=14) patients undergoing routine hemodialysis session have taken part in a two-part survey

consisting: Beck's Depression Inventory and IMB-Q - The Information-Motivation-Behavioural Skills Questionnaire. IMB test includes three subcategories as a basis for tailoring of the model to an individual health-related behavior – a) information about disease and treatment, b) motivation and c) behavioral skills to comply with treatment. Additionally, in all patients weight gain between dialysis session was analyzed.
Results: Seventeen patients (47.5%) fulfilled depression criteria, out of which 5 (12.5%) had moderate or severe grade disease. Depression symptoms were inversely correlated with behavioral skills to comply with treatment measured by IMB-Q test in men (r= -0,416; p=0,034). There was no significant correlation between results of Beck Depression Inventory and body mass change between dialysis sessions. There was also no significant difference in the interdialytic weight gain between patients with and without depression.
Conclusions: Depression is frequently found in male patients with end stage kidney disease treated with chronic hemodialysis. Male hemodialysis patients with depression are less likely to be compliant to medical recommendations because of weaker behavioral skills. Improvement of the compliance in hemodialysis patients may play an important role in the prolongation of life in these group.

Prevalence and types of psychological distress in breast cancer patients: An analysis of consultation delay

H. Ktari[1]*, A. Hadj Salah[1], L. Marzouki[2], A. Daldoul[2], S. Zaied[2] and B. Amamou[1]

[1]Psychiatry and [2]Cardiology, Fattouma Bourguiba Hospital, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1240

Introduction: Breast cancer is the leading cancer among women, and its early diagnosis is vital for improving survival rates. However, many women delay seeking medical attention after noticing symptoms. Factors such as lack of awareness, fear of diagnosis, financial constraints, and family responsibilities often contribute to these delays. In addition to the physical burden of cancer, psychological distress is a common but often overlooked aspect of the patient experience.
Objectives: To identify the prevalence and causes of delayed consultation as well as the different types of psychological distress (practical, familial, emotional, spiritual, and physical) among patients with breast cancer.
Methods: We conducted a descriptive and analytical study over a one-year period (June 2021 - May 2022) in the oncology department of the Maternity and Neonatology Center of Monastir. Data were collected using information sheets, interviews, and medical records. Psychological impact was assessed using the Distress Thermometer (DT), a visual scale from 0 to 10, accompanied by a questionnaire on practical, familial, emotional, spiritual, and physical issues. The median consultation delay and reasons for the delay were also examined.
Results: Among the 150 patients diagnosed with breast cancer who received treatment and follow-up at the Maternity and Neonatology Center of Monastir, the median consultation delay was 28 days, with delays ranging from 1 to 912 days. Thirty-five patients (23.3%) experienced late consultations, defined as a delay of more than 90 days. The main reasons for the delay included 62.2% of patients not suspecting cancer after the first functional signs, 11.1% fearing the diagnosis, and 8.9% facing financial issues or family and professional responsibilities. Among the 104 patients who completed the Distress Thermometer questionnaire, 31.7% had a distress level below 4, while 68.3% had a distress level of 4 or above. The most frequently reported practical problems were child care (26.92%) and meal preparation (18.26%). Familial problems mainly concerned relationships with children (26.92%). Emotional issues included fear (50%), nervousness (50.96%), and sadness (50%). Regarding spiritual concerns, 32.6% of patients had spiritual or religious concerns, and 67 patients reported physical problems.
Conclusions: The results show that the majority of patients experience high psychological distress, particularly in emotional and practical domains. The median consultation delay is 28 days, with a significant delay in 23.3% of patients. It is therefore crucial to improve awareness and psychological support to reduce consultation delays and optimize breast cancer management and patient well-being.

What's in a question-Using patterns in language to correctly identify psychiatric consultation requests

I. E. Leppla[1]* and M. Faeder[2]

[1]Psychiatry and Behavioral Sciences, Johns Hopkins School of Medicine, Baltimore and [2]Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1241

Introduction: In consultation-liaison work, oftentimes the "consult question" is elusive. Primary teams can sense that there is a need for psychiatric consultation, but may not be able to formulate those concerns into the "right question." Therefore, when the consult team receives the question, the presenting problem may be very different from the reason for consultation. This is never more true than in the case of delirium. Studies have shown that delirium often goes unrecognized by medical and surgical services. (Armstrong et al. Psychosomatics 1997;38:433-439).
Objectives: This study sought to determine the reasons for consultation when a diagnosis of delirium was given by the consulting psychiatrist.
Methods: A retrospective chart review of one year of consecutive consults to the Psychiatry Consult & Liaison service was done for three hospitals comprising the majority of consults to the University of Pittsburgh Medical Center C&L service originating from other teaching services. This yielded approximately 3000 new consults. Each consult was coded for the following variables: the exact quotation from the referring team, the summary statement of what the consultant felt were the most relevant issues, and the DSM-V F-code. We analyzed the consults that were either specific requests for help managing delirium or that resulted in a diagnosis of delirium by the C&L service.
Results: We found that a large majority of consults for "agitation" were ultimately aimed at helping to manage a patient with low cognitive reserve, in the form of dementia, delirium or traumatic brain injury. "AMA" consults were typically involving a patient

withdrawing from alcohol or opioids. "Lack of engagement with the treatment team" corresponded to many patients who were delirious. Of the consults that resulted in the diagnosis of delirium the most common reasons for consultation were: delirium/altered mental status (AMS) (21%), depression/adjustment (16%), agitation (11%), psychosis (11%), substance use or overdose (10%), and previously existing psychiatric disorder (26%). Often more than one reason was given for consultation. When only one reason was given previously existing psychiatric disorder (18%), depression (11%), and delirium/AMS (10%) were the most likely reasons for consultation.
Conclusions: The role of the psychiatric team is often to help primary teams figure out which question to ask, and this is then the first step towards getting the patient the help they need. This work adds to the literature because shows patterns between consultation requests and ultimate diagnoses. If we can notice patterns in the diagnoses based on the types of questions that are asked, this may help teach the teams to broaden their differential to include patterns that we have noticed.

doi: 10.1192/j.eurpsy.2025.1242

Introduction: We present the case of a 58-year-old male patient with a history of bipolar disorder, schizoaffective disorder, renal insufficiency and diabetes insipidus who developed malignant catatonia (MC), possibly related to the administration of ciprofloxacin. In a first admission to our care facility, the patient presented a neuroleptic malignant syndrome (NMS) due to antipsychotic medication, with partial remission following the discontinuation of these drugs and introduction of benzodiazepine (BZD) and dantrolene treatment. However, after this first hospital discharge, the patient required a second hospitalization due to a worsening of his general condition, apparently related to a urinary tract infection (UTI). During this last admission, antibiotic therapy with ciprofloxacin was administered, resulting in the worsening of his neuropsychiatric condition and developing clinical symptoms compatible with catatonia. The clinical presentation of his condition eventually requires treatment with BZD and electroconvulsive therapy (ECT).
Objectives: The aim of this work is to describe the course and therapeutic approach of a case of MC possibly induced by ciprofloxacin, clarifying the differential diagnosis between NMS and MC.
Methods: A thorough review of the patient's clinical history was performed from the onset of symptoms in the care facility through his ICU and inpatient hospitalizations. Pharmacological changes were documented, including antipsychotic interruption and BZD administration. Treatment with ECT was initiated after an insufficient response to BZD. Finally, a literature review was conducted to explore the relationship between MC and ciprofloxacin.
Results: Initially, the patient showed a partial remission of the catatonic symptoms with BZD and dantrolene after discontinuing antipsychotics, achieving a temporary stabilization. However, after the introduction of ciprofloxacin, he developed a severe catatonic symptoms characterized by central fever, extreme rigidity, mutism, and withdrawal from the environment. Despite BZD treatment, the catatonic symptoms persisted, leading to the decision to initiate ECT. After multiple sessions, the patient experienced a significant improvement on autonomic, motor and cognitive symptoms of catatonia, as well as a more robust clinical stabilization.
Conclusions: This case suggests a possible association between the administration of ciprofloxacin and the onset of MC in a chronic psychiatric patient with a history of NMS. The favorable response to ECT highlights the utility of this therapeutic option in the management of severe catatonia when other treatments are not fully effective. The chronology on this case suggests a neurotoxic effect of ciprofloxacin, emphasizing the importance of considering interactions between antibiotics and psychiatric pathologies in vulnerable patients.

Specificity of anxiety-phobic states in the structure of psychosomatic relations of hypertension as a criterion for differentiation of psychotherapeutic approaches

M. Markova[1]*, I. Sarvir[1], A. Avramenko[1] and S. Martynenko[1]
[1]Sexology, Psychotherapy and Medical Psychology, Kharkiv National Medical University, Kharkiv, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1243

Introduction: The study of anxiety-phobic states as an integral part of psychosomatic relationships in cardiovascular pathology allows us to detail the pathogenetic mechanisms of formation, develop approaches to early diagnostics, psychotherapy and psychoprophylaxis, which is of unconditional medical and social importance in solving this problem.
Objectives: Improving the effectiveness of therapy for patients with hypertension, including in combination with ischemic heart disease (IHD), with anxiety states based on the personalization of psychotherapy.
Methods: The survey included the use of clinical, sociodemographic, instrumental, clinical-psychopathological, psychodiagnostic and statistical methods.
Results: The study sample consisted of 120 patients who were treated at the Kharkiv Clinical Hospital on Railway Transport No. 1, JSC Ukrzaliznytsia. It was revealed that the main psychopathological variants of anxiety states in patients with hypertension are anxiety and combined fears (biological, situational and social, enhanced by psychotraumatic events related to war). The intensity and spectrum of anxiety states have a direct correlation with the duration, severity of the somatic disease and the severity of psychopathological symptoms.
For patients with hypertension with IHD, the dominant fear is typically focused on their own biological well-being (90.5%), for

patients with hypertension – on the biological and social well-being of significant others (74,4%).
The dynamics of anxiety states are different: in 57,7% of patients with hypertension, fear initially develops as a result of traumatic social or situational factors, in 69,1% of patients with hypertension with IHD, unreasonable anxiety acquired a plot due to somatic distress. Psychopathological symptoms in patients with hypertension with anxiolytic states are represented by pronounced asthenic manifestations (95,8%) in combination with hypochondriacal (37,5%), depressive (24,2%), and vegetative (15,0%).
A differentiated psychotherapeutic model for the correction of psychosomatic relationships has been developed, aimed at deactualization of fears, reduction of anxiety, elimination of psychopathological manifestations, improvement of the somatic state, improvement of the quality of life and social adaptation.
Conclusions: The application of the developed model has shown its high efficiency in the complex therapy of patients with hypertension.

Conversion disorder: an inclusive approach based on its history

M. M. Marques[1]
[1]Psychiatry, ULSAM, Viana do Castelo, Portugal
doi: 10.1192/j.eurpsy.2025.1244

Introduction: The conversion symptom, present in current medical practice, traces its origins to Ancient Egypt, having had, over time, several interpretations. Under the name Hysteria, it was studied by Charcot with hypnosis at the Salpêtrière Hospital. Currently, it belongs to Conversion Disorders, and neurology has given the term psychogenic nonepileptic seizures (PNES), to differentiate these phenomena from epileptic seizures.
Objectives: This work proposes to describe the history of Conversion disorder, from Freud's hysteria to the concept of psychogenic nonepileptic seizures, and to summarize useful concepts in approaching patients with conversion disorder, in different contexts.
Methods: Non-systematic review of the literature with selection of scientific articles, using PUBMED as database the following keywords: «Conversion disorder», «hysteria» and « psychogenic nonepileptic seizures». Seven articles were included. We also selected 5 reference books.
Results: In the 19th century, the conversion symptom constituted a very important milestone in Psychiatry, as it was through monitoring patients with hysteria that Freud created Psychoanalysis. Then, the physical symptoms of hysteria (paralysis, convulsions…) began to be understood as symptoms of psychic origin, and as a symbolic expression of a representation that was unacceptable to the Self and, therefore, repressed. According to psychoanalysis, in hysteria, body is invaded by psychic and serves as a stage for unconscious representations. Nowadays, the term hysteria can include psychogenic nonepileptic seizures, which are paroxysmal episodes of changes in behavior, movement, sensitivity or consciousness, similar to epileptic seizures, but which, unlike epileptic seizures, are not caused by a change in brain's electrical activity.
Conclusions: With the description of the evolution of conversion disorder, from Freud's hysteria to nowadays, it is possible to find that conversion pathology will not tend to disappear. It represents a specific mode of psychic functioning, characterized by an organization of defense mechanisms, cognitive styles, memory functions and specific personality traits. Therefore, it is important to continue investigating strategies to individualize the approach to these patients. Also, it would be beneficial to extend access to important psychological knowledge to more general doctors, in order to improve the capacity of managing conversion disorders cases that arise in different health contexts. We highlight the importance of understanding the suffering of these people. Patients with conversion symptoms do not choose to have a certain symptom and shouldn't be a target of stigma. Each person develops their own psychic functioning process, as each person constitutes an unique identity and deserves an individualized and inclusive approach.

Functional Movement Disorder to Huntington's Chorea: Unmasking the Underlying Condition in a Patient Initially Diagnosed with Anxiety Disorder

B. Marsap[1*] and M. H. Aksu[1]
[1]Psychiatry, Gazi University Hospital, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1245

Introduction: Huntington's disease (HD) is a hereditary neurodegenerative disorder characterized by motor, cognitive, and psychiatric symptoms. Initially, the patient's involuntary movements were attributed to anxiety-related restlessness and psychomotor agitation, leading to a diagnosis of anxiety disorder. During hospitalization, the patient was referred to neurology for his movements, where functional movement disorder was considered. However, due to worsening cognitive decline, apathy, and the psychiatrists' suspicion that the movements were not functional, further investigations were conducted. Cranial MRI, followed by a dementia protocol MRI, revealed caudate nucleus atrophy, leading to the diagnosis of HD.
Objectives: To illustrate the diagnostic challenges in identifying Huntington's disease in a patient initially misdiagnosed with anxiety disorder and functional movement disorder.
Methods: A 58-year-old male presented with anxiety and involuntary movements, leading to initial diagnoses of anxiety disorder and functional movement disorder. As symptoms progressed—including worsening involuntary movements and cognitive decline—a comprehensive reassessment was conducted. This included neurological examination, neuroimaging, neuropsychological testing, and genetic testing via blood test for CAG repeat analysis.
Results: Cranial MRI revealed bilateral caudate atrophy and dilated lateral ventricles, consistent with Huntington's disease. Neuropsychological assessment showed significant impairments in verbal learning, memory, and executive function. The patient was treated with venlafaxine 150 mg/day, mirtazapine 30 mg/day, and haloperidol 6 drops/day, leading to significant improvement in anxiety symptoms and a reduction in chorea.

Conclusions: This case underscores the importance of considering neurodegenerative disorders such as Huntington's disease in the differential diagnosis of patients presenting with psychiatric symptoms and involuntary movements. Early identification, comprehensive assessment, and a thorough understanding of HD's clinical presentation are crucial for appropriate management.

Alexithymia and emotional distress in patients with asthma: A case-control Study

I. Baati[1], N. Regaieg[1]*, F. Cherif[1], D. Mnif[1], K. Amor[1], I. Feki[1], F. Guermazi[1] and J. Masmoudi[1]

[1]Psychiatry A Department, University of Sfax, Faculty of medicine of Sfax, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1246

Introduction: Alexithymia is characterized by difficulty in verbally expressing emotions, a trait commonly observed in patients with psychosomatic symptoms, such as those with asthma. These individuals struggle to identify their emotions and are more prone to developing somatic health issues.
Objectives:
- To study the prevalence of alexithymia, anxiety and depression in asthma patients
- To identify the relationship between these aspects.

Methods: It was a cross-sectional, case-control, descriptive and analytical study, conducted in the pulmonology department at Hedi Chaker University Hospital in Sfax. The study involved 50 asthma patients and a control group consisting of 50 healthy nurses. Data collection was based on a sociodemographic and clinical questionnaire, as well as two psychometric scales: the Toronto Alexithymia Scale 20 (TAS-20) and the Hospital Anxiety and Depression Scale (HADS).
Results: The mean age of the patients was 44.08 ± 12.78 years and the male-to-female ratio (M/F) was 0.92.
More than half of the patients (62%) had experienced an acute severe asthma requiring hospitalization. The disease was controlled in 70% of the cases.
The prevalence of alexithymia was 40% in the asthma patients and 36% in the control group, with no significant difference between the two groups ($p = 0.68$).
The prevalence of anxiety was 38% in patients and 34% in the control group with a significant difference between the two groups ($p = 0.012$).
The prevalence of depression was 38% in patients and 28% in the control group with a significant difference between the two groups ($p = 0.002$).
Alexithymic patients were significantly more anxious ($p = 0.01$) and more depressed ($p = 0.01$) than non-alexithymic patients.
Conclusions: Patients with ashtma present high rates of anxiety, depression and alexithymia. This latter does not appear to be a determining factor in asthma. However, it seems to be associated with the emotional distress caused by anxiety and depression. Timely screening for emotional distress and its early management is essential in this population.

Mental health and Chemsex: A view from the Liaison and Emergency Psychiatry Service

P. Muñoz-Calero[1]*, M. Navas Tejedor[1], A. Fuentes Merlo[1], L. Nuñez Cantos[1], D. Gimeno Álvarez[1], P. De la Cruz Ballano[1] and A. Ramírez Ibernon[1]

[1]Instituto de Psiquiatría y Salud Mental, Hospital Clínico San Carlos, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1247

Introduction: Chemsex is typically described as the use of specific substances to enable or enhance sex during extended sessions with multiple partners among men who have sex with men (MSM). Numerous studies have linked chemsex with different physical and mental health risks and other potential harms.
According to the latest European online survey por MSM (EMIS-2017), the section on substance use revealed the prevalente of substance use for sexual purposes in the last twelve months was 14.1% with Spain being one of the countries with the highest prevalence of chemsex at the European level.
As the prevalence of chemsex is increasing, consequences from this phenomena arises and a progressive increase in the number of psychiatric consultations and admissions related to chemsex practice have also been described, with substance abuse disorders, depression,and anxiety as the most prevalent diagnoses.
From our Liaison and Emergency Psychiatry Service consultations related with mental health issues and chemsex are increasing with growing number of suicide attempts,psychotic, maniac and depressive episodes.
Objectives: Our objective in this poster is to describe the mental health risks of chemsex,its peculiarities and the main manage issuses in the Liaison and Emergency Pscychiatry Service.
Methods: Systematic review of the scientific literature related with chemsex and mental health risks will be carried out and we will also analyse some of our cases to describe presentation and management of the symptoms.
Results: Chemsex is related with an increased rate of mental health issues and consultations related with substance use disorders, depression and anxiety.Clinical features due to this disorders are unique and integral treatment in coordination with Infectious Medicine Specialist is needed.
Conclusions: Chemsex is an increasing phenomena and it is intimately related with psychiatric disorders.
Psychiatrists must be concerned about it and trained to approach and treat these complex disorders in an integrative way.

Traumatic Brain Injury and Neuropsychiatric Consequences

B. Peixoto[1]*, M. Cruz[1] and V. Ustares[1]

[1]Psychiatry, Hospital do Divino Espirito Santo, Ponta Delgada, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1248

Introduction: Post-traumatic brain injury (TBI) is a leading cause of long-term neuropsychiatric consequences, which can significantly impair quality of life and complicate recovery. These consequences include cognitive deficits in memory, attention, and executive functions, depression, anxiety, apathy, obsessive-compulsive disorder, psychosis, personality changes, impulsivity and agitation in moderate to severe cases. In cases of repetitive head trauma, there is a higher risk of developing chronic traumatic encephalopathy, a neurodegenerative disorder charaterized by dementia and motor abnormalities. Understanding the spectrum and prevalence of these disturbances is crucial for developing effective management and rehabilitation strategies.
Objectives: The aim of this study is to review the prevalence and treatment of neuropsychiatric consequences of traumatic brain injury.
Methods: The authors did a non-systematic review of the current literature.
Results: This review revealed that neuropsychiatric consequences are present in approximately 80% of post-TBI patients, depending on the severity of the injury and the time passed from the trauma. Depression and anxiety disorders were the most prevalent, followed by cognitive deficits. Personality changes, impulsivity, and agitation were commonly observed in moderate to severe cases. Factors such as the extent of frontal lobe injury and the time elapsed since the injury were strongly associated with the severity of neuropsychiatric symptoms. There is no pharmalogical treatment approved by the Food and Drug Administration (FDA), but the literature recommends the use of SSRI (in cases of depression), beta blokers (in high doses for agitation), antipsychotics (only if necessary and with caution, because these patients are more propense to the side effects and it can impair cognition and motor rehabilitation) and anticonvulsants (carbamazepine or valproate in cases of agitation or irritability).
Conclusions: Neuropsychiatric complications of TBI are common and have significant implications for long-term recovery and quality of life. Early identification and comprehensive management strategies, including pharmacological and psychological interventions, are essential to address these challenges and improve patient outcomes. Further research is needed to refine diagnostic tools and therapeutic approaches tailored to the neuropsychiatric consequences of TBI.

EPV0499

Post-ictal Psychosis: clinical case presentation and literature review

F. Ramalheira[1]*, M. D. C. Vasconcelos[1], M. Andrade[1] and M. Pereira[1]

[1]Hospital Júlio de Matos, Unidade Local de Saúde de São José, Lisboa, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1249

Introduction: Post-ictal psychosis is a kind of epileptic psychosis in which psychotic features appear 12h – 7 days after the epileptic seizure causing them.
Objectives: To present a challenging case reflecting upon presentation, management and considerations of post-ictal psychosis.
Methods: Case presentation and non-systematic literature review.
Results: A 40-year-old female, living in a European foreign country with her partner and child, flies to Lisbon 5 days previously to her admission as a sudden decision because she believed she was the daughter of a portuguese yoga master. She was brought to psychiatry ER by the police due to disorganized and aggressive behavior in public, where she presented with severe agitation, disorganized and coprolalic speech, persecutory, mistic and filiation delusions, somatic and affective passivity, and very uncollaborative. She had no analytic or image alterations except for positive cannabinoids in urine. She was admitted in psychiatry and started on risperidone titled till 6mg and diazepam 15mg, with remission of symptomatology. When she was able to collaborate, she admitted she had a history of Epilepsy for which she was not having treatment, and a previous post-ictal psychotic episode some years ago. Family confirmed she had a generalized tonic-clonic seizure about a week ago, and delusional ideas starting the following day, having left home unannounced. Although the EEG was normal, considering suggestive history post-ictal psychosis was admitted ad most probable diagnosis and she was slowly stopped medication without symptom resurgence. The importance of anti-epileptic treatment in order to avoid subsequent seizures and post-ictal psychosis was explained, however the patient denied treatment and was discharged back to her hometown with indication to follow-up in neurology.
Conclusions: Post-ictal psychosis corresponds to 25% of epileptic psychosis. It is associated with temporal lobe epilepsy, psychotic symptoms of mistic and religious themes, aggressive behavior, and increased suicide risk. It has a sudden onset and complete remission although a risk of recurrence as in this case. Treatment consists of seizure control to avoid following episodes. Antipsychotics that don't increase convulsive risk such has risperidone may be useful to acute control of psychotic features and behavior alterations.

1 / 1 Exploring the Clinical and Psychosocial Predictors of Suicidal Ideation in Patients with Systemic Lupus Erythematosus

M. Recio-Barbero[1]*, J. Cabezas-Garduño[1], J. Varona[2], G. Ruiz-Irastorza[2], S. Sanz-Gómez[3], M. Shahine[4], A. Lengvenyte[5], P. Courtet[5] and R. Segarra[1,6]

[1]Department of Psychiatry. Cruces University Hospital; [2]Autoimmune Diseases Research Unit, Internal Medicine Department, Biobizkaia Health Research Institute, Barakaldo; [3]Departamento de Psiquiatría, Universidad de Sevilla, Sevilla, Spain; [4]Univ. Montpellier, CNRS, INSERM, IGF; [5]Department of Emergency Psychiatry and Acute Care, Lapeyronie Hospital, CHU Montpellier, IGF, Univ. Montpellier, CNRS, INSERM, Montpellier, France and [6]CIBERSAM ISCIII, Centro de Investigación Biomédica en Red de Salud Mental, Leioa, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1250

Introduction: Systemic Lupus Erythematosus (SLE) is an autoimmune disorder characterized by systemic inflammation and high prevalence of neuropsychiatric symptoms. Among these, suicidal ideation represents a significant concern, with reported higher rates than in the general population. The etiology of suicidal ideation in SLE is multifaceted, encompassing both disease-specific factors and

psychosocial variables. Recent research has highlighted the intricate interplay between SLE and psychiatric symptoms, suggesting a bidirectional relationship mediated by inflammatory processes, neurological involvement, and psychosocial stressors. However, the specific contributions of these factors remain unclear.
Objectives: This study aims to elucidate the primary predictors of suicidal ideation in a cohort of SLE patients.
Methods: A cross-sectional study was conducted with a cohort of SLE patients from the Autoimmune Diseases Unit at Cruces University Hospital (Biscay,Spain). Each patient underwent a thorough clinical evaluation by a psychiatrist, and relevant clinical and sociodemographic data were collected. Suicidal ideation was assessed using the Plutchik scale, while predictor variables included autoimmune factors such as cumulative corticosteroid dose, disease activity, and accumulated organ damage. Psychiatric symptoms were assessed using various psychometric scales. A multiple linear regression model was employed to examine the associations between these variables and suicidal ideation.
Results: A total of 92 SLE patients in active follow-up were included, with a female predominance (91%). Most patients were in an inactive disease state, receiving low-dose prednisone and antimalarial therapy according to our clinical protocol; the majority were in remission, as reflected by a mean SLEDAI-2K score of 1.59(±2.44). Despite a median disease duration of over 10 years, cumulative organ damage was low (mean SDI score 0.33 ± 0.84). In a multiple linear regression analysis, the model showed a strong fit ($R=0.732$, $R^2=0.535$, $p<.001$), explaining approximately 53.5% of the variability in suicidal ideation. Suicidal ideation was significantly associated with cumulative corticosteroid dose ($\beta=0.172$, $p=0.011$), total anxiety score ($\beta=0.248$, $p<.001$), and frequency of traumatic experiences ($\beta=0.118$, $p<.001$). Collinearity statistics (VIF 1.03–1.07) indicated no significant multicollinearity issues.
Conclusions: Suicidal ideation in our SLE cohort was associated with corticosteroid use, anxiety, and traumatic experiences, highlighting the importance of addressing these factors in suicide risk management. The relationship between corticosteroid dose and suicidal ideation may be linked to the neuropsychiatric effects of these drugs, while anxiety and traumatic experiences contribute to the emotional burden of the patient. Notably, disease activity was not linked to suicidal ideation in this cohort.

EPV0502

Lipid-lowering Drugs as a Potential Cause of Psychiatric Adverse Reaction-A Case Report

N. Rijavec[1]
[1]University Psychiatric Clinic Ljubljana, Ljubljana, Slovenia
doi: 10.1192/j.eurpsy.2025.1251

Introduction: Cholesterol is important for the normal functioning of the central nervous system. However, its reduction by certain agents might be related to the psychiatric adverse reactions, which could vary in frequency, but some can be serious and even fatal, such as suicidality and severe aggression.
Objectives: With this case report, we would like to draw attention to the possibility of serious psychiatric adverse reactions in patients receiving lipid-lowering drugs.
Methods: Bibliographic search and description of a clinical case of a patient under follow-up in outpatient treatment.
Results: A-60year old woman with generalized anxiety disorder and hyperlipidemia in a previously good remission reported increased anxiety, nervousness, insomnia and irritability on a regular check-up. There were no external stressors, except for an approaching retirement, which she was looking forward to. However, she forgot to mention that she was switched from fenofibrate to a pill consisting of a combination of rosuvastatin and ezetimibe. Her antianxiety medication needed to be increased and some cognitive behavior interventions were administered. However, her condition continued to deteriorate in the following months. She even developed suicidal ideation and verbal aggression. She refused to be hospitalized, while going to a trip with her husband. During the trip, she was not taking her new antilipemic medication and she never restarted it. After two days of discontinuation of the combination pill, her psychiatric condition gradually improved. At the following examination, she revealed the modification of her antilipemic treatment and the new medication could be identified as a cause of intensification of her anxiety.Subsequently, she was switched to atorvastatin (later on ezetimibe was added). She went into a full remission and she remained in it, while her psychiatric medications were reduced to the initial dosages.
Conclusions: The treatment of the patient's symptoms in our case report was directed towards reducing a substantial worsening of the anxiety disorder while lacking the information on the previous replacement of a lipid-lowering drug. Luckily it ended well.With our case report, we would like to re-emphasize the importance of caution and monitoring of side effects, education of patient and interdisciplinary professional communication when treating with lipid-lowering drugs, especially in patients with a known mental disorder.

EPV0503

Interpersonal relations psychotherapy for breast cancer patients: a systematic review

T. Şahin Tokatlıoğlu[1] and F. Oflaz[2]*
[1]Istanbul Aydın University, Faculty of Health Sciences and [2]Koç University, School of Nursing, İstanbul, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1252

Introduction: Breast cancer (BC), one of the most common cancer types among women, affects one in four women according to global cancer statistics (Ferlay et al., 2021; Yusof et al., 2021; Sung et al. 2021; Li et al. 2023). Despite the increase in the life expectancy of cancer patients with advances in treatments and developing technology, its diagnosis as a disease with a high risk of death causes anxiety and stress in individuals (Solomon et al., 2000; WHO, 2018; Miller et al., 2019; Abdollahi et al., 2019).
In addition to physical and emotional changes, the diagnosis of cancer brings about changes in social relationships and roles. In coping with these processes, it has been reported that social support and social support management will have positive effects on coping with the problems brought by the disease,

improvement in prognosis and self-management levels of patients (Xiang, 2010).
Interpersonal Relationship Psychotherapy (IRPT), which has been recommended as monotherapy for mild to moderate depression in treatment protocols in recent years (Spinelli, 1997; Spinelli and Endicott., 2003; APA, 2010; Brandom et al. 2012) Interpersonal psychotherapy has been found to be effective in the short and long-term treatment of cancer patients with major depressive disorder (Blanco, Hershman et al., 2014). Grief, interpersonal conflicts, role changes and social isolation (lack of interpersonal skills), which are the focus of IPT, are frequently experienced problems in cancer-related processes. IPT works by associating the social support and interpersonal problems that patients receive with disease symptoms (Sayar & Omay, 2019).
Objectives: This study will examine the effect of Interpersonal Relationship Psychotherapy (IRPT), which is recommended as monotherapy for mild to moderate depression in treatment protocols, in breast cancer patients.
Methods: Studies conducted in the last 10 years and in Turkish-English are included.
95 publications were reached. 73 publications were reached after removing duplicate publications.
We included randomized controlled trials of interpersonal relationship psychotherapy in breast cancer patients, comparing it with combination therapy, and applying it by telephone.The study included 4 studies.
Results: Having examined a total of 73 abstracts, we retrieved 10 full-text papers for further study. Of these, we excluded 6 papers that did not meet inclusion criteria. A total of 4 studies met all inclusion criteria and were included in this systematic review.
Image 1:

Title	Author & Year	Aim of the Study	Sample	Study Design & Intervention	Outcome Measures	Results
A Pilot Study of Interpersonal Psychotherapy by Telephone with Cancer Patients and Their Partners	Donnelly J.M. et al., (2000)	a. To test the feasibility of telephone IPT for cancer patients and their partners during oncology treatment, b. To examine its efficacy in reducing psychological distress	14 women with BC and ten partners	Assessments were before chemotherapy began (baseline), after completion of chemotherapy (3months), and 2 weeks after the final session (5months). The therapist called the participants once a week by appointment. However, she emphasized the option of rescheduling if the patient felt ill.	*Mental Health Inventory Impact of Event Scale * Perceived Self Efficacy Scale * MOS Social Support Survey * OARS Services Assessment Questionnaire Relationship with the medical team *GHAA Consumer Satisfaction Survey * Orientation–Memory–Concentration Test *EORTC QLQ-C30 * CALGB Background Information Form	This study indicated the importance of outreach to family members as well as to cancer patients, intensive patient education about oncology treatment and the medical care setting, and psychosocial services that continue after cancer treatment has been completed.
A Pilot Study of Interpersonal Psychotherapy for Depressed Women with Breast Cancer	Blanco C. et al., (2014)	To examine the feasibility and preliminary efficacy IPT in the treatment of major depressive disorder among women with breast cancer.	Seven patients referred for treatment of depression by their treating oncologist.	12 sessions of IPT were applied.	Hamilton Depression Rating Scale Structured Clinical Interview for DSM-IV (SCID) Clinical Global Impression Scale Hamilton Rating Scale for Anxiety (HAM-A) Beck Depression Inventory (BDI-II) Global Assessment of Functioning Scale (GAF)	IPT a powerful treatment for depression among women with breast cancer. Patients reported both symptomatic and functional improvement and are associated with large effect sizes.

Image 2:

A randomized trial of interpersonal psychotherapy, problem solving therapy, and supportive therapy for major depressive disorder in women with breast cancer	Blanco C. et al., (2019)	Compared outcomes of three evidence-based psychotherapy (interpersonal psychotherapy (IPT), problem solving therapy (PST), and brief supportive psychotherapy (BSP)) 12-week therapies in treating major depressive disorder among women with breast cancer.	134 women with breast cancer screening positive for depression at the Columbia Cancer Center.	12-session IPT. In the New York State Psychiatric Institute. Assessments occurred at baseline, before sessions 4 and 8, and at week 12.	Hamilton Depression Scale The Clinical Global Impression Severity scale Beck Depression Inventory-II Quality of Life Enjoyment and Satisfaction Questionnaire the Medical Outcomes Study Short Form, version 2 (SF-12) The Client Satisfaction Questionnaire The SCID	This study suggests various psychotherapy approaches may benefit patients with breast cancer and major depression.
The effect of interpersonal psychotherapy on quality of life among breast cancer patients with common mental health disorder: a randomized control trial at Tikur Anbessa Specialized Hospital	Belay W. et al., (2022)	To determine the effect of interpersonal psychotherapy on anxiety, depression, and quality of life among breast cancer patients.	124 breast cancer patients with common mental health disorder (62 intervention, and 62 control).	4-6 IPT therapy sessions. At the oncology center of Tikur Anbessa Special- ized Hospital.	Hospital Anxiety and Depression Measurement Scale (HADS) Amharic version of the EORTC QLQ- C30	In this study, interpersonal psychotherapy for Ethiopian use affected anxiety, depression, and quality of life of breast can- cer patients with a common mental health disorder. Hence, health programmers may consider incorporating it as a treat-ment outcome.

Conclusions: When the results of four studies examining the effectiveness of interpersonal relationship psychotherapy were examined, it was found to have a positive effect for breast cancer patients. This study, which examines the effects of interpersonal relationship psychotherapy, a therapy with proven positive effects on depression in different samples, on breast cancer patients, is important because it provides evidence to the literature.

The Impact of Diabetes and Hypertension on Psychological Well-being

N. Sghaier[1]*, I. Zariat[2], S. Chelly[2], M. Mahjoub[2], M. Njah[2] and H. Ben Garouia[1]

[1]Psychiatry Departement, Ibn Jazzar University Hospital, Kairouan and [2]Departement of hospital Hygiene, Farhat Hached University hospital, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1253

Introduction: Diabetes and hypertension are chronic conditions that significantly impact mental health. Managing these diseases involves constant monitoring, lifestyle changes, and dealing with potential complications, which can lead to increased sleep disorders, anxiety, and depression.
Objectives: the objectives of our study were to determine the frequency of anxiety, depression and sleep disorders in patients with hypertension and diabetes and to investigate factors associated with their occurrence.

Methods: This is a descriptive cross-sectional study conducted over a three-month period from October 1 to December 31, 2022, involving 720 diabetic and/or hypertensive patients followed at the primary health centers (CSB) in Kalaa Kbira Sousse. The assessment of sleep disorders was performed using the Pittsburgh Sleep Quality Index. Anxiety and depression were assessed using the Hospital Anxiety and Depression Scale.
Results: Among the 720 patients included, the majority were women (70.6%), with a gender ratio M/F of 0.41. The average age of the participants was 63.45 ± 13.16 years.The chronic illness was hypertension in half of the cases (49.3%), diabetes in a quarter of the cases (26.3%), and both conditions together in a quarter of the cases (24.4%). Anxiety was present in nearly half of the participants (47.1%), depression affected 40.2%, while anxiety-depressive disorder concerned half of the cases (46.5%).The prevalence of sleep disorders was 54.3% according to the Pittsburgh Sleep Quality Index (PSQI) with a median score of 6 [IQR: 3-9]. The subjective quality of sleep was rated as poor in 41% of cases.The prevalence of sleep disorders was 46% among diabetics, 54.6% among hypertensive patients, and 62.5% among those with both conditions simultaneously.In multivariate analysis, factors associated with poor sleep quality according to the PSQI included age ≥ 65 years (p=0.026), comorbidities (p=0.012), anxiety-depressive disorder ($p \leq 10^{-3}$), poorly controlled diabetes ($p \leq 10^{-3}$), and insulin therapy (p=0.022).
Conclusions: Understanding the mental health challenges faced by individuals with diabetes and hypertension is crucial for developing comprehensive care strategies that address both physical and psychological needs.

Combined spinal cord sclerosis, alcohol and bipolar disorder

Z. Souhlal[1]

[1]New hospital of Navarre, france, France
doi: 10.1192/j.eurpsy.2025.1254

Introduction: The alcohol use disorder has consequences on the metabolic,gastroenterological and especially neurological levels.
The somatic complications of alcohol use disorder add to the psychological and psychiatric complications and repercussions.
This involves presenting the case of Mr D;D admitted as part of the emergency for psychiatric evaluation.
Objectives: Interest in highlighting multidisciplinary care for somatic and psychiatric liaison
Methods: Presentation of clinical case
Results: Patient case
Conclusions: The management of patients with a psychiatric disorder or a request for psychiatric evaluation within the framework of the emergency liaison requires multidisciplinary and coordinated care.
Close collaboration allows early diagnosis and better overall patient care.

Disclosure of Interest: None Declared

The relationship between depressive symptoms and medication adherence among individuals with hypertension: An updated systematic review

T. Stamoulis[1]*, E. Laiou[1], K. Dimou[1], M. Gouva[1] and M. Kourakos[1]

[1]Research Laboratory Psychology of Patients, Families and Health Professionals, Department of Nursing, School of Health Sciences, University of Ioannina, Ioannina, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1255

Introduction: Hypertension, a major global public health challenge, is often associated with mental health conditions, particularly depression. Several studies suggest a bidirectional relationship between depressive symptoms and hypertension, which may negatively affect individuals living with hypertension's ability to maintain essential self-care practices, including adherence to prescribed medications and necessary lifestyle modifications.
Objectives: This study aims to build upon our previous systematic review (doi: 10.5455/msm.2024.36.65-72) by incorporating new data to further investigate the relationship between depressive symptoms and various aspects of self-care, with a particular focus on medication adherence among individuals diagnosed with hypertension.
Methods: The electronic database CINAHL was added to those of PubMed, Scopus, and PsycInfo, with the search extending from April 2023 to the present. Given the substantial diversity among the studies, a narrative synthesis of the results was conducted.
Results: A total of five new studies were included alongside the existing eighteen, involving 11,733 individuals with hypertension who met our eligibility criteria. Among these studies, ten reported a statistically significant association, highlighting the negative impact of depressive symptoms on medication adherence. The remaining thirteen studies did not confirm this association.
Conclusions: This systematic review reaffirms the diverse landscape of research examining the relationship between depressive symptoms and medication adherence in individuals with hypertension. It is advisable to conduct more robust longitudinal studies to thoroughly explore this relationship.

The Impact of HIV and SSRI Treatment on Thrombocytopenia Risk

A. Stewart[1]* and B. Carr[2]

[1]College of Allopathic Medicine, Nova Southeastern Univeristy, Ft. Lauderdale and [2]Psychiatry, University of Florida, Gainesville, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1256

Introduction: Cytopenia is a common hematological issue in HIV/AIDS patients. Despite early disease identification and less toxic HAART reducing its prevalence, persistent thrombocytopenia remains. SSRIs, prescribed for depression in this population, can also cause thrombocytopenia. This review explores the

potential combined impact of HIV and SSRI treatment on thrombocytopenia risk.
Objectives: The objective of this study is to evaluate thrombocytopenia incidence in HIV/AIDS patients and those receiving SSRIs, and to provide clinical recommendations for monitoring in individuals affected by both conditions.
Methods: A comprehensive literature review was conducted using PubMed, MEDLINE, and the Cochrane Library. Studies on thrombocytopenia in HIV/AIDS patients or discussing SSRI-induced thrombocytopenia were included. Data on incidence and clinical management were extracted and synthesized to form a cohesive understanding of risks and recommended practices.
Results: Thrombocytopenia (<150,000 platelets/μl) is a sentinel event frequently seen in HIV/AIDS patients, often prompting further evaluation. A 1982 study reported thrombocytopenia in up to 40% of AIDS patients pre-HAART. Recent data from the CHORUS cohort (1997-2006) showed a decreased prevalence of thrombocytopenia to 14%. However, 23% of those with severe thrombocytopenia (<30,000 platelets/μl) remained symptomatic despite HAART. A BC-CfE study found a 0.6% prevalence of symptomatic thrombocytopenia among HAART-treated patients (1996-2012), highlighting non-HIV causes. SSRIs can cause thrombocytopenia by interfering with platelet serotonin uptake, reducing platelet function and lifespan. Several case series reported isolated thrombocytopenia following SSRI introduction. While the concurrent use of SSRIs and HAART's effect on thrombocytopenia risk is unclear, careful consideration and monitoring are necessary.
Conclusions: The relative risk of thrombocytopenia from the combined effect of HIV/AIDS and SSRI treatment has not been definitively established. HIV/AIDS patients on SSRIs should be carefully monitored due to the known hematological impacts of both the disease and medication. Regular monitoring of platelet counts is crucial, especially in those with advanced or poorly controlled HIV. Consider alternative psychiatric treatments with lower hematological risks where possible. Effective management requires interdisciplinary collaboration to address these patients' complexities. This review underscores the importance of vigilant monitoring and individualized treatment strategies for HIV/AIDS patients on SSRIs to manage and mitigate the potential risk of thrombocytopenia.

Suspected autoimmune encephalitis in the presence of neuropsychiatric symptoms. The importance of differential diagnosis

E. Talaya Navarro[1]*, L. Martín de Francisco Murga[1], L. Gallardo Borge[1], M. E. Gómez Fernández[1], S. N. Pecheykin Pajomov[1], M. Teijeiro Rebolo[1] and A. Peman Alcazar[1]

[1]Psiquiatría, Complejo Asistencial de Segovia, Segovia, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1257

Introduction: Autoimmune encephalitis is a new and increasingly well-described entity. The most common is encephalitis caused by antibodies against the N-methyl-D-aspartate receptor on the surface of neurons (NMDAR encephalitis). It is a predominant entity in women and young patients and it is often associated with ovarian teratomas, neuroblastomas, Hodgkin's lymphomas and others. NMDAR encephalitis can manifest with a diverse range of neurological and psychiatric symptoms (personality change, anxiety, insomnia, confusion, attentional and short-term memory deficits, emotional lability, psychotic symptoms, language impairment, fluctuations in the level of consciousness, seizures and dysautonomia).
Objectives: Clinical review of Anti-NMDAR Encephalitis for differential diagnosis with Functional Neurologic Disorder.
Methods: Clinical case and literature review.
Results: We present the clinical case of a 27-year-old woman with a history of depression and anancastic personality disorder. The patient went to the Emergency Department different days presenting both neurological (facial paresthesias, hypoesthesia, weakness, high-intensity occipital headache, dizziness, loss of consciousness and anterograde amnesia) and psychiatric symptoms (obsessive thoughts, anxiety, visual and auditory hallucinations). She was admitted to the Neurology Unit. Complementary tests were performed: EEG, cranial CT scan, MRI, lumbar puncture, blood tests (including tumour markers) and urinalysis, founding no alterations suggestive of encephalitis or other systemic pathologies. She was also evaluated by the Psychiatry service. The patient described that as a result of a recent change in her job she presented emotional lability, obsessive ruminative ideas and anxiety. Treatment with Sertraline 100mg/day and Lorazepam 1mg/8 hours was started.
After ruling out autoimmune encephalitis, the patient was diagnosed with Functional Neurologic Disorder, given the temporal relationship of the symptoms with the stressful history at work.
Conclusions: Given their growing prevalence autoimmune causes, such as NMDA anti-receptor antibody encephalitis, should always be considered in the cases of neuropsychiatric alterations. It is very important to carry out a correct organic screening prior to the diagnosis of psychiatric pathology. It is also essential an adequate coordination between different medical departments for an accurate and comprehensive approach to the patient.

EPV0509

The Interdisciplinary Challenge: A Case Report on Treating Recurrent Depressive Disorder Amidst Multiple Medical Comorbidities

Z. C. G. Tan[1]* and I. C. S. Tan[1]

[1]Department of Psychiatry and Behavioral Medicine, University of the Philiippines Philippine General Hospital, Manila, Philippines
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1258

Introduction: This case highlights the interdisciplinary management of a 28-year-old Filipino female with recurrent depressive disorder and multiple medical comorbidities, including HIV, tuberculosis, and sexually transmitted infections. Managing depression in patients with complex medical conditions is especially challenging in resource-limited settings like the Philippines, where drug-to-drug interactions and access to high-quality care must be carefully navigated.
Objectives: The objective of this case report is to illustrate the importance of personalized treatment decisions, the rationale for choosing Venlafaxine over SSRIs, and the value of psychodynamic psychotherapy in addressing underlying emotional conflicts in the context of maternal health challenges.

Methods: The patient was referred to the Psychiatry service due to suicidal ideations. She has a history of depressive episodes linked to family stressors and initial flashbacks and nightmares related to her physical abuse from her previous partner. Her extensive comorbidities made the usual first-line antidepressants (SSRIs) unsuitable due to drug interactions. Venlafaxine 75 mg/day was selected, and psychodynamic psychotherapy, trauma-informed psychotherapy, and psychoeducation were integrated into her treatment. Coordination with infectious disease, obstetrics, and internal medicine specialists ensured comprehensive care.
Results: Venlafaxine was effective in improving mood, sleep, and appetite, with no significant side effects. Regular follow-ups confirmed adherence to the medication, and psychodynamic psychotherapy helped her address deep-seated emotional conflicts, particularly surrounding her history of trauma. Ongoing psychiatric care, along with monitoring her medical conditions, provided a supportive framework for her continued improvement. Despite financial constraints, the patient adhered to her treatment regimen, showing improved mental health and commitment to her care.
Conclusions: This case underscores the complexity of treating depression in patients with multiple comorbidities, particularly in resource-limited settings. The selection of Venlafaxine was crucial due to the potential interactions of SSRIs with the patient's medical regimen. Psychodynamic and trauma-informed psychotherapy, combined with interdisciplinary collaboration, were key to the successful management of this case. This highlights the need for an integrated approach to mental health care, especially in low-resource environments, where interdisciplinary coordination is vital.

EPV0511

PANDAS have claws too: A case report of an adolescent female with concurrent PANDAS and Mood Disorder

C. I. C. Uy[1]* and M. D. J. L. Calleja[1]

[1]Department of Psychiatry, The Medical City, Pasig City, Philippines
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1259

Introduction: Pediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal Infection (PANDAS) is an autoimmune disease caused by Group A Streptococcus bacteria. It usually affects children 3 to 12 years of age, however, have also been reported among adolescents. PANDAS presents with neuropsychiatric symptoms which can overlap or coincide with existing psychiatric disorders that often emerge further as children get older. Identifying the causation of events may be challenging making such cases difficult to manage.
Objectives: To understand the presentation of PANDAS with concurrent mood disorder and its management.
Methods: Clinical case report
Results: A 16-year-old female was initially admitted due to blank stares, disorganized behavior, paranoia, aggression, and depressive symptoms. Her EEG and MRI were normal. She did not tolerate Fluoxetine but improved with Olanzapine (12.5mg). At 17 years old, she had throat discomfort, colds, and headache with supportive management done. She felt depressed and suicidal due to school stress prompting her second admission. She was started on Escitalopram and Olanzapine was shifted to Quetiapine. Subsequently, she developed manic symptoms with hallucinations and worsened paranoia. Escitalopram was discontinued and Quetiapine was increased (300mg). Bipolar I Disorder with Psychotic Features was considered. Shortly after, she developed explosive motor and vocal tics, involuntary screeching with head gagging and jerking and urges to choke herself or hit her head on the wall. Quetiapine was discontinued and was placed on Clonazepam (0.25mg/8h). Work ups revealed normal EEG, positive ASO and ESR, and findings of Mild Rheumatic Heart Disease on 2D Echo, hence, the assessment of PANDAS. Treatment is multidisciplinary involving antimicrobial, immunomodulatory, and psychotherapeutic interventions. Medications were then adjusted to: Co-amoxiclav (625mg/10days) followed by Penicillin V (250mg/12h), Aripiprazole (15mg), and Divalproex Sodium (1000mg). Intravenous immunoglobulin was suggested due to her moderate to severe presentation. Henceforth, improvement of symptoms were noted and she was reintegrated back home.
Conclusions: Diagnosing PANDAS can be complex among adolescent due to concurrent issues with similar symptom presentation. PANDAS is episodic in nature but may also have sawtooth-like presentation which may indicate first admission as an episode and the second, a flare up. The case could have also been a combination of PANDAS and Bipolar Disorder thus the severity. Regardless, the interplay of biological and psychological facets have evidently magnified her predispositions leading to an intense manifestation of symptoms.

Management of Functional Neurological Disorders: Turkiye Experience

I. Yildiz[1]*, G. YALÇIN ÇAKMAKLI[2], A. Fil Balkan[3], T. demirsöz[1], B. Elibol[2] and M. K. YAZICI[1]

[1]psychiatry; [2]neurology and [3]physical therapy and rehabilitation, hacettepe university, Ankara, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1260

Introduction: Functional neurological disorder (FND) is diagnosed in approximately one-third of admissions to the general neurology outpatient clinic. Although it affects both gender in a wide age range, it occurs more frequently in women between ages of 35 and 50. As a common neuropsychiatric disorder affecting mostly young people at productive ages, FND also leads to an important socioeconomic burden. For this reason, clinical and research activities tended to increase recently in order to develop new neuroscientific approaches for the treatment of this disorder. Various new clinical centers that offer specialized and multidisciplinary treatment to FND patients, have been established around the world. Likewise, a study group was established in Hacettepe University Adult Hospital, where FND patients were started to be treated by a multidisciplinary team, by also considering the specific needs of our country's population.
Objectives: Here, we aim to share the phenomenological and clinical characteristics and treatment response of patients with functional neurological disorders (FND) who received short-term inpatient multidisciplinary treatment in a university hospital between 2020 and 2023.

Methods: FND study group at Hacettepe University Adult Hospital was founded by 2 neurologists, 2 psychiatrists, 1 psychologist and 2 physiotherapists.
Within the framework of the protocol, FND patients were first informed about the disease process by a neurologist and a psychiatrist and then followed up for further need for an inpatient multidisciplinary approach.
During hospital admission in the room reserved for FND patients in the neurology ward, the treatment protocol was implemented in such a way that each session included **one hour of cognitive behavioral therapy-based psychotherapy** and **at least 2 hours of intensive physiotherapy including FND-specific approaches** for at least 5 days.
Demographic and clinical characteristics of the patients were noted, their fitness levels before and after treatment were evaluated with a visual analogue scale, and the patients' perceived improvement levels were also evaluated with VAS and recorded as a percentage.
Results: The majority of patients were women (19/11).
The age range was wide, between 19 to 75 (average 44 years).
Patients were classified under four groups based on the predominant symptom (gait disorders:15, fixed dystonia: 9, swallowing and speech problems:3, sensorial problems:3)
The level of improvement perceived by the patients was the best in those with sensorial problems, and the worst in those with swallowing and speech problems (%40).
Those with the lowest level of perceived wellness in terms of general health were patients with dystonia component.
Conclusions: Multidisciplinary FND rehabilitation may provide different degrees of benefit to FND patients of different subtypes. Our results may have the potential to contribute to clinicians and academicians in predicting treatment outcomes.

Predictors of depressive symptoms in patients with heart failure decompensation

M. Zalewska[1]*, K. Nowak[2] and T. Sanak[1]

[1]Department of Emergency Medicine, Faculty of Health Sciences, Jagiellonian University Medical College and [2]Department of Coronary Artery Disease and Heart Failure, Jagiellonian University Medical College, John Paul II Hospital, Krakow, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1261

Introduction: Acutely decompensated heart failure (HF) may be accompanied by depressive symptoms. Predictors of screening diagnosis of depression (SDD) in decompensated HF are poorly elucidated.
Objectives: We sought to investigate independent determinants of SDD in patients with HF decompensation.
Methods: Enrolled were fifty-one patients with a median age of 67 years and left ventricular ejection fraction (LVEF) of <40% hospitalized due to HF decompensation. SDD based on the result of the Beck Depression Inventory (>10 points), PHQ-9 (>12 points) or Hamilton Depression Scale (lack of depression: <7 points; mild [<12 points], moderate [<17 points] or severe [≥18 points] depression). Neurotrophic potential and response to stress were assessed by brain-derived neurotrophic factor (BDNF) and FK506 binding protein 5 (FKBP5), respectively.
Results: SDD was identified in 26 (51%) patients based on the Beck inventory and in 12 (24%) patients based on PFQ-9. According to the Hamilton scale mild SDD was found in 17 (33.3%), moderate in 9 (17.6%) and severe in 14 (27.5%) of patients. Male patients with HF decompensation had higher result of Beck inventory by 35% (P=0.029), PHQ-9 by 60% (P=0.014) and Hamilton scale by 64% (P=0.003) than female. The result of the Beck Depression Inventory was correlated with plasma levels of FKBP5 (R=0.34, P=0.017) and inversely correlated with BDNF (R=-0.39, P=0.004). In turn, LVEF was correlated with the result of PHQ-9 (r=0.33, P=0.020), Hamilton scale (r=0.33, P=0.18) and with BDNF (r=0.32, P=0.025) while inversely with FKBP5 (r=-0.32, P=0.023). By multivariate analysis the higher result of the Beck inventory was associated with male gender (β=0.26, P=0.048), a higher LVEF (β=0.27, P=0.042) and a lower plasma BDNF (β=-0.46, P<0.001).
Conclusions: SDD in patients with HF decompensation is independently associated with male gender, better preserved left ventricular systolic function and reduced plasma level of BDNF.

Comparative analysis of the impact of psychosocial stress on exacerbation and dynamic of psychosomatic pathology (on the model of psoriasis) in periods of large-scale social upheavals (Covid-19 and a large-scale war in Ukraine)

M. Markova[1]*, H. Prib[2], A. Markov[2] and R. Yaremkevich[3]

[1]Sexology, Psychotherapy and Medical Psychology, Kharkiv National Medical University, Kharkiv; [2]Psychology, Academy of Labour, Social Relations and Tourism, Kyiv and [3]Skin and Venereal Diseases , Uzhgorod National University, Uzhgorod, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.593

Introduction: The large-scale social stress of recent years (the COVID-19 pandemic, the large-scale invasion of the rf in Ukraine) has a powerful negative effect on the psyche of people and causes an increase in the incidence of stress-associated pathology. One of the vulnerable groups in the formation of distress conditions is patients with psychosomatic pathology, in particular, psoriasis, in the pathogenesis of which psychosocial stress plays an important role.
Objectives: To determine the existence of a differentiated impact of a contain of the large-scale stressful events on the health of patients with psychosomatic pathology.
Methods: 83 psoriasis patients interactively were examined using the Google Form developed by us, which provided for a structured interview with the purpose of determining anamnestic data and collecting subjective complaints of the patient in two time periods the year of quarantine due the Covid-19 pandemic (11.03.2020-11.03.2021), and the year from the beginning of full-scale russian aggression (24.02.2022-24.02.2023). Statistical analysis included descriptive statistics and assessment of the significance level of differences using Fisher's exact test (one-sided).
Results: In the 1st year of the Covid-19 pandemic, exacerbation of psoriasis was found in 36.1% of patients, of which 63.3% believed that this was associated with the

impact of stress through pandemic. The stress of war proved to be a more powerful psycho-traumatic factor (P<0.01): in the 1st year, exacerbation of psoriasis was observed in 61.4% of patients, 88.2% of whom associated it with the impact of war. The prevalence of almost all psychopathological symptoms in patients during a full-scale war was slightly higher than during the Covid-19 pandemic: fear and anxiety (80.0% VS 88.2%), reduced mood (66.7% VS 90.2%, P<0.01), dyssomnia (50% VS 45.1%), asthenia (36.7% VS 41.3%), emotional lability (33.3% VS 37.3 %).
Conclusions: The conducted study revealed the impact of strong social stress on the frequency of psoriasis exacerbations and mental maladjustment. The stress of the war turned out to be a more powerful stress factor, and the patients significantly more often associated this social stress, with the exacerbation of psoriasis. It is allows us to consider the content of the stress load and the peculiarities of individual perception of stress as a relevant factor in the exacerbation of psoriasis and comorbid mental disorders. But a larger study involving a larger number of patients is needed to reveal more subtle patterns.

Psychiatric symptoms in Long-COVID patients – how really affect the quality of life?

O. A. Caliman-Sturdza[1,2*] and S. Cristina[2,3]

[1]Faculty of Medicine and Biological Science, Stefan cel Mare University of Suceava; [2]Infectious Diseases, Emergency Clinical County Hospital New St John Suceava, Suceava and [3]Infectious Diseases, Grigore T. Popa University Iasi, Iasi, Romania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1262

Introduction: Prolonged symptoms of SARS COV2 infection known as Long COVID, are defined as symptoms persisting for more than four weeks after the initial diagnosis of COVID-19. Psychiatric symptoms such as anxiety, depression, cognitive deficits, fatigue, qualities poor sleep and somatic symptoms are common in patients with long-term COVID and could last weeks, even months, after recovery.
Objectives: In this study, we tried to identify the psychiatric symptoms that can start after infection with SARS COV2, what could be the risk factors for the onset of these symptoms and how the quality of life is affected in these patients.
Methods: The study included 116 patients diagnosed with COVID-19 in the Suceava County Clinical Hospital, who were monitored for 12 months by applying standardized questionnaires for depression (Patient Health Questionnaire-9), anxiety (General Anxiety Disorder-7) and cognitive disorders. (Montreal Cognitive Assessment), patients being periodically evaluated clinically, biologically, neurologically and psychologically.
Results: A percentage of 26.9% of patients presented the following psychiatric symptoms more than 4 weeks after the diagnosis of SARS COV2 infection: anxiety (6%), sleep disorders (7.7%) manifested by insomnia or hypersomnia, lack of concentration and attention (10.3%), memory disorders (8.6%), depression (4.3%). The most frequent psychiatric manifestations were cognitive disorders (10.3%) expressed by deficits in attention and memory, followed by sleep disorders (7.7%). Women presented a higher percentage of psychiatric manifestations manifested by anxiety and depression, but we did not find a correlation between the age of the patients and the mental manifestations after COVID-19. The 2 patients with depression in the antecedents, presented an exacerbation of mental symptoms post COVID. Depression and anxiety were more frequent in patients who had prolonged hospitalizations or moderate and severe forms of the disease. In 12 patients who presented cognitive disorders, increased values of C-reactive protein and lactic dehydrogenase were found during SARS COV2 infection. The use of questionnaires showed an important impact on the quality of life, especially in patients diagnosed with depression, anxiety and insufficient sleep.
Conclusions: Recognition and treatment of psychiatric symptoms that started after SARS COV2 infection should be included in the management of the patient with chronic COVID. The use of screening questionnaires for depression, anxiety and cognitive disorders must be implemented in the current practice of post-COVID-19 monitoring. The collaboration between infectious disease specialist, psychiatrist and psychologist can be the key to success in the treatment of psychiatric disorders in patients with long-term COVID.

[1]Occupational Medecine Department, University Hospital of Farhat Hached, Sousse, Tunisia; [2]University of sousse, Faculty of Medecine Ibn El Jazzar, 4000 sousse, Tunisia; [3]Research laboratory LR 19SP03, Study of the risks and prospects for the prevention of non-communicable diseases in the workplace; [4]University of sousse, University Hospital of Farhat Hached and [5]Occupational medecine department, University Hospital of Sahloul, Sousse, Tunisia, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1263

Introduction: Since the beginning of the health crisis caused by COVID-19, the impact of the pandemic context on the mental health of healthcare professionals has been widely studied. However, few studies have assessed psychological manifestations in healthcare workers affected by COVID-19.
Objectives: Determine the prevalence and factors associated with depressive symptoms in healthcare workers with COVID-19.
Methods: This is a cross-sectional analytical study of health professionals at Farhat Hached University Hospital with COVID-19 over a 6-month period from September 2020 to February 2021. Depressive symptoms were screened using the Depression Subscale of Hospital Anxiety and Depression Scale (HADS-D).
Results: Our study included 477 healthcare professionals. The mean age was 39.9 ±10.8 years, with a predominance of women (sex ratio =0.27). Almost a third of the participants were nurses (32.1%), followed by doctors (27.9% of cases). Most of the healthcare workers affected developed a pauci-symptomatic form of the infection (73.8%), with an average confinement time of 14.9

±6.9 days. On returning to work, 74 staff (15.5%) noticed that their colleagues were withdrawing from work. According to the HADS-D scale, depressive symptoms were observed in 19.1% of cases. The predictive factors were gender (p<10-3), age (p=0.016), the symptomatic form of COVID-19 (p= 0 ,038), the duration of confinement (p<10-3) and the withdrawn attitude experienced by colleagues on returning to work (p<10-3).
Conclusions: Our results showed that psychological suffering, particularly depression, among care staff depended on several predictive factors. Psychological support during and even after the period of confinement is therefore necessary

Prognostic Significance of CRP, BMI, and Ferritin Levels in Predicting COVID-19 Outcomes in Psychiatric Patients: A Comparative Analysis

K. Argyropoulos[1], A.-A. Argyropoulou-Grizanou[2], P. Gourzis[3]* and E. Jelastopulu[1]

[1]Public Health, School of Medicine, University of Patras, Patras; [2]Social Sciences, Hellenic Open University, Athens and [3]Psychiatry, School of Medicine, University of Patras, Patras, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1264

Introduction: This study investigates the predictive value of ferritin, CRP, and BMI levels in predicting COVID-19 outcomes among psychiatric patients.
Objectives: Understanding these markers is crucial given the increased vulnerability of psychiatric patients to severe COVID-19 outcomes.
Methods: We conducted a retrospective analysis of 100 psychiatric patients diagnosed with COVID-19. We collected clinical outcomes (survival or death) data, demographic characteristics, and comorbidities. Blood samples were analyzed for ferritin and CRP levels, and BMI was calculated based on recorded weight and height. Statistical tests, including t-tests and chi-square tests, were used to assess the relationships between these variables and COVID-19 outcomes. Survival analysis was performed using the Log-Rank test to evaluate the impact of these markers on patient survival.
Results: Our results showed that higher ferritin levels were significantly associated with poorer outcomes, with survivors having a mean ferritin level of 246.2 (SD = 150.3) compared to 416.9 (SD = 215.9) in non-survivors ($p < 0.001$). Similarly, mean CRP levels were lower in survivors (1.58, SD = 1.96) compared to non-survivors (3.46, SD = 2.92) with a p-value of 0.002. BMI did not show a statistically significant difference between survivors and non-survivors ($p = 0.429$). Survival analysis revealed that elevated CRP and ferritin levels correlated with decreased survival rates.
Conclusions: The study highlights the significant role of ferritin and CRP as prognostic markers in psychiatric patients with COVID-19, suggesting that elevated levels of these biomarkers are associated with worse outcomes. However, BMI did not significantly affect survival, indicating that inflammatory markers might be more relevant for assessing prognosis in this population. These findings emphasize the need for vigilant monitoring of these biomarkers in psychiatric patients to manage their COVID-19 treatment better and improve outcomes.

doi: 10.1192/j.eurpsy.2025.1265

Introduction: The COVID_19 pandemic has affected all facets of living, notably our sleep-wake cycle. In fact, sleep disturbances have been reported, not only during the acute phase, but also after the episode. Previous studies have shown that some socio-demographic characteristics are associated with sleep problems.
Objectives: To assess the relationship between sleep disturbances and the sociodemographic profile of the COVID-19 survivors.
Methods: We conducted a prospective cohort study including 121 Tunisian COVID-19 inpatients who had been discharged alive from hospital. Each enrolled patient was asked about the period before the hospital stay, and the 6-9 month-period after hospital discharge, using the Arabic validated version of Pittsburgh sleep quality index "PSQI" scale to assess sleep problems.
Results: The median age of our participants was 59 years old. Among them, 62 (51.2 %) were females. One hundred and eleven patients were married (91.7%), 102 patients (84.2%) had at least a primary educational level, while 19 (15.7%) patients were illiterate. Among the participants 86 (71.07%) had a job at the time of the infection, among them, 9 (7.4%) were Heath care providers. Ninety-five (78.5%) participants were non-smokers. As for alcohol use, 11 patients (9.1%) consumed alcohol. According to PSQI, the incidence of sleep disturbances after COVID was 48.8%. Sleep duration, sleep quality as well as sleep onset latency, sleep disturbances and sleep efficiency were the most affected domains in the PSQI. Females showed significantly higher PSQI after the COVID-19 infection (p<0.001). Non-married participants reported significantly higher scores of hypnotic drug use and daytime dysfunction (p=0.006, p=0.02 respectively). Quality of sleep was significantly poorer in illiterate patients (p=0.036). Health care providers had worse daytime dysfunction in comparison to other occupations (p=0.035). Non-smokers showed a deteriorated sleep efficiency as well as daytime dysfunction (p=0.03, p=0.021 respectively). No statistical association was found between sleep problems and age nor alcohol consumption.
Conclusions: Our study highlighted several associations between sleep problems and sociodemographic characteristics of COVID-19 survivors. This helps clinicians to pinpoint the at-risk people, in order to intervene when needed.

Empathy under prolonged stress situation (COVID-19 pandemic)

T. I. Medvedeva[1], O. M. Boyko[1]*, S. N. Enikolopov[1] and O. Y. Vorontsova[1]

[1]Clinical psychology, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1266

Introduction: Empathy is a fundamental component of the socio-emotional experience. Emotional empathy describes the emotional reaction of an observer to the emotional state of another person - "emotional contagion". People with high empathy can become objects of "emotional contagion" in a stressful situation.
Objectives: **The aim** of the study was to evaluate the mutual influence of stress and emotional aspects of empathy.
Methods: Online survey was used. The level of empathy was assessed by "empathy" of I7 (H.Eysenck), stress was assessed by SCL-90R; COPE and CTI (S.Epstein), questions whether they had ever sought psychiatric help, the presence of suicidal ideas and thoughts of death were used. N=157 (139 women) mean age 41,1. 47 had previously sought psychiatric help. Subgroups of "low" and "high empathy" were analyzed.
Results: People who had previously sought psychiatric help did not differ from "healthy" people in terms of empathy.

	Low empathy (N=86)	High empathy (N=71)	Sig.
GSI (SCL)	0,46±0,39	0,67±0,53	,004
PDSI (SCL)	1,38±0,45	1,53±0,53	,058
PSI (SCL)	26,34±16,29	35,49±18,06	,001
Global Constructive Thinking (CTI)	98,76±13,84	92,83±12,88	,009
Emotional Coping (CTI)	91,32±23,02	82,75±20,79	,022
Focus on and Venting of Emotions (COPE)	9,38±3,04	10,80±2,72	,003
Seeking Social Support for Emotional Reasons (COPE)	9,56±3,37	10,70±3,24	,032
Alcohol/Drug Use scale (COPE)	6,13±2,70	7,15±3,39	,036

Analysis of variance showed: "high empathy" subgroup had a higher level of experienced stress, including higher anxiety, depressive symptoms, and interpersonal sensitivity. Differences in coping strategies and thinking patterns highlight the personality traits of people with high empathy, which affect the stress resistance. The combination of focusing on one's own emotions and reducing emotional coping does not allow to regulate emotional state under stress. Separately, using correlation analysis, the relationship between the level of empathy and the characteristics of emotional regulation and possible suicidal ideas and thoughts about death was assessed in the subgroup of subjects who had previously sought psychiatric help and in the "healthy" subgroup. Both in the group of those who sought help from a psychiatrist and in the "healthy" subgroup, a connection was found between empathy and the level of emotional regulation. In those who had previously sought help from a psychiatrist, the level of empathy positively correlated with the presence of "thoughts about death".
Conclusions: Subjects with "high empathy" are distinguished by a higher level of experienced stress, which may be associated with a reduced ability to emotionally cope. Particular attention should be paid to people who have previously sought psychiatric help. Under stressful conditions with high "emotional contagion" they think about death more often and the risk of suicide may arise.

Neuropsychiatric Sequelae of COVID-19: A Review of Acute and Long-Term Manifestations

M. Demetriou[1]*, V. Anagnostopoulou[1], M. Peyioti[2], V. Markatis[1] and P. Argitis[1]

[1]Psychiatry Department, General Hospital of Corfu, Corfu and [2]University General Hospital of Alexandroupolis, Alexandroupolis, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1267

Introduction: The SARS-CoV-2 virus, responsible for COVID-19, has been shown to affect the central nervous system (CNS), leading to a wide range of acute and long-term neuropsychiatric symptoms. These symptoms can profoundly impair cognitive and emotional functioning, highlighting the need for a deeper understanding of their underlying mechanisms and clinical manifestations. Addressing these sequelae is critical for developing effective management strategies and improving patient outcomes. Long COVID has been associated with conditions such as brain fog, depression, anxiety, and fatigue, which can further exacerbate pre-existing mental health conditions and impair quality of life.
Objectives: This review aims to examine the neuropsychiatric manifestations associated with COVID-19, focusing on both acute and long-term (long COVID) effects, and to explore potential pathophysiological mechanisms, including neuroinflammation and immune dysregulation.
Methods: A systematic review of literature was conducted by searching databases such as PubMed and Scopus, using terms like 'COVID-19', 'neuropsychiatric symptoms', 'long COVID', 'inflammation', and 'CNS involvement'. Only peer-reviewed articles published between 2020 and 2023 were included, with an emphasis on studies reporting acute neuropsychiatric symptoms and post-acute sequelae of COVID-19.
Keywords: COVID-19, neuropsychiatric symptoms, long COVID, neuroinflammation, interleukin-6, CNS involvement
Results: Acute neuropsychiatric manifestations of COVID-19 include encephalopathy, delirium, seizures, and mood disturbances. Approximately 22.5% of COVID-19 patients present with neuropsychiatric symptoms during the acute phase, including anxiety, depression, and cognitive impairment. In long COVID, persistent symptoms such as fatigue, depression, anxiety, sleep disorders, and cognitive dysfunction have been reported, with neuroinflammation and elevated interleukin-6 (IL-6) levels proposed as key mechanisms. Neuropsychiatric symptoms are observed in both hospitalized and non-hospitalized individuals, with risk factors including severe infection, female sex, and pre-existing mental health conditions.
Conclusions: COVID-19 is associated with a broad spectrum of neuropsychiatric symptoms that persist beyond the acute phase. The underlying pathophysiology likely involves immune dysregulation, cytokine-mediated neuroinflammation, and direct viral invasion of the CNS. Early recognition and targeted interventions are essential to mitigate long-term neuropsychiatric complications.

Anxiety and depression during COVID-19 in Kosovo: literature review and analysis of repeated cross-sectional surveys

N. Fanaj[1,2]*, S. Mustafa[2,3] and E. Krasniqi[2,4]

[1]Alma Mater Europae Campus College Rezonanca, Prishtina; [2]PMSH, Prizren; [3]AAB College and [4]UBT College, Prishtina, Kosovo
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1268

Introduction: The literature review on anxiety/depression rates during Covid-19 is inconsistent due to significant methodological challenges in quantifying the impact of the pandemic on the mental health of the population.
Objectives: To identify and understand the prevalence of anxiety/depression as a result of the COVID-19 situation aiming to synthesize impact of COVID-19 in mental health of population in Kosovo.
Methods: It's a classic literature review which involves a thorough examination of existing research in internet, including raw data of the individual empirical results from several repeated cross-sectional surveys. We examined data of eight published researches and nine cross-sectional surveys conducted during the period 2020 to end of 2021.
Results: In the review of eight published studies (seven from 2020 and one from 2021) of cross-sectional type, online, with sample sizes from 155 to 904 (four with student population, two with healthcare workers and two with general population) the prevalence of anxiety was from 13% to 73% (average 47.07%; measured with HADS, DASS-21 and GAD-7) while the prevalence of depression was from 13.9% to 71.60% (average 34.42%; measured with HADS, DASS-21 and PHQ-9). The methodological quality of included studies was low. Analysis of raw data of our nine cross-sectional surveys conducted during the period 2020 to end of 2021 show pooled prevalence for anxiety (measured with GAD-7, ≥10) for 2706 participants (five samples) to be 34.59 % (95% CI, 33.11%-36.07%) and for depression (measured with PHQ-9, ≥10) for 3703 participants (seven samples) to be 40.84% (95% CI, 39.43%-42.25%). Mostly, younger age, females and low SES emerged as factors associated with higher levels of anxiety/depression.
Conclusions: Our anxiety/depression prevalence rates, mostly is above average in comparison to other countries in Europe. Despite awareness for methodological flaws of studies, measurement invariances and some evidence of variation in the estimated prevalence rates of depression and anxiety disorder across countries; high prevalence of mental health problems during the pandemic indicates need for mental health prevention, promotion and intervention programs to mitigate the consequences of the COVID-19 pandemic on the population.

Disaster and Distress: The Double Burden. Depression, Anxiety, and Post-traumatic Stress Disorder in Healthcare Providers during the COVID-19 Pandemic in Pakistan

M. Fatima[1,2]*, N. Imran[3], I. Aamer[1], S. Iqtadar[4] and B. Shabbir[5]

[1]Academic Department of Psychiatry and Behavioral Sciences, King Edward Medical University Lahore, Lahore, Pakistan; [2]Psychiatry, Dublin North Mental Health Service, Dublin, Ireland; [3]Child and Family Psychiatry Department; [4]General Medicine, King Edward Medical University Lahore and [5]General Medicine, Fatima Jinnah Medical University, Lahore, Pakistan
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1269

Introduction: Healthcare providers are at a high risk of occupational stress, psychological distress, and mental health problems due to unique job demands. The unprecedented negative impact of the COVID-19 pandemic on healthcare further intensified the risk.
Objectives: To find out the prevalence of anxiety, depression, and post-traumatic stress disorder (PTSD) in healthcare providers during the COVID-19 pandemic, and explore various associated factors.
Methods: We conducted a cross-sectional survey among clinicians across tertiary care hospitals in Lahore, Pakistan through online forms/ paper-based questionnaires, using the Patient Health Questionnaire (PHQ-9), Generalized Anxiety Disorder (GAD-7) Scale, and The Impact of Events Scale-Revised (IES-R) from July-November 2021. Physicians aged 20-60 years working at the public-sector hospitals of Lahore were included through non-probability convenient sampling. The non-parametric Mann-Whitney *U, Kruskal-Wallis, and Chi-square* test of independence were applied for inferential data analysis in SPSS version 26 at α=0.05.
Results: Of 302 participants, the majority were males (54.6%), from medicine and allied departments (76.9%), junior staff (72%), and frontline workers (75%). 9.5% had a history of psychiatric illness. The prevalence of depression was 25%, anxiety 31.9%, PTSD 15.8%, severe depression 13.8%, and severe anxiety 7.2%. The total median (IQR) scores of depression, anxiety, and PTSD were 5(2-9.5), 4 (0-7), and 10(1-23) respectively. Females and junior staff had comparatively severe symptoms of anxiety and depression. Psychiatric history was linked to severe depression (p=0.003) and PTSD (p=0.001) but not anxiety (p=0.136). There were no statistically significant differences in the anxiety and PTSD severity across genders, departments, and frontline/second-line work.
Conclusions: We found high levels of depression, anxiety, and PTSD in our physician sample even during the 4th COVID-19 wave. This has implications for emphasizing the significance of the mental well-being of healthcare providers and identifying effective interventions to prioritize it even after the pandemic.

Long-Term Psychological Impact of the COVID-19 Pandemic on Healthcare Workers

A. Gaddour[1,2]*, R. Nakhli[3], A. Chouchane[4], M. Bouhoula[4], K. Ben Amor[2], I. Jammeli[5], M. Bouhlel[5], I. Kacem[4] and S. Chatti[4]

[1]Occupational Medicine Department, Univerisity of Sousse, Ibn Jazzar University Hospital, Kairouan; [2]Department of Occupational Medicine, Faculty of Medicine of Sousse, Ibn Jazzar University Hospital, Tunis; [3]Occupational Medicine Department, University of

Sousse, Farhat Hached University Hospital; [4]Department of Occupational Medicine, Faculty of Medicine of Sousse and [5]Department of Occupational Medicine, Faculty of Medicine of Sousse, Ibn Jazzar University Hospital, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1270

Introduction: The COVID-19 pandemic has placed immense psychological pressure on healthcare workers (HCWs) worldwide. In addition to the physical risks of infection, HCWs have faced high levels of anxiety due to their proximity to the virus, overwork, and the challenges of providing care in an ever-evolving environment. These psychological effects are expected to persist well beyond the initial phase of the pandemic.
Objectives: This study explores the long-term impact of COVID-19 on both anxiety and depression among HCWs and identifies the main contributing factors.
Methods: This cross-sectional study was conducted among HCWs infected with SARS Cov-2 between January and August 2022. Sociodemographic and professional data were extracted from participants' medical records. Anxiety and depression were evaluated using the GAD-7 (Generalized Anxiety Disorder) and PHQ-9 (Patient Health Questionnaire) scales, respectively, through phone interviews conducted at least one year after their last COVID-19 infection
Results: This study included a total of 184 healthcare workers (HCWs). The mean age of the participants was 41.93 years (± 8.6), with 95.1% being over 30 years old. Women comprised 81.4% of the cohort, and the majority of participants were nurses (45.7%), followed by administrative staff (20.1%). The median occupational seniority was 16 years. Notably, 28.3% of HCWs were employed in COVID-19 wards. Anxiety symptoms were reported by 92.9% of participants, with 17.3% experiencing mild anxiety, and 38.5% severe anxiety. Depression was prevalent in 69.1% of HCWs, with 27.2% presenting mild symptoms, and 24.5% experiencing moderate to severe depression. Female HCWs and those aged over 40 were significantly more likely to report symptoms of anxiety and depression ($p < 0.001$). Furthermore, HCWs with pre-existing conditions, such as diabetes, as well as those directly exposed to COVID-19 patients, exhibited significantly higher anxiety and depression scores. Nurses demonstrated particularly elevated levels of psychological distress, especially those working in COVID-19 wards.
Conclusions: The COVID-19 pandemic has had a profound and lasting psychological impact on healthcare workers, with anxiety and depression levels remaining elevated long after the acute phase of the crisis. This study emphasizes the need for targeted psychological support interventions. Addressing the mental health needs of HCWs is crucial not only for their well-being but also for ensuring the ongoing efficacy and resilience of the healthcare workforce in times of crisis. Further research is warranted to explore long-term impacts and effective strategies for mental health support in this population.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1271

Introduction: Despite healthcare workers (HCWs) facing mental health challenges during COVID-19, their use of psychological support is limited. Understanding these dynamics is crucial for identifying mental health needs and vulnerable groups within Spanish healthcare services.
Objectives: This study analyzes psychological support use among Spanish HCWs post-pandemic onset over 2 years, and its link to workplace and COVID-19 factors from 2020 data.
Methods: Longitudinal research involved Spanish HCWs. Data from online surveys covered demographics (age and gender), depressive symptoms (PHQ-9), workplace-and COVID-19-related factors (type of job, direct exposure to COVID-19 patients, adequate access to personal protective equipment, social stigma for working with COVID-19 patients, decision making on patient prioritization, and perceived social network support at work), and psychological support use across 2020, 2021, and 2022. We received responses from 296, 294, and 251 participants at time points 1, 2, and 3, respectively.
Results: Predominantly female participants (n=242, 82%) and with a median age of 43 years. Psychological support seeking increased from 15% in 2020 to 23% in 2022. Notably, one in four HCWs not seeking help showed major depressive disorder symptoms. Predictors for seeking support included patient prioritization decision-making (OR 5.59, 95% CI 2.47-12.63) and probable depression (wave 2: OR 1.12, 95% CI 1.06-1.19; wave 3: OR 1.10, 95% CI 1.04-1.16). Table 1 shows the association between workplace- and COVID-19-related variables at baseline and use of psychological support at follow-up.

Table 1.

	Wave 2		Wave 3	
	Odds ratio	95% CI	Odds ratio	95% CI
Direct exposure to COVID-19 patients	2.03	(0.93, 4.41)	1.03	(0.53, 2.03)
Access to protective equipment	0.81	(0.55, 1.19)	1.10	(0.75, 1.60)
Social stigma for working with COVID-19 patients	1.20	(0.84, 1.71)	1.13	(0.80, 1.60)
Patient prioritization	5.59	(2.47, 12.63)	1.45	(0.64, 3.26)
Social support from colleagues	1.45	(0.88, 2.41)	1.17	(0.75, 1.85)

Conclusions: A significant portion of HCWs may seek psychological support post-pandemic, regardless of prior workplace or COVID-19 stressors. Targeted mental health initiatives are crucial, emphasizing health promotion, primary prevention, and support for individuals, including those with depressive symptoms.

Case study of previously healthy 52 years old woman after COVID – 19 infections

I. Ljutica[1]*, Z. B. Otasevic[2] and D. Otasevic[2]

[1]Psychiatric Clinic, Clinical Center of Montenegro and [2]Dusa, psychiatric branch, Filipovic outpatients clinic, Pogorica, Montenegro
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1272

Introduction: Stressful events are important causes of numerous psychiatric disorders, including anxiety disorders, depression and other psychiatric disorders.
The COVID-19 pandemic affects individuals and then all segments of society, and has threatened both physical and mental health.
We have noticed increasing number of the new patients seeking psychiatric help in period after COVID - 19 infections.
Also, tremendously increasing number of sick days.
Objectives: In this case study, we described a 52-year-old female patient. She is a psychologist, an employee in High school in Podgorica working with students.She has achieved 25 years of work experience.She is divorced, has one child. She has never asked for psychiatric help before Sars Covid-19 infection.
She faced first symptoms in terms of bad mood, withdrawal from social contacts, fear, insomnia, problems with attention and concentration. Those symptoms appeared after COVID -19 infections. The patient was hospitalized at the Psychiatry Clinic due to persistent symptoms Admission was due to organic personality changes of the anxious-depressive type, which occasionally reach the level of psychosis. She was absent from the work more than a year.
Methods: Case study
Results: During hospitalization, the patient was treated with anxiolytics, antidepressants and small dosses of antipsychotics medicine. Her general condition improved after month spent in hospital. She received supportive psychotherapeutic support on a daily basis. She participated in occupational therapy.
A CT scan of the endocranium was normal.
The patient still taking prescribed therapy and regularly attends psychiatrics checks - ups.
She went back to a work after two months.
Conclusions: Based on our daily work with patients, we came to the conclusion that sars covid-19 infection has led to a significant increase in mental health symptoms among the population in Montenegro. This problem must not be ignored"You don't need to fear anything in life, you just need to understand each other." Now is the time to understand more so that we would fear less" – Marie Currie

Features of affective disorders of the depressive spectrum after COVID-19 in patients with a history of mental disturbances

N. O. Maruta[1]*, V. Y. Fedchenko[1], T. V. Panko[1], I. O. Yavdak[1] and O. E. Semikina[1]

[1]Borderline Psychiatry, "Institute of Neurology, Psychiatry and Narcology named after P.V. Voloshyn of NAMS of Ukraine" SI, Kharkiv, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1273

Introduction: The structure of clinical manifestations in patients with a history of mental disturbances who suffered from COVID-19 and were exposed to the stressors of the SARS-CoV-2 pandemic is characterized by the predominance of affective disorders of the anxiety-depressive spectrum.
Objectives: To investigate the structure of affective disorders of the depressive spectrum after COVID-19 in patients with a history of mental disturbances by nosological groups.
Methods: 95 patients with a history of mental disorders who have experienced COVID-19 were examined and made up the main group (F 32.0-32.2, 33.1, 33.2 – 31 patients, F 06.3, 06.4 – 33 patients, F 41.1, 41.2, 42.2, 45.3, 48.0 – 31 patients). During the study, a thorough analysis of the anamnesis of the disease was carried out, including information about the experienced coronavirus disease COVID-19. Clinical-psychopathological, clinical-amnestic, psychometric (the Montgomery-Asberg Depression Rating Scale (MADRS)) and methods of statistical analysis were applied.
Results: According to the results of the psychodiagnostic study, the features of affective disorders of the depressive spectrum of various degrees of severity were established, which had certain differences according to nosological groups. Patients with depressive disorders have depressive disturbances in the form of sleep impairment (4.48 points, $p = 0.0001$), manifestations of sadness (4.27 points, $p \leq 0.021$), internal tension (3.95 points, $p = 0.01$), difficulties in experiencing feelings (3.87 points, $p \leq 0.019$), concentration difficulties (3.85 points, $p = 0.031$), appetite disturbances (3.11 points, $p \leq 0.012$), manifestations of fatigue (3.06 points, $p = 0.027$), pessimistic (2.78 points, $p \leq 0.026$) and suicidal thoughts (1.67 points, $p = 0.038$). Patients with mental disorders of organic genesis are characterized by depressive disturbances in the form of a feeling of fatigue (4.18 points, $p \leq 0.021$), significant concentration difficulties (4.16 points, $p = 0.024$), sleep deterioration (3.87 points, $p = 0.018$), feeling and expressing sadness (3.16 points and 3.49 points, respectively), difficulties in experiencing feelings (2.43 points, $p = 0.035$). Patients with neurotic, stress-related and somatoform disorders are characterized by depressive manifestations in the form of expression of sadness (4.78 points, $p = 0.034$), feeling of internal tension (3.67 points, $p = 0.027$), concentration difficulties ((2 .68 ± 0.29) points).
Conclusions: The results of the study of the structure of affective disorders of the depressive spectrum after COVID-19 in patients with a history of mental disturbances should be used as targets for effective therapeutic influence.

Disclosure of Interest: None Declared

EPV0543

Peculiarities of the course of mental disorders after the coronavirus disease COVID-19 in patients with a history of mental disturbances

N. O. Maruta[1]* and V. Y. Fedchenko[1]

[1]Borderline Psychiatry, "Institute of Neurology, Psychiatry and Narcology named after P.V. Voloshyn of NAMS of Ukraine" SI, Kharkiv, Ukraine
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1274

Introduction: The psychopathological consequences of the complex impact of the coronavirus disease COVID-19 become the basis for the deterioration of the mental state of persons with a history of mental disturbances.

Objectives: To investigate the impact of the clinical and psychopathological consequences of COVID-19 on the course of mental disorders in patients with a history of mental disturbances.
Methods: 95 patients with a history of mental disorders who have experienced COVID-19 were examined and made up the main group (F 32.0-32.2, 33.1, 33.2 – 31 patients, F 06.3, 06.4 – 33 patients, F 41.1, 41.2, 42.2, 45.3, 48.0 – 31 patients). The comparison group included patients with 3 or more episodes of mental disorders in the anamnesis, including the current one. Clinical-psychopathological, clinical-amnestic, psychometric (the Clinical Global Impression Scale (CGI)) and methods of statistical analysis were applied.
Results: A comparison of the course dynamics of current mental disorders after COVID-19 and previous mental disturbances in the anamnesis of the studied patients was carried out according to the indicators of the duration and severity of mental disorders, as well as the duration of the remission that preceded them. The duration of current mental disorders after COVID-19 in the examined patients in most cases ranged from 2 weeks to 6 months (46.32% of persons); duration of remission preceding mental disorders after COVID-19 – from 6 to 12 months (47.37% of persons); the initial degree of severity of psychopathological manifestations according to the CGI-S scale – as "moderate disorder" (36.84% of persons). In comparison with the duration of remission preceding mental disorders in the anamnesis, it was found that in significantly more patients, the duration of remission preceding COVID-19 corresponds to the shortest interval from 6 to 12 months ($p < 0.05$). When comparing with the severity of mental disorders preceding COVID-19, it was established that a "pronounced disorder" was detected in significantly more patients after COVID-19 ($p < 0.05$). In comparison with the duration of mental disorders preceding COVID-19, no significantly difference was found, however, when comparing indicators of minimum duration from 2 weeks to 6 months (46.32% of cases with current and 58.18% with previous disorders), the reliability indicator was $p = 0.0510$.
Conclusions: The obtained data indirectly confirm the complex impact of the SARS-CoV-2 pandemic on the formation and exacerbation of mental disorders, indicate a tendency to increase the severity of mental disorders as a result of the coronavirus disease, and also give reason to put forward a hypothesis about an increase in the duration of mental disorders after COVID-19, which is likely will appear on samples with a larger number of observations.

doi: 10.1192/j.eurpsy.2025.1275

Introduction: In this study, the scale's psychometric properties are estimated among South African high school learners during a period of the coronavirus-19 crisis. The study was a cross-sectional design. The data were collected from 1603 high school learners in four South African districts. The PHQ-4 was administered for data collection, and was anchored from 0 (not at all) to 3 (nearly every day) over a two-week period, with higher scores indicating the extent of symptom severity (Kroenke et al., 2009).
Objectives: The study sought to validate the PHQ-4 among South African school learners in various South African districts, and tested a model that included the PHQ-4 to investigate the obtaned factor structure's usefulness.
Methods: Useful questionnaires were collected from 1562 high school learners within a cross-sectional design. Grades 10 to 12 learners completed the PHQ-4 from March to May 2022.
Results: Confirmatory Factor Analysis (CFA) was conducted to validate the factor structure of the scale. CFA results show that all PHQ-4 items load onto a single factor. The factor structure reported in this study is unique. Whilst the PHQ-4 is commonly considered to measure anxiety and depression, the results suggest that the scale measures a unidimensional, psychological distress factor among the learners. The total score of the PHQ-4, characterized as psychological distress, could be predicated by associated factors, although the coefficients obtained were statistically significant but weak. The PHQ-4 was predicted by the Perceived Vulnerability and the Germ Aversion subscales but not the Fear of COVID-19 scale in girls. But the PHQ-4 was predicted by the Fear of COVID-19 scale and not the Perceived Vulnerability and the Germ Aversion subscales among boys.
Conclusions: Contrary to existing studies, the PHQ-4 did not consist of 2 factors. Evidence from the current study suggests that it should be used as a unidimensional, single factor scale. The PHQ-4 total scores of girls and boys were predicted by different factors, suggesting that gender should be considered an important factor when using the PHQ-4 in reseaerch.

Exploring factors influencing depression among Polish nurses during the COVID-19 pandemic

K. Rachubińska[1]*, A. M. Cybulska[1], E. Grochans[1], M. Stanisławska[1] and D. Schneider-Matyka[1]

[1]Department of Nursing, Pomeranian Medical University, Szczecin, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1276

Introduction: The COVID-19 pandemic has been recognized as an international public health emergency.
Objectives: The aim of our study was to identify contributors to nurses' depression.
Methods: This survey-based study was conducted in the Pomeranian Medical University Hospital no. 1 in Szczecin and involved 207 nurses. The following standardized research instruments were applied: the World Assumptions Scale, the Athens Insomnia Scale, the Impact of Event Scale - Revised, the Patient Health Questionnaire-9, the Generalized Anxiety Disorder, the Perceived Stress Scale, and a questionnaire of our own authorship.
Results: The study showed that 72.95% of the subjects experienced severe stress, and 40.58% sufferred from insomnia. In addition, 65.7% of the respondents had anxiety symptoms of varying degrees of severity, and 62.8% had depressive symptoms of mild to severe

severity. The mean score on the IES-R scale, reflecting a psychological impact of the COVID-19 pandemic, was 34.25 points.

Table 1. Influence of insomnia by AIS, anxiety by GAD-7, stress by PSS-10, World Assumptions Scale on the prevalence of depressive symptoms among nurses according to PHQ-9 (Model 1,2,3)
b - regression coefficient, βstand. - standardized regression coefficient, CI - confidence interval, ref - AIS reference level, Athens Insomnia Scale, GAD-7, generalized anxiety disorder; IES-R, Impact of Event Scale - Revised ; PSS-10, The Perceived Stress Scale; WAS, The World Assumptions Scale

Model	factor	b	$\beta_{stand.}$	-95% CI	+95% CI	p
Model 1	AIS (insomnia vs no insomnia)	1.571	0.250	0.155	0.344	0.000
	GAD-7 (total)	0.613	0.535	0.426	0.643	0.000
Model 2	AIS(insomnia vs no insomnia)	1.471	0.234	0.139	0.329	0.000
	GAD-7 (total)	0.600	0.524	0.416	0.632	0.000
	PSS-10 (steny)	0.402	0.101	0.001	0.200	0.047
Model 3	AIS((insomnia vs no insomnia)	1.536	0.244	0.148	0.340	0.000
	GAD-7 (total)	0.616	0.537	0.428	0.646	0.000
	PSS-10 (steny)	0.442	0.111	0.011	0.211	0.029

Conclusions: The COVID-19 pandemic affected the psychological health of medical staff, particularly through increased stress and anxiety symptoms. Anxiety levels and insomnia significantly affect the prevalence of depression among nurses.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1277

Introduction: Since the start of the pandemic, healthcare workers (HCWs) have faced a range of infectious and psychosocial risks. Contracting SARS-CoV-2 has impacted their physical, mental, and emotional well-being, with sleep also likely being affected.
Objectives: Our study aims to assess the impact of SARS-CoV2 infection on sleep quality in HCWs.
Methods: We conducted a descriptive cross-sectional study among staff at Sfax University Hospital who were infected with SARS-CoV-2 between October 2020 and June 2021, during post-COVID follow-up consultations. A questionnaire was utilized, with the medical section completed by a physician to assess sociodemographic, professional, and clinical characteristics of the infection. A self-administered section evaluated the impact of the infection on sleep quality using the Insomnia Severity Index (ISI).
Results: Our study included 200 healthcare workers with an average age of 42.97 years. Nurses comprised 53.5% of the sample, and 41% of the participants were involved in the care of patients with SARS-CoV-2. Workplace infections accounted for 39% of the cases. At the post-COVID follow-up consultation, 83% reported persistent symptoms. According to the Insomnia Severity Index (ISI), 47.5% had no sleep disturbances, 3.5% had mild insomnia, 26% had moderate insomnia, and 8% had severe insomnia. Additionally, 38% of the staff were dissatisfied with their sleep quality following their SARS-CoV-2 infection.
Conclusions: SARS-CoV-2 infection impacts the sleep of healthcare workers, highlighting the need for strategies to improve sleep quality. Addressing these issues is crucial for maintaining staff well-being and ensuring the quality of care provided.

Psychological Growth and Post-Pandemic Stress Among Healthcare Professionals: Challenges and Opportunities

M. Theodoratou[1]*, I. Skondra[1], C. Dafogianni[2], P. Andriopoulou[3], E. Denazi[4], V. Yotsidi[5] and A. Kalaitzaki[6]
[1]Social Sciences, Hellenic Open University, Patras; [2]Nursing, University of West Attica, Athens; [3]Psychology, University of Ioannina, Ioannina; [4]Psychology, University of Athens; [5]Psychology, Panteion University, Athens and [6]Social Work, Hellenic Mediterranean University, Herakleion, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1278

Introduction: The COVID-19 pandemic placed an unprecedented burden on healthcare workers worldwide, particularly those in primary care settings, who faced both physical and emotional challenges.
Objectives: The study aimed to assess the levels of psychological distress and anxiety, and the coping strategies among healthcare workers after the COVID-19 pandemic. It also examined changes in professional quality of life and the broader impact on personal life during the post-pandemic period.
Methods: A cross-sectional study was conducted on a sample of 100 healthcare workers from various primary care centers in Patras,Greece.The following validated psychometric instruments were used:

- Secondary Traumatic Stress Scale (STSS): assessing symptoms of secondary traumatic stress, reflecting the emotional impact of indirect exposure to trauma through patient care.
- Quality of Professional Life Scale (5th edition): assessing both the positive (compassion satisfaction) and negative (burnout, secondary traumatic stress) dimensions of professional life.
- Posttraumatic Growth Inventory (PTGI): measuring positive psychological changes and personal growth experienced as a result of coping with pandemic stressors.
- Brief-COPE Scale: identifying coping strategies used by nurses, distinguishing between adaptive and maladaptive mechanisms.

Results: The results of the study indicate a persistent and significant psychological distress among caregivers in the post-pandemic context of 2024. The STSS scores revealed elevated levels of secondary

traumatic stress, underscoring the enduring emotional impact of the pandemic on healthcare workers. As demonstrated by the Quality of Professional Life Scale, a divergence in outcomes was observed. While a subset of nurses reported elevated levels of compassion satisfaction, a considerable proportion continued to exhibit high levels of burnout and secondary traumatic stress. This finding suggests that the adverse impact of the pandemic on professional well-being persists. The PTGI results revealed that some HCW experienced post-traumatic growth, suggesting the potential for positive psychological development despite the challenges encountered. Analysis of the Brief-COPE Scale depicted a diverse range of coping strategies, with evidence of both adaptive coping mechanisms, such as problem-focused strategies, and less adaptive responses, including avoidance behaviors.
Conclusions: In conclusion, the results emphasize the persistent psychological impact of the ongoing pandemic on healthcare professionals, even in the post-pandemic era. These findings underscore the necessity for the provision of sustained psychological assistance and interventions that are specifically designed to address post-pandemic stressors, with the aim of ensuring the long-term well-being of healthcare workers.

Fear of COVID-19 and Its Relationship with eHealth Literacy: Impact on Mental Health and the Role of Personal Infection Experience

M. Theodoratou[1,2]*, K. Deligianni[3], K. Flora[4], K. Megari[5] and G. Tsitsas[6]

[1]Social Sciences, Hellenic Open University, Patras, Greece; [2]Psychology, Neapolis University of Pafos, Pafos, Cyprus; [3]Hellenic Open University, Patras; [4]Psychology, University of West Macedonia, Florina; [5]Psychology, Aristotelian University of Thessaloniki, Thessaloniki and [6]Psychology, Harokopeion University, Athens, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1279

Introduction: The advent of the Coronavirus Disease 2019 (Covid-19) pandemic in late 2019 precipitated a profound transformation in the daily lives of individuals across the world, with notable implications for global mental health. The fear of the virus became a significant source of anxiety and stress, compounded by the rapid dissemination of information, both accurate and inaccurate, through digital media. The growing reliance on digital platforms for health information during the pandemic underscored the significance of eHealth literacy, which pertains to the capacity to locate, comprehend, and utilize health data from digital sources. As reliance on digital platforms for health information increased, it became imperative to examine the potential impact of digital health literacy on fear and anxiety levels related to the novel coronavirus disease (2019-nCoV), also known as Coronavirus Disease 2019 (Covid-19).
Objectives: The objective of this study is to examine the relationship between fear of the Coronavirus disease 2019 (Covid-19) pandemic and mental health, while investigating the influence of eHealth literacy on these fears.
Methods: The study was conducted on a sample of 158 individuals from the general population, representing a diverse range of demographic characteristics. The data were collected using a structured questionnaire comprising three sections: demographic information, the Fear of Coronavirus Scale (FCV-19S), and the eHealth Literacy Scale (eHeals). A statistical analysis was conducted to investigate the relationships between demographic factors, levels of fear, and eHealth literacy. Additionally, a comparative analysis was performed to assess the differences between individuals who had and had not contracted the virus.
Results: The analysis revealed no statistically significant differences in the levels of fear regarding the novel coronavirus disease (Covid-19) or eHealth literacy between different demographic groups, including gender, age, education, and health status. Nevertheless, a statistically significant discrepancy was observed in the level of fear between individuals who had contracted the virus and those who had not. Specifically, those who had not been infected exhibited higher levels of fear compared to those who had previously contracted the virus. No significant differences were identified in eHealth literacy based on infection status.
Conclusions: In conclusion, the findings of this study indicate that while demographic factors do not appear to influence the level of fear or digital health literacy, personal experience with a confirmed case of infection does. Those who have not contracted the virus tend to experience greater fear, suggesting that familiarity with the disease may reduce anxiety. These findings underscore the necessity for interventions.

Determinants of Deliberate COVID-19 Spread: Exploring Psychological, Social, and Environmental Factors Behind Virus-Spreading Behaviors During a Pandemic in Saudi Arabia

S. Alsubaie[1]* and H. Alshahrani[2]

[1]Psychiatry, AFHSR, Khamees Mushait and [2]Psychiatry, SCHS, Abha, Saudi Arabia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1280

Introduction: While most individuals adhere to preventive measures during pandemics, a subset engages in behaviors that may intentionally spread COVID-19, presenting unique challenges to public health efforts.
Objectives: This study explores the psychological, social, and environmental factors influencing deliberate virus-spreading behavior in the Saudi Arabian population during the initial phase of the COVID-19 pandemic.
Methods: A cross-sectional online survey was conducted between April 3 and May 5, 2020, with 1,817 participants. The survey collected demographic information and variables related to virus-spreading inclinations. Descriptive statistics and Pearson's chi-squared tests were used to analyze associations between deliberate virus-spreading behavior and various characteristics, with statistical significance set at $p < 0.05$.
Results: Individuals who intentionally spread the virus (2% of the sample) were younger (mean age 22.9 vs. 29.3 years, $p < 0.001$),

predominantly female (81.1% vs. 65.6%, p = 0.033), and more likely to have a history of mental health issues (24.3% vs. 8.5%, p < 0.001) and conspiracy beliefs (45.9% vs. 26.2%, p = 0.003) compared to those who did not engage in virus-spreading behaviors. No significant differences were found regarding marital status, education level, or traumatic life events.
Conclusions: This study highlights key factors associated with intentional virus-spreading behaviors, such as younger age, mental health history, and conspiracy beliefs, underscoring the need for integrated mental health support and targeted misinformation interventions. Public health strategies should include age-appropriate messaging and digital outreach to mitigate the risks posed by intentional spread behaviors and enhance pandemic response efforts. Further research with larger, more diverse samples is recommended to expand understanding and improve intervention strategies

Reducing inequalities in Mental Health Services - how to be more culturally sensitive in a culturally diverse world?

M. Andrade[1]*, F. Ramalheira[1] and M. Magalhães[1]

[1]Hospital Júlio de Matos - Unidade Local de Saúde São José, Lisbon, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1281

Introduction: As psychiatrists, we provide care to patients from diverse cultural backgrounds, whose mental health is often affected by migratory trajectories and post-migration factors in the destination country, such as exposure to adversities and inequalities in access to healthcare. Moreover, culture plays a significant role in the presentation of symptoms and influences explanatory models of illness, health objectives, resources mobilized, and treatment styles. Thus, the social determinants of health are often distinct from those of the community of origin.
Objectives: The development of culturally sensitive and adapted services becomes essential to reduce healthcare inequalities. We intend to review the concept of cultural diversity and explore various models studied for intervening in mental health care in culturally diverse communities.
Methods: Narrative literature review through bibliographic research and publications in the Pubmed and Google Scholar databases, using the terms “cultural psychiatry,” “cultural competence,” and “migration.”
Results: Some barriers to healthcare access for the migrant population include ethnolinguistic barriers, stigma, resilience and minimization of symptoms and complaints, and issues related to accessibility and service costs. On the other hand, healthcare professionals also identify bureaucratic issues and report a lack of knowledge regarding different cultural practices, showing interest in obtaining more training in the area. Some strategies to adapt mental health services to cultural diversity include health literacy, “ethnic matching” techniques, interpreter and cultural mediator training, and building cultural competence for both healthcare professionals, institutions and healthcare systems. Cultural formulation uses specific tools to gather clinical information and cultural context, showing positive preliminary results.
Conclusions: Cultural competence represents a comprehensive response to the needs of migrant and culturally diverse population, requiring the acquisition of knowledge and skills at both the individual and organizational levels. Investing in training and research on cultural competence will further enhance the effectiveness and accessibility of mental health care, contributing to the reduction of inequalities and better health outcomes.

When transgenerational trauma meets family secrets : a case study in the Tunisian population

I. Ben Salem Planchaud[1]* and M. Ben Hmida[2]

[1]Centre municipal de santé, Saint Fargeau Ponthierry and [2]Psychology, Université d’Angers, Angers, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1282

Introduction: More than any other field in medicine, psychiatry is marked by an individual’s life experiences and the cultural context surrounding them. When a patient presents a set of somatic and seemingly unrelated symptoms that can’t be explained by an underlying physical condition, the diagnosis can become challenging. However, when these symptoms are seen through the lense of their particular cultural context and their traumatic family history, these manifestations start to make sense.
Objectives: This paper aims to examine the relationship between transgenerational trauma and somatic manifestations without an underlying physical condition in an adult female partient N.
Methods: In order to investigate the psychological functioning of the patient N, we conducted a semi-structured interview followed by a set of psychological tests. We administered the Draw-a-Family Picture Test, the Rorschach Test and the Thematic Apperception Test (TAT). We also analysed the patient’s diary entries.
Results: N initially came to us with unexplained somatic symptoms and a generally depressive mood, finding it difficult to discuss certain topics like her sexual issues. The various elements we have collected through the tests and the interviews with the patient N have shed light on an event that occured within the father’s family, an incestuous rape. This event was the cause of the family’s breakdown, and we believe that the depressive symptoms, suicide attempts, as well as the incestuous atmosphere related to the patient N and her family are connected to this event and have continued to be unconsciously transmitted across generations.
Conclusions: This case study showed the importance of taking family history and cultural context into consideration when examining psychological functioning. Family secrets and seemingly unrelated past events can cause a transgenerational trauma affecting the descendants mental and physical health.

Social integration and satisfaction in medical studies among foreign students in Tunisia

N. Bouattour[1]*, F. Guermazi[1], M. Lalaoui Rhali[1], N. Regaieg[1], I. Baâti[1] and J. Masmoudi[1]

[1]Psychiatry A, Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1283

Introduction: Foreign students are confronted to the multiple obstacles along their university studies. These obstacles can be related to the nature of the medical studies, the diversity and dense quantity of the subjects, and also to the interaction of the students with their colleges, their patients and the paramedical staff during the training. Psychological distress can, also affect the process of integration in society.
Objectives: To assess the factors influencing the social integration and the satisfaction of the foreign students in the faculty of medicine in Sfax-Tunisia.
Methods: We conducted a cross-sectional, descriptive and analytical study, carried out between July and September 2023 among foreign students at the Sfax Faculty of Medicine, via an anonymous self- questionnaire via "Google Forms shared via social media. Social integration was evaluated via the French version of the need to belong scale by Richer and Vallerand. The satisfaction of the medical studies was evaluated using the scale of satisfaction of studies by Vallerand and Bissonnette. Psychological distress was assessed using the "DASS-21" Depression, Anxiety and Stress Scale.
Results: Seventy-two foreign medical students completed the survey. The average age was 25 ± 3.45 years. Males represented 57% of the total participants. The majority of the participants were north Africans 87.5% (Moroccan: 68.05%, Mauritanian: 18.05% and Algerian 1.4%). The majority of respondents were single (77.8%). Sixty-one percent were enrolled in the third cycle of medical studies, 26.5% were enrolled in the second cycle of medical studies and 12.5% were enrolled in the first cycle of medical studies. The average length of stay in Tunisia was 6.5 years. Seventy-seven percent were satisfied with the choice of Tunisia for the medical studies. The male gender was statistically associated to the feeling of a better social integration (p=0.045). In addition, social integration was statistically associated to satisfaction in medical studies (p=0.004, r=0.034) and to academic performance (p=0.008). We found no statistical association between the level of the students nor the length of the stay in Tunisia. We found no statistical association between social integration and psychological distress.
Conclusions: The feeling of being an integral part of the social community can help alleviate the stress of adjusting to a new environment and improve emotional well-being, which can positively influence the learning experience and satisfaction of these foreign students.

Socio-cultural and personal profile of international medical students in Tunisia

N. Bouattour[1]*, F. Guermazi[1], M. Lalaoui Rhali[1], R. Masmoudi[1], I. Baâti[1] and J. Masmoudi[1]

[1]Psychiatry A, Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1284

Introduction: Foreign medical students in Tunisia represent a dynamic academic community, making an essential contribution to the global medical training. Their presence creates a vibrant academic ecosystem, conducive to discovery, intercultural exchange and medical innovation.
Objectives: To determine the socio-cultural and the personal profile of foreign medical students, in order to optimize their academic performance and facilitate access to a high-quality professional training.
Methods: We conducted a cross-sectional, descriptive and analytical study, from July to September 2023 among foreign students at the Sfax Faculty of Medicine via an anonymous self-questionnaire via "Google Forms" shared among students through social media. We used scale of satisfaction in studies, which is a 5-item scale, each rated on a 7-point Likert scale indicating the degree of agreement or disagreement with the statements.
Results: Seventy-two foreign student completed the survey. The average age was 25 ± 3.45 years. Students of Moroccan origin accounted 68.1%. The socioeconomic status was average in 93.1%. The majority of respondents were single (77.8%). One-third of the students lived with a roommate. Fifty-one per cent of the students had at least one family member in the healthcare field. Of those surveyed, 61.1% were enrolled in the third cycle of medical studies, 26.5% were enrolled in the second cycle of medical studies and 12.5% were enrolled in the first cycle of medical studies. The average length of stay in Tunisia was 6.5 years. Seventy-seven percent were satisfied with the choice of Tunisia for the medical studies. Seventy-nine percent of the students were satisfied with their academic performance. Coffee was the most consumed substance (88.9%) followed by tobacco (47.2%), alcohol (36.1%) and illicit drugs (26.7%). Fifty-nine percent (N=41) practiced sports and 16.7% had an artistic leisure activity. We found a statistical association between satisfaction and the practice of a leisure activity (p=0.007) and a statistical negative association with having a family member in the healthcare field (p=0.022). We found no statistical association with the choice of Tunisia as a destination even though the mean score was higher among the students that was satisfied with their choice. The quality of the studies in Tunisia as well as the geographic localization were the main reasons for choosing Tunisia No statistically significant association was found with gender, socioeconomic status or marital status, substance consumption.
Conclusions: The medical field studies are still challenging for students in general due heavy learning process and training process adding to that the personnel, cultural changes that a foreign student can face. Highlighting these aspects can contribute to improving their experience, by focusing on the learning process as well as making time to practice their leisure activities in order to break the routine.

EPV0561

Influence of strength of motivation for medical studies among foreign students

N. Bouattour[1]*, F. Guermazi[1], R. Jbir[1], F. Cherif[1], M. Lalaoui Rhali[1], R. Masmoudi[1] and J. Masmoudi[1]

[1]Psychiatry A, Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1285

Introduction: The process of successfully joining medical schools, represents an important event for each student globally. The transition from one year to another needs much effort, sacrifice and perseverance in order to obtain the final goal of being a practitioner.
Objectives: To assess the strength of motivation for medical studies in foreign students.
Methods: We conducted a cross-sectional, descriptive and analytical study, carried out between July and September 2023 among foreign students at the Sfax Faculty of Medicine. Data collection was carried out using an anonymous self-questionnaire via "Google Forms shared among students via social media. We used the strength of motivation for medical school "SMMS" in its French validated version.
Results: Seventy-two foreign medical students completed the survey. The average age was 25 ± 3.45 years. Males represented 57% of the total participants. The majority of respondents were single (77.8%). Sixty-one percent were enrolled in the third cycle of medical studies, 26.5% were enrolled in the second cycle of medical studies and 12.5% were enrolled in the first cycle of medical studies. Of those surveyed, 83.3% had chosen medical studies as their first choice. For 59.7% of students, this choice was their own. The mean score for the motivational strength questionnaire was 42.4, as for the sacrifice dimension 14.6, for the start-up readiness 13.7, and 11.02 for the perseverance dimension. The mean score for the strength of motivation for medical studies was significantly lower in students enrolled in second cycle of medical studies (p=0.043) and in those who did not have their own choice of medical studies (p=0.037). We found no statistical association between the strength of motivation and having a family member in the medical field.
Conclusions: Motivation is a crucial aspect of the academic life of international medical students, shaping their learning path and overall experience. These students, often driven by dreams of a medical career, face obstacles linked primarily to adapting to a new educational system. The motivating strength that drives them to embark on and pursue medical training may be fueled by the desire to acquire clinical skills that will contribute to the provision of healthcare in their home countries.

EPV0562

The misdiagnose of psychosis and its implications in some cultures. The experience of Doctors Without Borders (MSF) in South Sudan and Chad

C. Carreño Glaria[1]

[1]Medecins Sans Frontièrs, Barcelona, Spain
doi: 10.1192/j.eurpsy.2025.1286

Introduction: In certain cultures psychological suffering is expressed with more somatic symptoms. Besides, they tend to describe more often hallucinations and other forms of perception problems.
Objectives: To describe and warn about the risks of misdiagnose when culture is not an element considered in the diagnosis.
Methods: Descriptive methodology based on practice and observation.
Results: In the last year MSF has been working in more than 40 countries such as South Sudan and Chad with local and refugee populations. The teams have provided treatment to people with anxiety, trauma related and depressive disorders. However, we have also treated many people with hallucinations in the context of trauma, forced displacement. Several patients presented sudden, abrupt symptoms such as fear, insomnia, anxiety, and hallucinations. These hallucinations are often related to the potential traumatic event, to the witness of violence or displacement. When it appears accompanied by flashbacks, hypervigilance, and other PTSD symptoms it may be considered as PTSD with psychotic like symptoms. But other times these hallucinations seem to be more linked to a depressive episode or adjustment disorder. We have witness several cultures where hallucinations are very common during grief processes. The main risks of a misdiagnose of psychosis is the mistreatment.
On another note, it is known that migrant and refugee status are associated with a higher prevalence of psychosis. Using the cultural lenses, should we question these findings? Is there maybe a bias or misdiagnosis in some of these research?
Conclusions: Not all people with sensory perceptual alterations can be diagnosed with psychosis. A proper diagnose that is adapted to the culture of the person is essential for a good quality treatment.

Disclosure of Interest: None Declared

EPV0563

Psychoprophylaxis, art therapy, occupational and play therapy in neuropsychiatrical recovery and rehabilitation center

E. Chirila[1]

[1]NEUROPSYCHIATRICAL RECOVERY AND REHABILITATION CENTER, CLUJ COUNTY COUNCIL GENERAL DIRECTORATE OF SOCIAL ASSISTANCE AND CHILD PROTECTION COUNTY COMMUNITY CENTER, JUCU, Romania
doi: 10.1192/j.eurpsy.2025.1287

Introduction: Many beneficiaries are stuck and find it difficult to act creatively because they are used to being in a different place than where they are at that moment:
they lose their balance and the ability to move in harmony with the forces of the environment which, in the end, will support the expression.
They expect something different from what they are doing at that moment or they think that what they are doing is inadequate; they get stuck, they get caught in negative and confused thoughts.

Objectives: Even if a finished object or image is obtained, the research pursues, first of all, the way and the extent to which the creative process and execution of the artifact contributes to the improvement or healing of the studied beneficiaries. Correlative objective being the increase of their quality of life and their socio-professional integration. In assessing the motor functions of the beneficiaries, it is essential that the emphasis is placed on the outstanding and hidden motor abilities of each individual.The aim is to improve: coordination disorders, spatialization disorders, fine motor skills, sensoriality, creativity, socialization.
Methods: ORGANIZATION OF ACTIVITIES is done in three types of workshops, with different objectives and interventions,

- Occupational therapy workshop in the category that includes art therapy.
- Occupational therapy
- Relaxation, play therapy

CASE STUDY: Placement center Jucu PA, sex M, 16 years old.
Diagnosis: Secular infantile encephalopathy, behavioral disorders

- heteroaggressiveness, severe mental retardation, alalia.
- Uses modeling for self-expression and self-fulfillment. During work, he is not aggressive and relates to people who appreciate his work.

An advanced level is observed in modeling, even compared to normal people. Spatial abstract compositions from plasticine, expressive and balanced, are made at the beginning, the evolution is observed in the modeling of the figures (he starts to model personalized human figures), which he pairs chromatically, groups them into dancing figures, or groups them affectively and vertically. He also showed changes in his behavior: he smiled while working, clapped and recognized us when we entered the workshop, wanted to be photographed and petted (although normally he can't stand being touched). He showed interest in the camera and in the modeling works of other children from Placement center.
Results: Work in visual arts and design therapies aims to create a product. The benefits arise from experiences based on artistic creativity: materializing ideas and solving unexpected results.

From therapeutic to aesthetic value in education/art/occupational therapy: creative potential and tactile value

E. Chirila[1]

[1]omplex de Servicii Sociale Comunitare Pentru Copii și Adulți, CONSILIUL JUDEȚEAN CLUJ DIRECȚIA GENERALĂ DE ASISTENȚĂ SOCIALĂ ȘI PROTECȚIA COPILULUI CENTRUL COMUNITAR JUDEȚEAN, Cluj-Napoca, Romania
doi: 10.1192/j.eurpsy.2025.1288

Introduction: Fingerprints multiply man in space and time. Educating man with his hand, he learns how to master spatial extent, weight, density, proportion, organizes the activity in order to experience the action. The beneficiary creates a unique universe in which he leaves his mark everywhere. Ergonomics is considered as the "science of work", having the "man-work" relationship as its object of study. In art therapy, occupational and play therapy, which is based on traditional aesthetics, we talk about "sublimation". (ChirilăE & Câmpean & Drăgan-Chirilă.D, 2021- 10-13 April)

Objectives: By means specific to the visual arts, hidden, overdue individual skills are detected, which bring the beneficiary closer to normality, to real life. We can observe that all things in nature are shapes modeled in volumes made up of fillings and voids, which constantly transform the appearance of the world. All these angles are synthesized in the brain, in order to understand the three-dimensionality of the environment as a unitary whole. This happens when we are in a position to be aware, actively, of the deep relationships that the environment implies, in general.

Methods: Tactile value is the origin of any act of creation, the hand removes the sense of touch from receptive passivity. The evaluation of fine and gross motor skills is done by modeling, we use the sense of touch, we follow the use of hands during creation. In the testing activities through product analysis we use the visual language, that of the symbolic language of anthropomorphism. Holistic training is done on the potter's wheel or through 3D multimedia installations. Creating works of art, artefacts, or using arts-based jobs are test activities for art therapy, occupational therapy and ergotherapy, which provide us with information about the author with the help of images and shapes. Each beneficiary can create the images themselves, with which they want interact or can use arts materials and games according to his needs of expression.

Results: These activities allow the beneficiaries to reach a certain level of introspection and to "work through" their problems in a constructive manner. The activities can be approached in several distinct groups of people, who can be qualified in different artistic professions such as: visual artist, decorator, designer, they can practice adaptive-"raw arts". (Chirila, E 2011, PhD Thesis p 398)

Image 1:

Image 2:

Image 3:

Conclusions: The foundations are laid for an occupational therapy workshop for adults with special needs. In these types of activities, the beneficiaries who do not have artistic skills can learn useful skills for CES persons, who, to pursue a productive goal like "Work for the disabled". (Chirila, E 2018 p50)

Experiences of ethnic minorities engaging with mental health services during and beyond the pandemic

Y. Fu[1]*, M. Panagioti[2], S. Croke[2] and E. Stepanova[3]

[1]University of Liverpool, Liverpool; [2]University of Manchester, Manchester and [3]University of Newcastle, Newcastle, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1289

Introduction: The pandemic exacerbated existing mental health support disparities faced by ethnic minorities in the UK. Many ethnic minorities entered care through crisis pathways, receiving more severe diagnoses than their white British counterparts. Additionally, they were 40% more likely to access mental health services via the criminal justice system. Despite these challenges, research on their evolving experiences with mental health services remains limited.
Objectives: To explore the interactions between ethnic minorities and mental health services. By understanding their engagement and coping strategies, we aimed to capture how these experiences have impacted their mental health and well-being.
Methods: This study was conducted in Northern England, a region with high mental health needs but limited research activity. In-depth, semi-structured interviews were held with a purposive sample of ethnic minority adults with diverse mental health conditions (ethical approval 22/WS/0164).
Two independent researchers conducted interviews remotely or in person between March and September 2023, with consent confirmed before each interview. The topic guide, co-produced and piloted with an advisory group of ethnic minority individuals, carers, and clinicians, focused on service engagement, support experiences, coping strategies during the pandemic, and suggestions for improvement. Data were analysed using a framework approach, with themes and subthemes categorized in a matrix for each transcript. Two researchers independently double-coded a sample of interviews to ensure validity, with the team and advisory group reviewing and finalizing the analytical framework.
Results: Thirty-two ethnic minority individuals were interviewed, revealing five key themes: barriers to managing mental health; limited engagement with health services; preference for community support; reliance on community support during service interruptions in the pandemic; and the need for service-community collaboration. Cultural stigma often led to fear and reluctance to seek support, and participants struggled with non-culturally sensitive health services. Instead, they preferred community-based support, which persisted during the pandemic despite service disruptions. Participants advocated for collaboration between mental health services and ethnic minority communities to enhance cultural understanding and patient-centred care.
Conclusions: Ethnic minorities with mental health conditions face significant challenges in accessing and engaging with services. Addressing these issues requires integrating culturally sensitive approaches into existing frameworks, achieved through collaborations with ethnic minority communities to better understand their unique contexts. Incorporating cultural considerations into service delivery can enhance engagement and improve outcomes for diverse populations.

Is religion opium for the masses? Role of spirituality in mental health

P. Główczyński[1]*, P. Dębski[1] and K. Badura-Brzoza[1]

[1]Clinical Department of Psychiatry, Faculty of Medical Sciences, Medical University of Silesia, Tarnowskie Góry, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1290

Introduction: The relationship between human mental health and religiosity (or broadly understood spirituality) has been the subject of interest of scientists, including philosophers, for hundreds of years. For centuries, religion has played a key role in shaping people's psychosocial and moral development, both positively and negatively. Spirituality should also not be treated as a practice solely related to attending temples or praying. Certainly, a common feature of all types of spirituality is the search for a deeper meaning that goes beyond the material experience of life.
Objectives: The aim of the study was to analyze available scientific research in terms of the relationship between religiosity, spiritual practices and faith with selected parameters of human mental health.
Methods: The PubMed and Cochrane Library databases were searched for in this analysis. The search phrases used were: "spirituality/religion AND mental health", "spirituality/religion AND depression", "spirituality/religion AND anxiety", "spirituality/religion AND suicide" [Image 1].
Results: The relationship between spiritual practices or religiosity and the occurrence of depressive symptoms is not clear. By far the largest number of analyses was conducted in the United States, where, due to the heterogeneity of society, different beliefs and spirituality are present. Despite the high heterogeneity of studies, a high level of spirituality is usually associated with a lower intensity of anxiety symptoms. Obsessive thoughts are relatively often associated with religious motives. An interesting assumption is the concept that religion as a set of rules and practices that require strict adherence may be the foundation for the development of OCD. Religion may reduce the frequency of fantasizing about death, which is confirmed by studies conducted in various religious populations. Differentiating psychotic symptoms from spiritual experiences may be a significant diagnostic difficulty.

Image 1:

Conclusions: The intensive period of socio-cultural and economic changes has an impact on people's attitudes towards religiosity, their sense of belonging to a religious group, or spirituality in general. As the available analyses show, spirituality can be a protective or burdensome factor, or it can have no impact on a person's mental well-being. The studies available in medical databases show significant heterogeneity in this respect, which makes their direct comparison difficult. Another methodological problem seems to be the assessment of spirituality. We cannot forget about the cultural context in the assessment of societies. An interesting analysis would be to assess the relationship between specific forms of spiritual practice and their intensity with reference to tradition, gender, age, and geographical region. Considering the aspect of spirituality in human life is part of a holistic view in medicine.

Psychological Well-Being, Self-Esteem, and Body Image Satisfaction Among Pregnant Tunisian Women: A Study from Monastir Maternity Department

A. Hadj Salah[1]*, D. Bouhlel[2], I. Batbout[1], A. Haouala[1], M. ben mbarek[1], F. zaafrane[1], A. mhalla[1] and B. amamou[1]

[1]psychiatry and [2]gynecology, Fattouma Bourguiba Hospital, Monastir, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1291

Introduction: Pregnancy induces significant physiological and psychological changes. This study evaluates self-esteem, body image satisfaction, and psychological well-being among pregnant women at Monastir Maternity Center, Tunisia.
Objectives:
1. To assess self-esteem and body image satisfaction among pregnant women.
2. To evaluate the psychological well-being and the adequacy of support provided during pregnancy.

Methods: Conducted over two months (March-April 2022) with 62 participants (88.57% response rate) at Monastir Maternity Center. Self-esteem was measured using the Rosenberg Self-Esteem Scale (RSES), and body image satisfaction was assessed with the Body Image States Scale (BISS). Sociodemographic, obstetric, and psychosocial variables were collected.
Results: The study included 62 participants, with an average age of 31.68 ± 7.49 years. Most participants (62.9%) were stay-at-home individuals, and two-thirds reported their current pregnancy as desired.
Body image satisfaction, measured by the Body Image States Scale, averaged 5.32 ± 3.67, indicating moderate satisfaction.
Self-esteem was low in 79% of participants, while 74.2% had no depressive symptoms and 90.3% had no anxiety symptoms.
Half of the participants (50%) reported their psychological well-being was addressed during pregnancy, with the majority (41.9%) receiving support from family members. Three-quarters (75%) considered pregnancy consultations the best time to discuss psychological issues. Almost all (98.4%) wanted additional psychological support. Over half (56.5%) talked about their pregnancy difficulties with someone, while 22.6% did not address them, and 21.0% did not experience any difficulties.
Conclusions: The study highlights a significant prevalence of low self-esteem and moderate body image satisfaction among pregnant women.. The study also reveals that while many women discuss their difficulties with others, there remains a gap in addressing psychological issues adequately, particularly considering the majority of participants desire more support.

Mental health professional impact of dualistic approach on the biological model of depression

Ž. Kralj[1,2]*, S. Melissa Pranić[3], T. Mastelić[1], T. Borovina Marasović[1], T. Kozina[4] and S. Kozina[5]

[1]Department of Psychiatry, University Hospital of Split; [2]Department of Psychiatry; [3]Department of Public Health, School of Medicine University of Split; [4]Department of Professional Studies, University of Split and [5]Department of Psychological Medicine, School of Medicine University of Split, Split, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1292

Introduction: In psychopathology, a dualistic approach often refers to the conceptual separation of the mind and body as distinct entities, which can influence how mental disorders are classified and diagnosed. This separation may lead to biased judgments and contribute to the stigmatization of mental health conditions. It can also encourage alternative conceptualizations of mental health

disorders and promote new methods of classifying mental health issues beyond traditional biomedical or behavioral frameworks.
Objectives: The goal of our research was to examine the impact of psychiatrists' and psychologists' dualistic perspectives on the biological model of depression using the PLS-SEM model.
Methods: This cross-sectional study carried out in the Republic of Croatia in 2018, involved 238 participants, comprising 122 psychiatrists and 116 psychologists. We applied the Maudsley Attitude Questionnaire to examine the preferences of psychiatrists and psychologists in choosing the biological model of depression. Their dualistic perspectives were assessed using the Stanovich Mind-Body Dualism Scale. In the PLS-SEM modeling, dualism and monism were observed as exogenous latent variables in the model, and their impact on the biological model, which represents the endogenous latent variable, was analyzed. All model indicators are reflective.
Results: Psychiatrists (M = 14.71, SD = 2.27) and psychologists (M = 13.77, SD = 2.69) predominantly support the biological model out of Harlands' 8 models of mental disorders in defining depression. The PLS-SEM initial reflective model is significant ($p = 0.002$) even though the fit indices provided mixed results. The GFI (0.963) and SRMR (0.059) suggested a good or acceptable fit, but the CFI (0.862) and RMSEA (0.095) indicated that the model requires further refinement. The R^2 value revealed that the model explained 61.3% of the variance in the endogenous variables.
Conclusions: Mental health professionals prefer the biological approach in explaining the etiology, classification, research, and treatment of depression. Supporting a dualistic perspective had a significant negative total effect ($p < 0.05$) on the choice of the biological model of depression.

Importance of Religious Understanding in Psychiatric Evaluation: A Case Report of a Palestinian Christian Patient

N. Marzouqa[1]* and N. AlShaikh[1]

[1]Bethlehem Psychiatric Hospital, Bethlehem, Palestinian, State of
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1293

Introduction: Religion plays a big role in daily life in Palestine: it helps give meaning and purpose and creates communities and mutual understanding. Thus, individuals frequently bring up various thoughts and ideas with religious themes and undertones during psychiatric interviews, reflecting their inner and outer experiences. Religious references can be misunderstood when discussed by individuals of religious minorities, such as Palestinian Christians, who comprise around 1% of the Palestinian population in the West Bank (2023 Report on International Religious Freedom). Studies on the mental health of Palestinian minorities are almost nonexistent.
Objectives: Examining the responsibility of psychiatrists to provide culturally sensitive care to their patients, including religious minorities.
Methods: A case report of a Palestinian Christian patient admitted to an acute psychiatric ward in Palestine. This 37-year-old male patient, who has struggled with mental health issues for the past 4 years, presented to Bethlehem Psychiatric Hospital after 10 days of suspiciousness, disturbed behavior, and verbal aggression toward family members. On examination, the patient was found to have a tense elevated mood with persecutory, reference, and grandiose delusions. The patient frequently brought content and references from the liturgy and the New Testament. Blood and urine tests were within normal range and showed no substance use. The patient was started on Olanzapine 15mg and Valproate 400mg.
Results: A review of his hospital file revealed that after 2 weeks on medications, he no longer displayed ideas of delusional intensity. However, the patient mentioned events and lessons from the books of Revelation and Acts of the Apostles of the Christian Bible. He had a particular fascination with their relation to the Old Testament and the image of "tongues of fire" from the Pentecost. Due to his prior psychotic symptoms and limited overall knowledge of Christianity, it was difficult for many staff members to assess his thought content. These challenges were overcome by discussions with Christian hospital staff, gathering collaterals from his family, and self-education. The patient was using moments of transition in the Bible to describe his transition to a non-psychotic state. He was discharged soon after and referred to a community mental health center.
Conclusions: It is common for Arab patients to have psychiatric pathology of religious themes. These are important to distinguish from cultural expressions of emotions and experiences. To provide inclusive and comprehensive care, it is essential for clinicians to have an appropriate understanding of the religions, spirituality, and diversity of the populations they are serving.

God's Ultimatum: The Role of Delusional Guilt in Religious Psychosis

M. Rosa[1]*, G. Santos[1], A. Garcia[1] and G. da Ponte[1]

[1]ULS Arco Ribeirinho, Lisboa, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1294

Introduction: Religious content often shapes the nature of psychotic delusions, particularly those involving guilt or grandiosity. Patients may interpret their faith as direct communication from a divine source, influencing both their thoughts and actions. This case report presents a 27-year-old male with a strong Evangelical background who experienced a sudden onset of manic and psychotic symptoms, including messianic delusions. He believed God gave him a divine ultimatum: either fast for 28 days or his mother would die. His response to this delusion—self-imposed starvation—led to life-threatening behavior, showcasing the impact of delusional guilt in religious psychosis.
Objectives: This report aims to illustrate how delusional guilt in religious psychosis can lead to dangerous behavior, explore the role of religious context in shaping psychotic content, and discuss the clinical challenges and outcomes of pharmacological treatment in such cases.
Methods: Case report; a non-systematic review was conducted by searching academic databases such as PubMed and Google Scholar, using the key-words "religion and psychosis", "transcultural psychiatry", "religious delusions".
Results: The patient was admitted to a psychiatric unit after attempting self-starvation as a result of his belief that God had

given him a life-or-death ultimatum. His psychosis included messianic delusions, interpreting license plates as divine messages. The patient exhibited manic symptoms, such as elevated mood, hyperactivity, and pressured speech. A treatment plan with Paliperidone, titrated to 9 mg/day, and Sodium Valproate, titrated to 1000 mg/day, was initiated.After two weeks of treatment, the patient's symptoms showed significant improvement. His delusional intensity decreased, and he began to question the validity of his beliefs. Manic symptoms also diminished. By the end of the fourth week, the patient no longer exhibited psychotic thinking, and his insight into the irrational nature of his previous beliefs had increased. He resumed normal eating habits, and the risk of further self-harm related to delusional guilt was eliminated. The patient was discharged with ongoing outpatient follow-up and maintained on the same medication regimen.

Conclusions: This case illustrates the role of religious delusions in shaping dangerous behaviors, particularly when driven by delusional guilt. The patient's belief that he was receiving divine communication leading to self-starvation highlights the clinical complexity of managing psychosis intertwined with spiritual beliefs. Cultural competence played a vital role in treatment, as understanding the patient's religious context was essential in addressing his delusions. This case underscores the importance of individualized, culturally informed care in the management of religious psychosis.

The Impact of Separation Anxiety and Psychological Resilience on Parental Attitudes in Individuals Who Attended Boarding School During Adolescence

T. SARIKAVAK[1,2*] and N. ELKİN[3]

[1]Psychiatry, Istanbul Atlas University; [2]Psychiatry, Humanite Medical Center and [3]Child Development, Istanbul Gelisim University, Istanbul, Türkiye

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1295

Introduction: Boarding schools, seen across various cultures and regions, aim to broaden access to quality education, especially for disadvantaged groups. These schools, operated by different institutions, offer distinct educational approaches. State-affiliated boarding schools centralize resources to provide conditions not easily available elsewhere, fostering independence and discipline. Families often send their children to boarding schools, hoping they will gain opportunities to improve their lives and possibly benefit the family as a whole. However, early separation from family can have both positive and negative long-term effects on children's socio-emotional development.

Objectives: One of the potential outcomes is undoubtedly separation anxiety, which may arise from early separation from the family. On the other hand, this separation might also result in an increase in psychological resilience, as it forces individuals to live independently at an early age. In this study, we aimed to explore how separation anxiety and psychological resilience are impacted by this experience, and how these effects influence the parental attitudes that individuals adopt when raising their own children.

Methods: The study was designed as a case-control study, and participants were recruited through snowball sampling. Data were collected either through face-to-face interviews or online surveys. To gather data, a Sociodemographic Data Form, which included personal and educational information, along with the DSM-5 Separation Anxiety Disorder Severity Scale-Adult Form, the Resilience Scale for Adults (RSA) and Parentıng Attıtude Scale (PAS) were used. After examining whether the data were normally distributed based on Skewness and Kurtosis values, Student's t-test, Mann-Whitney U, and Chi-square tests were used for group comparisons. Relationships between variables were analyzed using Pearson and Spearman correlation tests, as well as Stepwise Regression analysis.

Results: A total of 107 volunteers who attended boarding school during adolescence participated in this study. Of these, 41 were male (38%), and 39 (36%) attended boarding school during high school. The average total score for separation anxiety was 0.890 for those who attended boarding school and 0.675 for those who did not.

Conclusions: This study has allowed us to gain a deeper understanding of the impact of an educational and social phenomenon, such as attending boarding school, on mental health. It is valuable in demonstrating the effects of established social institutions on individual mental health, and to the best of our knowledge, it is among the first studies of its kind. The examination of its impact on parental attitudes also sheds light on the intergenerational transmission of these changes.

Ethnoterritorial features of paranoid schizophrenia with comorbid dependence on synthetic cannabinoids

N. Bokhan[1,2,3] and G. Selivanov[1,4,5,6*]

[1]Mental Health Research Institute; [2]Siberian State Medical University, Tomsk, Russia; [3]Tomsk State University, Tomsk, Russia, Tomsk; [4]Saint Petersburg University of State Fire Service of Emercom of Russia; [5]Psychiatric Hospital of St. Nicholas the Wonderworker and [6]Rehabilitation Treatment Center "Child Psychiatry", St. Petersburg, Russian Federation

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1296

Introduction: It is indisputable that against the background of the popularity of various chemical addictions among patients with schizophrenia, it is relevant to study the joint clinical and pathomorphological deformation of two nosological phenomena of paranoid schizophrenia and dependence on modern, increasingly popular drugs, synthetic cannabinoids in various ethno-territorial groups. It is important to consider issues of mutual deformation of mental disorders, their progression, behavioral characteristics and adaptation.

Objectives: to study the ethno-territorial features of paranoid schizophrenia comorbid with abuse of synthetic cannabinoids, clinical dynamics, behavior and adaptations.

Methods: follow-up, clinical-psychopathological methods (PANS, SANS, CGI, MMPI, CGI, STAI, LSI, TPA, ICD-10), statistical (Python 3.11.0).

Results: 193 men (aged 18 to 35 years) were examined: 142 patients with paranoid schizophrenia dependent on synthetic cannabinoids F20.xx+F12.2xx and 51 - F20.xx without drug addiction. The study took place from 2018 to 2024 on the basis of psychiatric institutions in Russia - Tomsk Region, St. Petersburg, Noyabrsk and

Nizhnevartovsk. The phenomenon of abuse of synthetic cannabinoids leads to the development of diseases. Persistent exogenous visual and delirious disorders are included in the complex of symptoms of exacerbation of schizophrenia; A new symptom of pseudohallucinoids appears - thought disorders of an associative (fantasy) disease that arose against the background of long-term exogenous (toxic) effects of the drug on the subject type, usually against the background of a primary endogenous schizophrenic process.
Conclusions: The leading position among patients with schizophrenia who use synthetic cannabinoids in the temperate continental climate zone of Russia was occupied by the following ethnic groups, taking into account the hierarchy: Russians, Tatars; Uzbeks; Germans; Azerbaijanis and Armenians.

Intranasal esketamine in treatment-resistant depression: Descriptive study of our clinical experience

E. Abalde García[1]*, E. Lanchares Balboa[1], L. C. Ortega Sandoval[1], J. A. Campos Pérez[1] and J. M. Olivares Diez[1]
[1]Hospital Álvaro Cunqueiro, Vigo, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1297

Introduction: Major Depressive Disorder (MDD) represents a significant challenge for global public health, profoundly affecting social and economic well-being. It is estimated that around 30% of patients do not respond to standard therapies, being classified as Treatment-Resistant Depression (TRD) patients. Intranasal ketamine emerges as a promising therapeutic option for these patients.
Objectives: The objective of this study is to analyze the actual clinical use of intranasal esketamine in a sample of patients with treatment-resistant depression (TRD).
Methods: A descriptive study of different socio-demographic and clinical variables was conducted to analyze the profile of TRD patients treated with intranasal ketamine in the Vigo Health Area.
Results: A study was conducted on 33 TRD patients (48% women), with an average age of 52.77 years. In the current episode, it was observed that 24.2% had received electroconvulsive therapy and 41.7% had experienced at least one psychiatric admission. Additionally, 66.7% had visited the emergency room for psychiatric reasons, while 50% presented with comorbid anxiety, 15% with obsessive-compulsive personality disorder, and 21% with fibromyalgia.
The analysis showed that 88% of the participants had failed at least six lines of treatment, with an average of 4.18 concomitant treatments at baseline. The response to intranasal ketamine was evidenced, for the most part, in the second week of treatment, with a notable increase in the use of the 84 mg dose. In 60% of patients, the induction period was set at 4 weeks and a decrease in MADRS scale scores was observed at weeks 4, 8, and 12. No adverse effects were reported that had not been previously recognized in clinical trials. Adverse effects were rare and mild.
Conclusions: The study indicates that patients presented with highly complex depression, which explains the prolonged induction periods. The good tolerability of ketamine has facilitated a rapid increase to 84 mg dosage in most cases. Although this sample does not align completely with the typical profile of patients who respond well, intranasal ketamine was effective in 70% of cases, similar to the findings of clinical trials. It is suggested that the accumulated knowledge about the drug has contributed to these clinical improvements. Additionally, a more flexible approach has helped patients with low expectations of response.

Prevalence and Risk Factors of Modern-Type Depression in Oman: Validation of the Arabic TACS-22 Scale

S. Al Busaidi[1]*, S. Al Adawi[2] and M. F. Chan[3]
[1]psychiatry, Resident doctor at Oman medical speciality board; [2]Department of Behavioral Medicine and [3]Department of Family Medicine & Public Health, College of Medicine & Health Sciences, Sultan Qaboos University, muscat, Oman
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1298

Introduction: Emerging mental health crises in the global south highlight challenges in applying psychological frameworks that primarily originate from wealthy nations in the global north. The concept of modern-type depression (MTD), first recognized in Japan, has recently gained attention due to its divergence from the DSM criteria. MTD manifests itself as a reluctance to engage in social roles, a withdrawal from social norms, and vague omnipotence. Oman, a rapidly developing nation, shows patterns of social withdrawal similar to MTD. This study aims to validate the Arabic version of Tarumi's Modern Depression Trait Scale (TACS-22), evaluate its factor structure, and explore the prevalence and risk factors of MTD in Oman.
Objectives: The entrance of urbanization and digitation has heralded 'de novo psychopathologies' such as those that go under the umbrella of modern-type depression (MTD). To date, the presence of the MTD and the factors associated with it have yet to be explored. Related aims are to conduct exploratory factor analysis (EFA) and confirmatory factor analysis (CFA) to confirm the factorial validity of the 22-item Tarumi's Modern-Type Depression Trait Scale.
Methods: An online survey was conducted in March 2023 with a convenience sample of Omanis aged 18 and over. The survey included the Arabic-translated TACS-22 scale and the PHQ-9 to assess depressive symptoms. An exploratory factor analysis (EFA) was performed to determine the structure of the TACS-22 factor and internal consistency was assessed using Cronbach's alpha. Sociodemographic and clinical data was collected to explore possible risk factors for MTD and univariate and multivariate logistic regression analyses were performed to examine associations.
Results: A total of 1009 participants completed the survey, with a response rate of 50%. The majority were female (70.3%) with a

mean age of 31.1 ± 8.5 years. The prevalence of MTD was 25.3%, with significant associations found between MTD and socio-demographic factors such as sex, marital status, age, and occupation ($p < 0.05$). Furthermore, clinical factors such as mental illness, adverse childhood experiences (ACE), and depressive symptoms were also significantly associated with MTD. The EFA revealed a three-factor structure: Avoidance of social roles, low self-esteem, and complaints, consistent with previous studies, with acceptable internal consistency (Cronbach's $\alpha = 0.77$).

Conclusions: MTD is prevalent in Oman, particularly among younger individuals, students, and the unemployed. The Arabic TACS-22 scale demonstrates acceptable validity and reliability, providing a useful tool for identifying MTD traits in non-Western contexts. Socioeconomic changes in Oman can contribute to the emergence of MTD, and further research is needed to explore tailored interventions for this population.

EPV0584

Esketamine Nasal Spray in the Treatment of Depression: A Comprehensive Analysis of its Efficacy and Safety in 107 Patients of Sulwan Psychiatric Hospital in Kingdom of Bahrain

A. M. Al Hamada

Psychiatry, Sulwan Psychiatric Hospital, Manama, Bahrain
doi: 10.1192/j.eurpsy.2025.1299

Introduction: Depression is one of the most disabling diseases worldwide, but despite numerous attempts to investigate novel drugs, no significant step forward has been taken so far. Traditional antidepressants, including selective serotonin reuptake inhibitors and serotonin and norepinephrine reuptake inhibitors, have been shown to have a slow onset of action and require assessing these drugs for up to eight weeks to determine their effectiveness. As a result, there is an urgent medical need for new, rapid, and effective treatments like Esketamine Nasal Spray for the large number of patients suffering from the disease.

Objectives: In our study, treated with esketamine nasal spray in an inpatient setting, we were able to show better functioning and severe depression, and, at the same time, a reduction in suicidal thoughts was documented. Our 107 analyzed patients demonstrated that this drug is safe and suitable for short-term use.

Methods: One hundred and seven (107) participants with major depressive episodes (MDE) were examined at Sulwan Psychiatric Hospital. The study, spanning 12 weeks, comprised two treatment protocols. After they had been educated concerning the two groups, the subjects decided their preferred treatment protocols. During the four-week induction phase, 56 mg - 84 mg of drug treatment twice a week was administered to the subjects. Then, based on whether they showed clinical response during the induction phase, the subjects entered the eight-week maintenance phase with 28 mg-56 mg twice monthly.

Results: In total, after 14 administrations, all depressive scores decreased significantly, indicating an improvement in depressive symptoms. Esketamine had a fast onset of action, so that already half of the patients felt better after the 2nd administration and 75% showed an effect after the 4th administration; not only the reduction of the mean but also that of the median illustrated a quick relief.

Conclusions: Our main results confirm the unique contribution of this study. In summary, the intranasal administration of esketamine is effective in patients with treatment-resistant depression (TRD) due to major depressive disorder (MDD) and bipolar disorder (BD).

Disclosure of Interest: None Declared

EPV0586

Efficacy of accelerated intermittent Theta-Burst Stimulation (aiTBS) in treatment-resistant depression: study protocol for a randomized controlled trial

J. Andreo-Jover[1,2*], R. Mazuecos[3], C. Rízea[4], J. Marin Lozano[3], E. Jiménez Solá[3], J. M. Pastor[3], P. Sánchez-Castro[3], M. F. Bravo Ortiz[1,2,3] and R. Villanueva Peña[2,3,5]

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1300

Introduction: New antidepressant treatments are needed that not only demonstrate strong efficacy but also act quickly, are safe for long-term use, and are well-tolerated by patients. Accelerated intermittent Theta-Burst Stimulation (aiTBS) is a promising form of noninvasive brain stimulation in the treatment of depression (1). iTBS stimulation is a time saving and cost-effective technique, and could provide long-lasting improvement of treatment-resistant depression (TRD) (2). Currently, there is limited evidence regarding the role of aiTBS within treatment algorithms for TRD compared to placebo.

Objectives: This is a single-center, double-blind, randomized, placebo-controlled pilot intervention study, designed to evaluate the efficacy and safety of aiTBS for TRD.

Methods: Stimulation will be administered in 10 daily sessions, one session every 50 minutes, over 5 days, for a total of 50 sessions. Each session will consist of 3 minutes of stimulation at a frequency of 50 Hz, delivering 600 stimuli per session, with an intensity of 120% of the motor threshold targeted at the left dorsolateral prefrontal cortex.

Results: Participants must be adults aged 18 to 75 years (inclusive), and meet the criteria for TRD, unresponsive to two antidepressants at an adequate dose and for an adequate duration with a stable dose for at least 4 weeks. Assessments, including HDRS, PHQ-9, EQ-5D-5L, SDS, CGI-S, and MGH-ATRQ, will be conducted at the baseline visit, at the end of the treatment, one and three months after the treatment.

Conclusions: Accelerated protocols are an emerging area of interest in the treatment of TDR, but several issues remain to be clarified, including the durability of their effects, safety, and feasibility of implementing these protocols in outpatient settings in routine clinical practice.

doi: 10.1192/j.eurpsy.2025.1301

Introduction: Adapting to a new socio-cultural environment presents a major challenge for African medical students, often leading to the development of anxiety-depressive disorders. To date, a number of therapeutic approaches including psychotherapy, educational programmes and pharmacological treatments are available, but their comparative effectiveness for this group remains poorly researched.
Objectives: The present study aims to comparatively evaluate different methods of psycho-emotional state correction.
Methods: The study included 72 African undergraduate medical students (age range 18-23 years, 54.9% female, 45.1% male).
Participants were assigned to three therapeutic groups. Statistical processing with post-hoc test and Bonferroni correction confirmed the benefit of the psychotherapeutic approach in reducing levels of anxiety and depression ($p \leq 0.01$). An 8-week cognitive-behavioural therapy programme demonstrated the greatest effectiveness. A one-day educational workshop showed moderate efficacy. Medication therapy with antidepressants for 8 weeks resulted in minimal improvement.
Results: Participants were assigned to three therapeutic groups. Statistical processing with post-hoc test and Bonferroni correction confirmed the benefit of the psychotherapeutic approach in reducing levels of anxiety and depression ($p \leq 0.01$). An 8-week cognitive-behavioural therapy programme demonstrated the greatest effectiveness. A one-day educational workshop showed moderate efficacy. Medication therapy with antidepressants for 8 weeks resulted in minimal improvement.
Conclusions: Cognitive-behavioural therapy demonstrated the greatest efficacy in the correction of anxiety-depressive disorders in international medical students, outperforming both educational and pharmacological interventions. Subjective satisfaction of participants was also higher in the psychotherapy group, indicating that it is appropriate to prioritise the use of non-pharmacological methods in this population.

Exploring Postpartum Depression : Sociodemographic and Pregnancy-Related Influences

N. Messedi[1]*, O. Bouattour[1], F. Khanfir[2], R. Ben Jmeaa[1], I. Chaari[1], F. Charfeddine[1], L. Aribi[1], K. Chaabene[2] and J. Aloulou[1]

[1]Psychiatry « B » department and [2]Gynecology department, Hedi Chaker University Hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1302

Introduction: Postpartum depression is a widespread mental health condition affecting mothers in the weeks and months following childbirth, with potentially significant impacts on both maternal and child well-being. Several factors have been linked to an increased risk of postpartum depression, including perceived social support, sociodemographic characteristics, and pregnancy-related factors.
Objectives: This study aims to investigate postpartum depression prevalence among postpartum women and its associated factors.
Methods: We conducted a cross-sectional descriptive and analytical study targeting women in their first week postpartum who had been admitted to the gynaecology-obstetrics department of the Hedi Chaker University Hospital in Sfax, Tunisia. The study was conducted over a three-month period (October, November and December 2023). To assess the prevalence of postpartum depression, we used the Tunisian Arabic version of the Edinburgh Postnatal Depression Scale (EPDS). A cut-off score of 10 or more on the EPDS Scale indicates the presence of postpartum depression.
Results: Our sample consisted of 220 paturients. The mean age of patients was 31.1 ± 6.6 years. Among the participants, 50.9% came from rural areas. Unwanted pregnancy was reported by 41.8%, with 13.2% having considered abortion. Socioeconomic challenges were notable, with 32.7% of participants reporting low socioeconomic status. Poor marital relationships were reported by 10.9% of the parturients. Additionally, 7.3% had a poor relationship with their mother.
Post partum depression (EPDS ≥ 10) was present in 20.9% of participants.
Depression was significantly linked to: younger age ($p=0.001$), being single or divorced ($p=0.003$), lower level of education ($p=0.005$), unemployment ($p=0.03$), and low socioeconomic status ($p=0.007$). Poor marital relationships also showed a strong association with depression ($p=0.013$). Additional risk factors included unwanted pregnancy ($p=0.003$), difficulty accepting the pregnancy ($p<0.001$), exaggerated sympathetic signs ($p=0.011$), lack of pregnancy follow-up ($p=0.004$), and pregnancy complications such as gestational diabetes and hypertension. Depression was also associated with post-partum stressors, including spontaneous labor ($p=0.044$), complications after delivery ($p=0.022$), infant malformations ($p=0.001$), prematurity ($p=0.001$), poor infant health ($p<0.001$), and lack of breastfeeding ($p<0.001$).
Conclusions: These findings highlight the role of both socioeconomic and pregnancy-related factors in maternal mental health. Understanding these interconnected factors is essential for identifying at-risk populations and implementing targeted interventions to support maternal mental health.

Real clinical experience of inhaled esketamine in depression and chronic pain. A retrospective study

S. Benavente López[1]*, I. Pedrero Torrejon[1], E. Toro Carrasco[1], A. Lara Fernández[1], A. Parra González[1], M. Mejia Quiterio[1], A. Viñas Arboleda[1] and E. Baca García[1]

[1]Department of Psychiatry, Hospital Universitario Infanta Elena, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1303

Introduction: Chronic pain is very prevalent in the population, with an estimated prevalence of 20.5% of the adult population experiencing pain every day or most days. Chronic pain is one of the main factors that generate dysfunctionality in patients, and it can even lead to dependence in activities of daily living. Chronic pain is strongly associated with depression, and can induce a major depression which, due to its characteristics, will become chronic. Several studies have shown that intravenous ketamine can be effective in the treatment of chronic pain. Major depression associated with chronic pain has a worse outcome and is more frequently associated with resistance to pharmacological treatment, making the management of these patients a clinical challenge.
The present study shows the response in a series of cases with major depression and chronic pain treated with inhaled esketamine, showing their evolution through the Montgomery-Asberg Depression Rating Scale (MADRS) and Fibromyalgia Impact Questionnaire (FIQ) as main outcomes.
Objectives: The main objective of this study is to describe the use of inhaled esketamine in patients with major depression and chronic pain in real clinical practice, using the MADRS and FIQ as main outcomes to show the evolution.
Methods: Retrospective descriptive study with a sample selected by non-probabilistic consecutive sampling, retrospective type, in a time interval of 2 years. The patients selected were those who completed treatment with inhaled esketamine and had a diagnosis of major depression and a diagnosis of chronic pain at Hospital Universitario Infanta Elena. A descriptive analysis was performed. Mean and standard deviation were calculated for quantitative variables and N and percentage for categorical variables.
Results: A total of 5 patients with a diagnosis of major depression and chronic pain (n: 5) all treated with inhaled esketamine were included in the study. The efficacy of inhaled esketamine was high in the reduction of pain during the months of treatment with it, presenting an improvement in the MADRS and the FIQ. At the end of treatment, there was a significant difference between patients who had made changes in their daily life habits (sport, improved daily activities, improvement in the quality of life) and those who had not made changes in their daily life habits.
Conclusions: This study shows that inhaled esketamine may be a useful drug in the treatment of major depression associated with chronic pain. Treatment with esketamine improved depressive symptoms and also chronic pain. A significant influence of changes in lifestyle habits was observed in maintaining the response to pain relief once treatment with esketamine was finished. Longitudinal studies must be carried out to confirm this hypothesis.

EPV0591

Real clinical experience of inhaled esketamine in psychotic depression. A retrospective study

S. Benavente López[1]*, E. Toro Carrasco[1], I. Pedrero Torrejon[1], A. Lara Fernández[1], A. Parra González[1], M. Mejia Quiterio[1], A. Viñas Arboleda[1] and E. Baca García[1]

[1]Department of Psychiatry, Hospital Universitario Infanta Elena, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1304

Introduction: Psychotic depression is a severe mental disorder that can cause severe suffering and dysfunctionality in the patient. It is characterised by the presence of major affective symptoms together with the presence of psychotic symptoms in the form of delusions and/or sensory-perceptual alterations. Psychotic depression is particularly severe when it becomes resistant to pharmacological treatment, often requiring the combination of antipsychotics with antidepressants and even the use of electroconvulsive therapy. Lifetime prevalence of psychotic depression ranges from 0.35% to 1%, being more frequent in the elderly. Previous studies have shown positive experience with intravenous ketamine in the treatment of psychotic depression, improving psychotic symptomatology and showing a good safety and tolerability profile. The present study shows the response in a series of cases with psychotic depression treated with inhaled esketamine, showing their evolution through the Montgomery-Asberg Depression Rating Scale (MADRS) as well as their safety and tolerability profile.
Objectives: The main objective of this study is to describe the use of inhaled esketamine in patients with psychotic depression in real clinical practice, using the MADRS as main outcomes to show the evolution.
Methods: Retrospective descriptive study with a sample selected by non-probabilistic consecutive sampling, retrospective type, in a time interval of 2 years. The patients selected were those who completed treatment with inhaled esketamine and had a diagnosis of psychotic depression at Hospital Universitario Infanta Elena. A descriptive analysis was performed. Mean and standard deviation were calculated for quantitative variables and N and percentage for categorical variables.
Results: A total of 5 patients with a diagnosis of psychotic depression (n: 5) all treated with inhaled esketamine were included in the study. The efficacy of inhaled esketamine was very high in the treatment of patients with psychotic depression, achieving a 100% response rate (MADRS<10). All 5 patients showed a rapid improvement in psychotic symptomatology, with cessation of psychotic symptoms in the initial phases of treatment, showing a rapid response. No worsening of psychotic symptoms was observed at any time with the administration of inhaled esketamine. Tolerability was excellent, with no serious adverse effects occurring during treatment administration.
Conclusions: The present study shows a high efficacy of esketamine in the treatment of psychotic depression, with a high response rate and an excellent tolerability profile. Inhaled esketamine could be a useful tool in the treatment of psychotic depression, helping to rapidly restore patients' functionality. Longitudinal studies must be carried out to confirm this hypothesis.

Hostility and self-destructive behavior in depression

T. I. Medvedeva[1], O. M. Boyko[1]*, S. N. Enikolopov[1] and O. Y. Vorontsova[1]

[1]Clinical psychology, Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1305

Introduction: Self-destructive behavior in depression is most often a pathological way of emotional self-regulation, but it may increase

suicidal risk. In this regard, the identification of risk factors for self-destructive behavior is of practical importance.
Objectives: The aim was to study hostility as risk factor self-destructive behavior in depression.
Methods: The study included 155 women from 16 to 25 years old (mean age 19,77) hospitalized with depression in a clinic of FSBSI MHRC. The Buss-Perry Aggression Questionnaire (BPAQ), the Symptom Checklist-90-reserved (SCL-90-R), the Physical Appearance Comparison Scale—Revised (PACS–R), the Body Investment Scale (BIS), anamnestic data about self-destructive behavior, a question to assess the level of autoaggression («Sometimes I deliberately injure myself » was measured on a Likert scale from 0 to 5) were used. ANOVA and Spearman's rank correlation coefficient were used. To analyze the features associated with the level of hostility, the sample was divided into subgroups "with low hostility" (78 people, mean age 19.91) and "with high hostility" (77 people, mean age 19.6), according to the median value of the "Hostility" parameter of BPAQ - 23.
Results: Correlation analysis showed a statistically significant relationship between the level of "Hostility" and the frequency of "deliberately injure" ($r=0.19$, $p<0.05$). Comparison of subgroups according to the parameters of SCL-90-R showed a higher level of psychopathologic symptomatology in the group with high hostility: SOM (1.11±0.80 in the "low hostility" group vs. 1.50±0.85 in the "high hostility" group at p=0.001), OC (1.60±0.87 vs. 2, 16±0.77 at p=0.000), INT (1.32±0.84 vs. 2.16±0.90 at p=0.000), DEP (1.73 ±0.98 vs. 2.27±0.87 at p=0.000), ANX (1.27±0.92 vs. 1.90±1.01 at p=0.000), HOS (0, 89±0.87 vs. 1.41±0.89 at p=0.000), PHOB (0.81 ±0.86 vs. 1.42±0.89 at p=0.000), PAR (0.74±0.65 vs. 1.43±0.84 at p=0.000), PSY (0.87±0.65 vs. 1, 26±0.78 at p=0.000), GSI (1.22±0.66 compared to 1.77±0.71 at p=0.000), PDSI (2.12±0.60 compared to 2.39±0.56 at p=.002), PSI (48.66±17.14 compared to 64.20±16.16 at p=0.000). BIS scores on the "body Investment subscale" (3.18±1.18 compared to 2.55±1.12 at p=0.001) on the total scale (3.38±0.58 compared to 3.15±0.54 at p=0.008) The PACS-R scale data demonstrate differences in the physical comparison parameter (2.02 ±1.37 versus 2.66±1.23 at p=0.002).
Conclusions: A higher level of hostility in depression in women with self-destructive behavior is associated with both a worse mental status and a stronger rejection of one's body, manifested in a decreased concern for it and an increased need to compare oneself with others. This allows us to consider hostility as one of the markers of high risk of self-harming behavior in depression.

EPV0594

Fat Chance: The risk of Vortioxetine-induced Hypertriglyceridaemia

E. Cahalan[1]

[1]Psychiatry, HSE, Galway, Ireland
doi: 10.1192/j.eurpsy.2025.1306

Introduction: Hypertriglyceridaemia as a side effect of antidepressants including venlafaxine and mirtazepine has been described in the literature. A relatively new SSRI, vortioxetine has never been reported to contribute to hypertriglyeridaemia and it is not mentioned in the prescribing information for this agent. Dyslipidaemia is an important risk factor for morbidity in people who suffer with mental illness, most often observed in patients who are prescribed antipsychotic medications. Evidence to date with antidepressant medication is mixed but may represent a clinically relevant additional cardiovascular risk.
Objectives: This case report explores the possible relationship between Vortioxetine and worsening hypertriglyceridaemia in a patient with depressive illness.
Methods: Clinical case report and brief literature review
Results: A 58 year old female, with a history of Recurrent Depressive Disorder was admitted to an acute psychiatric inpatient unit with a relapse in depressive illness with anxious distress and suicidality. Prior to admission, her medications included Mirtazepine 60mg, Duloxetine 120mg and Olanzapine 7.5mg. She had a family history of dyslipidaemia. A blood panel was taken which revealed mildly deranged lipid profile - Total Cholesterol of 7.72mmol/L (Upper limit of Normal - 5.0mmol/L); HDL 1.02mmol/L (ULN - 2.0mmol/L) ; LDL 5.44mmol/L (ULN - 3.0mmol/L) ; Triglycerides 2.78mmol/L (ULN - 2.0mmol/L).
The patient's Duloxetine was switched to Venlafaxine and repeat lipid levels one week later revealed a dramatic rise in triglycerides to 12.16 mmol/L, and then 14.07 mmol/L 2 days later again. Venlafaxine was discontinued in view of these findings with a reduction in serum triglycerides to 11.43mmol/L within 24h.
Vortioxetine 10mg was commenced and the patient's lipid profile was again repeated with an upswing in triglyceride levels to a peak of 15.4mmol/L within 48h of commencement. Vortioxetine was discontinued and fenofibrate was commenced to treat the patient's dyslipidaemia due to a risk of acute pancreatitis and atherosclerotic disease. Serum triglycerides reduced to near-normal levels within days.
Conclusions: This case report highlights the risk of dyslipidaemia associated with antidepressant prescribing and identifies vortioxetine as an agent which may contribute to this. This patient had a number of risk factors for developing hyperlipidaemia including co-prescription with olanzapine and mirtazepine which have known metabolic effects, as well as a family history for hyperlipidaemia and a post-menopausal state. However, it was notable that her significant hypertriglyceridaemia was cause by venlafaxine, and exacerbated further by vortioxetine. Cardiovascular risk profiles must always be considered in the psychiatric patient population and we feel that this case report may add to the literature around commonly prescribed antidepressant medications and their contribution to this risk.

Depressive symptoms among heterosexual and sexual minority college students: network analyses

E. B. Camargo Júnior[1]*, G. G. Silva[1], M. N. D. F. Fernandes[2] and E. C. D. S. Gherardi-Donato[3]

[1]University of Rio Verde, Rio Verde; [2]Federal University of Maranhão, Imperatriz and [3]Ribeirão Preto College of Nursing, Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1307

Introduction: Depression is one of the most prevalent mental disorders worldwide, and network analyses in psychopathology allow for an improved understanding of its development,

maintenance, and treatment. Evidence suggests that sexual minority individuals are more vulnerable to depression.
Objectives: The objective of this study was to analyze the correlations between depressive symptoms in heterosexual and sexual minority students using network analysis.
Methods: This cross-sectional study was conducted with 1,271 university students to assess depressive symptoms using the Patient Health Questionnaire-9 (PHQ-9). Network analyses were performed to identify influential symptoms and their correlations.
Results: The results showed that sexual minority students had significantly higher scores for all symptoms of depression than heterosexual students did. Guilt and suicidal ideation had the strongest association with the symptom network of heterosexual students. Among sexual minority students, the strongest associations were between lack of energy and depressed moods. The most influential symptom in the heterosexual student network was suicidal ideation, whereas in the sexual minority student network, guilt was the most influential symptom.
Conclusions: These results demonstrate that in network analyses, different depressive symptoms play distinct central roles between heterosexual and sexual minority groups. These differences indicate the need for interventions that are adapted to the specificities of each group to promote mental health.

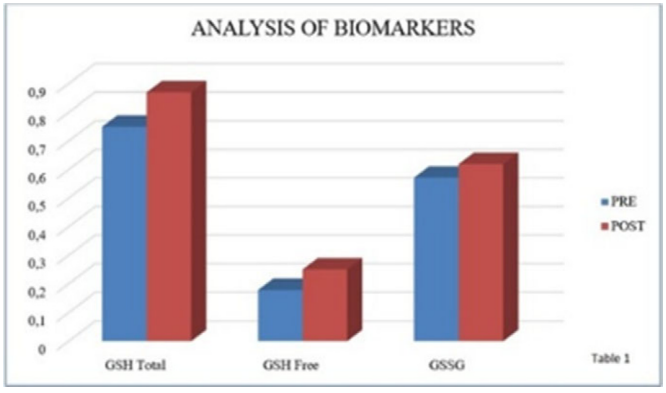
Inflammatory biomarkers and risk factors in depression: a longitudinal study in adults

G. Cano-Escalera[1,2,3,4]*, I. Gómez Grávalos[2,3], M. Melero González[2,3], I. Zorrilla[1,2,3], P. Lopez Pena[1,2,3], K. S. MacDowel[1,5], J. C. Leza[1,5] and A. Gonzalez-Pinto[1,2,3]

[1]CIBER de Salud Mental, Instituto de Salud Carlos III, Madrid; [2]Department of Psychiatry, Araba University Hospital; [3]Bioaraba Health Research Institute, BIOARABA, Vitoria; [4]Department of Computer Science and Artificial Intelligence, Computational Intelligence Group, Donostia and [5]Department of Pharmacology and Toxicology, Facultad de Medicina, IIS Hospital 12 de Octubre, IUIN-UCM, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1308

Introduction: Depression is a chronic and recurrent mental condition, causing a high burden of disease, functional impairment, and significant economic costs worldwide.
Objectives: To compare the neuropsychological profile, inflammation, and functionality in patients with a major depressive episode before and after treatment.
Methods: A longitudinal study was conducted, recruiting a total of 39 subjects, with a mean age of 42 years (12 men - 30.8% and 27 women - 69.2%) diagnosed with major depressive disorder (MDD). The neuropsychological profile was measured using the Screening of Cognitive Impairment in Psychiatry (SCIP) and the level of functionality with the Brief Assessment of Functioning (FAST) test. Both total scores and subscales were used, along with inflammatory biomarkers (IL-6, IL-1ß, TNF-α, PGE2) and oxidative stress markers (TAS, GSHtot, GSHfree, GSSG, CAT, SOD, GPx, and BDNF).
Statistical analysis: The paired t-test was used through the statistical program SPSS. A unilateral p-value less than 0.05 was considered statistically significant.
Results: Significant differences were observed in both the Hamilton Depression Rating Scale ($p < 0.001$) and in the biomarkers total GSH ($p < 0.15$), GSH free ($p < 0.029$), and GSSG ($p < 0.027$) of patients at three months from the start of pharmacological treatment compared to baseline (Table 1). Differences were also observed at 3 months of treatment in the SCIP scale ($p < 0.001$) as well as in its subscales: Immediate verbal learning ($p < 0.001$), Working memory ($p < 0.001$), Verbal fluency ($p = 0.007$), and Delayed verbal learning ($p < 0.001$), and in the FAST scale ($p < 0.001$) and its subscales: Autonomy ($p = 0.002$), Cognitive ($p = 0.004$), Finances ($p = 0.004$), and Relationships ($p < 0.001$) (Table 2).
Image 1:



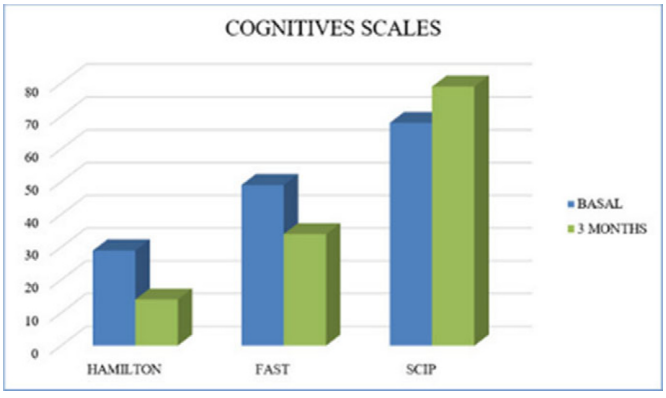


Image 2:

Conclusions: Our results indicate that there are improvements at the cognitive and functional level in subjects taking antidepressant treatment. Changes in GSH and GSSG biomarkers were also observed, whose antioxidant function is crucial for protecting cells from oxidative damage. The findings suggest that oxidative stress is a crucial factor in the pathophysiology of MDD. The study highlights the potential of these biomarkers to guide therapeutic strategies and improve the management of depression.

Depression and Suicide Risks Among Nurses at Sahloul University Hospital in Sousse (Tunisia)

J. Ben khelifa[1], F. Chelly[1,2,3*], N. Bel Hadj chabbah[1,2,3], A. Fki[1,2,3], C. Sridi[1,2,3], N. Ben Gadha[1] and S. Ksibi[1]

[1]Department of Occupational Medicine, Sahloul University Hospital; [2]Faculty of Medicine Ibn Al Jazzar, University of Sousse and [3]Research laboratory LR 19SP03, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1309

Introduction: Depression and suicide risk are particularly concerning mental health issues in the workplace, especially among nurses. This group of workers often faces high levels of stress and pressure due to the demanding nature of their job.
Objectives: Our study focuses specifically on describing depression and suicide risk among nurses.
Methods: This is a descriptive study, conducted during January and February 2023, involving 55 nurses working at Sahloul University Hospital in Sousse. Data were collected through a self-administered questionnaire and the Beck Depression Inventory which assesses subjective aspects of depression.
Results: 51% of the participants report that working as a nurse constitutes a significant mental burden. During their hospital careers, 47% have faced violence from patients' family members or companions. (43%) experienced violence from colleagues, mainly in the form of verbal aggression. Nearly all the nurses surveyed (94%) reported demotivation toward their work, with (97.9%) attributing it to work overload and (39.4%) to workplace conflicts. According to the Beck scale, (38%) of the nurses did not present depression, moderate depression was found in (58%) of participants and only 4% had severe depression. Reduced job performance was noted in (16%) of cases. Concerning suicidal ideation, it was reported by only 2 nurses.
Conclusions: Early identification of mental distress and the implementation of appropriate psychological support strategies, are crucial to mitigating these risks. Recognizing psychological risks in hospitals not only improves the well-being of nurses but also enhances the quality of care they provide to patients.

Esketamine and Ketamine use in the Adolescent Population for Treatment Resistent Depression: A Systematic Review

G. Chen[1*] and Y. Li[2]

[1]Psychiatry, Lehigh Valley Health Network, Allentown and [2]Medical School, Virginia Tech, Roanoke, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1310

Introduction: Ketamine is widely recognized for its dissociative anesthetic properties, particularly in procedural sedation and severe pain management among children, adolescents, and young adults. Despite its noted applications, research investigating ketamine's impact on mood and suicidality within this specific demographic remains limited. This retrospective review seeks to address this gap by characterizing ketamine usage and psychiatric comorbidities in Treatment-resistant depression (TRD).
Objectives: This review aims to provide an initial assessment of the safety and efficacy of esketamine in adolescents suffering from TRD with concurrent comorbidities such as GAD and SUD, and infer common drug-drug interactions that may arise from utilizing esketamine in adolescents.This preliminary overview will contribute valuable insights toward optimizing treatment strategies for this vulnerable population.
Methods: This systematic review evaluates the evidence for ketamine use in children with treatment-resistant mood disorders. Two to four authors independently screened studies and extracted data on safety, tolerability, and efficacy. We searched two electronic databases for English-language studies on the therapeutic effects and side effect profiles of ketamine in youth aged 14-23 with treatment-resistant mood disorders, including those with treatment-resistant depression (with and without psychotic features) and bipolar disorder.
Results: Recent studies, including a randomized, midazolam-controlled trial, indicate that IV ketamine can effectively reduce depressive symptoms in adolescents with treatment-resistant depression (TRD), with mild and manageable side effects like dissociation. No serious adverse events or instances of misuse were reported.
Conclusions: In conclusion, esketamine has demonstrated effectiveness in treating treatment-resistant depression. Additionally, when combined with SSRIs, esketamine improves depressive symptoms in TRD patients, irrespective of their anxiety status. These findings highlight the potential of esketamine as a valuable treatment option for this challenging patient population. Future research will focus on optimizing dosing, exploring complementary therapies such as cognitive behavioral therapy (CBT), and identifying biomarkers for response, while considering the unique risks to the developing adolescent brain.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1311

Introduction: Postpartum depression (PPD) is a serious mental health condition that can be challenging to diagnose due to its varying symptoms. As a result, multiple healthcare providers collaborate in its prevention, screening, and treatment. Nurses

play a pivotal role in this process, requiring essential knowledge and skills
Objectives: To assess nurses' knowledge and attitudes regarding PPD.
Methods: A cross-sectional study was conducted among maternity nurses at a university hospital who have direct contact with postpartum patients. Our sample was a convenience sampleData was collected using a self-administered anonymous questionnaire. The questionnaire consisted of two parts : the first part collected demographic information about the nurses, and the second part assessed nurses' knowledge and attitudes regarding postpartum depression.
Results: A total of 50 nurses participated in the study. Nearly half (49%) of participants had over 10 years of professional seniority. The majority (92%) were aware of the postpartum period during which the disorder occurs, as well as the early warning signs of PPD (82%). However, more than half of the participants (52%) were unaware of the risk factors for PPD. The majority (92%) were aware that nurses play a major role in early detection of this disorder. Only 52% knew that the Edinburgh Postnatal Depression Scale (EPDS) is the screening tool for PPD. Nearly half of the suggestions to improve the management of PPD (46%) focused on improving patient conditions and well-being. Moreover, 40% of participants made suggestions centered on collaboration and communication.
Conclusions: Despite their involvement in postpartum care, nurses demonstrated limited knowledge of postpartum depression risk factors, emphasizing the need for enhanced education and support.

Gender Differences in Depressive Symptomatology Among Turkish Immigrants: An Analysis of PHQ9 Scores

E. D. Cindik-Herbrueggen[1]

[1]Psychiatry, Neuro-Psychiatric Center, München, Germany
doi: 10.1192/j.eurpsy.2025.1312

Introduction: Depression is a pervasive mental health disorder that can significantly influence symptomatology, which remains a crucial area of research. This study aims to investigate whether gender correlates with PHQ-9 total scores, enhancing the general understanding of depression across different demographic groups.
Objectives: This study examines the correlation between gender and PHQ-9 total scores, investigating the hypothesis that gender influences various depressive symptoms as measured by the PHQ-9. We aim to determine whether there is a significant difference in depression severity between male and female participants.
Methods: To fulfill this purpose, we collected data from a total of 146 participants, primarily Turkish immigrants of the first and second generation, who were recruited from the Neuro-Psychiatrisches Zentrum Riem. First, we gathered the participants' sociodemographic data, including gender, marital status, and education level. Furthermore, they were asked to complete the PHQ-9 questionnaire, and we conducted a Pearson correlation analysis.
Results: The PHQ-9 total scores and gender show a significant correlation, with a p-value of 0.040. Furthermore, these results indicate that female participants had higher average PHQ-9 scores compared to male participants, suggesting a greater intensity of depressive symptoms among women. Since the participants were predominantly Turkish immigrants, these findings may suggest that Turkish women are more prone to severe depressive symptoms, potentially as a consequence of their immigration history.
Conclusions: This study emphasizes the significance of gender in relation to depressive symptoms, as measured by the PHQ-9 questionnaire. However, future research should investigate other factors, besides gender, that may influence the severity of depressive symptoms in immigrant participants. It is recommended that these studies focus on the long-term effects of immigration, depression, and gender by including a diverse range of participants, such as immigrants from the first, second, third, and fourth generations. These generational differences could indicate significant variations in the experiences and consequences of severe depressive symptoms.

Predictive significance of constellation factors of the newborn in the onset of postpartum depression

M. Davidovic[1], L. Simic[1]*, M. Tomic[1], A. Rankovic[1] and D. Davidovic[1]

[1]Clinic for Mental Disorders, Dr Laza Lazarevic", Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1313

Introduction: Postpartum depression (PPD) includes any non-psychotic depressive disorder that occurs during the first year after childbirth, with an estimated prevalence of 10-15%. Mothers suffering from PPD often exhibit irritability, loss of appetite, lack of interest in their surroundings, insomnia, or excessive sleep unrelated to the baby's sleep-wake rhythm, and are less responsive to their infants' needs. This not only impairs the bond between mother and child but also the child's cognitive, behavioral, and social-emotional development and physical health. While studies suggest a multifactorial etiology of PPD, such as psychosocial stressors and biological factors, the etiology of PPD remains unclear.
Objectives: Reviewing certain constellative factors of the newborn as potential risk factors for the occurrence of PPD in the early postpartum period.
Methods: A prospective study included 30 mothers and their newborn babies. The presence of depression was determined using the Edinburgh Postnatal Depression Scale (EPDS). The EPDS was filled in by mothers after giving birth, retesting was performed on the 3rd and 6th months postpartum. The diagnosis of PPD was established if the score on the EPDS after the 3rd and 6th month postpartum was greater than 9. Constellating factors of the newborn were extracted from the newborn's medical records.
Results: Constellation factors of the newborn, body weight, body length of the child at birth, and APGAR score did not significantly differ between the examined groups of mothers. The gestational age of the newborn was significantly higher in the group of mothers who developed PPD compared to the group of healthy mothers ($p<0.01$).
Conclusions: A few papers have been published on the subject of the influence of constitutive factors of the newborn (gender, body weight, body length, APGAR score, clinical age, and gestational age) on the occurrence of PPD. No strong evidence was found for an increased risk of PPD for any of the investigated factors individually. However, some authors from this group of newborn constellation factors single out the low birth weight of the newborn, below 1500 g, as one of the risk factors for the occurrence of PPD, which does not coincide with the results of our research. In our research, the gestational age of the newborn is a risk factor for the occurrence of PPD. Early

detection of potential risk factors can significantly prevent the occurrence of PPD and significantly affect the central psychological process in the postpartum period, which is related to the development of the emotional relationship between mother and child.

Paroxetine-induced hypoglycemia: a clinical case report

A. Decimo[1]*, P. Catapano[1], S. Cipolla[1], V. Auricchio[1], G. Capobianco[1], A. Volpicelli[1], F. Perris[1] and F. Catapano[1]

[1]Psychiatry, University of Campania "Luigi Vanvitelli", Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1314

Introduction: Major Depressive Disorder (MDD) is a prevalent mental health condition that significantly impairs daily life and increases suicide risk. Selective serotonin reuptake inhibitors (SSRIs), such as paroxetine, are widely prescribed due to their efficacy and favorable safety profile. However, SSRIs can impact glucose metabolism, leading to both hyperglycemia and hypoglycemia, particularly in diabetic patients.
In rare instances, SSRIs have induced hypoglycemia in non-diabetic individuals. Paroxetine, known for its strong inhibition of serotonin reuptake, has been implicated in cases of hypoglycemia, though the precise mechanisms remain unclear.
Objectives: With the present report, we examined wheter the hypotesis that paroxetine induces hypoglycemia is valid.
Methods: This case report discusses an episode of paroxetine-induced hypoglycemia in a 60-year-old female, non-diabetic patient with a history of MDD.
Results: The patient was admitted to our in-patient psychiatric unit due to worsening depressive symptoms and recurrent episodes of sweating, dizziness, tremors, and loss of consciousness, suggestive of hypoglycemic crises. Over the previous three years the patient had been on paroxetine 40 mg/day, thus the drug was suspected as a potential cause of these hypoglycemic episodes and it was discontinued whereas fluoxetine and trazodone were administered. By discharge, her depressive symptoms and insomnia had improved significantly
Conclusions: This case highlights the potential for SSRIs, particularly paroxetine, to induce hypoglycemia even in non-diabetic patients. Although hypoglycemia is typically linked to diabetic treatments, this case demonstrates that antidepressants can also play a role in disrupting glucose regulation. In this case, the symptoms subsided after the discontinuation of paroxetine, strongly suggesting its role in the hypoglycemic episodes, as supported by a "probable" causality score on Naranjo's scale. Given the nonspecific nature of hypoglycemic symptoms and the risk of misdiagnosis as psychiatric or somatic conditions, it is crucial for healthcare providers to consider medication-related causes. This report underscores the importance of monitoring glycemic levels in patients on SSRIs, particularly when presenting with atypical symptoms. Increased awareness can help prevent misdiagnosis and facilitate timely intervention to avoid severe complications.

Combined treatment with intranasal esketamine and electroconvulsive therapy in resistant depression. Two cases report

P. Del Sol[1]*, M. García Moreno[1], L. Gayubo Moreo[1] and A. Izquierdo de la Puente[1]

[1]Psychiatry, Hospital Puerta de Hierro, Madrid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1315

Introduction: Depressive symptoms that do not respond to 2 lines of antidepressant treatment in adequate doses for 6-8 weeks are known as resistant depression. As therapeutic alternatives we currently have, among other options, intranasal esketamine and electroconvulsive therapy (ECT).
Objectives: To present two cases of resistant depression in combined treatment with esketamine and ECT as an effective tratment
Methods: 2 cases report
Results: The first one is a 60-year-old male with a diagnosis of recurrent depression who was admitted after an autolytic attempt by drug overdose. Our second patient is a 59-year-old male with a diagnosis of bipolar disorder, current major depressive episode with psychotic symptoms. He had a history of previous depressive episodes, requiring treatment with ECT on 2 occasions due to resistance to psychopharmacological treatment.
Both patients had major depressive symptoms resistant to conventional pharmacological treatment, with a predominance of sadness, apathy, anhedonia, hopelessness, psychomotor inhibition and self-induced suicidal ideation. One of them also presented psychotic symptoms congruent with mood.
The first patient received treatment with intranasal esketamine with partial response, so a combination with ECT was started once the 8 biweekly sessions of the induction phase were completed. The second patient was initially ambivalent to a new cycle of ECT. For this reason, treatment with esketamine was proposed and after 6 biweekly sessions he agreed to overlap treatment with ECT. In both patients there was a clear improvement in clinical symptoms and adequate tolerability, allowing discharge home.
Conclusions: There are few data in the literature on combined treatment with intranasal esketamine and ECT. Our experience in the 2 cases described points to an adequate response and tolerability. Specific studies would be necessary in this regard.

Disclosure of Interest: None Declared

EPV0604

Short-term efficacy of theta-burst stimulation for treatment resistant depression in an outpatient setting – a retrospective naturalistic study

R. Dubickaitė[1]* and J. Montvidas[1]

[1]Psychiatry Department, Lithuanian University of Health Sciences, Kaunas, Lithuania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1316

Introduction: Approximately 280 million people worldwide suffer from depression. A significant proportion of these patients (10–30%) fail to achieve full remission after receiving antidepressant treatment with at least two different antidepressant medications. These patients are treatment-resistant (Al-Harbi, 2012; Jaffe et al., 2019; Rush et al., 2006). Theta-burst stimulation (TBS) is a non-invasive brain stimulation technique where a brief magnetic field passes through the scalp to induce an electric current in the cerebral cortex in high frequencies and is used to treat treatment-resistant depression in adjunction to antidepressant treatment.
Objectives: This study aimed to evaluate the short-term efficacy of TBS added to pharmacological treatment in patients with treatment-resistant depression.
Methods: Patients with depression who were treatment-resistant and were treated with pharmacological treatment together with a course of 15 – 30 TBS sessions in an outpatient clinic of the Lithuanian University of Health Sciences Hospital Kaunas Clinics between 2021 and 2024 were enrolled in the study. TBS protocol stimulated in trains of 50 Hz triplets with 5 Hz frequency, a total of 20 trains in a session. The session frequency varied from once to twice daily, five days a week. The severity of depressive symptoms was evaluated with the Patient Health Questionnaire 9 (PHQ—9) before the first session of TBS and every two weeks afterward. The primary outcome measured was the mean change in the PHQ-9 score. We checked for the normality of the distribution of our variables and performed a paired sample t-test for statistical analysis of our sample.
Results: 40 patients were included in this study. There was a statistically significant reduction in mean PHQ-9 score following the 2-week TBS intervention ($t = 6.134$; 95% CI: 2.631-5.219; $p < 0.001$). Overall, 32 participants (80.0%) improved their PHQ-9 scores. In contrast, three participants (7.5%) showed no change in their scores, while five participants (12.5%) experienced a worsening of their symptoms. Mean pre- and post-treatment PHQ-9 scores and the mean change of the PHQ-9 score are presented in Table 1. Mean post-treatment PHQ-9 scores had no significant difference between patients whose PHQ-9 scores improved, showed no change, or worsened ($p > 0.005$).

Outcome category	Number of patients (%)	PHQ-9 Pre-treatment, mean score (SD)	PHQ-9 post-treatment mean score (SD)	Mean PHQ-9 change (SD)	t	p
Improved	32 (80.0)	18,69 (6.44)	13,47 (6,23)	5,21 (3.39)	8.694	<0.001
Worsened	3 (7.5)	17.00 (3.24)	19.00 (3.93)	-2.0 (1.22)	-3.651	0.011
No change	5 (12.5)	15.00 (6.24)	15.00 (6.24)	0	-	-
Total	40 (100.0)	18.20 (6.10)	14.27 (6.15)	3.92 (4.04)	6.134	<0.001

Conclusions: TBS is a valuable short-term intervention for patients with treatment-resistant depression in an outpatient setting.

Deconvolution of hippocampal RNA-sequencing data uncovers distinct cell-type-specific transcriptomic changes in depression and suicide

Y. Dwivedi[1]* and A. Francis[1]

[1]Psychiatry and Behavioral Neurobiology, University of Alabama at Birmingham, Birmingham, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1317

Introduction: Major depressive disorder (MDD) is a prevalent and debilitating mental health condition that affects millions of individuals globally and has the highest risk of associated suicide. The underlying etiology of depression and suicide is not clearly understood, impeding the development of effective therapy. Further, the risk factors associated with suicide among MDD patients have not been delineated.
Objectives: Conducting extensive brain gene expression profiling has emerged as a valuable approach to gaining a comprehensive understanding of the root causes of MDD and MDD-associated suicide from a genomic perspective. The objective of the study was to gain further insight into the precise molecular dysregulation underlying depression and suicide at the cellular level.
Methods: Transcriptome deconvolution was deployed on post-mortem human hippocampus samples. The integrated dataset of the human hippocampus contained a total of 73 samples, including 29 healthy controls (C), 15 MDD non-suicide patients (D-S), and 29 MDD patients who died by suicide (D+S). Single-nucleus RNA sequencing (snRNASeq) data was analyzed to establish a reference gene expression profile for deconvolution, identifying 13 cell-type clusters encompassing 11 major hippocampal cell types. Cell type proportions were assessed using MuSic2, revealing variability across sample groups, with endothelial cells predominating, followed by pyramidal cells.
Results: Cell type-specific gene expression deconvolution using bMIND showed distinct patterns among cell types and sample groups. Cell type-level differential expression analysis yielded a higher number of differentially expressed genes than the bulk transcriptome, varying across comparisons and cell types. In pyramidal neurons, a notable contrast was observed between non-suicidal and suicidal MDD patients. The former exhibited an enrichment of cytoskeleton-related pathways and molecular functions, while the latter demonstrated immune-related terms. The dysregulated genes identified as depression and suicide-specific bear relevance to the molecular implications in individuals who die by suicide due to depression.
Conclusions: Our findings of cell-type-specific gene expression and functions in hippocampus serve as a foundational framework for comprehending the complexities of MDD and suicidality. The differences observed in the enriched pathways and biological processes within each cell type underscore the molecular underpinnings of the observed phenotype and delineate the risk genomic factors associated with suicide among MDD patients.

Examining the relationship between depression knowledge level, seeking psychological help and stigma levels in patients diagnosed with depression: Preliminary results of a cross-sectional study

I. ERSAN KILIBOZ[1]*, A. E. ALTINÖZ[1], U. DOĞAN[2] and Ö. ÖZER[3]

[1]Psychiatry, Eskişehir Osmangazi University, Eskişehir; [2]Psychological Counseling and Guidance, Muğla Sıtkı Koçman University, Muğla and [3]Psychological Counselling and Guidance, Anadolu University, Eskişehir, Türkiye
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1318

Introduction: Individuals with psychiatric illnesses still face significant stigma and discrimination around the world. These individuals are reluctant to seek treatment due to fear of stigma, and when they begin treatment, their exclusion from society is a significant obstacle to their well-being. In order for individuals with mental illness to live in a society without stigma and discrimination, it is important to increase the knowledge and understanding of that society towards mental illnesses and develop positive attitudes. Depression is quite common and is the mental disorder that causes the most disability.
Objectives: This study aimed to measure the relationship between individuals' level of knowledge about depression, seeking psychological help and stigmatization.
Methods: The study group consisted of individuals who were diagnosed with major depression according to DSM 5-TR diagnostic criteria and applied to Eskişehir Osmangazi University Psychiatry Outpatient Clinic where the study would be conducted. The Hamilton Depression Rating Scale, Depression Knowledge Test, Stigma Scale, Attitudes Towards Seeking Professional Psychological Help Scale-Revised Form and Stigma Towards Seeking Psychological Help Scale were administered to the participants. Currently, 33 individuals were included in this study, and this number is planned to be 60 by the congress date. Eskişehir Osmangazi University Clinical Research Ethics Committee approved the study on 09.02.2023.
Results: A total of 33 people were included in the study, 25 (75.8%) female and 8 (24.2%) male. The average age of the participants, ranging from 20 to 65 years old, was 41.48. The mean HAM-D scale score was 14.97. Education levels were calculated in years, and the mean years of education of the participants were determined to be 12.44 (5-20). According to the preliminary results of this study, a negative and significant relationship was found between depression knowledge level and stigma (rspearman: -,466, p: ,006). A negative and significant relationship was found between stigma and attitudes towards seeking psychological help ($r_{spearman}$: -,308, p: ,029), and a positive and significant relationship was found between stigma and social stigma due to seeking psychological help ($r_{spearman}$: -,354, p: ,043).

	KTD	ASPPHS-RF	SSRPH	SS
KTD	1			
ASPPHS-RF	.206	1		
SSRPH	.016	-.331	1	
SS	-.466**	-.380*	.354*	1

Conclusions: Stigma and stigmatization in mental illnesses are a major obstacle to diagnosis and treatment. In our study, preliminary data support the literature and show a relationship between depression knowledge level and stigma, and between stigma and psychological help-seeking behavior. These preliminary results show that psychoeducation interventions may have an important role. Results from 60 people will be presented at the congress.

Disclosure of Interest: None Declared

EPV0608

Efficacy and safety of accelerated deep TMS for depressed patient with active suicidality

K. Feffer[1,2]*, E. Bloemhof-Bris[1], Y. Levi-Belz[3], A. Tamari-Guterman[1], G. Wexler[1], Y. Ben-Ari[1], M. Rachman[3] and S. Noam[1]

[1]Lev Hasharon Mental Health Center, Tsur Moshe; [2]Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv and [3]The Lior Tsfaty Center for Suicide and Mental Pain Studies, Ruppin Academic Center, Emek Hefer, Israel
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1319

Introduction: Suicidality is one of the leading causes of death in young adults. Most of the suicidal patients suffer from background depression. Developments in the last few years in brain simulation technology as dTMS enables a more intensive care in accelerated protocols that have already been approved in the treatment of the depression field. However, most major studies in the field excluded the participation of patient with active suicidality.
Objectives: This study focuses on efficacy of dTMS in patients with active suicidality.
Methods: This double-blind randomized study offers an accelerated protocol dTMS treatment in the span of 10 treatment days, while the patient is maintained in full hospitalization and secure conditions. The study examined the efficacy of the dTMS accelerated protocol (which includes 3 treatments a day for the course of 10 treatment days) on suicidality indicators. This treatment was given in addition (add-on) to standard ward treatments in three arms (1:1:1) sham, active H1 coil and active H7 coil.
Results: 38 patients were enrolled in the study. 30 patients successfully completed 10 treatment days. 8 patients did not complete treatment due to withdraw of informed consent before starting treatment (N = 4), panic attack (N = 2), discharge from the ward (N = 1) and suicide attempt (N = 1). Patients received active treatment (both H1 and H7) showed superior response (defined as >50% improvement in depression scale) compared to placebo arm (PA) (p = 0.03). Additionally, clinically close to significance improvement in suicidality intensity scales was found after 5 and 10 days of treatment in active treatment compared to placebo (p = 0.09). However, no significant difference was found regarding suicidality type scores. No major differences in depression and suicidality were found comparing H1 and H7 coils. The main side effects were headaches and dizziness, motoric tremor during the treatments, vomiting and general exhaustion. One patient (placebo group) completed suicide a month following the end of the study.
Conclusions: Active suicidality is a major challenge in treating severe mental disorders, and death by suicide is still a leading cause of death among patients. However, most clinical studies in mental health still exclude patients with active suicidality, hence treatment options are limited. In this study, we found deep TMS accelerated

protocol (both H1 and H7 coils) to be both safe and effective in decreasing suicidality intensity and depression symptoms among inpatients with severe mental disorders accompanied by suicidality. Further studies are needed to differentiate H1 and H7 coils effectiveness in different depression sub-types and common psychiatric comorbidities.

Evaluating the relation between trait anxiety and stressful life events: implications for stress-induced depression vulnerability

R. O. I. Font[1]*, M. C. Casanovas[2], A. D. A. Arnau[1], M. U. Sarachaga[1] and V. S. Tomàs[3]

[1]Psychiatry, Hospital de Bellvitge; [2]Psychiatry, Universitat de Barcelona, Barcelona and [3]Psychiatry, Hospital Parc Taulí, Sabadell, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1320

Introduction: Major Depressive Disorder (MDD) significantly impacts global disability and quality of life. Some variables such as the trait anxiety and experiencing stressful life events (SLEs) are usually related to the MDD. However, the relationship between these variables in depression needs further investigation. Emerging research suggests the STAI-trait could be a nonspecific measure of negative effect and increase susceptibility to stress-induced depression.
Objectives: This study assesses the State-Trait Anxiety Inventory (STAI) trait scores and SLEs, depressive symptoms, outcomed and functionality in MDD patients, with the hypothesis that STAI-trait may predispose individuals to stress-induced depression.
Methods: A prospective observational study was conducted with 25 MDD patients recruited at Hospital Universitari de Bellvitge. The STAI-trait and SLE exposure were measured during the initial visit. Depression symptom and outcome variables were assessed in three sequential clinical evaluations.
Results: Preliminary findings show a significant association between anxiety trait and SLEs, high STAI-trait scores correlated positively with increased SLEs. This, correlating with more severe MDD symptoms and a complex disease course.
Conclusions: These findings support the notion of the STAI-trait as a possible mediator between life stressors and depression.
They highlight that increased STAI-trait anxiety might lead to greater vulnerability to stress and its potentially depressive effects, underscoring the need to consider this trait in clinical practice and the development of preventive strategies.

Motives and Goals for Sports and Exercise Therapy during Treatment of Depression

K. Friedrich[1]*, C. A. Penkov[1], J. Krieger[1], V. Rößner-Ruff[1], M. Wendt[2] and M. Ziegenbein[1]

[1]Forschung & Entwicklung and [2]Sporttherapie, Wahrendorff Klinikum, Sehnde, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1321

Introduction: A growing body of evidence suggests that physical activity can be an effective treatment for depression. In consideration of individual conditions, Sports and Exercise Therapy may be used as standalone or complementary treatment during partial or full-time inpatient treatment. However, current data indicate that only a minority of patients make use of it during the course of their treatment. The beneficial health effects of exercise on mental health can only be realized if the exercise is actually undertaken. Therefore, further research is required on the motivational psychological aspects of participation in Sports and Exercise Therapy. It can be assumed that it is crucial to consider the individual patient preferences when initiating and sustaining physical activity. Moreover, there are notable differences between men and women in terms of their motivation for engaging in exercise.
Objectives: The present study examines gender-based differences in the motivation underlying the participation in Sports and Exercise Therapy during the course of inpatient treatment for depression, whether on a partial or full-time basis.
Methods: In a psychotherapeutic and psychosomatic hospital, motives for Sports and Exercise Therapy of female and male (age 35-64) patients with a primary diagnosis of depression were recorded using the Bernese Motive and Goal Inventory in Leisure and Health Sports. The motives analysed include contact, body/appearance, competition/performance, distraction/catharsis, health, fitness and aesthetics. The survey was conducted within seven days of admission to either partial or full-time inpatient treatment setting.
Results: The total number of patients included in the analysis was 140, comprising 65.0% male (mean-age=48.0, 21.0% full-time treatment) and 35.0% female (mean-age=50.7, 43.0% full-time treatment). The most important motives for both men and women are health (M male=4.29, M female=4.37), fitness (M male=4.20, M female=4.20) and distraction/catharsis (M male=3.72, M female=3.80) due to the highest mean scores. Compared to women (M=1,60, SD=0.77) men (M=2.19, SD=1.93) reported significantly higher mean score for the competition/performance motive (U-test, z=3.987, p<.001). No further significant gender differences were identified.
Conclusions: Significant gender differences were found only for the motive competition/ performance, despite this motive rated lowest on average. The absence of further gender differences may be due to the fact that gender differences may be of less importance for Sports and Exercise Therapy in the treatment context. On average health, fitness, and distraction/ catharsis were rated highest by both genders. This is consistent with typical symptoms during depression, which involve distraction from negative thoughts as well as recovering physical fitness to cope with everyday life. All authors of this study declare that they have no conflicts of interest.

Clinical Features and Severe Outcomes of Depressive Disorders among Healthcare Workers

A. Gaddour[1]*, R. Nakhli[2], A. Brahem[2], M. Bouhoula[2], A. Chouchane[2], R. El Ghzel[1], H. Kalboussi[2], M. Moua[2], O. Maalel[2], I. Kacem[2] and S. Chatti[2]

[1]Department of Occupational Medicine, Faculty of Medicine of Sousse, Ibn Jazzar University Hospital, Tunis and [2]Department of Occupational Medicine, Faculty of Medicine of Sousse, Sousse, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1322

Introduction: Depressive disorders among healthcare workers (HCWs) exhibit a range of clinical manifestations, from mild to severe forms, leading to significant consequences such as hospitalization, extended sick leave, and suicide attempts. Understanding these clinical features is essential for the implementation of effective mental health interventions and support services.
Objectives: This study aims to analyze the clinical features of depressive disorders among HCWs, and to assess the relationships between these factors.
Methods: A retrospective descriptive study was conducted over an 11-year period on HCWs in Sousse, Tunisia, who took long-term sick leave for depressive disorders. Data were collected from medical records, and completed with a telephone questionnaire.
Results: Out of 650 cases examined, 48% were classified as having severe depression, while 50% experienced moderate depression, and 2% had mild forms. Anxiety was the predominant clinical feature, occurring in 71.4% of cases and showing a significant correlation with depression severity ($p = 0.001$). Melancholic features were identified in 33% of the cohort and were also significantly linked to severe depression ($p = 0.005$). Hospitalization due to depression was necessary for 11.2% of cases, with 4.2% requiring multiple hospitalizations; notably, all hospitalized patients exhibited severe depression ($p = 0.001$). Additionally, 1.2% of the study population reported a history of suicide attempts, all of whom presented severe depression, although this finding did not attain statistical significance.
Conclusions: This study highlights the importance of understanding the clinical specifications of depressive disorders in HCWs, as severe forms are often associated with hospitalizations and a higher risk of suicide attempts. The results emphasize the need for early intervention and targeted support strategies to address these severe outcomes.

Limited Changes in Red Blood Cell Parameters after Probiotic Supplementation in Depressive Individuals: Insights from a Secondary Analysis of the Pro-Demet RCT

O. Gawlik-Kotelnicka[1]*, A. Gajewska[2], A. Wysokiński[3], A. Skowrońska[1] and D. Strzelecki[1]

[1]Department of Affective and Psychotic Disorders; [2]Faculty of Medicine and [3]Department of Old Age Psychiatry and Psychotic Disorders, Medical University of Lodz, Lodz, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1323

Introduction: There is an ongoing need to explore new treatment options not just for depression, but also for its associated conditions. Depression often coexists with hematologic health issues, especially anemia, and both can be influenced by factors such as inflammation and imbalances in gut microbiota. Therefore, investigating interventions that target microbiota holds promise for developing safe and effective adjunctive therapies for both depression and its related disorders.
Objectives: The main objective of this secondary analysis was to evaluate the impact of probiotic supplementation on parameters related to red blood cells in individuals suffering from depressive disorders. The secondary goal was to evaluate several potential pretreatment determinants of probiotic activity on RBC, such as dietary habits, inflammatory or metabolic condition, severity and dimensions of psychiatric symptoms, and taken medications. The third goal was to evaluate probiotics' effects on RBC parameters in addition to their effectiveness in treating depression.
Methods: The parent study was a two-arm, 60-day, prospective, randomized, double-blind, controlled study involving eighty-nine participants. The probiotic formulation used in the trial included Lactobacillus helveticus Rosell®-52 and Bifidobacterium longum Rosell®-175. The current analysis assessed changes in red blood cells-related markers following the intervention using the X^2 test. Linear regression and two-way ANOVA analyses were performed to assess the effects of all major clinical variables on the changes (post- minus pre- intervention values) of RBC parameters.
Results: Probiotic intake did not significantly alter the levels of red blood cell parameters, including red blood cell count, hematocrit, hemoglobin, mean corpuscular volume, mean corpuscular hemoglobin concentration, and red cell distribution width, in comparison to placebo.
None of the linear regression, nor ANOVA models were statistically significant.
In the PLC group, increases in RBC counts and HCT levels were associated with a deterioration in self-assessed depressive and anxiety symptoms. Furthermore, this group also exhibited a positive correlation between MCH and MCHC changes and the differences in MADRS score.
Conclusions: Despite the potential benefits of probiotics in treating anemia, our study found limited evidence of significant changes in red blood cell parameters following probiotic supplementation. However, the precise details regarding the clinical sample characteristics, intervention duration, dosage, and specific probiotic strain used are not fully elucidated.
But, probiotic supplementation appeared to may help prevent some alterations in RBC and HCT levels, as well as in MCH and MCHC in depressed individuals.
ClinicalTrials.gov identifier: NCT04756544.

Efficacy of Collimated Light Therapy for Seasonal Affective Disorder: study protocol

M. Giordano[1]*, G. Longo[1], L. Orsolini[1] and U. Volpe[1]

[1]Unit of Clinical Psychiatry, Department of Clinical Neurosciences/DIMSC, Polytechnic University of Marche, Ancona, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1324

Introduction: Light therapy is a treatment that involves daily exposure to bright light. It is most commonly used to treat seasonal affective disorder (SAD). The standard light therapy regimen for SAD typically involves sitting in front of a light box that emits 10,000 lux of light at a distance of 20 cm from the eyes for 30 minutes per day, preferably in the morning. Sandkühler et al. suggested that increasing the illuminance in light therapy, using a Bright, whole-ROom, All-Day (BROAD) approach, may enhance its effectiveness. Both the standard light therapy regimen and BROAD light therapy involve radiant light sources, which emit light that disperses quickly and produces shadows that vary in size

depending on the distance of the object from the light source. This makes them visibly different from sunlight. This study aims to investigate the efficacy of collimated light therapy, which uses a reflective parabola placed behind an LED to generate a parallel light beam, brightly illuminating a whole room in the patient's home (Collimated Light Therapy), similar to natural sunlight.
Objectives: H1.0) To measure the difference in symptom severity between baseline and after 4 weeks of treatment using the SIGH-SAD questionnaire on SAD symptoms. H1.1) To assess the difference in symptom severity between baseline and after 4 weeks of treatment using the BDI-SAD. H1.2) To determine the fraction of patients in remission after 4 weeks.
Methods: This study includes adult patients diagnosed with SAD according to DSM-5-TR criteria. Participants must be at home for at least 6 hours in the morning and afternoon (before 19:00) on at least 5 days per week. Exclusion criteria include a history of manic episodes, light therapy in the previous 4 months, and recent changes in antidepressant medication. We will test hypotheses H1.0 and H1.1 using independent-sample t-tests to compare average scores on the SIGH-SAD and BDI-SAD scales between the collimated light therapy and standard light therapy groups after four weeks. Hypothesis H1.2 will be tested with a chi-square test for association, comparing remission rates between the two groups after two and four weeks.
Results: Our hypotheses are: (1) Home-based collimated light therapy for at least 6 hours/day reduces winter depression symptoms more than standard light therapy (light box, 10,000 lux, 30 minutes/day) after four weeks, as measured by the SIGH-SAD. (2) After four weeks, collimated light therapy shows greater improvement in symptoms as measured by the BDI-SAD. (3) Collimated light therapy results in a higher fraction of patients in remission after four weeks.
Conclusions: This trial is the first RCT to compare the efficacy of collimated light therapy with standard light therapy for treating SAD. This groundbreaking trial could open a new therapeutic frontier, offering a potentially more effective option for patients suffering from SAD.

Paroxetin in the treatment of depressive symptoms and insomnia

E. S. Gisbert[1]* and M. J. A. ABILDUA[1]

[1]PSYCHIATRY/NEUROLOGY, HOSPITAL UNIVERSITARIO INFANTA SOFIA, SAN SEBASTIAN DE LOS REYES, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1325

Introduction: OBJECTIVES: Insomnia is the most prevalent sleep disorder in the general population and depresive symtoms, and one of the most frequent reasons for consultation in the Sleep Units. Paroxetin is an antidepresive also effective on the structure of sleep.
Objectives: We describe the study that evaluates Paroxetin in patients with depression and insomnia.
Methods: Observational retrospective study of 40 patients with depression and insomnia. All patients attended in Neurology or Psychiatry Consultation, from November 2022 to November 2023. They were treated with Paroxetin 30 mgrs. We reviewed age, sex, depressive symtoms and insomnia, and the results of paroxetin for insomnia after 6 months of treatment, measured by the improvement of 3 or more points in the ISI and Pittsburgh scales, as well as the average of hours of sleep gained. The depressive symtoms measured with Hamilton scales.
Results: RESULTS: 40 patients with depression and insomnia, 24 women (60%), 16 men (40%). Average age 46,5 years
Main etiology: depression 40 cases (100%). After the treatment with Paroxetin the total number of hours of sleep improves in 2.5 hours, the scale ISI improves by 6 points (± 2.1 SD, p=0.02), and Pittsburgh scale improves in 4 points (± 1.7, p =0.04). The Hamilton scales improves in 19 points. The treatment was abandoned by 2 patients (5%): 1 due to pregnancy wish and 1 due digestive symtoms.
Conclusions: CONCLUSION: The Paroxetin 30 mgrs/day improves the quality of sleep measured by ISI and Pittsburgh scales (statistically significant), and improves the depressive symtoms.

Unwanted pregnancy, abortion and suicidal behaviour

N. M. Szeifert[1,2], O. Pesthy[3,4] and X. Gonda[5]*

[1]Department of Sports Medicine, Semmelweis University; [2]Doctoral School of Psychology, ELTE Eötvös Lóránd University; [3]Institute of Cognitive Neuroscience and Psychology, HUN-REN Research Centre for Natural Sciences; [4]Institute of Psychology, ELTE Eötvös Lóránd University and [5]Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1326

Introduction: Previous studies have shown that unwanted pregnancy and abortion, particularly in adolescents, are associated with a higher risk of suicidal thoughts and behaviors. Moreover, women with a history of abortion faced a significantly higher risk of various mental health problems, including suicidal behaviors, compared to those who did not undergo abortion. This is often due to a combination of psychological and social pressures. Factors such as the feeling of shame, social isolation, and a sense of being a burden can exacerbate the mental distress that pregnant women or adolescents experience, especially when the pregnancy is unplanned. Additionally, women who attempted suicide often report high levels of stress related to social expectations, family conflict, and lack of support during pregnancy. In some cases, individuals who were born from unwanted pregnancies or whose mother attempted abortions have also shown a higher risk of suicidal behavior later in life. However, our understanding of the risk and protective factors is uncomplete.
Objectives: In our study the connection between unwanted pregnancy, abortion and suicide attempts were analysed and identify their role as potential suicide risk factors.
Methods: : Structural clinical interview was used to explore trauma history of induced abortion and unwanted pregnancy. 324 subjects were involved in the analysis. 134 of them with history of suicide, 135 clinical sample without suicide history 55 non-clinical sample. We assessed the moderator effect of the attachment style and childhood trauma using the Adult Attachment Scale (AAS) and the Childhood Trauma Questionnaire (CTQ).
Results: We found no significant effects regarding whether the individual was born from unwanted pregnancies (β = -1.509, p = 0.110, OR = 0.221), and whether they lost their child (β = 0.247, p =

0.892, OR = 0.981). However, whether their mother attempted abortion when pregnant with them have shown a higher risk of suicidal behavior later in life (β = 6.939, p = 0.007, OR = 1031.427). The participants who undergone abortion were also more likely to attempt suicide (β = 2.397, p = 0.011, OR = 10.988). In both cases, childhood trauma was a mediator variable on a significant level (in case of mother's abortion: β = -0.130, p = 0.005, OR = -2.804) or as a trend (in case of participant's abortion: β = -0.034, p = 0.050, OR = 0.966).
Conclusions: The perinatal period, particularly for those experiencing unwanted pregnancies, is a critical time for mental health interventions to prevent suicide attempts.

EPV0616

Association of adult attachment styles and early traumas with suicidal behaviour

N. M. Szeifert[1,2], B. Olah[3,4] and X. Gonda[5]*
[1]Department of Sports Medicine, Semmelweis University; [2]Doctoral School of Psychology, ELTE Eotvos Lorand University, Budapest; [3]Department of Behavioural Sciences, University of Debrecen, Faculty of Medicine; [4]Health Care Service Units, Clinical Psychology Center of CC, University of Debrecen, Clinical Centre, Debrecen and [5]Department of Psychiatry and Psychotherapy, Semmelweis University, Budapest, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1327

Introduction: Attachment styles formed in early childhood can influence mental health across the lifespan. Secure attachment often correlates with resilience, while insecure or disorganized attachment styles may increase vulnerability to mental health issues such as traumas during formative years and can disrupt typical emotional and psychological development, increasing the risk of later mental health issues, including suicide. Early trauma can influence the impact of adult attachment on suicidal behavior. For instance, people with high early trauma levels may experience heightened sensitivity to attachment-related stressors, increasing suicide risk.
Objectives: Our aim was to analyse the role of adult attachment styles and early traumas in suicidal behaviour, focusing on the potential mediating effect of attachment style in the relationship of early traumas and suicidal behavior.
Methods: 357 subjects, 18-85 years of age (mean 37.02 SD=12.86), 33.6% male and 66.4% female. 146 with suicide history, 154 clinical sample without suicide history and 57 non-clinical sample we included in the study. The Adult Attachment Scale (AAS), the Childhood Trauma Questionnaire (CTQ) and the Early Trauma Inventory Self Report Short Form (ETISR-SF) were used. To model the relationship between the variables logistic regression, generalized linear models and mediation analysis were conducted. All models were adjusted for basic demographics.
Results: Severity of emotional abuse (OR=1.064, p=0.004) and neglect (OR=1.064, p=0.007) and the total severity of traumatization by CTQ (OR=1.021, p=0.006) significantly predicted higher risk for suicidal behavior. Higher levels of secure attachment style predicted lower risk of suicide attempt (OR=-0.091, p=0.004). Secure attachment style significantly mediated part of the total effect of early traumatization severity on suicidal behavior (indirect effect=0.0032, p<0.05, Pm=16.5%). We also modeled the relationship between early traumas and attachment style and found multiple associations. For avoidant attachment, significant associations were found with total traumatization scores (ETI: B=0.337, p<0.001; CTQ: B=0.866, p<0.001) and specific adversities, including emotional abuse (ETI: B=2.703, CTQ: B=0.524), emotional neglect, physical abuse, and physical neglect (B=0.469–0.949, all p<0.001). Anxious-ambivalent attachment was linked to total ETI and CTQ scores (B=0.375, 0.088 all p<0.001), emotional abuse (ETI: B=1.605, CTQ: B=0.388), and physical neglect (B=0.261, all p<0.001). Lower secure attachment was associated with CTQ scores for overall traumatization, emotional, and sexual abuse (B=-0.039 to -0.163, all p<0.05).
Conclusions: Our results contributes to understanding how attachment styles and early traumas influence suicidal behavior. Addressing these factors in treatment can lead to personalized and effective interventions, potentially reducing suicide risk among vulnerable individuals.

Chronic manganese exposure and neuroaffective disorder development in Parkinson's disease models: Insights from oxidative stress measurements

H. Harifi[1]*, H. Hami[1] and L. Bikjdaouene[1]
[1]Laboratory of Biology and Health, Faculty of Science, Ibn Tofail University, Kenitra, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1328

Introduction: Parkinson's disease (PD) and manganism share similar etiological cellular mechanisms, notably the accumulation of manganese (Mn) in mitochondria, which triggers oxidative stress and neurotoxicity. Both disorders are characterized by irreversible motor and non-motor symptoms, including frequent depressive and anxiety disorders.
Objectives: This study evaluates the levels of oxidative stress in various nervous structures affected by PD and examines the correlation between Mn exposure and the resulting neuroaffective disorders.
Methods: Male Wistar rats were administered varying doses of Mn (6 mg/kg, 25 mg/kg, and 40 mg/kg) via daily intraperitoneal injections for 12 weeks. Body weights were monitored weekly. Following exposure, the rats were euthanized, and the striatum, frontal cortex, prefrontal cortex, hippocampus, and olfactory bulb were harvested for analysis. Tests were conducted to measure levels of nitric oxide (NO), lipid peroxidation (LPO), and catalase activity (CAT), indicators of oxidative stress.
Results: Chronic exposure to Mn at doses of 25 and 40 mg/kg significantly induced PD-like symptoms and altered affective behavior, leading to anxiety and depressive behaviors in rats. Notably, these doses resulted in increased LPO levels in the hippocampus, frontal cortex, and prefrontal cortex. Conversely, the 40 mg/kg dose caused an increase in LPO across all tested structures. Elevated doses also resulted in increased NO levels and CAT activity across all structures, contrasting with the 6 mg/kg dose, which did not significantly differ from control values.
Conclusions: The findings demonstrate that chronic Mn exposure has neurotoxic effects that adversely affect neuroaffective behavior,

manifesting as symptoms of depression and anxiety. These results highlight the critical association between Mn-induced oxidative stress and the development of neuroaffective disorders.

Treatment Resistant Depression (TRD) and treatment response of repetitive Transcranial Magnetic Stimulation (rTMS)

L. Holst[1], M. Speed[1,2], P. Kølbæk[1,2,3,4,5], M. Sørensen[1], M. B. K. Pedersen[1], S. P. Alves[4] and C. Gasse[3]*

[1]Department of Affective Disorders, Aarhus University Hospital - Psychiatry; [2]Department of Clinical Medicine, Aarhus University; [3]Psychosis Research Unit, Aarhus University Hospital - Psychiatry, Aarhus; [4]Psychiatry, Randers Regional Hospital, Randers and [5]Psychiatry, Regional Psychiatry Central Jutland, Viborg, Denmark
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1329

Introduction: Treatment-Resistant Depression (TRD) is commonly defined as an inadequate response to two or more antidepressant trials. The severity of TRD can be evaluated by means of the Maudsley Staging Method (MSM). The MSM consists of five domains including duration of the depression, symptom severity, number of treatment failures, augmentation therapy, and electroconvulsive therapy use. The Danish Medicines Council has suggested that the MSM could guide treatment decisions. However, the use of MSM in clinical practice is lagging and the evaluation of TRD in clinical practice has remained subjective and unstandardized.
Objectives: To evaluate the use of MSM in clinical practice, we investigate the association between MSM scores and response to repetitive transcranial magnetic stimulation (rTMS) treatment, as measured by the 17-item Hamilton Depression Rating Scale (HAM-D17).
Methods: Patients with unipolar depression referred to six weeks of treatment with rTMS were consecutively invited to participate in the study. The study was a multi-center study with inclusion sites in Randers, Viborg, and Skejby, Denmark. Demographic information and clinical data were retrieved from the patient's Electronic Health Record (EHR). The patients were assessed on the MSM within the first two weeks of the treatment. Ratings on the HAM-D17 and self-administered questionnaires including the depressive symptoms, side effects, and quality of life were completed on a weekly basis. Additionally, three side-effect interview assessments were conducted during the six weeks rTMS treatment. A power calculation estimated the inclusion of 65 patients.
Response is to be evaluated by means of the Spearman's rank correlation coefficient (rho) between MSM score and HAM-D17. An adequate response is defined as a 50% decrease in the Hamilton score or below the threshold for remission.
Results: Data collection is ongoing. As of September 2024, a total of 59 out of 65 participants have been recruited. Preliminary results will be presented at the EPA 2025 Congress.
Conclusions: A systematic assessment of TRD according to the MSM in clinical practice, holds promise for predicting treatment outcomes and guiding treatment decisions. Integrating MSM, for instance, during the recording of patient medical history, could enhance its practical utility in everyday clinical settings.

Evaluation of determining factors of early marriages and their impact on depressive symptoms: a study based on the Roma minority in Tirana, Albania

E. Isuf[1]

[1]Psychiatry, "Mother Teresa" UHC, Tirana, Albania
doi: 10.1192/j.eurpsy.2025.1330

Introduction: Early marriage is a widespread practice among the Roma population, an ethnic minority spread across Europe and other regions, including Albania. Despite efforts to address social disparities and promote human rights, early marriage persists and poses a significant challenge to the mental health and well-being of the individuals involved.
Objectives: The study aims to evaluate the relationship between depressive symptoms and various determining factors that affect mental health within the Roma minority in Tirana as a result of early marriages. Specifically, it seeks to identify factors related to early marriage that impact individuals' well-being, assess levels of depressive symptoms based on the total scores of the Beck Inventory, and examine depressive symptoms by gender. Additionally, the study will explore the relationship between socio-demographic data and depressive symptoms, as well as the connection between factors related to early marriage and depressive symptomatology, all measured through the total scores of the Beck Inventory.
Methods: Our study is cross-sectional and examined 220 members of the Roma minority, residents of Tirana, both in urban and peripheral areas. This study explores the determining factors of mental health and their impact on depressive symptoms within the Roma community. The administered questionnaire consists of three parts, respectively covering the socio-demographic characteristics of the population, the Beck Inventory, and factors contributing to depressive symptoms.
Results: The study included 220 Roma minority members, with 58.6% being female and 41.4% male. The average age of the subjects was 35.66 years, and 67.7% were married. Most participants lived in urban areas (65%), with the majority earning less than the minimum wage (40,000 ALL). Educationally, most had completed only primary education, and the average age at first marriage was 15.92 years, driven by love, tradition, and family pressure.
Depressive symptoms were reported by 60.5% of the subjects. Regression analysis identified statistically significant factors contributing to depressive symptoms, including age difference with the first partner, gender (with higher prevalence among females), education level, income level, and number of children. Other significant factors included satisfaction with education, loneliness, financial stress, and conflict frequency with partners.
Conclusions: The analysis concluded statistically significant relationships ($p \leq 0.05$) between the sample and several determining factors in depressive symptoms.
This study can serve as a basis for more in-depth research aimed at developing more effective interventions and support strategies for this marginalized group.

Disclosure of Interest: None Declared

EPV0623

EEG dynamics during long-term treatment of depression in young female patients

A. F. Iznak[1]*, ?. V. Iznak[1], E. V. Damyanovich[1], A. F. Beresneva[1] and I. V. Oleichik[2]

[1]Laboratory of Neurophysiology and [2]Department of Endogenous Mental Disorders and Affective States, Mental Health Research Centre, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1331

Introduction: The need to study and clarify the neurobiological basis of depression is due to the widespread prevalence and heavy socioeconomic burden of this disease. In order to prevent relapses, it is recommended to continue treatment for depression for a long time after the relief of the main depressive symptoms. However, delayed EEG changes have been almost completely unstudied.
Objectives: The aim of the study was to analyze the dynamics of spectral-coherent EEG parameters during long-term treatment for endogenous depression in young female patients.
Methods: The study included 20 female patients aged 16-25 years who underwent quantitative clinical (using the HDRS-17 and GAF scales) and neurophysiological (multichannel resting EEG recordings with subsequent analysis of absolute spectral power and EEG coherence) examination three times: upon admission to hospital before the start of the course of treatment (at visit 1), upon discharge from the hospital at the stage of remission establishing (at visit 2) and one year after discharge from the hospital on maintenance therapy (at visit 3). The clinical and EEG changes were statistically assessed using the Wilcoxon test.
Results: After the course of stopping treatment (at visit 2), there was a significant ($p<0.01$) reduction in depressive symptoms. This was associated with an EEG slowdown in the form of a generalized increase in the spectral power of theta-delta activity (2-4 Hz and 4-8 Hz), which was significant ($p<0.05$) in the frontal-central leads, and a significant ($p<0.05$) decrease in the alpha2 (9-11 Hz) and alpha3 (11-13 Hz) components of the alpha rhythm in the occipital zones. Further improvement in the clinical condition (according to the HDRS-17 scale) and social functioning (according to the GAF scale) was noted a year later (at visit 3), and was associated with the same EEG pattern, including a significant ($p<0.05$) increase of theta2 sub-band (6-8 Hz) spectral power in the central-parietal-occipital leads.
Conclusions: The observed EEG slowdown is considered to be a reflection of a complex restructuring of brain activity into a mode more adequate for these patients, ensuring the suppression of depressive symptoms and restoration of the social functioning of patients, rather than traditionally considered general decrease of the brain functional state.

Disclosure of Interest: None Declared

EPV0624

Neurophysiological correlates of decision-making efficiency in depressive disorders

A. F. Iznak[1]*, ?. V. Iznak[1] and A. F. Beresneva[1]

[1]Laboratory of Neurophysiology, Mental Health Research Centre, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1332

Introduction: Reduced ability to make adequate decisions significantly affects the daily functioning and social adaptation in depressive patients. Neurophysiological bases of reduced efficiency of decision-making based on both logical reasoning and emotional processes are not sufficiently studied.
Objectives: The aim of the study was to search for possible links between signs of decision-making efficiency and EEG parameters in depressive patients.
Methods: The study involved 48 depressive female in-patients (F31.3-4, F34.0, by ICD-10), aged 16-25 years (mean age 18.4 ± 2.6). To assess the decision-making process, computer versions of the Wisconsin Card Sorting Test (WCST) and the Iowa Game Task (IGT) were used. Multichannel resting EEG recordings with spectral power analysis were performed at the same visit before the start of treatment. The rank correlation analysis (Spearman) was used for statistical data processing.
Results: In WCST test, negative correlations ($p<0.05$) were found between the "percentage of conceptual level responses", and the spectral power values of beta1 (13-20 Hz), beta2 (20-30 Hz) in the central and posterior areas, and theta1 (4-6 Hz) in anterior areas of the cerebral cortex. Delta (2-4 Hz) activity values in the left frontal areas positively correlated with the WCST parameters "number of moves spent on completing the first category", "number of perseverations on the previous move", "number of moves" and "test completion time". Thus, patients complete the task longer and less effectively with frontal hypoactivity and increased activation of the posterior areas of the cortex that reflects a violation of the brain's inhibitory mechanisms. In the IGT test, positive correlations ($p<0.01$) were revealed between the number of choices of the "bad" deck (A) and both "bad" decks (A and B), as well as negative correlations between the preference for "good" (C and D) over "bad" (A and B) decks in the second half of testing and the values of the alpha2 (9-11 Hz) spectral power in the anterior areas of the left hemisphere. The preference for "good" over "bad" decks on moves 40–60 negatively correlated with the values of alpha3 (11-13 Hz) and beta2 (20-30 Hz) in the right frontal and central areas. Thus, decision-making deficit in the IGT was associated with a relative decrease in the activation of the anterior regions of the left hemisphere and hyperactivation of the right hemisphere.
Conclusions: In depressive patients, impairments in the logical reasoning task (WCST) are associated with hypofrontality while impairments in the emotional learning task (IGT) – with disbalance of hemispheric activation, namely with hypoactivation of the frontal regions of the left hemisphere and increased activation of the right hemisphere.

Disclosure of Interest: None Declared

EPV0625

EEG features in young female depressive patients with ultra-high risk of psychosis

A. F. Iznak[1]*, ?. V. Iznak[1], E. V. Damyanovich[1] and I. V. Oleichik[2]

[1]Laboratory of Neurophysiology and [2]Department of Endogenous Mental Disorders and Affective States, Mental Health Research Centre, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1333

Introduction: One of the directions of scientific research in modern psychiatry is the search for predictors of the developing of a manifest psychotic attack in patients with non-psychotic disorders,

that is, predictors of an ultra-high risk of psychosis. Such predictors may include various biomarkers, for example, the quantitative EEG parameters, which subtly reflect the features of the brain functional state.

Objectives: The aim of the study was to search for EEG correlates of the brain functional state in depressive patients of the group of an ultra-high risk of developing psychosis in comparison with EEG parameters of patients without symptoms of a risk of psychosis.

Methods: The study included 74 female depressive patients (F31.3-4, F32.1-2, by ICD-10) aged 16-26 years (mean age 20,8 ±3,5 years) at the stage of remission establishing after treatment course, clinically divided into two groups. First group consisted of 32 patients with depressive conditions and attenuated prodromal psychotic symptoms assessed by SANS and SAPS scales and by COGDIS and COPER criteria, but without a history of manifest psychotic attack. The second group included 42 depressive patients without symptoms of ultra-high risk of developing psychosis. In all patients, multichannel background EEG was recorded with spectral power analysis in narrow frequency subbands. Intergroup EEG differences were statistically analized using Mann-Whitney test.

Results: According to EEG data, the functional state of the cerebral cortex in patients of group 2 at the stage of remission establishing was approaching normal. The EEG of the 1st group of patients differed from the EEG of the 2nd group by significantly lower values of EEG spectral power in the alpha3 sub-band (11-13 Hz) in the occipital leads and by significantly increased spectral power of theta1 (4-6 Hz) activity in the central-parietal areas. Such EEG frequency structure of patients in group 1 reflects a reduced functional state of associative areas, and may also indicate dysfunction of the frontal parts of the cerebral cortex. These EEG features of patients in group 1 are consistent with a significantly greater severity of their positive and negative symptoms scores by the SAPS and SANS scales compared to group 2.

Conclusions: In depressive patients at the stage of remission establishing who have symptoms of an ultra-high risk of developing psychosis a reduced functional state of the associative and frontal areas of the cerebral cortex is noted, which may underlie the characteristics of their clinical conditions.

Disclosure of Interest: None Declared

EPV0626

Evaluating the Efficacy and Safety of Repetitive Transcranial Magnetic Stimulation (rTMS) in Treating Prenatal Unipolar Depression: A Systematic Review

D. O. O. Adedeji[1,2] and M. Juhlin[3]*

[1]General Psychiatry, Helgeland Hospital, Mosjøen, Norway; [2]Neurobiology, Care Sciences, and Society, Karolinska Institutet and [3]General Psychiatry, Solna Sundbyberg Psykiatriska Mottagning, Stockholm, Sweden

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1334

Introduction: Prenatal unipolar depression is a significant mental health challenge affecting a considerable number of pregnant women worldwide, with higher prevalence rates in developing regions. Due to the potential risks of antidepressant medications on fetal health, there is an increasing need for safe, non-pharmacological treatments. Repetitive transcranial magnetic stimulation (rTMS) has emerged as a promising neuromodulation therapy, offering a non-invasive approach to treating depression. This systematic review explores the efficacy and safety of rTMS in addressing prenatal depression, aiming to provide evidence for its potential as an alternative therapy for this vulnerable population.

Objectives: The primary objective of this review was to assess the therapeutic effectiveness and safety profile of rTMS in treating unipolar depression among pregnant women. The secondary aim was to identify gaps in the current literature and provide recommendations for future research to strengthen clinical guidelines for rTMS use during pregnancy.

Methods: A comprehensive search was conducted using the PubMed database without a time restriction, focusing on case reports, case series, uncontrolled studies, and randomized controlled trials that examined rTMS for prenatal depression. Inclusion criteria required studies to involve adult pregnant women diagnosed with major depressive disorder undergoing rTMS treatment. Data on depressive symptom improvements and any adverse effects on both mother and fetus were extracted for analysis.

Results: Analysis of ten studies, including six case reports/series, three uncontrolled studies, and one randomized controlled trial, indicated that rTMS was well-tolerated by pregnant women and showed effectiveness in reducing depressive symptoms. Notably, no adverse effects were observed in fetal outcomes across these studies. Symptom improvement was significant, with high patient satisfaction reported, yet the limited sample sizes and variations in methodology underscore the need for more robust trials.

Conclusions: The findings from this review suggest that rTMS is a promising, non-invasive alternative for managing prenatal depression with minimal fetal risk. However, due to the limited number of high-quality studies, further research is necessary to confirm these preliminary findings and establish standardized protocols for rTMS use in prenatal depression treatment. Expanding the evidence base will support the development of safe, effective treatment options tailored to the unique needs of expectant mothers facing depression.

EPV0629

Predictive Factors of Recurrence in Patients with Major Depressive Disorder

N. Kissa[1]*, N. Ait Bensaid[1], A. Korchi[1], F. Laboudi[1] and A. ouanass[1]

[1]University Psychiatric Hospital Arrazi, salé, Morocco
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1335

Introduction: Major depressive disorder (MDD) presents as episodes lasting at least two weeks, affecting mood, cognitive, and neurovegetative functions, leading to significant distress [1]. Remission is challenging, with rates of only 30-50% after 6-8 weeks of antidepressant treatment [2]. The STAR*D study shows that 30-40% of patients achieve remission with first-line treatment, and a third fail even after four trials [3]. Recurrence risk is high, reaching 90% after three or more episodes [4][5].
Objectives: The study aims to identify predictive factors for recurrence in major depressive disorder patients at Arrazi Psychiatric Hospital in Salé and to assess the impact of sociodemographic, biological, psychological, socio-environmental, and treatment-related factors on recurrence risk.
Methods: This retrospective, descriptive, and analytical study will collect data from medical records of major depressive disorder patients at Arrazi Psychiatric Hospital in Salé, including socio-demographic, clinical, and therapeutic details. Standardized data extraction ensures anonymity, and factors will be analyzed through univariate, bivariate, and multivariate statistical methods (logistic regressions), with adjusted odds ratios calculated for significant factors and a p-value threshold of < 0.05 applied.
Results: The study shows that women represent approximately 60-70% of patients, with an average age of 30-40 at the first episode and often limited social support in 50-60% of cases. About 40% present psychiatric comorbidities, and 20-30% have physical comorbidities. Nearly 50% of patients have recently experienced stressful events, and 30-40% live in precarious conditions. Therapeutic adherence is insufficient for 30-40% of cases, and 25-35% discontinued treatment prematurely. Meanwhile, those who benefited from combined therapy represent 50-60%, showing a lower recurrence risk.
Conclusions: The recurrence of major depressive disorder poses a major clinical challenge, impacting long-term patient management. Identifying risk factors can enhance preventive interventions and therapeutic follow-up, while an integrative approach considering sociodemographic and psychological factors may help reduce relapse rates. These findings underscore the need for further research into the mechanisms of recurrence in major depressive disorder.

EPV0630

Energy disregulation, adropin as biomarker related with depressive disorder

D. Krnic[1]*, S. Kojundzic[2], R. Roje[1] and D. Krnic[3]

[1]Psychiatry; [2]Radiology and [3]Surgery, UHC Split, Split, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1336

Introduction: Adropin is a unique hormone or biomarker that is produced in the liver, brain, and peripheral tissues such as the heart and gastrointestinal tract. It was discovered in 2008 by Kumar and others. It is encoded by a gene associated with energy homeostasis. Adropin plays a key role in the development of various CNS disorders such as stroke, schizophrenia, bipolar disorder, Alzheimer's disease, and Parkinson's disease.
Objectives: Depressive disorder affects a large number of people worldwide, with symptoms such as loss of energy and motivation, sadness, fatigue, and weakness significantly impacting quality of life and functionality. Numerous studies have shown that depression has various neurobiological mechanisms. Deregulation of energy metabolism in the brain is one of the mechanisms associated with the onset of depressive disorder. Adropin can activate BDNF, and since BDNF plays a crucial role in neurogenesis, synapse formation, plasticity, learning, memory, and has a neuroprotective function, adropin may play an important role in the development of depression.

Methods: We conducted a study in which we examined adropin concentrations in depressive disorder in individuals who were diagnosed with depression for the first time and compared adropin levels with healthy controls. We followed up with depressive patients after six months of introducing SSRIs (Selective Serotonin Reuptake Inhibitors) antidepressants.
Results: The adropin values after the introduction of antidepressants and improvement of depressive symptoms were significantly higher after six months compared to the initial blood draw.
Conclusions: Our study measured serum adropin levels in patients who had not previously been treated for depressive disorder. After introducing SSRIs (Selective Serotonin Reuptake Inhibitors) and six months after the initiation of therapy, we repeated the adropin measurements. The results showed a statistically significant difference between the first and second measurements. In the second measurement, adropin levels were higher than in the first. We can conclude that with the improvement of depressive symptoms, the serum adropin levels, as a neuroprotective biomarker, also increased.

An Exploration of Gender and Age Differences in Psychosomatic Responses to Depression and Stress: An Analysis of Beck and DASS-42 Scales

W. Wójtowicz[1], A. Zielazek[1], Z. Wydrych[1], N. Wyroba[1], N. Wojdacz[1], P. Omylak[1] and K. Krysta[1]*

[1]Department of Rehabilitation Psychiatry, Medical University of Silesia, Katowice, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1337

Introduction: This research investigates gender differences in psychosomatic responses among individuals of various ages, who had been diagnosed with depressive or anxiety disorders, or were in remission. It evaluates symptoms using the Beck Depression Inventory–Second Edition (BDI) and DASS-42 scales in a cohort of 30 adults in an outpatient clinic environment.
Objectives: The aim of the study was to demonstrate the relationship between the degree of development of nicotine and the severity of symptoms related to emotions and mood with patients suffering from schizophrenia.
Methods: A total of 30 adult participants (ages 21-69) were assessed using the BDI and DASS-42 scales. The study is focused on somatic symptoms (as measured by specific DASS-42 items) and their relationship to gender, age, and the severity of depression. The severity of depression was classified into mild, moderate, and severe categories based on BDI scores.
Results: The study revealed that depression significantly affects both daily functioning and emotional responses to stress, with individuals suffering from severe depression showing psychosomatic symptoms most often, regardless of gender. The findings revealed that women diagnosed with depression reported higher rates of psychosomatic symptoms, such as dry mouth, breathing difficulties, and increased heart palpitations, compared to men. Men, on the other hand, exhibited difficulties in emotional regulation in response to stress, which can potentially indicate a general sense of insecurity and anxiety. Younger female individuals, under the age of 40, diagnosed with depression according to the BDI, exhibited more intense psychosomatic symptoms compared to older female patients. Furthermore, within the same cohort of women under 40, the intensity of psychosomatic symptoms was significantly higher in comparison to men in the same age group.
Conclusions: The study uncovered the strong and interconnected relationship between stress and depression. Moreover, it indicated that the severity of psychosomatic symptoms associated with depression and stress is influenced by gender and age. As a result, it is crucial to adopt a comprehensive and personalized approach when treating patients, considering the severity of their conditions. The BDI and DASS-42 scales are effective in capturing these differences, highlighting their usefulness in both clinical and research contexts.

"Electroconvulsive Therapy: A Lifeline for Depression with Psychotic Features and Cognitive Decline" A case series

M. Ligero Argudo[1]*, I. M. Peso Navarro[1], C. García Cerdán[1], C. Munaiz Cossío[1], C. Payo Rodríguez[1], R. K. González Bolaños[1], P. Andrés Olivera[1] and E. Domínguez Álvarez[1]

[1]Psychiatry, Clinical Hospital of Salamanca, Salamanca, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1338

Introduction: Depressive disorders with psychotic symptoms in elderly individuals are serious conditions whose diagnosis may be complicated by confusion with neurocognitive disorders. Electroconvulsive therapy (ECT) is an effective intervention for these patients when pharmacological treatments are either ineffective or not feasible due to medical comorbidities.
Objectives: To describe three clinical cases of women over 69 years of age with an initial diagnosis of depression with psychotic symptoms versus neurocognitive disorder.
To assess the clinical response to ECT during their hospitalization.
Methods: A retrospective observational case series was conducted. Three female patients over 69 years old, admitted with a diagnosis of major depression with psychotic symptoms and signs of cognitive impairment, and who received ECT as part of their treatment, were included. The patients' medical records were reviewed to gather information on their diagnosis, evolution, and response to treatment.
Results: Case 1: Patient A (80 years old): psychomotor slowing, delayed response latency, nihilistic delusions with major affective symptoms. She received 10 sessions of ECT, with significant improvement in psychotic, depressive, and cognitive symptoms. She was discharged for outpatient follow-up.
Case 2: Patient B (70 years old): delusions of guilt, impersonation, and persecution, with concomitant major affective symptoms. She received 11 sessions of ECT, with significant improvement in affective, psychotic, and cognitive symptoms. Upon discharge, she continued follow-up with her Mental Health team.

Case 3: Patient C (72 years old): perplexed gaze, hypomimic facies, psychomotor slowing, thought blocking, no delusional symptoms, and major affective symptoms. She received 10 sessions of ECT, with little response in the affective and cognitive spheres. Care continued in the Convalescence Unit (subacute), and she was later institutionalized in a senior residence.
ECT was effective in two of the three patients in terms of psychotic, affective, and cognitive symptom response. In the third patient, where symptoms were more indicative of a neurocognitive disorder, ECT was ineffective, requiring long-term follow-up coordinated between Psychiatry and Neurology.
Conclusions: ECT is effective in treating major depression with psychotic symptoms in elderly patients, although it may have limited response in cases of cognitive impairment. Therefore, a comprehensive approach and multidisciplinary follow-up are required to manage these cases.

Disclosure of Interest: None Declared

EPV0636

Approach to depression in Parkinson's Disease. A case report

B. Lopez Abellan[1]*, P. Abril Bohórquez[1], N. Linero Rios[1], R. Justicia González[1] and N. Echeverría Hernández[1]

[1]Psiquiatría, Complejo Asistencial de Ávila, Ávila, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1339

Introduction: Parkinson's Disease is associated with depigmentation of the substantia nigra and locus coeruleus, with specific pathophysiological alterations. It is characterized by tremor at rest, bradykinesia, postural instability and rigidity. But there are also other comorbid psychiatric disorders that accompany it, such as cognitive impairment, psychotic symptoms (hallucinations and delusions), mood disorders and sleep disorders, among others.
Objectives: The main objective of this work is to review the current scientific evidence on the management of depression in Parkinson's Disease.
Methods: The case of a 75-year-old man with a neurological history and a diagnosis of depression with a poor evolution is presented. A detailed search was performed on UpToDate using the search terms "Parkinson's Disease" and "Depression".
Results: This is a 70-year-old man with a history of Parkinson's disease and comorbid depression with a poor evolution. A multitude of therapeutic options have been tried, such as SSRIs, SNRIs, antipsychotics, tricyclic antidepressants and an intensive psychotherapeutic approach. Despite what has been described, the expected improvement is not obtained and, given the difficulties in the treatment of his Parkinson's Disease, an update is necessary according to the scientific evidence collected.
According to the scientific evidence consulted, among the antidepressants most studied in Parkinson's Disease are SSRIs, SNRIs and tricyclic antidepressants. The choice of antidepressant treatment will depend on the patient's main symptoms and the risk-benefit assessment of starting treatment. The importance of cognitive-behavioral treatment is also highlighted.
Conclusions: Depression is one of the most common psychiatric disorders seen in PD. Depressive symptoms in PD are associated with increased motor disability and decreased quality of life. It is estimated that up to 50% of patients have depressive symptoms.
In conclusion, the approach to depression in Parkinson's Disease must be multidisciplinary and comprehensive, with both psychopharmacological and psychotherapeutic treatment.

Music therapy and pharmacotherapy as a combination treatment: a case of periodic depression in comorbidity with subthreshold autism

H. N. Lund[1]* and A. Drago[1]

[1]Unit for Depression, Aalborg University Hospital, Psychiatry, Aalborg, Denmark
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1340

Introduction: This case study investigates the combined use of pharmacotherapy and music therapy in treating a 44-year-old male patient with recurrent depression and subthreshold autism traits. These traits contributed to emotional rigidity and reduced treatment outcomes, requiring an interdisciplinary approach to enhance treatment effects.
Objectives: To explore the efficacy of pharmacotherapy and music therapy in treating recurrent depression complicated by subthreshold autism traits, focusing on emotional regulation and coping strategies in a neuroatypical patient.
Methods: The patient was treated in outpatient psychiatry with citalopram (10 mg/day) and nortriptyline (100 mg/day) while attending 18 months of individual music therapy at Aalborg University Hospital. The music therapy involved listening and improvisation aiming at addressing neuroatypical emotional rigidity and sensitivity.
Results: While pharmacotherapy alleviated depressive symptoms, music therapy enabled expression and management of difficult emotions improving emotional flexibility and enhancing coping strategies. The patient was not diagnosed with Asperger's syndrome, but exhibited traits of autism that influenced the treatment response.
Conclusions: The combination of pharmacotherapy and music therapy proved beneficial for the patient, offering a non-verbal approach to emotion regulation. This case highlights the value of interdisciplinary approaches for treating depression in patients with subthreshold autism, especially in complex, treatment-resistant cases.

EPV0638

Using computational psychiatry for identifying risk factors for depressive disorder

I. Marinić[1]* and L. Mužinić Marinić[1]

[1]Department of Psychiatry, Dubrava University Hospital, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1341

Introduction: Computational psychiatry uses computer models to improve the understanding, diagnosis, and treatment of mental health disorders. These models can integrate large datasets from various sources, including genetic, neurobiological, and environmental factors, to predict the likelihood of developing depression.
Objectives: The aim of the study is to explore the potential of computational psychiatry methods in identifying risk factors for the development of depressive disorders.
Methods: A review of relevant studies was conducted using the PubMed database. The search focused on articles examining computational psychiatry approaches, particularly those assessing risk factors associated with the onset of depressive disorders.
Results: The study highlights computational models that show potential in identifying risk factors for depressive disorders.
Conclusions: Computational psychiatry offers new insights into identifying risk factors for psychiatric disorders and has the potential to contribute to the prevention and treatment of depressive disorders. However, further research is needed to improve the generalizability and applicability of the models.

D'Annunzio, Chieti, Italy and [5]Psychopharmacology, Drug Misuse and Novel Psychoactive Substances Research Unit, School of Life and Medical Sciences, University of Hertfordshire, Hatfield, United Kingdom
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1342

Introduction: Treatment-resistant depression (TRD) is a severe condition with substantial economic and social impacts, defined by a lack of response to two or more adequate antidepressant treatments. Esketamine, an NMDA receptor antagonist, acts as an antidepressant by modulating glutamatergic transmission. Some studies suggest that dopaminergic system activation is crucial for the antidepressant effect of (S)-Ketamine (*Jelen LA et al. J Psychopharmacol. 2021 Feb;35(2):109-123*). Recently, nasal spray esketamine (ESK-NS) has been approved for TRD by the EMA and FDA, showing high response rates in some studies (*Martinotti ed al. 2022 J. Affect. Disord. 319, 646–654*). However, while the efficacy of ESK-NS varies among patients, studies on predictive factors of response, especially clinical ones, are limited, and no research has yet examined personality traits as predictors of ESK-NS response.
Objectives: In this multicenter study we aim to investigate correlations between personality traits and response to ESK-NS in a real-world sample of subjects with TRD.
Methods: Eighteen patients with TRD were enrolled in two different centers in Genoa. Sociodemographic and clinical data were collected through semi-structured interviews. The Temperament and Character Inventory (TCI) was administered before therapy (T0) to assess personality traits, while the Hamilton Depression Scale (HAM-D) was used at T0 and three months (T3) to evaluate depression severity and treatment response.
Results: The mean age of patients was 56 years with SD 11,3 years. 66,6 % of patients (n=12) were female. The enrolled patients were divided into two groups (responders 55,6% and non-responders 44,4%) as determined by a reduction of at least 50% in the HAM-D score from T0 to T3. In a multivariate analysis with TCI as the dependent variable and HAM-D severity at T0 as a covariate, a statistically significant difference (p=0.018) was found between the responders and non-responders groups in the TCI Reward Dependence (RD) subscale with higher values in responders compared to non-responders.
Conclusions: Previous studies have examined the link between personality traits and antidepressant response, but this correlation with ESK-NS hasn't been previously investigated. This study, for the first time, demonstrates the correlation between Esketamine responders and RD traits, even when accounting for depressive severity (HAM-D). This may be because individuals with high RD are more sensitive to positive reinforcement. If ESK-NS improves mood and rewarding experiences, these patients might benefit more quickly. Additionally, RD is linked to dopamine, and since ESK-NS influences dopaminergic pathways, those with high RD may respond better to the treatment. This finding supports earlier research that anhedonic features predict better responses in TRD patients (*Pettorruso et al. Psychiatry Res. 2023 Sep;327:115378*).

Patient-Reported Outcomes of Antidepressant Drug Therapy: A Comparative Analysis

P. Marinovic[1]*, J.-C. Radermacher[2], J. Stingl[2], N. Bozina[3], A. Mihaljevic-Peles[1,3] and M. Zivkovic[1,3]

[1]Clinic of psychiatry and psychological medicine, University Hospital Center Zagreb, Zagreb, Croatia; [2]University Hospital RWTH Aachen, Aachen, Germany and [3]University of Zagreb, School of medicine, Zagreb, Croatia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1343

Introduction: Patient-reported outcomes are becoming increasingly important in the evaluation of antidepressant drug therapy. They capture the patient's perspective on their symptoms, treatment experiences, and overall well-being, unlike traditional clinical measures that focus only on objective assessments (clinical scales measuring symptom reduction and psychological changes). These outcomes provide a more comprehensive understanding of the impact of antidepressants on daily living.
Objectives: The main objective of the study was to determine patient-reported outcomes of antidepressant drug therapy.
Methods: 300 patients from three study centers were included - a geriatric hospital (Germany), a Specialized psychiatric clinic (Germany), Outpatient psychiatric clinic (Croatia). Patients were assessed with the same questionnaire that consisted of two parts - the first one included questions about the patient's current state (possible symptoms) and the second one included questions about possible antidepressant side effects. The main inclusion criterium was continuous antidepressant therapy, and the main exclusion criterium was the inability to communicate via a questionnaire.
Results: Comparative analysis of patient perceptions in an acute psychiatric, outpatient psychiatric and geriatric patient cohort showed all patient cohorts were adherent to taking their medication but differed significantly in the level of awareness of any information regarding their medication taking (why are they taking it, when, what is the prescribed dose, etc.) with geriatric patients being the least aware. The results also show other differences between the three cohorts, especially between the Croatian and German cohorts. An interesting difference is shown in the open question about medication side effects - 99 Croatian patients didn't report having side effects, while only 31 patients from one German center and 71 from another German center answered that they had no side effects when asked openly. When asked specifically, patients from all three cohorts gave similar answers.
Conclusions: Understanding patient-reported outcomes can be extremely beneficial, as antidepressant efficacy as well as side effect severity varies widely among individuals and affects adherence to treatment. Patient-reported outcomes are a great starting point for moving in the direction of patient-centered medicine and can help healthcare providers make more informed decisions regarding antidepressant drug therapy.
This study is a part of ArtiPro ERA PerMed (Multidisciplinary research projects on personalized medicine- development of clinical support tools for personalized medicine implementation) project. The main goal is to establish an artificial intelligence-based platform that integrates data from clinical research involving biomarkers as predictors of illness and treatment outcomes with a goal to identify robust multimodal biomarkers and outcomes for depression.

Disclosure of Interest: None Declared

EPV0641

Resistant depressive disorder: electroconvulsive therapy versus esketamine

M. P. Pando Fernández[1], P. Martínez Gimeno[1], M. A. Andreo Vidal[1], M. Calvo Valcárcel[1], M. D. L. Á. Guillén Soto[1], O. Martin Santiago[1]*, G. Medina Ojeda[1], A. Rodríguez Campos[2], L. Rodríguez Andrés[1], N. Navarro Barriga[1], B. Rodríguez Rodríguez[1], M. Fernández Lozano[1], M. J. Mateos Sexmero[1], A. Aparicio Parra[1], L. Rojas Vázquez[1], G. Lorenzo Chapatte[1], M. Ríos Vaquero[1], A. Monllor Lazarraga[1], L. Sobrino Conde[1], L. del Canto Martínez[1], F. J. González Zapatero[1] and M. E. Espinosa Muth[1]
[1]Psiquiatría and [2]HCUV, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1344

Introduction: Electroconvulsive therapy (ECT) has long been regarded as highly effective in the treatment of Treatment-Resistant Depression (TRD), with remission rates ranging from 50% to 70%. In recent years, esketamine, an N-methyl-D-aspartate (NMDA) receptor antagonist, has emerged as a novel treatment option for TRD due to its rapid and potent antidepressant effects (1).
Objectives: This case aims to reflect on the comparative use of esketamine versus ECT in the management of TRD, considering clinical outcomes, side effects, and patient response.
Methods: A literature review was conducted using PubMed to gather evidence on the efficacy of esketamine and ECT for TRD. We also present a case study of a 53-year-old female patient with TRD to illustrate the clinical application and response to esketamine.
Results: The patient, a 53-year-old divorced woman with a 31-year-old son, has a history of three psychiatric admissions in 2021 due to major depressive episodes. She was previously treated at a day hospital and continues follow-up care in outpatient settings. Her current psychopharmacological regimen includes Venlafaxine 300 mg and Mirtazapine 30 mg, with Aripiprazole recently discontinued.
The patient presented to the emergency department with a marked deterioration in mood, neglect of daily activities, and increased social isolation. Psychiatric evaluation revealed a depressed appearance, slowed speech, bradypsychia, and passive thoughts of death, though without suicidal ideation. Her biological rhythms were disrupted, and she experienced unquantified weight loss, despite good family support.
The patient received her first intranasal dose of esketamine (56 mg) without complications, followed by six additional doses twice weekly. Mild side effects included nausea and occasional depersonalization and derealization. Over time, the patient showed progressive improvement in both affective symptoms and daily functioning.
Conclusions: This case highlights the rapid antidepressant effects of esketamine in TRD patients, aligning with current literature. Esketamine is noted for its quick action and efficacy compared to second-generation antipsychotics (2, 3). Despite these benefits, ECT remains a more cost-effective option with higher remission rates for TRD, even though it is slightly less expensive than esketamine (1). The patient experienced significant clinical improvement with esketamine, which was well-tolerated with minimal side effects. However, the long-term efficacy and cost-effectiveness of esketamine relative to ECT remain under discussion. Further research is needed to clarify esketamine's role in TRD treatment and to establish the best approach for long-term management.

Neuropsychiatric disorders: post-stroke depression. A review

M. Martínez Grimal[1]*, J. J. Tascón Cervera[1], A. M. Morales Rivero[1], F. A. Rodríguez Batista[1] and E. E. Morales Castellano[1]

[1]Hospital Universitario de Gran Canaria Doctor Negrín, Las Palmas de Gran Canaria, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1345

Introduction: Post-stroke depression (PSD) is the most common neuropsychiatric disorder after stroke, and also the main factor limiting recovery and rehabilitation in stroke patients, which leaded to poor quality of life. A prevalence of 30% is estimated between 1 to 5 years after stroke. More than half of all cases are neither diagnosed nor treated.
Objectives: The aim of this paper is to review the latest updates regarding post-stroke depression and progress in its diagnosis and treatment.
Methods: A systematic review of the scientific and clinical literature on PSD was conducted. The review included databases such as PubMed and Cochrane, covering articles from the past 10 years. The scientific evidence obtained was analyzed and synthesized.
Results: Currently, the diagnosis of PSD is mainly based on the DSM guidelines and combined with various depression scales. Symptoms usually occur within the first three months after stroke, the patient presents symptoms of a depressive episode such as low mood, anhedonia, loss of appetite, sleep disorders, vegetative symptoms or social withdrawal. Several mechanisms, including biological, behavioural, and social factors, are involved in its pathogenesis. The main predictors are personal history or cognitive impairment, as well as sequelae of the stroke. Left hemispheric strokes are those with the highest risk of early depression, as well as small subcortical vessel pathology. Treatment is mainly pharmacological, with SSRIs. The probability of recovery is between 15 and 57% in the first year, with a recurrence of 38% at two years, up to 100% at 15 years. In addition, there is an increase in mortality, especially in those under 65 years of age.
Conclusions: There are still many unanswered questions in the treatment of PSD, such as the best time to start treatment or the effects of antidepressants on cognition and motor function, among others. Although great advance has been made by researchers, the mechanism of PSD is not completely clear.

EPV0643

Successful Pharmacological Management of a Severe Suicide Attempt

O. Martin Santiago[1]*, B. Arribas-Simon[1], O. Segurado-Martin[1], M. Rios-Vaquero[1], M. Calvo-Valcarcel[1] and M.-P. Pando-Fernandez[1]

[1]Hospital Clinico Universitario de Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1346

Introduction: Psychotic depression, a severe subtype of major depressive disorder with delusions or hallucinations, increases suicide risk due to distressing symptoms and hopelessness. Suicide attempts in psychotic depression can be severe and violent. Combining antidepressants and antipsychotics shows promise in reducing suicidal ideation and improving prognosis. This case presents a patient with a severe suicide attempt and self-harm in the context of psychotic depression, highlighting successful treatment with a combination of antidepressants and antipsychotics.
Objectives: To present a case study of a patient with a depressive episode that progressed to psychotic features.
Methods: A comprehensive literature search was conducted to identify relevant studies on the treatment of depression with psychotic features. A case report was then developed, detailing the patient's clinical presentation, diagnosis, and treatment regimen.
Results: A 53-year-old male was hospitalized following a serious suicide attempt. The patient had a history of a recent work-related accident, leading to a depressive episode that progressed to psychotic features, including delusions of guilt and economic ruin, attempted suicide using a firearm, leading to significant self-inflicted injuries. Emergency surgical intervention was required for tendon and arterial damage. Psychiatrically, the patient exhibited profound hopelessness, delusional guilt, and active suicidal ideation. Following hospital admission, the patient was treated with a combination of sertraline, olanzapine, and mirtazapine, which resulted in significant improvement in mood, a reduction of delusions, and cessation of suicidal ideation over a three-weeks period. The patient returned to social activities and expressed interest in resuming his professional responsibilities, with no recurrence of psychotic symptoms or suicide attempts.
Conclusions: This case illustrates the severity of suicidal behavior in psychotic depression and the critical importance of combining antidepressants with antipsychotics for effective management. Research has consistently shown that psychotic depression carries a heightened risk of severe suicide attempts due to the intensity of delusions and hopelessness. Antidepressant-antipsychotic combinations, particularly those involving selective serotonin reuptake inhibitors (SSRIs) like sertraline, and atypical antipsychotics such as olanzapine, have demonstrated efficacy in reducing both depressive and psychotic symptoms, thereby mitigating suicide risk. In this case, the patient's marked improvement and remission of psychotic features underscore the role of combined pharmacotherapy in stabilizing mood and preventing future suicidal behavior.

ECT: A Rapid and Sustained Response in Treatment-Resistant Psychotic Depression in the Elderly

O. Martin Santiago[1]*, B. Arribas-Simon[1], O. Segurado-Martin[1], P. Martinez-Gimeno[1], M.-J. Mateos-Sexmero[1] and M. Rios-Vaquero[1]

[1]Hospital Clinico Universitario de Valladolid, Valladolid, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1347

Introduction: Electroconvulsive Therapy (ECT) is a proven treatment for treatment-resistant depression (TRD), especially in elderly patients. Managing depression in this population is challenging due to comorbidities and medication intolerance. Research suggests that factors like melancholic features and early symptom improvement predict a positive response to ECT. ECT offers rapid and sustained antidepressant effects.

Objectives: To present the case of a 74-year-old woman with TRD who successfully underwent ECT after failing multiple medications.
Methods: A literature review was conducted on ECT for TRD in elderly patients. The clinical case is detailed, focusing on treatment, ECT application, and outcomes.
Results: The patient had a history of severe depressive episodes. Previous hospitalizations were managed with tricyclic antidepressants, lithium, and olanzapine. However, lithium was discontinued after discharge due to subclinical hypothyroidism and renal function impairment. Although the patient remained stable for a time, her mood progressively worsened, leading to a marked decline in daily functioning and eventual admission to the psychiatric unit. Upon admission, the patient presented with severe depression, including loss of functionality, self-neglect, and passive suicidal ideation, hyporeactive state, significant vegetative symptoms, and moderate-to-severe anxiety. Given the lack of response to a comprehensive pharmacological regimen, ECT was initiated. The patient underwent six sessions of ECT, with initial improvements observed after the first session. By the third session, she showed marked improvements in mood, energy, and anxiety levels. By the end of the ECT course, she had regained full functionality and emotional stability.
Conclusions: This case underscores the effectiveness of ECT in managing psychotic depression in elderly patients when pharmacological treatments are ineffective or poorly tolerated. The patient's rapid response aligns with previous findings suggesting that early symptom improvement predicts favorable ECT outcomes. Additionally, the presence of melancholic features may have contributed to the success of ECT, as described in the literature. Given the patient's history of lithium intolerance and multiple pharmacological failures, ECT emerged as the most viable treatment option. ECT also demonstrated long-term benefits.
This case also highlights the importance of considering ECT earlier in the treatment process for elderly patients and demonstrates the crucial role of ECT in achieving rapid and sustained recovery in elderly patients with psychotic depression resistant to pharmacological treatments. Early intervention with ECT was essential for the patient's full functional recovery, reinforcing its value as a therapeutic option in severe, treatment-resistant cases.

The efficacy of combined antidepressant therapy in depressed patients

Z. Mitic[1]* and A. Spasovska Trajanovska[2]
[1]Psychiatry Practice "Zora Mitic" and [2]Psychiatry Hospital Skopje, Skopje, North Macedonia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1348

Introduction: According to certain researches, it is known that depressed patients are represented by a high percentage of psychiatric diseases. In these patients, there is a reduction of volitional dynamism, especially the drive to live as well as the social drive.
Failure to treat these patients can lead to serious consequences, suicides and social dysfunction (reluctance for any activity and social isolation).
That is why it is of great importance to apply adequate antidepressant therapy. On the other hand, according to data from the literature, it is known that depression abounds with a multitude of symptoms that cannot be overcome with the use of only one type of antidepressant, so a combination of them is needed.
Objectives: The Aim of this study is to assess the effectiveness of combined antidepressant therapy in the treatment of depressed patients
Methods: This prospective present study included groups of 30 patients of either sex between 26-55 years with diagnosis F32, F33 evaluated in Private Psychiatric Institution Zora Mitic, Skopje . The study was conducted for 6 month. All the patients was written informed consent. Exclusion criteria was exist depressive disorders, patients with another psychiatric disorders and another organic disorders were not included in the study. The patients were examination before treatment and after treatment with Mirtazepine 15-30mg/day and Sertraline 50-100mg/day doses. The patients were assess using sociodemographic information by semi-structured questionnaire specially designed for the study. The sociodemographic data was:, marital status, education status and employment. Depression in patients was assessed by HAMD scale: 21 items graded ranging 0-4. The results obtained were compared using the t-test and Chi-square test. The quantitative data was expressed in number and percentage.The p value of statistical significance was set at $p<0.05$
Results: Results The obtained results indicated that there is a statistical difference in depressive patients before treatment and after six months of treatment with antidepressant therapy the level of education (p=0,07), marital status (p=0,12); employment (p=0, 09) were without statistical significantly. But we got that the HAMD scale score were statistically significant when compare before treatment and after treatment with antidepressant therapy (p=0,03).
Conclusions: ConclusionThe results obtained in the study confirmed that the combined antidepressant therapy in patients with rich symptomatology reduced the depressive symptomatology and enabled an improvement in the functioning of the individuals.

Diferences in concetration of transforming growth factor beta and interferon gama in adults with major depressive disorder regarding on seveirty of disorder

A. M. Munjiza Jovanovic[1,2]*, M. Kostic[1,2], D. Pesic[1,2], M. Jeremic[2,3] and I. Markovic[2,3]
[1]Institute of Mental Health; [2]Faculty of Medicine, University of Belgrade and [3]Institute for Biochemistry, Belgrade, Serbia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1349

Introduction: Over the past 30 years, cytokines have been extensively studied in relation to neuroplasticity, modulation of neurosignaling, and various psycho-immunological aspects of depression. Interferon gamma (INF-γ) is traditionally recognized for its

pro-inflammatory role, but it also possesses regulatory functions by antagonizing Transforming Growth Factor beta (TGF-β). TGF-β acts as an anti-inflammatory and regulatory cytokine. The interaction between these cytokines remains inadequately explored in patients with depression.
Objectives: The aim of our study was to analyze the differences in serum concentrations of INF-γ and TGF-β between patients with Major Depressive Disorder (MDD) and healthy controls.
Methods: Blood samples were obtained from 55 patients who met the DSM-IV-R criteria for a current MDD episode without psychotic symptoms, and from 45 healthy controls, matched for age and gender. Participants were assessed using the Beck Depression Inventory (BDI) and the Hamilton Depression Rating Scale (HDRS). Serum concentrations of INF-γ and TGF-β were determined using enzyme-linked immunosorbent assays.
Results: The concentration of TGF-β was significantly higher in patients compared to healthy controls, while no differences were observed for INF-γ between the groups. Moreover, INF-γ concentrations were statistically higher in patients with more severe depression, as measured by HDRS and BDI. TGF-β levels increased with severity only as assessed by HDRS. Among various factors (sociodemographic, clinical, and hereditary), INF-γ was positively correlated solely with the number of hospitalizations, whereas TGF-β levels correlated with the duration of treatment and symptoms.
Conclusions: The interplay between TGF-β and INF-γ is frequently considered a crucial component of the inflammatory hypothesis in depression. Further research is needed to understand why concentrations are elevated in patients with more severe forms of depression, yet show no correlation with other clinical or sociodemographic factors.

Lifting Spirits: Exploring the Link Between Strength Training Intensity and Depression

S. Ben Aissa[1]*, C. Najar[1], K. Razki[1], M. Cheour[1] and F. F. Romdhane[1]

[1]Razi Hospital, La Manouba, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1350

Introduction: In recent years, the appealing aspect of strength training has grown beyond its physical benefits, promoting interest in its potential impact on mental health. Despite the curiosity, the association between it and depression remains unexplored.
Objectives: The purpose of this study is to examine at the link between strength training intensity and depression levels among active gym-goers in Tunisia.
Methods: This is a cross-sectional study, conducted from February to March 2024. Participants were recruited online through social media platforms (Tunisian facebook groups and fitness forums) using a posted survey link. We've included respondents who are 18 years of age or older who have been active in strength training with a gym membership for 1 month or more. The respondents were required to answer a questionnaire that included questions related to socio-demographic data and to provide strength training intensity related details (sessions frequency, duration, perceived overall intensity using likert scale)
Depression levels were measured using the Patient Health Questionnaire-9 (PHQ-9).
Results: The overall number of participants was 72, with 86% being male. The majority of responders (n=65, 90.2%) indicated that they performed strength training exercises at least three times per week, with an average session length of 45 minutes. In terms of strength training intensity, 38.8% (n= 28) of participants reported high-intensity sessions, 48.6%(n=35) moderate-intensity sessions, and the remaining participants reported low-intensity sessions.
The mean depression score on the PHQ-9 scale was 4.3 (SD = 2.1). Implying a prevalence of minimal to mild depressive symptoms among the research population.
Strength training intensity was found to have a negative correlation with depression scores ($r = -0.36$, $p = 0.03$), suggesting that higher intensity sessions were linked with fewer symptoms of depression.
Conclusions: This study serves to shed light upon the association between strength training intensity and depression levels among Tunisian gym-goers. The findings emphasise the positive impact of strength training with higher intensity, on depressive symptoms

EPV0651

Vagal Nerve Stimulation for Depression: A Review of Side Effects in Unipolar and Bipolar Disorders

K. Noor[1]* and M. Baig[1]

[1]Psychiatry, PsychCare Consultants Research, Ballwin, United States
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1351

Introduction: Vagal Nerve Stimulation (VNS) therapy has emerged as a promising treatment for individuals suffering from treatment-resistant unipolar and bipolar depression. Initially approved for epilepsy, VNS therapy's potential to improve mood symptoms in patients unresponsive to conventional treatments like antidepressants, psychotherapy, ECT, and TMS has garnered growing interest in psychiatry.This systematic review provides a comprehensive overview of the side effects associated with VNS therapy. It aims to offer a balanced perspective on the therapy's safety profile, aiding informed decision-making for depression.
Objectives:
1. To identify the most common side effects of VNS therapy.

Methods: A literature search was conducted within 2 databases (PubMed and Google Scholar). The PubMed search employed MeSH terms as follows: ((vagus nerve stimulation) OR (vagal nerve stimulation)) AND ((major depressive disorder) OR (MDD) OR (depression) OR (unipolar depression) OR (bipolar depression)) AND (side effects). Google Scholar search utilized Boolean operators as follows: "vagus nerve stimulation for depression" "adverse effects" "side effects." Tools that were native to the browsers of these respective databases were used to apply the following filters: publication date (2019-2014), free full text, English, no abstracts, no miscellaneous documents and the remaining results were reviewed independently by 2 investigators to screen for the remaining

inclusion and exclusion criteria. Specifically, studies were only included if they reported on the side effects of VNS therapy for depression. Studies were excluded if they did mention the side effects, or if they were not accessible to the investigators due to pay-walls, for example.
Results: A total of 380 articles were identified from searching in both databases, and screening with application of our inclusion and exclusion criteria left 14 articles to be considered. The side effects of VNS therapy can range from mild and transient to more significant, and most frequently mentioned side-effects included: headache, local skin irritation, intolerable pain, and voice alteration (Jung 2023). Headache and dizziness was common for all forms of VNS, while local skin irritation was far more common in non-invasive methods of VNS involving electrodes, and serious complications from damage to the vagus nerve resulting in arrhythmias and aspiration (Bruer 2022) potentially impacting the overall quality of life and adherence to treatment.
Conclusions: Vagus Nerve Stimulation (VNS) offers a promising treatment option for patients with treatment-resistant depression, providing symptom relief when other therapies fail. However, side effects, particularly laryngeal, and variability in patient response highlight the need for personalized approaches. Future research on transcutaneous VNS and optimized protocols is essential to enhance outcomes.

Depression and Acute Myocardial Infarction: What's New in Their Association?

K. M. Panoutsopoulou[1]*, M. Efstathiou[1], A. Grammeniati[1], S. Mantzoukas[2], M. Gouva[1], K. K. Naka[3] and E. Dragioti[1]

[1]Department of Nursing,Research Laboratory Psychology of Patients, Families & Health Professionals; [2]Department of Nursing, Research Laboratory Intergrated Care, Health & Well-being and [3]Department of Medicine, Second Department of Cardiology, University of Ioannina, School of Health Sciences, Ioannina, Greece
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1352

Introduction: Depression and myocardial infarction (MI) are leading causes of disability worldwide. Their interconnectedness, along with the burden that these impose on patients, is of particular clinical interest.
Objectives: We conducted a systematic review, that aimed to synthesize recent data on the association between depression and MI, highlighting their outcomes and identifying contributing risk factors.
Methods: Data were extracted from 17 studies, including only prospective and longitudinal cohort studies, published between 2019 and 2024. These studies were selected from an initial pool of 67 relevant articles, retrieved from PubMed, PsycINFO, and Embase databases.
Results: Prevalence of depression was higher among MI survivors (OR 1.21; 95% CI 1.15-1.27), with increased rates observed in patients with comorbid type 2 diabetes (IR 131.1; 95% CI 109.6-155.6). A significant correlation was found between depression and adverse clinical outcomes post-MI (HR 3.41; 95% CI 2.49-2.674), including 30-day hospital readmissions (HR 1.11; 95% CI 1.07-1.15). Additionally, individuals diagnosed with depression had a higher likelihood of experiencing MI (HR 2.07; 95% CI 1.79-2.40), particularly those from lower socioeconomic backgrounds (HR 1.47; 95% CI 1.36-1.60) or with chronic kidney disease (HR 1.29; 95% CI 1.03-1.62). However, depressed men and patients using SSRIs had a reduced risk of MI compared to women and non-SSRI users (HR 1.39; 95% CI 1.35-1.42 and HR 0.91; 95% CI 0.64-1.29, respectively).
Conclusions: Depression increases the risk of developing MI and worsens clinical outcomes, and vice versa. Comorbid conditions, including type 2 diabetes and chronic kidney disease, gender differences, and no antidepressant use, are critical factors that compound their association.

Can Esketamine Become a Viable Alternative for Treating Treatment-Resistant Depression in Ecuador?

E. Pazmiño[1,2]* and K. Armas[3]

[1]Psiquiatría, Instituto Psiquiátrico Sagrado Corazón; [2]Psiquiatría, Hospital Metropolitano and [3]Medicina Interna, Clínica Pasteur, Quito, Ecuador
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1353

Introduction: Treatment-resistant Depression (TRD) nowadays it is consider a public health problem. Studies had demonstrate that TRD has higher prevalence of psychiatric comorbid conditions, twice the utilization of outpatient health care resources, 3 times the number of inpatient bed-days, and 23% higher all-cause mortality. -Esketamine, the *S*-enantiomer of ketamine, has been recently approved for depression that has failed to respond to two or more antidepressants [2]. Nevertheless, considering its steep cost, accessibility in Ecuador becomes a crucial factor. Comprehensive studies are essential to substantiate its efficacy
Objectives: Evaluate the effectiveness and safety of esketamine nasal spray in a clinical sample of patients with TRD
Methods: This is an observational, retrospective and multicentric study comprising a total of 16 TRD patients treated with esketamine nasal spray, the sample was collected over a period of 2 years. Anamnestic data and psychometric assessment (MADRS and Columbia scale for suicidal ideation) were collected from -medical records at baseline (T0), one month (T1) and two month (T2) follow-ups.
Results: Clinical response was achieved in 68% at T1 and 81% by T2. Remission rates of 50% was detected by T2. Few side effects were seen in this study, 25% (4) present disossiacion 13% (3) hypertension and anxiety 12% (2) all of them were autolimited and no treatment was required. Based on the Columbia scale to assess suicidal ideation, the disappearance of suicidal risk was observed before T1 in all cases. It is important to emphasize that 2 of the patients taken into account for the study abandoned treatment before the time established. The first patient abandoned

it in the second application for economic reasons and the second patient because he observed total remission of the symptoms by T1
Conclusions: Taking into account the results, it can be concluded that esketamine is a safe medication, given the low percentage of observed adverse effects, all of which were mild and self-limiting. Moreover, the high rates of clinical response and remission allow us to conclude its effectiveness. However, the restriced accessibility should be taken into acount due to the elevated cost of esketamine which also limits this study due to the small sample size

Vegan diet and the importance of nutritional self-concept in the treatment of unipolar depression: a new perspective

C. A. Penkov[1]*, K. Friedrich[1], J. Krieger[1] and M. Ziegenbein[1]
[1]Wahrendorff Klinikum, Sehnde, Germany
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1354

Introduction: Studies on the psychological impact of a vegan diet and its effect on mental health are still, although the interdisciplinary literature points to significant diet-related cognitions associated with the active choice of a plant-based diet. This study addresses this research gap by framing veganism as an identity-associated aspect of self-concept in young vegans and examines the influence of self-esteem resulting from the vegan diet on symptoms of unipolar depression in a biopsychosocial framework model.
Objectives: veganism as an identity-associated aspect of self-concept
influence of self-esteem resulting from the vegan diet on symptoms of unipolar depression
alternative perspective on the connections between psyche and nutrition
Methods: In a representative sample of n = 659 students from German universities, the absolute and additional influence of diet-related self-esteem on depressive symptoms was investigated using hierarchical regression, taking biopsychosocial covariates into account.
Results: It was found that the self-esteem experience of the test subjects specifically gained from the vegan diet exerts a statistically significant influence on depressive symptoms (B = - 37, SE(B) = 0.02, p <.001) and can also explain a statistically significant additional proportion of the total variance in a biopsychosocial model of depression (ΔR2 = .18, F [1,649] = 272.34, p <.001). Together, the model of eight covariates and nutrition-related self-esteem can explain 57% of depressive symptoms (R2 = .57, F [9,649] = 94.81, p < .001¸ f2 = 0.13). This statistically significant influence of diet-related self-esteem also persists in an exploratory study of different severity levels of depressiogenic distress
Conclusions: The results provide evidence of a psychological impact factor in relation to a vegan diet and identify psychological consequences and thus open up a new research perspective in clinical psychology.

EPV0656

Clinical Features of Late-Life Depression with Different Neurobiochemical characteristics

V. Pochueva[1]*, O. Yakovleva[1] and T. Safarova[1]
[1]FSBSI Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1355

Introduction: Depression is one of the most important medical and social problems in old age due to its high prevalence (10-25%) and a significant increase in the burden on social services and medical institutions. A diverse combination of biological factors of aging contributes to the polymorphism of clinical manifestations of late-life depression.
Objectives: Study of the clinical features of depressed patients of late age of three identified neurobiochemical models of energy, antioxidant and glutamate metabolism.
Methods: The study material consisted of 52 hospitalized patients (40 women and 12 men) aged 60-86 years with a depressive episode of recurrent depressive disorder, bipolar affective disorder and a single depressive episode (ICD-10). The patients were examined by clinical, psychometric, biochemical and statistical methods. Before starting therapy, psychometric assessments were performed using the Hamilton Anxiety and Depression Rating Scales and the Mini-Mental Status Examination. On the same day, the activity of enzymes of energy (cytochrome c oxidase - CO), antioxidant (glutathione reductase - GR and glutathione S-transferase - GST) and glutamate (glutamate dehydrogenase - GDH) metabolism enzymes in blood platelets was determined in patients.
Results: In patients with a decrease in energy and antioxidant metabolism (↓GR, GST, HD and ↑GDH), there was a predominance of shallow apathetic depression of a "seasonal" nature with the presence of mild cognitive impairment, a later age of manifestation, and a high incidence of cerebrovascular pathology. Patients with "disharmonious" metabolism (↓ GR, GST, GD and ↑ CO) were characterized by an early onset of the disease, its longer duration, more severe and complex depression with a pronounced anxiety component. Patients with a conditionally "normal" metabolism were more likely to experience typical melancholy depression and the lowest incidence of severe cerebrovascular pathology.
Conclusions: The relationship has been established between the clinical features of late-life depressions and changes in the activity of enzymes of energy, antioxidant and glutamate metabolism. It was revealed that the type of metabolism with "reduced" and "disharmonious" activity of these enzymes corresponds to the parameters of late and early manifesting depression. Thus, the clinical heterogeneity of late-life depression is closely related to different neurobiochemical types of metabolism.

EPV0657

The course of the late-life depression with different immunophenotypes

V. Pochueva[1]* and T. Safarova[1]

[1]FSBSI Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1356

Introduction: According to epidemiological data, about a third of elderly and senile people suffer from mental disorders. The most common are depression and dementia. An urgent problem of modern research is the search for neurobiological correlates of the course and outcomes of late-life depression.
Objectives: To study the outcomes of depression at a late age during a 3-year prospective follow-up in patients with various immunophenotypes.
Methods: A cohort of patients with depressive disorders who were treated in hospital and re-examined in 1 and 3 years. The work carried out a comparative analysis of the course of the disease in patients with different immunophenotypes. The follow-up observation group with immunophenotype A (group 1) included 20 people, 6 men (30.0%) and 14 women (70.0%), median age was 68 years old [62.5; 76.5]. 13 patients (65.0%) were diagnosed with a depressive episode of DE in the framework of recurrent depressive disorder (DDR-F33), 7 patients (35.0%) - in the framework of bipolar affective disorder (BAR-F31). The group with immunophenotype B (group 2) included 31 people, 10 men (32.3%) and 21 women (67.7%), median age was 68 years old [64.0; 72.0]. In 20 patients (64.5%) DDR was diagnosed, in 9 patients (29.0%) - BAR, and in 2 patients (6.5%) – single DE. The patients were examined using clinical, psychometric, immunological and follow-up assessment in 1 year and 3 years.
Results: A comparative study of the course and outcomes of late-age depression in groups of patients with different immunophenotypes, both immediate (1 year) and distant (3 years of follow-up) showed a statistically significant predominance of a favorable course of the disease in patients of group 1 compared with patients of group 2.
In patients of group 1 (in 95% of cases), a favorable course of the disease was noted with the formation of qualitative remissions after 1 year and persisted after 3 years of follow-up. In most patients of the 2nd group, the unfavorable course of the disease prevailed, which was noted both with short-term (1 year - 83.9% of cases) and long-term (3 years - 87.1% of cases) observation. The unfavorable course of the disease in group 2 patients was characterized by a statistically significantly more frequent ($p<0.05$) formation of incomplete remissions with the preservation of residual depressive disorders, the development of repeated depressive phases on their background according to the type of “double depressions”, as well as cases of chronic depression by 3rd year of observation.
Cases of dementia formation and deaths were noted in this group.
Conclusions: The results of the follow-up observation of patients with late depression indicate that the variants of the further course of the disease are closely related to immunological features. The depressions of the apathetic-adynamic structure, in complete remissions in the anamnesis is a marker of a prognostically less favorable course of the disease.

Disclosure of Interest: None Declared

EPV0658

Clinical characteristics of depression in late life

V. Pochueva[1]* and T. Safarova[1]

[1]FSBSI Mental Health Research Center, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1357

Introduction: The relevance of studying late-life depression is determined by the increase in its prevalence,difficulties in diagnosis and therapy.Depression in old age aggravates the course of comorbid somatic pathology,leads to a deterioration in the quality of life of the elderly, the development of mental insolvency and social maladjustment. In addition,depression accelerates the aging process,accompanied by an increased risk of mortality and the development of dementia.
Objectives: To study the clinical features of late-life depression in patients of a gerontopsychiatric hospital.
Methods: Patients with depressive disorders who were treated in the conditions of the gerontopsychiatric hospital .The study used clinical, psychopathological and statistical methods. A total of 333 patients were examined: 87 men (26.1%) and 246 women (73.39%) aged 60 and older (average age 69.05±6.66). According to the ICD-10 classification, all patients were diagnosed with a depressive episode of various etiologies: in 20 patients (6.0%) - a single DE, in 86 patients- a depressive phase within the framework of the BAR(25.9%)and in most patients–227people– a depressive phase within the framework of DDR. According to the ICD-10criteria, depression corresponded to a moderate depressive episode in 246 patients (73.9%), a mild depressive episode in 64 (19.2%)and a severe depressive episode in 23 patients (6.9%).
Results: Analysis of the psychopathological structure of the examined inpatient patients with late-age depression revealed the predominance of psychopathological conditions characteristic of late age, in the structure of which anxiety and anxiety-melancholy disorders dominated (152people-45.7% of cases), depression with the dominance of apathetic and adynamic disorders,which were observed in 135people (40.5%), were somewhat less common. Complex psychopathological depressions with a predominance of senesto-hypochondriac disorders, as well as delusional depressions, were less common – in 39 people–11.7% and 7 people-2.1% of cases, respectively. A characteristic feature of late-age depressions was the presence in their structure of dissomnic, anxiety and hypochondriac disorders,which were noted, respectively, in100%, 94.6% and 93.1% of cases, as well as subclinical cognitive disorders: subjective cognitive impairment (complaints of memory loss)- in 64.3% of patients.
Conclusions: The study shows the polymorphism of psychopathological symptoms of endogenous depression in late life, the presence of anxiety, senesto-hypochondriac, dissomnic and cognitive disorders in the structure of depression.

Disclosure of Interest: None Declared

EPV0659

Significant reduction of cognitive distortions after total sleep deprivation in patients with major depression: a preliminary study

S. Poletti[1]*, G. D'Orsi[1], M. Carminati[1], R. Zanardi[1], C. Colombo[1] and F. Benedetti[1]

[1]IRCCS Ospedale San Raffaele, Milano, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1358

Introduction: Cognitive distortion is a central feature of depression, encompassing dysfunctional personality styles and attitudes, and negative thinking. One of the cognitive schemas characteristics of depressed individuals is the tendency to overestimate causal responsibility for negative events, but not for positive ones. Total sleep deprivation (TSD) has been shown to cause rapid and sustained antidepressant effects in depressed patients and to revert the biased self description present in these patients.
Objectives: The aim of the study was to investigate if TSD treatment would change cognitive distortion in a sample of patients diagnosed with major depressive disorder (MDD).
Methods: Seven patients with MDD (all females), completed the Cognition Questionnaire (CQ) to assess cognitive distortions and were assessed before and after TSD treatment. TSD protocol involved three cycle of sleep deprivation, each one lasted 36 hours and was followed by a night of recovery sleep. Light therapy was administered for 30 minutes at 3 am during waking nights and in the morning after the recovery sleep.
Results: A significant reduction of the depressive symptomatology was observed at both objective (Hamilton depression rating scale -HDRS F=9.85, p=0.008) and subjective (Beck depression Inventory – BDI F=54.73, p<0.001) measures. Investigating the 5 dimensions assessed through the CQ, we observed that the reduction of the dimension "attribution of causality" (r=-7707, p=0.043) and the total CQ score (r=-.8865, p=0.008) after TSD were significantly associated with the reduction of depressive symptomatology as measured by the BDI.
Conclusions: This is a preliminary study on the effect of TSD treatment on cognitive distortion in MDD. TSD treatment improved not only clinical symptoms but also cognitive distortion. Our preliminary findings suggest that TSD could be added to antidepressant treatment to rapidly improve the depressive symptomatology and cognitive distortion which may hamper the compliance with pharmacologic treatments and consequently the reduce the possibilities of a favouble outcome of pharmachologic interventions.

EPV0660

Esketamine-induced dissociation: just a side effects or a potential antidepressant effect booster?

F. Raffone[1]*, P. Sarasso[2], M. Billeci[3], G. Di Petta[4] and V. Martiadis[5]

[1]Department of Mental Health, Asl Napoli 1 Centro, Naples; [2]Department of Psychology, University of Turin, Turin; [3]Department of Mental Health, Asl Napoli 2 Nord, Pozzuoli; [4]Department of Mental Health, Asl Napoli 2 Nord, ozzuoli and [5]Department of Mental Health, Asl Napoli 1 Centro, Neaples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1359

Introduction: Dissociative experiences are considered typical esketamione's side effects. Several investigations have have shown that ketamine/esketamine-induced dissociation may be linked to improved responsiveness, although other studies have not supported this association. Despite these controversial findings, it's possible that dissociative experiences are crucial to the antidepressant effects, at least in specific subtypes of depression. In fact, current understanding of the therapeutic potential of ketamine (the anaesthetic from which esketamine is derived) converges on the so-called "relaxed prior hypothesis", suggesting that glutamatergic blockade up-weights bottom-up surprising somatosensory/affective states. Consequently, ketamine improves short-term plasticity in depression by enhancing sensitivity to interoceptive signals.
Objectives: This study describes and discusses two case studies in which the experience of esketamine dissociation was particularly effective in enhancing antidepressant effects.
Methods: We selected 2 case studies for their paradigmatic description of "depersonalised depression" (Entfremdungsdepression). Patients were interviewed both 4 weeks before and at the peak of esketamine effects during a 6-month treatment. Following a neurophenomenological approach, we combined subjective reports from unstructured clinical interviews with review of previous objective neuroimaging results and neurocomputational models to elucidate the relationship between esketamine's effects and interoceptive sensitivity. Patients were administered the HAM – D at T0 and T6 and the Dissociative Experience Scale (DES-II) and the Structured Clinical Interview for Depersonalization-Derealization Spectrum (SCI-DER) at T0.
Results: According to our observations, esketamine-induced dissociation may be particularly effective in the depersonalised depression subtype, in which interoceptive awareness and interaffectivity are significantly impaired. In particular, disembodiment may suspend previously acquired patterns of feeling, perception and behaviour. As previously described by Richard Yansen, ketamine disrupts the assertion of bodily tensions so that they cannot tighten in the way they used to tighten, and they cannot hold back emotionally in the way they used to hold back: then many of the feelings behind the armour can pour out with a softening, cathartic release. Our patient D.P. sketches this phenomenon nicely when he says that "esketamine makes you change your own personal attitude, your own grammar".
Conclusions: Consistent with previous findings, we suggest that esketamine-induced disembodiment allows for a temporary window of psychological plasticity and heightened sensitivity with the body regaining its permeability to affective affordances. Future research should address the relationship between esketamine-induced disembodiment, sensitivity to interoceptive signals, and depression outcomes.

Metacogntive training add-on to esketamine treatment in TRD patients: effects on depressive rumination

F. Raffone[1]*, D. Atripaldi[2], S. Testa[1], R. Cerlino[1] and V. Martiadis[1]

[1]Department of Mental Health, Asl Napoli 1 Centro and [2]Department of Advanced Medical and Surgical Sciences, Università degli Studi della Campania "L. Vanvitelli", Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1360

Introduction: Depressive rumination has been the subject of increasing clinical and research interest in recent years. Numerous studies have demonstrated its central role in the etiopathogenesis and maintenance of depressive disorders. It refers to the struggle to control repetitive and passive thoughts with a hyper-focus on depressive symptoms, their causes, meanings and consequences. It is, therefore, a process that is often active in people with depressive mood and that can exacerbate and prolong depressive symptoms by promoting their chronicity. It can therefore be argued that depressive rumination may contribute to treatment resistance. The metacognitive model of major depressive disorder and its derived treatment focuses on rumination supporting beliefs and on their modification, with the aim of reducing their negative effects.
Objectives: The aim of this study was to evaluate the improvement in depressive rumination using the metacognitive approach in TRD patients treated with intranasal esketamine.
Methods: Twenty-five patients (13F) with a mean age of 55.88 years (±11.31) diagnosed with treatment-resistant major depression (TRD) received an 8-session weekly metacognitive training (MCT) intervention in addition to the standard intranasal esketamine treatment protocol. Patients were assessed at baseline and after 3 and 6 months of treatment using the Penn State Worry Questionnaire (PENN) and the Ruminative Response Scale (RRS) to assess depressive rumination, and the Montgomery-Asberg Depression Rating Scale (MDRS) to assess depressive symptomatology.
Results: At baseline MADRS and RRS total scores did not differ significantly by gender or age. To assess the effect of MCT as an adjunct to esketamine therapy, a repeated measures ANOVA was performed comparing participants at different time points (T0, T3, T6). The analysis showed an effect of treatment on MADRS total score (η^2=0.45; F=18.22, p=0.001), MADRS item 9 (pessimistic thoughts) (η^2=0.18; F=4.85, p=0.02) and RRS total score. Post-hoc comparisons were significant for MADRS and RRS total scores, with progressive decreases between T0 vs T3, T0 vs T6 and T3 vs T6; for item 9, comparisons were significant between T0 vs T3 and T0 vs T6, with stability between T3 and T6. MCT treatment combined with intranasal esketamine resulted in significant improvements in depressive symptoms. It also reduced depressive rumination and maladaptive metacognitive beliefs.
Conclusions: These preliminary results show that MCT as an adjunct to esketamine treatment is effective for depressive rumination, with stable results up to 6 months after treatment. The generalisability of the results is limited by the lack of a control group and the relatively small sample size. Further studies in larger populations and comparing MCT with other psychotherapies or usual care are needed to confirm these findings.

Brain Damage after ECT? No significant changes of Neurofilament Light Chain and Glial Fibrillary Acidic Protein in Cerebrospinal Fluid

S. Riessland[1,2]*, M. Ponleitner[2,3], V. Millischer[1,2], S. Macher[2,3], R. Lanzenberger[1,2], P. Rommer[2,3], R. Frey[1,2], D. Rujescu[1,2] and P. Baldinger-Melich[1,2]

[1]Department of Psychiatry and Psychotherapy, Clinical Division of General Psychiatry; [2]Comprehensive Center for Clinical Neurosciences and Mental Health and [3]Department of Neurology, Medical University of Vienna, Vienna, Austria
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1361

Introduction: Electroconvulsive therapy (ECT) is an effective treatment for major depressive disorder (MDD). Only few studies have measured CSF in patients undergoing ECT; thus far, no prognostic candidate biomarkers for treatment response have been found (Kranaster *et al.* Neuropsychobiology. 2019;77(1):13-22). Neurofilament light chain (NfL) is a protein found in the axons of neurons. If elevated in blood or cerebrospinal fluid (CSF), it is an indicator of neuroaxonal damage. A recent study including 15 patients with MDD who underwent ECT found no significant change in serum NfL concentrations after completion of treatment (Besse et al. Eur Arch Psychiatry Clin Neurosci 2024; 274(5):1187-95). The astrocyte marker glial fibrillary acidic protein (GFAP) is elevated in MDD and neuroinflammatory diseases. Serum GFAP levels in 40 MDD patients decreased after ECT compared to baseline (Xu *et al.* Psychiatry Clin Neurosci. 2023; 77(12):653-64). No studies measuring CSF levels of both markers have been performed.
Objectives: In this prospective study we aimed to measure changes in CSF of NfL and GFAP in patients undergoing an ECT series.
Methods: In a sample of 9 MDD patients undergoing bilateral ECT, CSF was analyzed before and after the 8th ECT session. Patients took antidepressant medication in a steady state over the course of ECT. A mixed-effects linear regression analysis was done using the log-transformed NfL and GFAP levels as outcome variables. The timepoint (pre-ECT, post-ECT) were entered as fixed effects, patient ID was included as a random effect to account for individual variability. We corrected for multiple testing and defined alpha = 0.05/2 = 0.025. Statistical analyses were performed using R version R-4.3.2.
Results: The mean age ± SD was 34 ± 11 years, 6 out of 9 patients (67%) were women. Mean elevations of NfL by 19,9 pg/ml (95% CI: -120.3 to 160.0) and GFAP by 445.8 pg/ml (95% CI: -1279.6 to 2171.4), there was no significant change in NfL (p = 0.213) or GFAP (p = 0.362) levels after ECT. Figure 1 shows concentrations of both NfL and GFAP pre and post ECT.

Image:

Conclusions: This study found no significant changes of NfL or GFAP levels in CSF after an ECT series, suggesting no evidence of neuroaxonal damage or brain damage through astrocyte activation related to ECT. However, the small sample size may have obscured potential effects. Future research with larger sample sizes is therefore essential.

EPV0663

Measuring the efficiency of treatment with neurofeedback method in patients with Affective disorders

A. Risteski[1], S. Arsova[2] and S. Mitrovska[2]*

[1]Department of Affective Disorders and [2]Day Hospital, University Clinic of Psychiatry, Skopje, North Macedonia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1362

Introduction: Affective disorders are in constant rise and they are a serious medical and social problem. All the latest studies suggest that the incidence of affective disorders is about 14%, which makes them one of the most common psychiatric disorders. Because of that, there is a need for alternative forms of treatment of affective disorders.

Objectives: The main goal of this study is to evaluate the effectiveness of the combined treatment of pharmacotherapy together with the Neurofeedback method in the treatment of affective disorders in adult individuals.

Methods: A prospective randomized study including a total of 100 outpatients from University Clinic of Psychiatry in Skopje. The subjects were randomly divided into 2 groups of 50 patients, of which the patients in the study group were treated with a combined treatment that includes the neurofeedback method as an augmentation to antidepressant therapy, while the control group with monotherapy with antidepressant medications. Subjects were examined for 2 months, with evaluation of despressive symptoms 2 weeks after the start of treatment, and then after 1 month, using the following psychodiagnostic instruments: psychiatric interview; short non-standardized sociodemographic questionnaire, CGI, HAMD, HAMA and Beck depression scale.

Results: Patients in the study group, treated with a combined approach of antidepressant therapy and the neurofeedback method, showed a significantly greater reduction in symptoms of depression and anxiety compared to patients in the control group treated with antidepressants as monotherapy. According to the HAMA anxiety scale, the mean score in the study group (SG) decreased by 2.86 points ($p<0.0001$), compared to a decrease of 0.84 points in the control group (CG) ($p=0.0017$). On the Beck Depression Scale, the mean score in the decreased by 2.08 points ($p<0.0001$), compared to a decrease of 0.44 points in the CG ($p=0.022$). On the HAMD depression scale, the average score in the study group (SG) decreased by 2.42 points ($p<0.0001$), while in the control group (CG) the decrease was 0.12 points ($p=0.63$), the CGI scale showed a significant reduction in global symptoms in (SG) ($p=0.0035$), which further confirms the positive effects of the combined treatment.

Conclusions: The research shows that neurofeedback treatment in addition to pharamcological therapy leads to significant improvement in depressive and anxiety symptoms.

Omega-3 and Postpartum Depression: Assessing the Effectiveness of Omega-3 Polyunsaturated Fatty Acids in Preventing Postpartum Depression

F. M. A. Santos[1]*, P. Coelho[1], P. Jorge[1], A. Silva[1], R. Lopes[1], V. Melo[1], C. Rodrigues[1], C. Matias[1], T. Vieira[1], L. Delgado[1], F. Costa[1] and V. Santos[2,3]

[1]Department of Psychiatry and Mental Health, ULS Médio Tejo, Tomar; [2]Department of Psychiatry and Mental Health, Cova da Beira Local Health Unit and [3]Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1363

Introduction: Postpartum depression (PPD) affects approximately 9% of new mothers and can have profound consequences on both maternal well-being and infant development. Additionally, around 50% of women experience depressive symptoms or mood disturbances during pregnancy and lactation. A growing body of research suggests a potential link between omega-3 polyunsaturated fatty acids (PUFAs) and mood regulation, particularly in the prevention of PPD. Omega-3 PUFAs, primarily docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA), are found in high concentrations in oily fish and seafood. Over the past century, dietary intake of omega-3 fatty acids has significantly declined in industrialized societies, coinciding with increased rates of mood disorders. Notably, populations with higher fish consumption, such as those in Hong Kong, China, and Japan, report lower incidences of depression compared to Western countries, where lower fish consumption has been linked to higher rates of PPD. During pregnancy and lactation, women become particularly depleted in omega-3 PUFAs, as these essential fats are preferentially diverted to support fetal development, potentially increasing the risk of depression in mothers.
Objectives: This study aims to explore the effectiveness of omega-3 PUFAs in preventing PPD.
Methods: A comprehensive literature review was conducted to evaluate the effectiveness of Omega-3 in preventing PPD. The search was performed on PubMed using key terms such as "Omega-3," "Postpartum Depression," and "Prevention."
Results: In one study, women with low LCP intake were supplemented with 220 mg of DHA, which had no effect on depression, like in another study that reported no effect of 1,8 g of Omega-3 PUFAs on maternal depressive symptoms. Another trial involving 2,399 women found no significant difference in depressive symptoms between those receiving 800 mg of DHA and a control group during the first six months postpartum. A randomized controlled trial of 126 women at risk PPD also showed no benefit from EPA or DHA supplementation in reducing Beck Depression Inventory (BDI) scores compared to placebo. A meta-analysis of 11 trials (N = 3,181) similarly found no significant difference in depression scores between Omega-3 and placebo groups, and no association between the daily doses of DHA or EPA and PPD prevention
Conclusions: Based on the reviewed trials, there is insufficient evidence to recommend Omega-3 fatty acid supplementation (DHA and EPA) at any dosage for the prevention of postpartum depression.

Results of Studying the correlation Between Stress and Depression of Miner Workers

P. Sarantuya[1]*, B. Purev[1], M. Tuul[2] and T. Urtnasan[1]

[1]Medical Department and [2]Basic Medical Department, Etugen University, Ulaanbaatar, Mongolia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1364

Introduction: Mining work and environment are the hardest and most difficult jobs in the labor market, increasing the risk of physical and mental illness. A study was conducted to determine the level of stress in mine workers and evaluate the relationship between depression and stress.
Objectives: To determine the level of stress in mine workers and evaluate the relationship between depression and stress.
Methods: Questionnaires were collected from mine workers using the stress detection test (SRQ) and depression detection test (PHQ9) developed by the World Health Organization for doctors.
Results: 2.2% (95) of the respondents are male and 7.8% (8) are female workers. Of these, 70.9% work night shifts, 24.3% do not work night shifts, and 4.8% occasionally work night shifts. Comparing the stress levels of the respondents by age, 1.9% (2) of 20-24-year-olds are moderately stressed, 3.9% (4) of 25-29-year-olds are moderately stressed, and 4.8% (5) are stressed. 30-34-year-olds have moderate stress, 1.9% (2) have high stress, 1% (1) of 35-39-year-olds have moderate stress, 1.9% (2) have high stress, and 1% (1) have high stress. 40-44 have moderate, 1% (1) high, and 1% (1) 45-49 have moderate stress. The depression status of the participants compared to the 20-24-year-olds was 1% (1) transient mood depression, 1% (1) moderate depression, and 25-29-year-olds self-correcting transient mood 4.8% depression (5), 4.8% moderate depression (5), 1% (1) moderate depression, 1% (1) severe depression, 5.8% (6) depressed, 4.8% ((5)) moderate depression, 1.9% (2) moderate depression, 35-39-year-old spontaneous self-correction (68%). 7) with depression, 1.9% (2) with moderate depression, temporary self-correction at the age of 40-44 1.9% (2) with depression, 1% (1) with severe depression, temporary at the age of 45-49 2.9% (3) have depression. According to this, it can be considered that 25-44-year-olds are at risk of depression with a high depression index.
Conclusions: The study concluded that 25-44-year-olds are at risk of depression with a high depression index, indicating that they are at risk of depression.

Effects of vitamin D levels on lipid, glucose profiles and depression in perimenopausal women

D. Schneider-Matyka[1]*, A. M. Cybulska[1], K. Rachubińska[1], D. Kostecka[2], M. Nowak[1] and E. Grochans[1]

[1]Department of Nursing and [2]Pomeranian Medical University in Szczecin, Szczecin, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1365

Introduction: Vitamin D deficiency is a significant problem that affects the population living in most countries. This issue is independent of place of residence, gender, age or skin color. It is mainly influenced by the climate we live in and anti-healthy lifestyle, including bad eating habits.
Objectives: The aim of the study was to evaluate lipid profile, glucose level, vitamin D level, taking into account sociodemographic variables, smoking and alcohol consumption. The study also included assessment of depression taking into account sociodemographic variables and vitamin D levels in perimenopausal women.
Methods: The study was conducted in a group of 191 women. The study consisted of two stages. The first part was carried out by means of a diagnostic survey with the use of questionnaire technique. The survey form consisted of two parts: a questionnaire that included questions about sociodemographic data and selected medical information, and the Beck Depression Inventory. The second stage of the study involved the collection of peripheral blood from each respondent in order to determine lipid profile, glycemia and serum vitamin D levels.
Results: The age of the female respondents ranged from 45 to 65 years, mean age was 53.1±5.37 years, median 53 years. Vitamin D result was below normal in 78%. 77% had elevated total cholesterol levels. 91.6% of the respondents had HDL fraction cholesterol levels within the normal range. On the other hand, 64.4% were characterized by too high LDL fraction cholesterol and 84.8% of women showed normal triglyceride levels. Among the respondents, 91.1% had normal glycemic levels. Analysis of collected data showed a weak negative correlation between serum vitamin D concentration and concentrations of: total cholesterol (rho=-0.14; p=0.05), LDL fraction cholesterol (rho=-0.16; p=0.026) and triglycerides (rho=-0.22; p=0.002) of the examined women. Only in the case of HDL fraction cholesterol (p=0.067) there was no statistically significant correlation. There was also no statistically significant correlation between serum vitamin D levels and glycemia and severity of depression (p=0.152).
Conclusions: Most of the women studied did not manifest depressive disorders. Of the various factors affecting the severity of depression, only education was associated with depression severity. Smoking adversely affects serum vitamin D concentration in the examined women.
Cessation of menstruation influenced carbohydrate metabolism and vitamin D concentration. Blood glucose concentration increased with the age of the studied women.
There was a relationship between vitamin D concentration and values of total cholesterol, LDL fraction cholesterol and triglycerides. Therefore, considering the biological functioning of the studied women, it is important to maintain normal vitamin D levels.

Disclosure of Interest: None Declared

EPV0667

Assessment of treatment adherence in liver transplant patients in relation to levels of depression, anxiety, disease acceptance and social support

D. Schneider-Matyka[1]*, A. M. Cybulska[1], K. Rachubińska[1], M. Stanisławska[1], A. Kisielska[2] and E. Grochans[1]

[1]Department of Nursing and [2]Department of Infectious Diseases, Hepatology and Liver Transplantation, Pomeranian Medical University in Szczecin, Szczecin, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1366

Introduction: Nonadherence in transplantology stands for a not cooperating patient in terms of taking medication, having the laboratory, and imaging tests taken, missing appointments, not following dietary and lifestyle recommendations related to smoking tobacco, drinking alcohol, and other high-risk behaviours. Factors of not following therapeutic recommendations in patient after liver transplantation are high costs, psychiatric disorders, convictions regarding harmfulness of the immunosuppressive medicine and its side effects as well as rejection episodes, infections, stress related to suffering from a chronic disease and inadequate social support.
Objectives: The aim of this study was to assess the adherence to therapeutic recommendations in patients after liver transplantation including the level of depression, anxiety, degree of acceptance of the disease and social support.
Methods: Study was carried out among 112 respondents after liver transplantation.The Delphi method was used and the following standardised tools were used: ISSB, AIS, BDI, STAI X-1 and X-2 as well as a questionnaire form regarding sociodemographic data.
Results: An average level of adherence to therapeutic recommendations was on an average level (6.8±1.85). A statistically significant positive correlation between disease acceptance and following therapeutic recommendations was observed ($r = –0.20$, $t = –2.040$; $p = 0.044$). The adherence to recommendations increased with growing disease acceptance. Six factors were distinguished from the analysed predictors which in a relevant way influenced the level of adherence to therapeutic recommendations in the group of patients after liver transplantation. Regression model consisting of six independent variables explains 55% of variation of the dependent variable (r2corrected= 0,55, $F(6, 98) = 22.127$; $p<0.001$). Such positive factors include always following recommendations ($\beta = –0.23$; $p = 0.002$) and seeking various sources of information ($\beta = –0.34$; $p<0.001$), while negative ones constituted of illness duration ($\beta = 0.18$; $p = 0.008$), experiencing side effects ($\beta = 0.40$; $p<0.001$), suffering from concomitant diseases ($\beta = 0,40$; $p<0,001$).
Conclusions: Patients who have accepted their disease constitute a group that adheres to therapeutic recommendations to a lesser extent.
The main factors affecting adherence to therapeutic recommendations are the search for other sources of information and declarative adherence to therapeutic recommendations. Negative predictors-duration of disease, experiencing adverse effects of treatment, and comorbidities.
The way in which a physician communicates to the patients after liver transplantation the information about the results indicating that the medications were taken irregularly significantly more often influenced not following therapeutic recommendations which might suggest an unintended non-adherence.

EPV0668

The relationship between adherence, life satisfaction, and acceptance of illness among patients with mood disorders

D. Schneider-Matyka[1]*, K. Rachubińska[1], E. Grochans[1], A. Jeżuchowska[2], A. Reginia[3], M. Panczyk[4] and A. M. Cybulska[1]

[1]Department of Nursing, Pomeranian Medical University in Szczecin, Szczecin; [2]Department of Clinical Nursing, Wroclaw Medical University, Wrocław; [3]Department of Psychiatry, Pomeranian Medical University in Szczecin, Szczecin and [4]Department of

Education and Research in Health Sciences, Medical University of Warsaw, Warszawa, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1367

Introduction: Mood disorders are among the most prevalent and debilitating mental conditions in worldwide populations. Non-adherence to treatment recommendations may have serious consequences for patients with mood disorders. There are several methods to show whether the patient cooperates with the doctor and follows his recommendations, or whether he or she skips the prescribed doses of medications. These include objective methods, such as detecting the drug in the blood, urine or saliva by analysis or special markers, pill counting, electronic monitoring, and an electronic record of filled prescriptions. Subjective methods involve assessment of the patient, medical staff, and those in the patient's immediate environment. The most commonly used subjective methods are an interview, filling out a questionnaire, and assessment by health care professionals and the patient's relatives The problem arises when the patient inadvertently skips medications, which makes it difficult to assess adherence. This may be due to the severity of the disease and poorer cognitive function, and sometimes a change in daily routine.
Objectives: The aim of the study was to identify factors influencing life satisfaction, disease acceptance and therapeutic adherence among people with mood disorders.
Methods: This survey-based study included 103 people with mood disorders. It was performed using the author questionnaire, and standardized research tools, namely: the Adherence to Refills and Medication Scale (ARMS), the Acceptance of Illness Scale (AIS), the Beck Depression Inventory (BDI), and the Satisfaction with Life Scale (SWLS).
Results: The level of life satisfaction decreased with an increase in the severity of depressive symptoms (βstd. = -0.665, $p < 0.001$). Mood disorder patients with more severe depressive symptoms had significantly higher scores on the adherence scale (βstd. = 0.290, $p = 0.003$). Patients with higher levels of depressive symptoms showed a lower level of acceptance of the disease (βstd. = -0.215, $p < 0.001$).
Conclusions:

1. The dosage of medications taken, and the severity of depressive symptoms determine life satisfaction of people with mood disorders.
2. Respondents with greater severity of depressive symptoms scored higher on the adherence scale, which means that they were more likely to be non-adherent to treatment recommendations. The type of mood disorder may affect patient adherence. Subjects with bipolar disorder showed higher and those with anxiety-depressive disorder—lower adherence than patients with depression.
3. Subjects with more severe depressive symptoms showed a lower degree of acceptance of the disease.

Selenium as a factor moderating depression and obesity in middle-aged women

D. Schneider-Matyka[1]*, A. M. Cybulska[1], E. Grochans[1], M. Panczyk[2], I. Cerzniewska[1], M. Stanisławska[1] and K. Rachubińska[1]

[1]Department of Nursing, Pomeranian Medical University in Szczecin, Szczecin and [2]Department of Education and Research of Health Sciences, Warsaw University, Warszawa, Poland
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1368

Introduction: Selenium seems to have the ability to alleviate inflammatory signaling path-ways. Obesity is associated with chronic low-grade inflammation. Depression is also defined as an inflammatory disorder. PPAR-γ has been shown to have antidepressant-like effects The levels of inflammatory cytokines that are parameters associated with obesity—are also related to the severity of depression. Studies confirm an increased risk of depressive symptoms in middle-aged women. Therefore, it seems reasonable to consider the influence of selenium, PPAR-γ, and selected proinflammatory cytokines in the context of obesity and depression among middle-aged women.
Objectives: The aim of this study was to evaluate the effect of serum selenium on PPAR-γ and selected proinflammatory cytokines (IL-1β, IL-6, TNF-α) in relation to depressive symptoms and obesity in middle-aged women.
Methods: The study sample included 443 middle-aged women living in north-western Poland.The research procedure: a survey performed using the authors' questionnaire and the BDI, anthropometric measurements, and analysis of blood for the levels of selenium, cytokines, and genetic analysis of the PPAR-γ polymorphism.
Results: It has been found that BMI increases along with the concentration of IL-6. No moderating effect of selenium was observed, although cut-off values for "p" were established for IL-β*Se (p=0.068) and IL-6*Se (p=0.068), so there is a potential association with these two markers. At high selenium levels, the effect of higher IL-β levels on a decrease in BMI was stronger. So was the effect of an increase in IL-6 levels on an increase in BMI.
Conclusions: No effect of selenium on PPAR-γ has been found in relation to depressive symptoms and obesity. 2. Higher selenium levels may have a beneficial effect on BMI even at high IL-β concentrations, however, at high IL-6 concentrations, this effect was not observed. 3. Selenium levels had no impact on depressive symptoms.

Occupational exposure to anesthetic agents and mental health among anesthetic technicians

M. A. Ghrab[1], I. Sellami[1,2]*, A. Haddar[1], A. Feki[3], M. Hajjaji[1], M. L. Masmoudi[1] and K. Jmal Hammami[1]

[1]Occupational medicine, University Hospital Hedi Chaker; [2]LR/18/ES-28, University of Sfax and [3]Rheumatology, University Hospital Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1369

Introduction: Exposure to anesthetic agents (AA) has long been a subject of concern, both for patients and healthcare workers. Recent studies highlighted potential associations between a prolonged exposure and healthcare concerns, including psychological effects such as depression.
Objectives: The aim of this study was to assess signs of depression among anesthetic technicians (AT) and evaluate its associated factors.
Methods: We conducted a cross-sectional study among AT in two University Hospitals in Sfax, Tunisia, between January and July

2024 during periodic health assessment visits. Sociodemographic and professional data were collected. The Patient-Health-Questionnaire-9 (PHQ-9) was used to assess signs of depression.
Results: Our population consisted of 60 AT with a mean age of 47.9±7.1 years. Two participants (3.3%) were males. Nine participants (15%) had a known psychiatric history. The mean seniority was 24±7.5 years in healthcare and 10.4±8.1 years in the current ward. The mean duration of exposure to anesthetic gases was 18.3 ±10.7 years. Sevoflurane was the most utilized AA, used by 75% of the population. Ninety-five percent of the population had shift work.
The median PHQ-9 score was 7 interquartile range IQR [2;11]. Moderate to severe signs of depression were found in 26.7% of the population. Duration of exposure to anesthetic gases was significantly lower among those presenting moderate to severe signs of depression (11 IQR [5;21]) compared to those presenting no or mild signs of depression (20 IQR [11;28]) (p=0.02).
Conclusions: Long professional exposure to AA showed lower depression scores among AT. Comprehensive studies are needed to evaluate the broader mental health and cognitive effects of these agents. Understanding these dynamics is essential for ensuring the safety of healthcare professionals.

A Comparative Study of Depression Score in Anesthesia vs Radiology Technicians

M. A. Ghrab[1], I. Sellami[1,2]*, A. Haddar[1], A. Feki[3], M. Hajjaji[1], M. L. Masmoudi[1] and K. Jmal Hammami[1]

[1]Occupational medicine, University Hospital Hedi Chaker; [2]LR/18/ES-28, University of Sfax and [3]Rheumatology, University Hospital Hedi Chaker, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1370

Introduction: Healthcare workers are exposed to many psychological constraints, making them vulnerable to mental health issues, like depression. However, these constraints, in addition to other organizational and environmental exposures, vary between specialties and wards.
Objectives: The aim of this study is to compare depression score in anesthesia technicians (AT) and radiology technicians (RT).
Methods: We conducted a cross-sectional study among AT and RT in both University Hospitals in Sfax, Tunisia, between January and July 2024 during periodic health assessment visits. Sociodemographic and professional data were collected. The Patient-Health-Questionnaire-9 (PHQ-9) was used to assess signs of depression.
Results: A total of 79 technicians participated in the study, with 60 AT and 19 RT. Their mean age was 46.4±7.6 years and six of them were males. Ten participants (12.7%) had a known psychiatric history. The mean seniority was 22.2±7.7 years. Sixty-two percent of the population had night shift work. The median PHQ-9 score was 7 interquartile range IQR [4;12]. Moderate to severe signs of depression were found in 32.9% of the population. Depression scores were significantly higher among RT with a median of 10 IQR [6;15] compared to a median of 7 IQR [2;11] among AT (p=0.04). PHQ-9 was not associated with age (p=0.15), sex (p=0.9) or seniority (p=0.06).
Conclusions: Both AT and RT presented signs of depression. The difference of scores between the two groups stirs interests about the explaining factors. Further studies detailing different occupational constraints and exposure are needed.

Barriers to motivation for physical activity in patients with affective disorders

E. Petrov[1] and N. Semenova[2]*

[1]Pirogov Russian National Research Medical University and [2]Moscow Research Institute of Psychiatry, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1371

Introduction: Affective disorders, including but not limited to major depressive disorder, bipolar disorder, and persistent depressive disorder, comprise a group of disorders characterized by clinically significant mood disturbances. Depression, which makes the most important contribution to the DALY index among all mental disorders, was the primary focus of this study. Physical activity, regardless of changes in body weight, has been shown to reduce symptoms of depression and the likelihood of a new episode of the disease.
Objectives: This qualitative study aimed to explore the barriers to motivation for physical activity in patients with affective disorders.
Methods: This study comprised a qualitative investigation using semi-structured interviews with thematic analysis. Following ethical approval, a convenience sample of 10 participants with affective disorders was drawn: all of the sample were female, aged 18 years or older, with 69% falling into the 27–35 years age bracket. Diagnostic and clinical information were collected, and barriers to engagement in physical activity were explored. All interviews were recorded and transcribed verbatim.
Results: Ten face-to-face qualitative interviews were completed and lasted between 30 and 60 min. The findings were summarized under the key thematic areas of Anhedonia, Fatigue, Lack of time, Fear of condemnation, and Embarrassment, illustrated by texts. The key thematic areas were further grouped under the overarching themes of 1. Personal characteristics and the influence of low mood: anhedonia and fatigue; 2. External factors: need more time; 3. Social factors: embarrassment and fear of condemnation. Then, the following barriers were identified: “Lack of Strength” barrier, “Lack of Time” barrier, and “Rejection of physical characteristics” (or self-stigma) barrier.
Conclusions: While small and exploratory, the study provides significant insights into the barriers to motivation for physical activity in patients with affective disorders. Although these findings are not generalizable to other populations or males with affective disorders, they offer valuable considerations for future research and interventions in this field. This study’s findings have profound implications for future psychosocial interventions for patients with affective disorders. By identifying and understanding the barriers to motivation for physical activity, it paves the way for more effective, individualized interventions, including those aimed at reducing self-stigma.

Pathogenetic substantiation of depressive disorders in old age as factors of premature brain aging

A. P. Sidenkova[1]

[1]Psychiatry, Ural State Medical University, Ekaterinburg, Russian Federation
doi: 10.1192/j.eurpsy.2025.1372

Introduction: A systems approach to understanding late-onset depression points to its association with cardiovascular disease, cerebrovascular disease, tissue and organ trophic disorders, cognitive impairment, anergy, and decreased lifespan. These features are consistent with progressive aging
Objectives: literature analysis
Methods: general scientific method
Results: Cellular senescence is characterized by irreversible cell growth arrest. Characteristic features of senescent cells include increased cell size, accumulation of β-galactosidase and lipofuscin in the cytoplasm, accumulation of DNA damage foci, condensed heterochromatin regions, shortened telomeres, and increased expression of cell cycle regulatory markers. Telomere attrition has been linked to depression. Individuals with MDD have shorter white blood cell length compared to subjects without a history of depression. Telomere attrition is also associated with more unstable IL-6 levels and oxidative stress markers in major depressive disorder. Postmortem studies of the brain have revealed that severe depression leads to depletion of various areas of the cerebral cortex and oligodendrocytes. According to the authors, there is a link between severe depressive disorders and cellular aging of the brain. **Mitochondrial dysfunction.** Mitochondrial dysfunction in depression and aging includes genomic instability, defects in biogenesis, electron transport chain and mitochondrial scavenging, nutrient regulation mechanisms, proteostasis. In late depression, the number of mitochondrial DNA copies decreases. Increased production of ROS is a marker of mitochondrial dysfunction. In contrast, depressed individuals have elevated lipid peroxidation markers and an imbalance between oxidative stress and antioxidant stress markers. MtDNA oxidation and fragmentation are consequences of elevated OS, with high levels of fragmented mtDNA being associated with more severe depressive episodes and also a biomarker of aging and tissue damage. In patients with late-onset depression, ccf mtDNA has been found to correlate with chronic levels of IL-6, a master regulator of inflammation and a major component of SASP.
Conclusions: Total scores assess indicators of mitochondrial dysfunction, telomere length, cognitive tests, and structural changes on MRI in women with late depression higher than in elderly men.

Hair cortisol concentration in early pregnancy on postpartum depressive symptoms

M. Sobol[1], A. Błachnio[2], I. Hryhorchuk[3], E. Plucińska[1]*, J. Stasiniewicz[3], P. Szczepaniak[3], M. Meisner[4] and M. K. Sobol[3,5]

[1]Uniwersytet Warszawski, Warszawa; [2]Katolicki Uniwersytet Lubelski Jana Pawła II, Lublin; [3]Szpital Żywiec, Żywiec; [4]Akademia Humanitas, Sosnowiec, Poland and [5]Hospital Center Châlons-En-Champagne, Châlons-En-Champagne, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1373

Introduction: Knowledge of the prenatal predictors of postpartum depressive symptoms is of fundamental importance in preventing them.
Objectives: This study aimed to examine whether first trimester maternal hair cortisol influenced maternal postpartum depressive symptoms.
Methods: The women ($N = 75$) were tested twice: in the first trimester of pregnancy and within three months after delivery. In the first trimester, they had hair samples taken and were examined using a sociodemographic survey and questionnaires: the Edinburgh Postnatal Depression Scale (EPDS), the Perceived Stress Scale (PSS-10), and the Zimbardo Time Perspective Inventory (ZTPI). After delivery, women completed a survey about the course of delivery and their child's health, EPDS, PSS-10, and ZTPI.
Results: A multiple hierarchical regression analysis was conducted to identify the predictors of postpartum depressive symptoms. In the first step, presence of maternal chronic illness and birth length were added, since these variables were associated with postpartum stress in our study. In the second step, we added the scores on depressive symptoms (EPDS) and stress (PSS-10) in the first trimester. After including hair cortisol concentration in the third step, depressive symptoms, stress, and hair cortisol concentration in the first trimester turned out to be predictors of postpartum depressive symptoms. The results showed that higher levels of depressive symptoms and stress and a lower level of hair cortisol concentration in the first trimester were associated with higher levels of postpartum depressive symptoms.We conducted mediation analyses to test time perspective as a mediator in the relationship of hair cortisol concentration in the first trimester to postpartum depressive symptoms.The results suggested that fatalistic time perspective mediated the relationship between hair cortisol concentration in the first trimester and postpartum depressive symptoms. In other words, women with lower hair cortisol concentration in the first trimester were more likely to develop postpartum depressive symptoms, and this relationship was explained by fatalistic time perspective.
Conclusions: The results of our study indicate that women with very low hair cortisol concentration in the first trimester are at greater risk for postpartum depression. These are the first data to show that low level of cortisol in the first trimester can be a predictor of maternal postpartum depressive symptoms. The results of our study suggest that examining hair samples in the first trimester of pregnancy may be a valuable method for identifying women at risk of developing postpartum depression.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1374

Introduction: Major Depressive Disorder (MDD) affects up to 20 million people worldwide over their lifetime. 30% will not attain lasting symptom relief even after multiple treatment attempts. Mindfulness-based interventions (MBIs) have recently been added as adjunctive therapy for MDD. However, their efficacy as adjunctive therapy for difficult-to-treat depression (DTD) remains unclear.
Objectives: This systematic review and meta-analysis sought to evaluate the efficacy of MBIs in treating DTD.
Methods: We conducted a search of MEDLINE, Embase, Web of Science, PsycINFO, Cochrane Central Register of Controlled Trials, the World Health Organization International Clinical Trials Registry Platform, and ClinicalTrials.gov. No restrictions on language or publication date were enforced. We included randomized controlled trials that compared MBIs with usual care or other treatments for unipolar DTD. In this context, DTD refers to the inability to achieve full remission of depressive symptoms despite receiving an adequate course of antidepressant medication. When a sufficient number of studies were available for the outcome analysis, we employed a random-effects model to address the variability between interventions. For outcomes based on a smaller number of studies, we used a fixed-effects model. Additionally, we performed influential and subgroup analyses to investigate the data further. To assess the risk of bias, we utilized the Risk of Bias 2 tool.
Results: Eight studies met our inclusion criteria, comprising 449 participants (mean age = 42.6, predominantly female). The MBIs evaluated included mindfulness-based cognitive therapy, breathing-based meditation, and dialectical behavior therapy with mindfulness components. We found that adjunctive MBIs significantly reduced depressive symptom severity, with an effect size of g = -0.80 (95% CI [-1.32, -0.27], p = 0.0004). Additionally, MBIs caused significant improvements in anxiety (g = -0.57, 95% CI [-0.94, -0.20], p = 0.002) in four studies (n = 126), mindfulness (g = 0.32, 95% CI [0.06, 0.57], p = 0.02) in three studies (n = 243), and psychological well-being (g = 0.66, 95% CI [0.25, 1.07], p = 0.002) in three studies (n = 97).
Conclusions: MBIs demonstrate a substantial benefit for patients with DTD, with a large effect size in reducing depressive symptoms, a medium effect size in improving anxiety and psychological well-being, and a smaller effect size in enhancing mindfulness. Their ability to significantly alleviate depressive symptoms and improve overall mental health supports their integration into treatment plans for DTD. However, this review was limited by the small number of eligible studies, small sample sizes, and high heterogeneity between studies. To better understand the effectiveness of MBIs for DTD, larger clinical studies are needed.

Depressive disorders after cervical spine injuries in amateur athletes

?. Syrmos[1]

[1]Aristotle University, Thessaloniki, Greece
doi: 10.1192/j.eurpsy.2025.1375

Introduction: Cervical spine injuries are serious traumatic situations with negative effects in the overall health and also in sports performace and health
Objectives: Aim of this study is to present cases of deppresive disorders after cervical spine injurie in amateur athletes
Methods: 12 cases are presented. Range of age between 30 and 40 years old. All of them reported depressive disorders during the post traumatic period after cervical spine injuries mainly during amateur athletic activities
Results: All of them they receive appropriate neurological, psychiatric, psycological and rehabilitation support and treatment. They managed to have a good outcome after 24 months follow up.
Conclusions: The development of depressive disorders after such traumatic events remains a strong predictor of a variety of difunctions (social, personal, work etc). The emergence of depressive disorders in many cases remains unexplored and poorly understood. The effect into the the overall health remains a very important factor to investigate. The combination and collaboration of the various medical disciplines is essential in order to help young people.

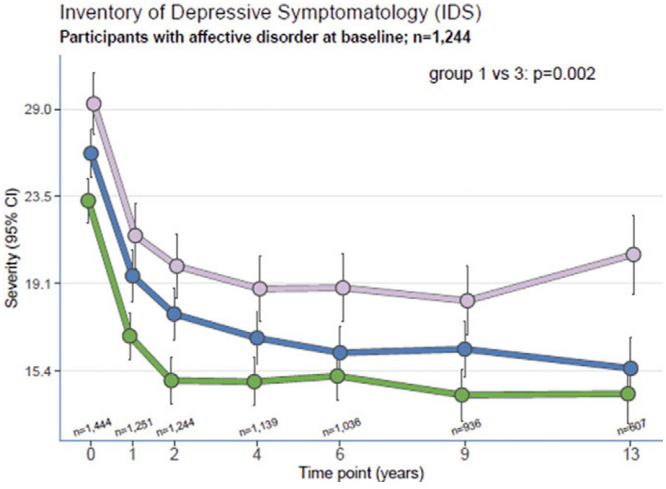
Thirteen-Year Trajectories of Depressive and Anxiety Symptoms in Individuals with and without Migraine: Insights from the NESDA Cohort

N. Van Veelen[1]*, N. Pelzer[1,2], B. Penninx[3], G. M. Terwindt[1] and E. J. Giltay[2,4]

[1]Neurology, Leiden University Medical Center, Leiden; [2]Public Health and Primary Care, Leiden University Medical Center, The Hague; [3]Psychiatry, Amsterdam UMC, Amsterdam and [4]Psychiatry, Leiden University Medical Center, Leiden, Netherlands
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1378

Introduction: Migraine is strongly associated with depressive and anxiety disorders, as migraine patients have over a twofold higher risk of major depressive disorder and nearly a threefold higher risk of anxiety disorders compared to non-migraine individuals.
Objectives: This study investigates the 13-year trajectories in individuals with a depression or anxiety disorder with and without comorbid migraine. Additionally, the time to recovery of the depressive or anxiety disorder was compared.
Methods: The NESDA cohort consists of participants with an affective disorder at baseline, according to the Composite International Diagnostic Interview (CIDI). Depressive symptoms were measured using the Inventory of Depressive Symptomatology (IDS) and anxiety symptoms with the Beck Anxiety Inventory (BAI). The participants were divided at baseline into three subgroups: migraine, non-migrainous headache and non-headache. The individual symptom trajectories were evaluated over 13 years with linear mixed models. Additionally, the time to recovery of the affective disorders with or without migraine were compared with a Cox-proportional hazard analysis.
Results: In total 1,448 participants had either a depressive or anxiety disorder or a combination of both at baseline, 327(23%) had additional comorbid migraine, 518(36%) non-migrainous headache. Participants with comorbid migraine consistently reported higher severity of depressive and anxiety symptoms than non-headache participants over the 13-year follow-up, with an estimated higher IDS sum score of 0.22 (p<0.001) and a higher BAI sum score of 0.28 (p<0.001) (see Figure 1 and 2). The time to recovery of an affective disorder was similar for migraine and non-headache individuals (HR: 1.13 (p=0.17)).

Image:



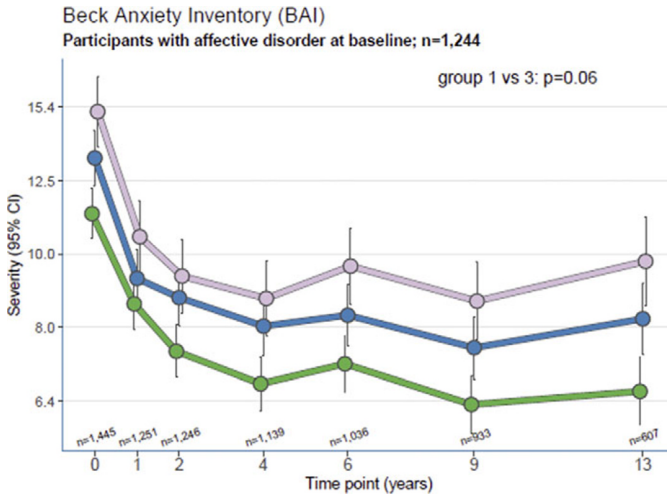


Image 2:

Conclusions: In this cohort, individuals with comorbid migraine showed consistently higher severity of depressive and anxiety symptoms than non-headache individuals over 13 years. Recovery time from an affective disorder was similar for migraine and non-headache individuals.

Pharmacological management of late-onset major depression – Evidence-based approaches from the first episode to treatment-resistant cases

O. Vasiliu[1,2*], A. M. Ciobanu[1,3], B. M. Petrescu[1,2] and A. G. Mangalagiu[1,2]

[1]Neuroscience Department, "Carol Davila" University of Medicine; [2]Psychiatry Department, "Dr. Carol Davila" University Emergency Central Military Hospital and [3]Psychiatry Department, "Prof. Dr. Alexandru Obregia" Clinical Hospital of Psychiatry, Bucharest, Romania

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1379

Introduction: Depression in older adults may present itself as a recurring disorder originating from earlier life, as a new onset depression (late-onset depression, LOD), or as a depression due to organic diseases (e.g., vascular depression). An estimated 30% of all cases of depression in older adults are represented by LOD. Low tolerability due to the changes of the pharmacodynamic and pharmacokinetic profile (e.g., lower volume of distribution, reduction of renal clearence, longer half-time, different receptoral sensitivity and density), as well as low efficacy of antidepressants and high risk of completed suicide, have been reported in this population.

Objectives: To explore the current state of evidence for the pharmacological treatment of LOD through a narrative literature review.

Methods: This review included three databases (Web of Science/Clarivate, PubMed, and Cochrane), explored from their inception to June 2024, for papers published in English using the keywords "late-onset depression," "geriatric depression," "old age depression," and "antidepressants" or "treatment."

Results: Based on the results of 27 selected primary and secondary reports, selective serotonin reuptake inhibitors (SSRIs), especially escitalopram and sertraline, are considered the first line of treatment for LOD, with >50% rate of responsiveness being reported. SSRIs are followed by serotonin-norepinephrine reuptake inhibitors (SNRIs), and other new-generation antidepressants, mainly mirtazapine, vortioxetine, and bupropion. The therapeutic guidelines recommend the correct treatment of comorbid neurocognitive disorders; however, the available evidence shows that antidepressants have very limited efficacy in the presence of dementia. The number needed to treat (NNT) for LOD was between 6.7 and 14.4 (Alexopoulos *Transl Psychiatry* 2019;188 9). For treatment-refractory LOD (TRLOD), augmentation with lithium, aripiprazole, memantine, or methylphenidate, as well as switching to phenelzine, nortriptyline, desipramine, or a combination of antidepressants, such as bupropion and nortriptyline have been suggested as potential solutions, but the evidence to support such recommendations has low quality. Regarding the tolerability of antidepressants in this specific population, electrolyte imbalance, worsening of cognitive dysfunction, increased coagulation time, and falls should be considered.

Conclusions: SSRIs are the first-line pharmacological approach in LOD, with SNRIs and other new-generation antidepressants as the second-line. The pharmacological recommendations for TRLOD are based on low-quality data. Due to the tolerability and safety-specific aspects, special care should be given when monitoring these patients during the pharmacological treatment.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1380

Introduction: In the ESCAPE-TRD study, esketamine nasal spray (ESK-NS) significantly increased chance of remission at Week 8 versus (vs) quetiapine extended release (Q-XR) in patients (pts) with treatment resistant depression (TRD; Reif *et al.* NEJM 2023; 389:1298–309). Changes in disability and functional impairment due to depressive symptoms assessed with the Sheehan Disability Scale (SDS) are reported.
Objectives: To assess the effect of ESK-NS vs Q-XR on pts' daily functioning using SDS, considering their symptom evolution.
Methods: ESCAPE-TRD was a randomised phase IIIb trial comparing the efficacy of ESK-NS vs Q-XR, both alongside an ongoing selective serotonin/serotonin-norepinephrine reuptake inhibitor, in pts with TRD. Clinical response (CRes) was defined as ≥50% improvement in Montgomery-Åsberg Depression Rating Scale (MADRS) score from baseline or total score ≤10, clinical remission (CRem) was defined as total MADRS score of ≤10, and functional remission (FRem) was defined as SDS total score ≤6. The Kaplan-Meier method was used for time to event analyses, and hazard ratios (HRs) were estimated using Cox regression models. Time in each state was estimated by treatment arm and compared between arms using analysis of covariance.
Results: 336 and 340 pts were randomised to ESK-NS and Q-XR, respectively. Significantly more ESK-NS treated pts achieved CRes, CRem and FRem (HRs: 1.848, 1.711 and 1.819, respectively; all p<0.001), and achieved these faster, compared to Q-XR (**Figure 1**). In each arm and at each time point, more pts reached CRes than CRem, and more reached CRem than FRem, illustrating that FRem is more difficult to achieve (**Figure 1**). Total time in CRes was 5.4 weeks greater for ESK-NS compared with Q-XR; total time in CRem was 3.7 weeks greater and in FRem 2.0 weeks greater for ESK-NS vs Q-XR, respectively (**Table 1**).

Image 1:

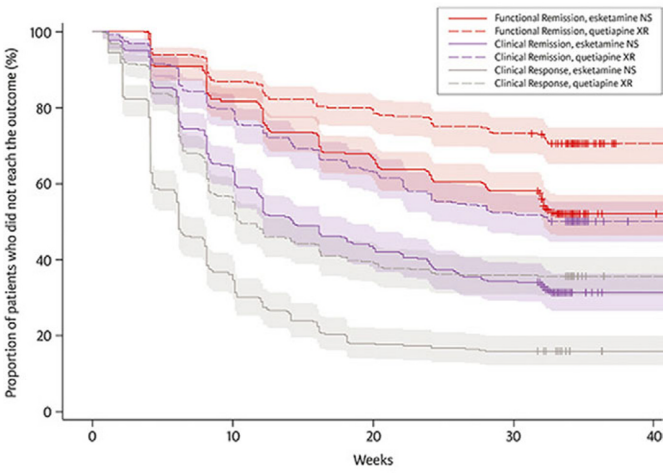

Table 1. Difference in cumulative time in health states between treatment arms (weeks)

Outcome	Esketamine nasal spray + SSRI/SNRI LS-means N=336 (SE) [95% CI]	Quetiapine extended release + SSRI/SNRI LS-means N=340 (SE) [95% CI]	Difference Estimate (SE) [95% CI], p value	% increase
Clinical response	17.0 (1.0) [15.0, 19.0]	11.6 (1.0) [9.6, 13.7]	5.4 (0.8) [3.7, 7.1], p<0.0001	+46.4
Clinical remission	10.5 (0.9) [8.7, 12.3]	6.8 (0.9) [5.0, 8.6]	3.7 (0.8) [2.2, 5.2], p<0.0001	+55.0
Functional remission	6.7 (0.8) [5.1, 8.2]	4.7 (0.8) [3.1, 6.2]	2.0 (0.7) [0.7, 3.3], p=0.0023	+43.2

Full analysis set. CI: confidence interval; LS: least squares; SE: standard error; SNRI: serotonin-norepinephrine reuptake inhibitor; SSRI: selective serotonin reuptake inhibitor.

Image 2:

Figure 1. Time to clinical response, clinical remission and functional remission

Full analysis set: includes all randomised patients. NS: nasal spray; XR: extended release.

Conclusions: These data support a temporal cascade of events from CRes to CRem to FRem; ESK-NS improved time to, and in, each outcome vs Q-XR. Treatments that reduce clinical symptoms better and faster provide the best chance of improving functional impairment.

Disclosure of Interest: None Declared

Social support and financial status are associated with depression symptoms among healthcare workers one year after the onset of the COVID-19 pandemic in France

C. Vincent[1,2*], H. Scarlett[2,3], M. Melchior[2,3] and C. Vuillermoz[2,4]
[1]Team of social epidemiology, Institut Pierre Louis d'Epidémiologie et de Santé Publique; [2]Inserm; [3]Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris and [4]Université de Versailles, Saint-Quentin-en-Yvelines, France
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1381

Introduction: One year after COVID-19's emergence, studies show healthcare workers (HCWs) face significant depression risk linked to pandemic stressors. While the pandemic impacted social and economic factors, the link between depression and social support/financial hardship in HCWs remained unclear.
Objectives: This study leaded in France investigates depression prevalence and its association with these factors among HCWs one year after the onset of the COVID-19 pandemic.
Methods: Data collection was conducted in 2021 where participants completed an online questionnaire to assess probable major depressive disorders (MDD) using the 9-item Patient Health Questionnaire (PHQ-9).
Results: Among the 655 respondents, 21.1% had probable MDD. Using log-binomial regression, we found an association between perceived loneliness, lack of psychosocial support at work and

deterioration of one's financial situation with probable depression. Further adjustment on mental health comorbidities revealed an association between both a deterioration of financial situation and living alone with probable depression.
Conclusions: This study shown an association between social support and financial conditions and depressive symptoms among HCWs, regardless of level of education, pandemic and work-related factors and mental health comorbidities. This emphasises the need to improve working conditions for HCWs, combat their loneliness, increase wages and provide support for HCWs at high risk of depression.

The Discovery and Development of KH607 as a Treatment for Postpartum Depression(PPD)and Major Depressive Disorder (MDD)

J. Wu[1]*, P. Chen[1], L. Song[1] and K. Mu[1]
[1]Kanghong Pharmaceutical Group Co., Ltd., Chengdu, China
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1382

Introduction: Depression is a serious CNS-related disease that may require long-term treatment. Postpartum depression is a critical medical condition that affects the mother, as well as has a short and long-term impact on the growth of the infant. There is an urgent medical need to develop new treatments for these diseases. GABAA receptor is a cell membrane receptor in the brain that responds to the neurotransmitter gamma-aminobutyric acid (GABA). It is a ligand-gated ion channel and help maintain the balance between excitation and inhibition in the central nervous system, by reducing the likelihood of neuronal firing. It is proven that positive allosteric modulation of GABAA receptor has the potential to treat postpartum depression and major depression disorder.
Objectives: To discover a pre-clinical compound that meets our targeted product profile, i.e., good potency, orally bioavailable, in vivo efficacy in animal disease models, a good safety profile, etc. The compound was to be advanced into clinical development.
Methods: With the help of CADD and AIDD, we have discovered lead molecules that bound to GABAA receptor. Structural optimization of these molecules led to the discovery of a potent GABAA receptor positive allosteric modulator as our pre-clinical candidate (PCC) compound with excellent pharmacokinetic properties and efficacy in a variety of animal models. Safety studies showed that the compound has a good safety profile.
Results: We have discovered a positive allosteric GABAA modulator, KH607, with high potency against all three subtypes of GABAA receptors, especially the α5β3γ2 subtype. PK studies showed that the compound had high oral bioavailability in mice, rats, dogs, and monkeys, ranging from 60% to 125%. KH607 effectively penetrates the blood-brain barrier. In anxiety and depression animal modes, KH607 showed anti-anxiety and antidepressant efficacy through oral administration at a dosage of 0.3 mg/Kg to 1.0 mg/Kg. The phase 1 clinical trial up to 40 mg qd dosage orally in human showed that KH607 was well-tolerated with no severe adverse events (AEs) and low discontinuation rate. The PK result demonstrated good pharmacokinetic characteristics and a linear correlation between dosage and exposure.
Conclusions: PPD and MDD are serious CNS-related diseases that need new treatments. Our newly discovered compound, KH607 is a potent GABAA receptor positive allosteric modulator. Pre-clinical studies showed significant efficacy to improve anxiety and depression-like behaviors in a variety of animal models. The compound has an acceptable safety profile for the development as an anti-depressive drug. Therefore, it was advanced to human clinical studies. A phase 1 clinical trial in human was completed. Phase II clinical studies are currently ongoing. We expect that the compound to be developed as a new treatment to address the unmet medical needs for PPD and MDD patients.

EPV0689

Prevalence and correlates of eating disorders in bipolar patients

M. Abdelkefi[1]*, S. Ellouze[1], W. Abid[1], R. Jbir[1], N. Bouattour[1], N. Halouani[1], M. Turki[1] and J. Aloulou[1]
[1]Psychiatry B, Hedi Chaker university hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1383

Introduction: Bipolar disorder is a chronic mood disorder that often coexists with a range of psychiatric and physical comorbidities. Among these, eating disorders (ED) have emerged as a significant concern due to their impact on the course and prognosis of BD.
Objectives: This study aims to investigate the prevalence of ED in stabilized bipolar patients and identify clinical and demographic factors associated with this comorbidity.
Methods: We conducted a cross-sectional, descriptive, and analytical study of patients followed for bipolar disorder at the psychiatry outpatient unit at the Hedi Chaker University Hospital in Sfax. The questionnaire included sociodemographic data, medical and psychiatric history, and anthropometric characteristics. Eating disorders were assessed using the Eating Attitude Test 40 (EAT-40).
Results: Our study included 93 patients. The mean age was 41.49 ±12.33 years, with a M/F sex ratio of 2.58. Among the patients, 58.1% were married, 45.2% had secondary education, and 47.3% were unemployed. Personal somatic history was reported by 35.5% of participants, and 11.8% had psychiatric comorbidities alongside bipolar disorder.
The mean body mass index (BMI) was 27.4 kg/m² (SD=5.96). Of the patients, 29% were overweight, and 31.2% were obese. The prevalence of eating disorders was 18.3%.
EAT-40 scores were significantly associated with age (p=0.018), female gender ($p<10^{-3}$), living alone (p=0.031), lack of formal education (p=0.009), history of medical comorbidities ($p<10^{-3}$), weight (p=0.05), and BMI (p=0.003).
Conclusions: The significant associations between EAT-40 scores and sociodemographic factors underscore the need for targeted screening and interventions in this population. Early detection and management of eating disorders in bipolar patients are crucial to improving clinical outcomes and overall quality of life.

Bulimic behavior in euthymic bipolar disorder patients

M. Abdelkefi[1]*, S. Ellouze[1], R. Jbir[1], W. Abid[1], N. Bouattour[1], N. Halouani[1], M. Turki[1] and J. Aloulou[1]

[1]Psychiatry B, Hedi Chaker university hospital, Sfax, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1384

Introduction: Bulimic behavior has been increasingly recognized in patients with bipolar disorder (BD). Even during euthymic phases, individuals with BD may remain vulnerable to disordered eating patterns such as bulimia and binge eating.
Objectives: This study aims to examine the occurrence of bulimic behavior in euthymic patients with BD and identify associated clinical and sociodemographic factors.
Methods: We conducted a cross-sectional, descriptive, and analytical study of 93 patients followed for bipolar disorder at the psychiatry outpatient unit at the Hedi Chaker University Hospital in Sfax. The questionnaire included sociodemographic data, medical and psychiatric history, and anthropometric characteristics. Bulimic behavior was assessed using the Bulimic Investigatory Test Edinburgh (BITE).
Results: The mean age of the participants was 41.49±12.33 years, with a M/F sex ratio of 2.58. Among the patients, 58.1% were married, 45.2% had secondary education, and 47.3% were unemployed. Personal somatic history was reported by 35.5%, while 11.8% had psychiatric comorbidities in addition to bipolar disorder.
The mean body mass index (BMI) was 27.4 kg/m² (SD=5.96), with 29% of patients being overweight and 31.2% classified as obese.
Eight patients (8.6%) had BITE scores above the threshold of 20, indicating bulimic behavior.
Significant associations were found between elevated BITE scores and female gender (p=0.012), comorbid medical conditions (p=0.005), family history of schizophrenia (p=0.024), weight ($p<10^{-3}$), BMI ($p<10^{-3}$), hypomanic residual symptoms ($p<10^{-3}$), irregular follow-up (p=0.027), and delayed management of BD (p=0.04).
Conclusions: Our results highlight the importance of early identification and comprehensive management of disordered eating in bipolar patients, even during periods of mood stability, to optimize overall health and psychiatric outcomes.

Correlation of Symptoms of Anxiety-Depressive and Obsessive-Compulsive Spectrum and BMI in Patients with Eating Disorders

M. S. Artemieva[1]*, A. M. Vasilyev[1] and D. A. Yudelevich[1]

[1]Psychiatry and Medical Psychology, RUDN University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1385

Introduction: Eating disorders (EDs) are characterized by intrusive thoughts about food, weight loss, and body image, often accompanied by compulsive behaviors related to weight control. Obsessive-compulsive behavior is frequently observed in individuals with EDs. The relationship between obsessive-compulsive disorder (OCD) and EDs is complex due to overlapping symptoms. Research indicates that individuals with both OCD and EDs are prone to depression and anxiety, which may manifest as secondary responses to stress. Symptoms of OCD can significantly impair functioning, leading to maladjustment. Some studies have noted a correlation between increased body mass index (BMI) and reduced depressive symptoms in patients suffering from anorexia nervosa.
Objectives: This research aimed to investigate the severity of anxiety-depressive and obsessive-compulsive symptoms in relation to changes in BMI among patients with eating disorders.
Methods: The study was conducted at the Center for Eating Disorder Research in collaboration with the Department of Psychiatry and Medical Psychology at the Peoples' Friendship University of Russia. A sample was created from patients undergoing inpatient treatment with diagnoses according to ICD-10 (F50.0, F50.1). Clinical interviews were conducted during the first and fourth weeks using PHQ-9 (for depression), GAD-7 (for anxiety), and the Yale-Brown Obsessive Compulsive Scale. Statistical analysis was performed using Jamovi 2.3.28.
Results: Thirty female patients participated in the study. All received psychopharmacotherapy. The average age was M=14.4, SD=1.5. The mean BMI at the start was M=13.3, SD=1.69, increasing by M=1.20, SD=0.612 by the second assessment. Depressive symptoms were observed in 28 (93.33%) during week one and in 25 (83.33%) during week four. Elevated anxiety levels were noted in 24 (79.99%) during week one and in 25 (83.33%) during week four. Significant OCD symptoms were present in 25 (83.33%) during week one and in 21 (70%) during week four. Correlation analysis revealed no significant relationships ($p > 0.01$) between BMI levels and OCD symptoms on the Yale-Brown scale ($r = 0.099$), depressive symptoms on the PHQ-9 scale ($r = 0.28$), or anxiety levels on the GAD-7 scale ($r = 0.369$).
Conclusions: Findings indicate certain relationships between BMI and psycho-emotional states among patients with eating disorders; however, statistically significant correlations were not identified ($p > 0.01$). This underscores the need for further research to deepen understanding of these relationships, especially since none of the respondents achieved normal BMI values (18.5). Future studies should involve larger sample sizes and extended time frames for more reliable data.

EPV0692

The Impact of Periconceptional Alcohol Use on the Etiology of Eating Disorders

M. S. Artemieva[1]*, R. A. Suleymanov[1] and I. E. Danilin[1]

[1]Psychiatry and Medical Psychology, RUDN University, Moscow, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1386

Introduction: The adverse social impact of parental alcoholism on children's development is well known and is primarily associated with difficulties in social adaptation, a higher risk of anxiety, depression, personality disorders, etc. At the same time, in the genesis of neuropsychiatric disorders in such children, parental alcoholism can be both a socio-psychological and biological factor, through its

impact on germ cells, the developing fetus, and postnatal development. The dates of birth of the studied cohort of patients fell in the period of the late 1970s - first half of the 1980s - years of steady growth in alcohol consumption in the late Soviet Union, when, according to the USSR State Statistics Committee, the average resident of the USSR consumed (excluding production by the population, primarily moonshine) an average of 10.7 liters of pure alcohol per capita. Soviet tradition prescribed the mandatory presence of alcoholic beverages on the holiday table. At the same time, the longest and most widespread alcohol consumption in the USSR occurred on summer vacations and official state holidays, for which extraordinary non-working days were established. Along with traditional summer holidays (July and August), such periods were, the second half of February – the first half of March (passing from one to another, the celebration of February 23 (Soviet Army Day and March 8), the end of December/ the non-working first half of January (a ten-day celebration of the New Year), the celebration of Revolution Day (the first half of October).

Objectives: To investigate the possible role of increased alcohol abuse during the periods of conception of children who will later suffer from nervous anorexia and bulimia.

Methods: The approximate dates of conception (considering the terms of full-term pregnancy and the date of birth) of patients (N=191) with eating disorders (AN and NB) born before 1991 were analyzed in relation to the periods of traditional mass alcohol consumption in the late USSR.

Results: The frequency of conception of future patients with eating disorders in the study group during periods of traditionally stable growth in alcohol consumption was 1.4–1.7 times higher ($p < 0.01$) than in other periods. A clear pattern emerged from the analyses. That is, eating disorders, like other chronic psychiatric diseases, are the product of multiple factors, however, alcohol abuse during conception clearly increases the risk of having daughters with AN and BN.

Conclusions: In conclusion, periconceptional alcohol consumption appears to significantly elevate the risk of offspring developing eating disorders, specifically anorexia nervosa and bulimia nervosa. The study reveals a marked increase in conception during peak alcohol consumption periods, suggesting alcohol's potential role in the etiology of these disorders.

Efficacy, safety and tolerability of Lisdexamfetamine Dimesylate Treatment Compared to Placebo in Adults with Binge-Eating Disorder: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

M. Prätzel Ellwanger[1], V. Astori[2]*, B. Westphalen Pomianoski[3], D. Lopes Vieira[4] and M. Frizzo Messinger[5]

[1]Universidade do Contestado, Mafra; [2]Escola Superior de Ciências da Santa Casa de Misericórdia de Vitória, Vitória; [3]Universidade Nove de Julho, São Paulo; [4]Universidade Federal de Minas Gerais, Belo Horizonte and [5]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

*Corresponding author.

doi: 10.1192/j.eurpsy.2025.1387

Introduction: Binge-Eating Disorder (BED) is characterized by frequent episodes of consuming excessive amounts of food, leading to both psychological and physical symptoms. Treatment typically involves a combination of psychotherapy and antidepressants. The disorder is often associated with dysfunctions in the dopamine and norepinephrine systems and to address these dysfunctions, lisdexamfetamine dimesylate (LDX) may offer potential benefits by targeting impulse control and reward pathways, thereby addressing these underlying issues.

Objectives: This study aims to evaluate the efficacy, safety, and tolerability of LDX compared to placebo in adults with BED through a systematic review and meta-analysis.

Methods: We systematically searched PubMed, Embase, and Cochrane Central for randomized controlled trials (RCTs) comparing LDX versus placebo in patients with BED. Primary outcome was binge eating days per week (BEDW) and secondary outcomes were Yale–Brown Obsessive–Compulsive Scale modified for binge eating (YBOCS-BE), Clinical global impressions-improvement scale (CGI-I), weight reduction (WR) and specific occurrence of treatment-emergent adverse event (TEAEs), like dry-mouth and insomnia. Mean differences (MDs), standardized mean differences (SMDs) and risk ratio (RR) were used for all outcomes. $p<0.05$ presented significant statistical results, while $I^2>40\%$ represented a high heterogeneity.

Results: A total of 5 RCTs were included, involving a total of 963 patients, of whom 517 patients received LDX. BEDW (MD: -1.29; 95% CI [-1.65, -0.93]; $p<0.01$; $I^2=60\%$; Figure 1A) was significantly reduced when comparing LDX with placebo. YBOCS-BE (MD: -6.16; 95% CI [-8.35, -3.97]; $p<0.01$; $I^2=66\%$; Figure 1B) has shown an indication of reduction of obsessive-compulsive behaviors (OCB) in patients using LDX. CGI-I (RR: 1.72; 95% CI [1.12, 2.63]; $p=0.032$; $I^2=71\%$; Figure 2A), WR (SMD: -1.31; 95% CI [-1.55, -1.07]; $p<0.01$; $I^2=59\%$; Figure 2B). The use of LDX exhibit an increase on dry-mouth (RR: 5.08; 95% CI [3.39, 7.61]; $p=0.001$; $I^2=0\%$; Figure 3A) and insomnia (RR: 3.00; 95% CI [1.52, 5.94]; $p=0.014$; $I^2=0\%$; Figure 3B) when compared with placebo.

Image 1:

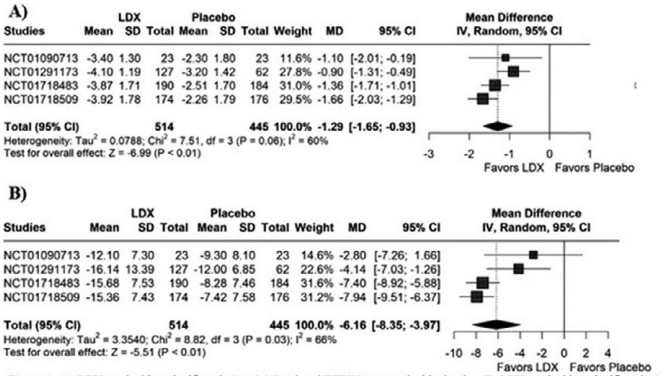

Figure 1 – A) LDX resulted in a significantly ($p < 0.01$) reduced BEDW compared with placebo. **B)** LDX resulted in a significantly ($p < 0.01$) reduced OCB as measured by YBOCS-BE compared with placebo.

Image 2:

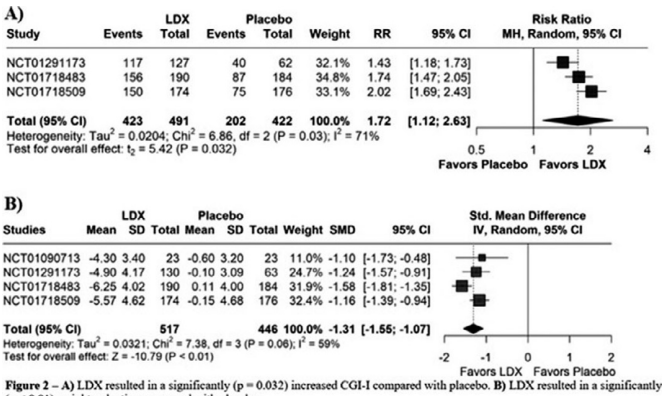

Figure 2 – A) LDX resulted in a significantly (p = 0.032) increased CGI-I compared with placebo. **B)** LDX resulted in a significantly (p < 0.01) weight reduction compared with placebo.

Image 3:

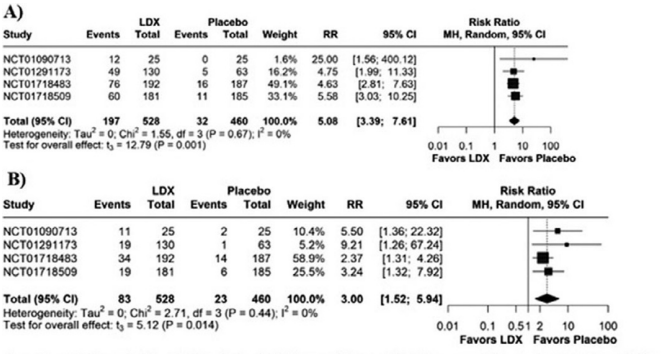

Figure 3 – A) LDX resulted in a significantly (p = 0.001) increased dry-mouth TEAE compared with placebo. **B)** LDX resulted in a significantly (p = 0.014) increased insomnia compared with placebo.

Conclusions: Our study has shown significant improvements in the use of LDX in BED. Patients presented a reduction in OCB, CGI-I, WR, and BEDW. Although some TEAEs were observed, LDX treatment in BED shows a greater benefit.

EPV0696

Exploring Health Professionals' Knowledge and Attitudes on Eating Disorders

E. Barone[1]*, L. Marone[1], V. Ruzzi[1] and A. M. Monteleone[1]

[1]Psychiatry, University of Campania "L. Vanvitelli", Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1388

Introduction: Non-mental health professionals play an important role in the diagnosis and treatment of Eating Disorders (EDs).
Objectives: This study aimed to explore attitudes toward EDs and knowledge of diagnosis, aethiology, and management of EDs among health professionals.
Methods: A new questionnaire was validated and administered to residents and consultants working in disciplines involved in the management of EDs. Health professionals were grouped in the following areas: internal medicine, general practitioners, psychiatric area, psychological area, and surgical area. One-way ANCOVA and chi-square tests were employed to compare knowledge and attitudes among the study groups.
Results: For all health professionals, the most deficient area was the aetiopathogenesis, while the best one was the management of physical complications. A gap in the knowledge of diagnosis, aetiopathogenesis and treatment emerged in nonmental health professionals. Psychotherapy effectiveness and the role of family members in the therapeutic process were not sufficiently acknowledged, and general psychological factors contributing to the onset of EDs were not recognized. Stigma was found primarily among surgeons, although all nonmental health professionals often considered those patients responsible for their ED.
Conclusions: Inadequate knowledge and impaired attitudes toward EDs occurr among health professionals. This type of stigma may impair early diagnosis and treatment of EDs. Educational programs should provide continuous education to update and improve the knowledge of EDs among non-mental health professionals.

EPV0697

Exploring the impact of early emotional abuse on eating disorder psychopathology: a multiple mediation analysis

E. Barone[1]*, M. Carfagno[1], G. Patriciello[1] and A. M. Monteleone[1]

[1]Psychiatry, University of Campania "L. Vanvitelli", Naples, Italy
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1389

Introduction: Childhood emotional abuse (EA) is a well acknowledged risk factor promoting the association between any type of childhood maltreatment and eating disorder (ED) psychopathology.
Objectives: This study investigated the association between EA and ED specific symptoms exploring multiple potential mediators to better understand this complex relationship.
Methods: The study sample included 151 individuals with Anorexia Nervosa (AN), 115 with Bulimia Nervosa (BN), and 108 healthy participants. Before entering treatment programs, participants completed the following questionnaires: the Childhood Trauma Questionnaire, the Toronto Alexithymia Scale, the Behavioral Inhibition System/ Behavioral Approach System, BAS, and the Eating Disorder Inventory-2. A multiple mediation model was run including EA as independent variable, eating symptoms as dependent variables, and ineffectiveness, sensitivity to punishment, alexithymia, and impulsivity as mediators.
Results: In individuals with AN impulsivity emerged as mediator between EA and desire for thinness and bulimic behaviors. In those with BN sensitivity to punishment mediated the relationship between EA and dissatisfaction with body image. In both clinical groups ineffectiveness and difficulty identifying emotions were mediators of the relationship between EA and eating-related symptoms. No mediation effect was observed in healthy controls, although a total effect of EA on dissatisfaction with one's body was observed.

Conclusions: Impulsivity, sensitivity to punishment, ineffectiveness, and alexithymia may make individuals with childhood EA more vulnerable to ED psychopathology with some differences between AN and BN. Addressing these psychological problems and their connections with early emotional abuse may represent treatment targets for individuals with EDs and a history of childhood trauma.

Eating Disorders: Prevalence of Anorexia Nervosa Among Tunisian Military Nursing Students

Y. Ben Othmene[1]*, S. Bejaoui[1], W. Kabtni[1], A. Baatout[1], S. Eddif[1], I. Gafsi[1], H. Kefi[1] and A. Oumaya[1]

[1]Psychiatry, Military Hospital of Instruction, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1390

Introduction: The societal pressure to maintain a thin appearance combined with the academic stress has a significant influence on eating disorders in young people.
Anorexia Nervosa (AN), a severe eating disorder characterized by a distorted body image, restrictive eating habits, and an overwhelming fear of gaining weight, is often misdiagnosed.
Early detection is critical to improve treatment management.
Objectives: The present study aimed to determine the prevalence of Anorexia Nervosa among Tunisian military nursing students.
Methods: A cross-sectional descriptive survey was conducted from March to May 2024 on nursing students at the Military Health School of Tunisia, using a data file for data collection and an Arab version of a self-report questionnaire: Eating Attitudes Test (EAT40), validated in Tunisia. The EAT40 is designed to assess attitudes related to eating and body image serving also as a tool to identify Anorexia Nervosa. To analyze the obtained data, Excel software was used.
Results: The study enrolled 148 students, mostly male (57.4%), with an average age of 21.3 [19-24] years. Of them, 48.6% were in their third year and 19.6% in their second one. Geographically, 57.4% was from the north of Tunisia. The majority (85.8%) was in a middling socioeconomic position and 9.5% was in a high one.
With an average weight of 75.1±14.8kg and extremes between 48kg and 105kg, 52.7% of the population weighed less than 70kg. Also, 67.56% of them were taller than 1m70 of whom 35.81% stood between 1m70 and 1m80. The average Body Mass Index was 23 [17-32]. Among the students, 71.6% had a normal BMI, whereas 2.7% were underweight.
Regarding outward look, 89.9% of respondents said they were happy with their bodies' looks and 67.6% with their weight. When they were younger, the majority (73.6%) did not experience any weight issues. Prior to completing the EAT40, 57.4% said they had no eating disorders.
Of the surveyed, 83.3% expressed dissatisfaction with school meals for a variety of reasons, the most common being insufficient quantity, poor quality, or tasteless food.
According to the study, the average of the EAT40 score was 20±14. Of the participants, 10.8% (N=16) had Anorexia Nervosa; their ETA score was 30 or higher. The majority (62.5%,N=10), were female; females' EAT40 average score was 23±15 [1-44] while males' EAT40 average score was 21±10 [1-41].
The results also revealed that students suffering from AN had an average BMI of 19±4 [weight: 60±10kg, height: 1m60±.08m], compared to students without eating disorders with a BMI of 25±3 [weight: 69±12kg, height: 1m70±0.15m].
Conclusions: This study reveals a concerning prevalence of Anorexia Nevrosa among Tunisian military nursing students, highlighting the necessity of early detection for effective management and of interventions such as raising awareness within educational institutions aspiring to better mental health outcomes for healthcare students.

EPV0701

Eating Disorders: Prevalence of Bulimia Nervosa Among Tunisian Military Nursing Students

Y. Ben Othmene[1]*, S. Bejaoui[1], W. Kabtni[1], A. Baatout[1], S. Eddif[1], I. Gafsi[1], H. Kefi[1] and A. Oumaya[1]

[1]Psychiatry, Military Hospital of Instruction, Tunis, Tunisia
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1391

Introduction: Eating disorders are life-threatening. They affect both physical and mental well-being, specially among young adults in high-stress environments such as military training.
Bulimia Nervosa (BN) is characterized by binge eating and inappropriate compensatory behavior to control weight with potentially dangerous sequelae.
Early recognition is essential to optimise treatment management.
Objectives: This study sought to determine the prevalence of Bulimia Nervosa, its symptoms and its severity, among military nursing students in Tunisia.
Methods: Between March and May of 2024, **a** cross-sectional descriptive survey was conducted for nursing students at the Tunisian Military Health School. Data were gathered using a data file and a self-report questionnaire: Bulimic Investigatory Test, Edinburgh (BITE). The BITE is designed to identify binge eating and compensatory behaviors, providing information on cognitive and behavioral aspects of bulimia nervosa. The scores are classified into two subscales: symptoms and severity. Excel software was used to analyze the obtained data.
Results: The study enrolled 148 nursing students with 57.4% male. The average age was 21.3 [19-24] years. Among our participants, 57.4% came from northern Tunisia. Of them, 48.6% were in their third year and 19.6% in their second one. Of the surveyed, 85.1% were in a middling socioeconomic position followed by 9.5% in a high one.
With an average weight of 75.1±14.8 [48-105]kg, 47.3% weighed more than 70kg with 4.05% between 90kg and 100kg and 2.02% exceeding 100kg. Of the students, 67.56% were taller than 1m70. The average Body Mass Index BMI was 23[17-32]. Around 71.6% had a normal BMI, while 24.32% were overweight[BMI:25-30], and 1.35% were obese[BMI>=30].
In terms of physical appearance, 89.9% expressed satisfaction with their bodies' looks and 67.6% with their weight. Growing up, 73.6% (N=109) did not have any weight issues while 8.1%(N=12) reported they were obese.
Prior to completing the BITE, 57.4% said they had no eating disorders while 18.2% estimated they had BN.
Of the surveyed, 83.3% expressed dissatisfaction with school meals mainly due to insufficient quantity, poor quality, or tasteless food.

According to the study, the BITE's average score was 8±6 [0-34]. Of the participants, 17.5%(N=26) had Bulimia Nervosa with a BITE score of 20 or above. The majority (76.92%,N=20) were female with one reported severe case; their average BITE's score was 23±15 [1-32]; the male's BITE average score was 20±9 [0-34].
Furthermore, according to the survey results, students suffering from BN had a BMI of 29±5 [weight:81±11kg] whereas those without eating disorders had a BMI of 25±3 [weight:69±12kg].
Conclusions: This study highlights the remarkable prevalence of Bulimia Nervosa among Tunisian military nursing students underscoring the urge to pay attention to early symptoms for better targeted interventions and mental health promotion.

Pathopsychological characteristics of patients with extreme obesity 12 months after SADI-GP

F. Császár[1]*, I. B. Bálint[2], R. Jávor[3] and I. B. Bálint[2]

[1]Psychiatry, Vas County Markusovszky University Teaching Hospital, Szombathely; [2]Department of Urology, Kanizsai Dorottya Hospital, Nagykanizsa and [3]Faculty of Humanities and Social Sciences, University of Pécs, Pécs, Hungary
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1392

Introduction: Morbid obesity is correlated with hypertension, dyslipidaemia, prediabetes and T2DM. If lifestyle modifications and pharmacotherapeutic or mixed interventions fail, bariatric surgery is advised for morbidly obese patients. Psychological characteristics of such patients, especially after bariatric surgery, are a vastly under-researched area.
Objectives: This research presents the short-term results of the LASAGNE trial (LAparoscopic Single-Anastomosis duodeno-ileal bypass with Gastric plication (SADI-GP) in the maNagEment of morbid obesity) regarding psychopathological values.
Methods: This study used a cohort of consecutively admitted patients to assess complication rates and efficacy of SADI-GP. Patient recruitment began in October 2018 and ended in June 2019. Preoperative evaluation followed by surgery and postoperative follow-up visits (at 1, 3, 6 and 12 months) with Minnesota Multiphasic Personality Inventory (MMPI-2) recorded at 12-month follow-up. Participants' age was between 18 and 65 years, with BMIs of > 40 (without comorbidity related to morbid obesity) or > 35 (with comorbidity related to morbid obesity, especially glucose metabolism). Psychological characteristics of patient groups were analyzed based on weight loss outcomes and Body Mass Index (BMI) changes. Substance Use Disorder was among other exclusion criteria.
Results: Scales of affective function deficit (RCd, RC1, RC2, RC7) were elevated at 13 cases, scales of behavioural dysfunction (RC4, RC9) were elevated at 11 cases, scales of thought dysfunction (RC3, RC6, RC8) were elevated at 8 cases, RC2 and RC7 showed emotion dysregulation tendencies (Table 1). No subject scored within the normal range on the Introversion/Low Positive Emotionality (INTR/LPE) scale (Table 2). We distinguished and compared the low and high scorers on the INTR/LPE scale (Table 3). This study has limitations regarding sample size, higher-than-expected drop-out rate, strict exclusion criteria, male-to-female ratio, short-term results, no longitudinal data on psychological characteristics.

Image 1:

Table 2. Frequencies along the Revised Clinical Scales (Rc)

	High score	%	Low score	%
Demoralization (Rcd)	4	25%	0	0
Somatic Complaints (Rc1)	2	12,5%	0	0
Low Positive Emotions (Rc2)	7	43,75%	0	0
High/Low scores on Cynicism (Rc3)	5	31,25%	3	18,75%
Antisocial Behavior (Rc4)	7	43,75%	0	0
Ideas of Persecution (Rc6)	2	12,5%	0	0
Dysfunctional Negative Emotions (Rc7)	4	25%	0	0

Conclusions: Our results suggest that the majority of bariatric surgery patients, 12 months after the procedure, show signs of affective dysfunction, thought dysfunction and emotion dysregulation, all signs of a depressive state. Greater weight loss carries a greater probability of depression along with a lesser likelihood of positive emotional experiences; therefore, psychological support during follow-up is necessary to maintain weight loss.

Comorbidity between Anorexia Nervosa and Autism Spectrum Disorder, a therapeutic challenge and worse prognosis? A case series

P. Del Sol[1]*, A. Izquierdo[1], R. Fernández[2], M. García Moreno[1] and J. Sanchez Cerezo[1]

[1]Hospital Puerta de Hierro, Madrid and [2]Hospital Infanta Cristina, Parla, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1393

Introduction: Anorexia nervosa (AN) and autism spectrum disorder (ASD) share symptoms that complicate diagnosis and treatment,

including rigidity in thinking and behavior. This inflexibility often manifests as strict food routines in anorexia. Both conditions involve excessive preoccupation with control and perfection, leading to restrictive behaviors and heightened anxiety.
Objectives: To show the clinical presentation of Anorexia Nervosa and austism spectrum disorder through the presentation of two cases.
Methods: Cases presentation and literature review
Results: Case 1
A 15-year-old girl is receiving psychiatric follow-up for restrictive eating habits. She developed normally and has used sophisticated language since childhood. However, during her infancy, she did not engage in symbolic play. Academically, she performs exceptionally well. She describes herself as having a very rigid personality and struggles with understanding irony and certain social behaviors. She has few friends, viewing friendships as a waste of time. Her interests lie deeply in literature and science, and she tends to wear childish clothing. She expresses feelings of jealousy towards her younger sister and mentioned that she reduced her food intake to prevent growing taller and to achieve "thinner ankles." As she begins psychotherapy, she shares that she finds it challenging to grasp what the psychologist means due to her tendency for literal thinking.
Case 2
The patient is a 14-year-old male from Peru, who arrived in Spain 8 months ago. Developmental milestones within the normal range. Little symbolic play and difficulty with non-verbal language. Highly ritualised behaviours and tendency to obsessions, requiring psychological intervention due to compulsion to clean in the COVID-19 pandemic. The patient was admitted to the inpatient unit for weight loss of 6 kilograms in one month, with food restriction and excessive increase in physical exercise. Selective mutism is associated with months of selective mutism, as 'he does not speak to people who do not speak with a Peruvian accent'. Parents speak of a rigid and literal idea of 'having to be thin in order to make friends and strong in order not to be weak'.
Both cases reflect how the rigidity and literal thinking of autistic disorder can lead to extreme behaviours such as 'don't eat so as not to grow up' in the first case, or 'don't eat to make friends' in the second case, lived with no flexibility
Conclusions: There is a recognized connection between ASD and AN, with studies indicating a prevalence of 20-25%. Inflexible thinking associated with ASD can negatively impact the prognosis of AN, as ASD may contribute to the chronicity of the eating disorder. Additionally, psychotherapy can present challenges, and research suggests that behavioral techniques, particularly Applied Behavior Analysis (ABA), tend to yield better outcomes for individuals with AN.

Suicide risk and depressive symptoms in obese patients treated with GLP-1 receptor agonists

M. Del Valle Martín[1]*, N. Román Avezuela[2], R. De Hita Santillana[3] and M. L. Costa Ferreira da Silva[3]

[1]Psychiatry, Hospital Universitario Severo Ochoa, Leganes; [2]Psychiatry, Clínica San Miguel, Madrid and [3]Psychiatry, Hospital Universitario José Germain, Leganes, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1394

Introduction: The Atlas study, conducted in 2023, shows that the global prevalence of high body mass index (BMI) is expected to increase significantly by 2035, both in adults (from 42% to over 54%) and in young people aged 5-19 years (from 22% to 39%). Also in 2023, the European Medicines Agency (EMA) published a statement warning about the risk of suicidal thoughts and self-harm with glucagon-like peptide-1 receptor agonists (GLP-1 RAs), including semaglutide, tirzepatide and liraglutide. The psychiatric safety of recently developed anti-obesity drugs has not been adequately studied.
Objectives: The objective of this study was to collate and evaluate the existing evidence regarding the psychiatric safety of GLP-1 RAs in individuals without major psychopathology.
Methods: A narrative literature review was carried out in the PubMed, Cochrane and Embase databases, selecting only the articles published in the last 4 years, using the following keywords: depression suicidal ideation, GLP-1 receptor agonists, semaglutide, tirzepatide, liraglutide.
Results: There is a complex relationship between body weight and depressive and anxiety disorders. Obesity can be understood as chronic low-grade inflammation of adipose tissue, and the activation of inflammatory pathways could lead to the development of depression and anxiety. Also, due to cultural norms, obesity contributes to increased body dissatisfaction and lower self-esteem, both of which are associated with depression and anxiety. All of these factors can contribute to the maintenance and worsening of anxiety and depression. In most trials, there was no evidence of an association between treatment with GLP-1 RAs and an increased risk of developing depression or suicidal thoughts/behaviour. Psychiatric adverse events were rare, occurring in only 1.2-1% of patients. Depression was the most common adverse event reported, followed by anxiety and suicidal ideation. Fatal outcomes occurred mainly in men and in people treated with liraglutide, which is associated with a higher risk of suicide than semaglutide.Tagliapietra et al suggest that the patient population receiving GLP-1RAs compared with other diabetes pharmacotherapies is a group with a higher basal risk of developing depression, rather than a causal effect of the drugs. Recent but limited real-world evidence suggests that the use of semaglutide is associated with reduced suicidal ideation and major depression.
Conclusions: The results of our analysis suggest that GLP-1 RAs did not increase the risk of developing symptoms of depression or suicidal thoughts. However, the severity and fatal outcomes of some of these reports warrant further investigation. People with obesity should be monitored for mental health problems so that they can receive appropriate support and care.

Parental Overcontrol and Its Role in the Development of Anorexia Nervosa: A Case Report

L. Demiraj[1]* and E. Sotiri[1]

[1]Psychiatry, UHC "Mother Teresa", Tirana, Albania
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1395

Introduction: Anorexia nervosa is a complex eating disorder often associated with various psychological factors, including maladaptive coping mechanisms and dysfunctional family dynamics. This case report illustrates the impact of parental overcontrol on the development and persistence of anorexia nervosa in a young female patient.

Objectives: To present the case of a 19-year-old female patient with anorexia nervosa, emphasizing the influence of her childhood experiences, particularly parental overcontrol, on her eating behaviors and psychological state.
Methods: Case report.
Results: The patient presented to the emergency room accompanied by family members due to extreme weight loss (29.6 kg; BMI 11.4 kg/m^2) and severe purging behaviors, including self-induced vomiting and the consumption of 400 laxative tablets daily for six months. Her history of mental health issues began in 2013, characterized by severe anxiety related to separation from her parents and academic performance, culminating in a suicide attempt. In 2019, she developed purging behaviors and received outpatient treatment for eight months, which she discontinued. Symptoms resumed, and after reaching a target weight of 30 kg, she set a new target weight of 20 kg. The patient's behavior was influenced by insecure attachment modeled by her father, who exhibited controlling and intrusive parenting styles.
A review study (Gale C.J., et al. A review of the father-child relationship in the development and maintenance of adolescent anorexia and bulimia nervosa. *Issues Compr. Pediatr. Nurs.* 2013;36:48–69. doi: 10.3109/01460862.2013.779764.) investigated the role of the father–child relationship as a risk or maintenance factor of Eating Disorders in developmental age. Results showed that within the relationship of the father and child, and especially with daughters, there are several themes such as conflict and communication, parental protection and psychological control, emotional regulation and self-esteem, and self-perfectionism that appear to condition the child's level of self-determining autonomy and can consequently impact maladaptive eating attitudes and psychopathology. (Criscuolo, M., et al (2023). Parental Emotional Availability and Family Functioning in Adolescent Anorexia Nervosa Subtypes. *International Journal of Environmental Research and Public Health*, 20(1), 68. https://doi.org/10.3390/ijerph20010068)
Conclusions: This case highlights the significant association between parental overcontrol and the development of anorexia nervosa, illustrating the need for targeted interventions that address both psychological and familial factors contributing to the disorder. Further discussion is warranted on the implications of parenting styles in the management and prevention of eating disorders.

Dying to be Thin: The complex relationship between Eating Disorders, Epilepsy and Treatment Resistant Depression

D. J. K. Fones[1]* and H. Y. Lee[1]

[1]Psychiatry, Singapore General Hospital, Singapore, Singapore
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1396

Introduction: Depression is a common comorbidity in patients with eating disorders. Epilepsy significantly impacts mood and personality, with up to one-third of epilepsy patients experiencing psychiatric comorbidities. The coexistence of eating disorders, epilepsy, and depression presents a clinical challenge due to complex neurological, psychiatric, and psychosocial interactions. Despite well-established links between these conditions, little literature explores their convergence in a single patient.
Objectives: We describe a case of anorexia nervosa (AN) in a premorbidly well woman who subsequently developed idiopathic generalized epilepsy. She then developed depression and an intractable urge to end her life solely because she felt "fat". We discuss the complex relationship between these conditions and propose hypotheses that may explain this interaction.
Methods: Informed consent was obtained from Ms. O to access her medical records for this case report. We reviewed her medical history, psychiatric evaluations and treatment interventions.
Results: Miss O is a 24-year old ex-nursing student with no past psychiatric history and was described as a bubbly young girl. She first presented in Nov 2018 with AN (BMI 14.0) achieving weight restoration by Aug 2019 after developing binge-eating episodes. In Jan 2020, she was diagnosed with epilepsy. Shortly thereafter, she developed severe depression, accompanied by personality changes, self-harm behaviours, and intractable suicidal ideations. She attributed her suicidality to her body image disturbances and perceived weight gain. She continues to restrict and purge but her weight has stabilized around BMI 20-22. Since then, she has had 13 admissions for suicide attempts and 7 for managing depression. Her treatments included antidepressants, mood stabilizers, antipsychotics, electroconvulsive therapy, repetitive transcranial magnetic stimulation and intravenous ketamine but her condition remained treatment-resistant.
We propose several hypotheses to explore the interactions between AN, epilepsy, and treatment-resistant depression. These include hypothalamic-pituitary-adrenal axis dysregulation and neuroinflammation, potential common neurological pathways between AN and epilepsy, the possible development of personality disorders, and cognitive distortions where disordered eating and suicidal behaviours serve as maladaptive control mechanisms. We also explored concepts like epileptic personality, interictal dysphoric disorder, and the interplay between antiepileptic drugs and mood.
Conclusions: These hypotheses collectively highlight the complex mechanisms that likely underlie Ms. O's comorbid AN, epilepsy, and treatment-resistant depression emphasizing the need for integrated, multidimensional treatment approaches. Further research is essential to develop targeted interventions for such challenging comorbidities.

Orthorexia Nervosa and Social Media: A Literature Review

J. M. S. Gonçalves[1]

[1]Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal
doi: 10.1192/j.eurpsy.2025.1397

Introduction: Orthorexia Nervosa (ON) is an emerging disordered eating pattern marked by an excessive focus on healthy eating, leading to psychological, social and physical impairments. While ON remains outside formal diagnostic systems, such as the DSM-5, increasing research highlights its prevalence and association with social media use. Social media platforms, particularly image-based platforms, play a dual role, often fostering rigid dietary ideals while simultaneously providing recovery support for users. This study reviews the influence of social media on ON development and its socio-cultural underpinnings.

Objectives: This literature review aims to examine the interplay between ON and social media, focusing on the extent to which social media exacerbates or alleviates ON symptoms. We explore the influence of platform-specific content on ON behaviors, considering factors such as exposure to "clean eating" ideals, dietary pressures and social validation.
Methods: A literature review was conducted, analyzing 17 studies encompassing various methodologies, including cross-sectional, qualitative and mixed-method approaches. Studies were sourced from databases including PubMed and Scopus, focusing on publications from diverse cultural contexts. Data extraction followed the PRISMA guidelines, with attention to PICO criteria, evaluating ON's psychological, behavioral and social dimensions alongside the impact of social media.
Results: Findings consistently indicate that social media intensifies ON tendencies through heightened exposure to "idealized" eating behaviors. Instagram users frequently encounter diet-focused content that promotes obsessive eating habits under the guise of health, while Twitter discussions reflect societal pressure and the emerging medicalization of ON. Studies reveal that frequent social media users demonstrate higher ON symptom severity, with platforms like Instagram and Grindr contributing uniquely to ON among specific demographics. Moreover, qualitative insights show that social media also fosters community support, with some users seeking recovery guidance.
Conclusions: The relationship between social media and ON is complex, encompassing both risks and recovery potential. While social media can reinforce disordered eating patterns, it also serves as a support mechanism, offering peer connections and recovery tools. Future research should prioritize cross-cultural analyses and interventions targeting social media literacy to mitigate ON risks and enhance positive engagement.

*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1398

Introduction: Suicidal behavior could be one of the declinations of destructiveness in patients with Eating Disorders (EDs), and represents an important cause of death in these patients. In recent years some theoretical models aimed at a deeper undestanding of suicidal behaviors have been developed and proposed, including the Interpersonal Theory of Suicide (IPTS) by Thomas Joiner, and it has been applied to EDs patients with mixed results.
Objectives: The objective of this study was to deepen the understanding of the problem of suicide in EDs, with the aid of the IPTS.
Methods: Multicenter study coordinated by the Department of Psychology - University of Milano-Bicocca (UniMiB) and the Psychiatry of the Università del Piemonte Orientale (UPO); the recruitment of patients with EDs involves: Novara Mental Health Center and Psychiatry outpatient clinic of the Maggiore della Carità University Hospital in Novara, Regional Expert Center for the Diagnosis and Treatment of Eating Disorders in Turin, outpatient clinic for Nutrition and Eating Disorders, IRCCS San Gerardo dei Tintori Foundation in Monza. Healthy controls were enrolled through UPO and UniMiB. Variables related to suicidal ideation and suicide attempts, IPTS constructs and psychological factors (anxiety, somatic and mental pain, reasons for living, enteroceptive awareness, self-esteem, body image, etc.) were assessed.
Results: Preliminary analyses involving 28 EDs patients (ED group) and 45 healthy controls (HCs). The ED group reported increased lifetime and past-two-weeks suicidal ideation and a greater number of lifetime suicide attempts. With regard to IPTS, a higher Perceived Burdensomeness (INQ-PB) emerged in the ED group compared to HCs; no differences emerged in Thwarted Belongingness and in the Acquired Capability for suicide. In the EDs group, state and trait anxiety, mental pain, Visual Analogue Scale scores for somatic and psychological pain are higher; self-esteem is lower. Correlations emerged between INQ-PB, mental pain and self-esteem in EDs patients: as mental pain increases and self-esteem decreases, INQ-PB increases. The EDs sample has currently almost doubled, and new analyses will be performed to see whether the findings described above are confirmed in a larger sample; analyses comparing different subtypes of EDs will be run as well.
Conclusions: With the limitations of the sample size recruited in the pilot phase, which we aim to overcome by running new analyses in a larger sample as recruitment is ongoing, the preliminary data of this study offer preliminary support to the existing data in the literature on IPTS in EDs. An increase in IPTS construct scores appears to be independent of the severity of body image disorder in these patients.

Eating disorder in Down's Syndrome and GLUT-1 Detection

D. Labunskiy[1*], G. Kukina[1], S. Kiryukhina[1], N. Kolmykova[1] and V. Podsevatkin[1]

[1]Ogarev Mordovia State University, Saransk, Russian Federation
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1399

Introduction: The results of many previous studies report a high prevalence of overweight and obesity in children and adults with Down syndrome (hereinafter DS). According to different authors, the incidence of obesity in them varies between 23 and 70%. The age of onset of overweight formation was 2–3 years.
Objectives: Glucose transporter (abbreviated GLUT) is a large group of membrane proteins responsible for the transport of glucose across the cell membrane. Since glucose is a vital source of

energy, these proteins are present in all types of living organisms. GLUT, or SLC2A, is a separate family of glucose transport proteins found in most mammalian cells. Thus, the human genome encodes twelve proteins of the GLUT family. They are transport uniporter proteins.
Methods: We studied PCR of scrapings of the mucous membrane of the inner side of the cheek to search for GLUT1 genes in 31 patients with DS, ьen and women aging from 8 to 39 years. The control group consisted of 67 healthy donors by the same ages and genders.
Results: It was found that the expression of GLUT1 genes was significantly reduced. A decrease in the expression of these genes correlated with an increase in body weight and symptoms of bulimia in patients with Down syndrome.
Conclusions: Eating disorders, namely bulimia, in DS is a serious condition that aggravates the course of the underlying disease. Hereditary factors affect the expression of glucose transporter genes. Taking these circumstances into account would help in developing personalized pharmacotherapy.

"How I wished to be like Bruce Lee. Eating Disorders and Psychotic Symptoms" A case report

M. Ligero Argudo[1]*, I. M. Peso Navarro[1], C. García Cerdán[1], C. Munaiz Cossío[1], R. K. González Bolaños[1], J. I. de la Iglesia Larrad[1], N. M. Casado Espada[1], A. Macia Casas[1] and D. González Parra[1]

[1]Psychiatry, Clinical Hospital of Salamanca, Salamanca, Spain
*Corresponding author.
doi: 10.1192/j.eurpsy.2025.1400

Introduction: Eating disorders (ED) can sometimes present with psychotic symptoms, including delusions and cenesthetic or auditory hallucinations. In a minority of patients, these symptoms may stem from an underlying psychotic disorder, such as schizophrenia, which is more common in males (Bou Khalil R, Hachem D, Richa S. (2011). Eating disorders and schizophrenia in male patients: a review. Eat Weight Disord, 16(3) , 150-6). Therefore, early detection and intervention are critical in cases where EDs are accompanied by prodromal or attenuated psychotic symptoms.
